Pianists may find an instrument such as the Yamaha Disklavier useful for the study of structural communication. This is essentially an acoustic piano in which the timing and dynamics of each key pressure can be registered on a computer. The computer can also control the instrument so that a recorded performance can be listened to directly on the instrument. The Disklavier has been used regularly by the second author of this chapter in teaching advanced courses in piano performance (Battel et. al., 1998). One such course consisted of two parts: (1) music performance analysis, and (2) analytical methods for performance. The participants played the first 10 bars of Mozart's Sonata K. 333 in B♭ Major on the Disklavier. Variations in dynamics and timing produced by the players were displayed on a computer screen. The data were compared to those of the second author's performance recorded earlier on a Disklavier and to those produced by a performance rule system implemented in MELODIA (Bresin, 1993). Finally, the musical meaning of performance variables in the historical period, style, and performance tradition of the composer was analyzed and discussed.

In summary, recent research on music performance has opened up a range of new possibilities for teaching expression in the sense of structural communication. The development of new software tools for this purpose would further facilitate the use of the computer as a complement in the classroom.

Emotional Communication

PATRIK N. JUSLIN & ROLAND S. PERSSON

To communicate specific emotions to listeners, performers simultaneously manipulate a range of musical parameters. The research findings on emotional expression in music may be organized according to a theoretical framework that describes the communicative process in terms of E. Brunswik's (1956) *lens model*. We discuss traditional strategies for teaching expression including the use of metaphors, aural modeling, and felt emotion and conclude that these strategies rarely provide informative feedback to the performer. A new, empirically based approach to teaching expression called *cognitive feedback* is outlined and its efficacy evaluated. The goal is to provide performers with the tools they need to develop their own personal expression.

With regard to musical performances, experience has shown that the imagination of the hearer is in general so much at the disposal of the [performer] that by help of variation, intervals, and modulation he may stamp what impression on the mind he pleases.

Francesco Geminiani, cited in Meyer,
Emotion and Meaning in Music

Of all the subskills that make up music performance, the ones associated with emotional communication are often viewed as the most elusive. They go right to the core of why people engage in musical behavior, either as performers or as listeners. The performance of a piece of music is crucial in shaping its emotional expression. Thus the emotional impact of particularly expressive performers—for example, C. P. E. Bach, Niccolò Paganini, and Jimi Hendrix—has always been a source of great fascination. What is the origin of their expressiveness? How is it achieved?

It should be noted at the outset that there are different uses of the word *expression* in the literature. In studies of music performance, *expression* has been used to refer to the systematic variations in timing, dynamics, timbre, and pitch that form the *microstructure* of a performance and differentiate it from another performance of the same music (Palmer, 1997; chapter 13 in this volume). The word *expression* has also been used to refer to the *emotional* qualities of music as perceived by listeners (Davies, 1994). These two senses of the word are of course related in that performers use systematic variations in performance parameters to convey emotions to listeners.

Much has been written about expression in music—far more than we can hope to cover in this chapter. A review of the literature, from antiquity to modern times, reveals a variety of ideas about what music is able to express: emotion, beauty, motion, expressive form, energy, tension, events, religious faith, personal identity, and social conditions. In this chapter, we have chosen for pragmatic reasons to focus on expression of emotion and also limit our review to psychological research. One final limitation reflects the focus of this volume: while not wishing to deny the crucial role of the composer, we shall focus on how the *performer* contributes to emotional expression in music. (For a discussion of the composer, see Juslin & Sloboda, 2001, section 3.)

Questions about music and emotion have occupied humans ever since antiquity. The ancient Greeks argued that specific musical features are associated with specific emotions. This notion received its most precise formulation in the *doctrine of the affections* during the seventeenth and eighteenth centuries (cf. Mattheson, 1739/1954). Since then, conceptions of musical emotions have changed, throughout history, along with changing conceptions of emotions in general (e.g., eighteenth-century affect as a rationalized emotional state in contrast to nineteenth-century emotion as personal and spontaneous expression, see Cook & Dibben, 2001). Influential modern theories of music and emotion include Langer (1942), Meyer (1956), Cooke (1959), and Clynes (1977). Empirical research on emotional expression in music has been conducted for a century, including the pioneering studies by Hevner (1936). This work explored the expressive properties of various musical features, such as pitch or mode (for a review, see Gabrielsson & Juslin, in press). From this research we have learned much about how different aspects of a musical composition may influence emotional expression but less about how different aspects of a *performance* may influence expression.

Few studies have investigated how performers conceptualize and assign meaning to a piece of music while preparing it for performance. However, both empirical research (e.g., Persson, 1993; Woody, 2000) and biographical accounts (e.g., Blum 1977; Menuhin, 1996; Schumacher, 1995) confirm that performers often conceive of performance in terms of emotions and moods. Many performers consider expressivity to be one of the most important aspects of performance (Boyd & George-Warren, 1992; Persson, 1993).

Despite the strong emphasis on expressiveness among musicians, a number of studies suggest that expressive aspects of performance are neglected in music education. Specifically, teachers tend to spend much more time and effort on

technical aspects than on expressive or aesthetic aspects (Persson, 1993; Tait, 1992). As a result, students may come to focus on expressive aspects fairly late in their artistic development (Woody, 2000). Critics often complain that young musicians acquire a high technical skill without being able to induce an emotional experience in the listener (e.g., Dubal, 1985). Consequently, music educators have been encouraged to devote more attention to emotion and expression in music (Reimer, 1989). Such a change of emphasis should lead to an increased concern with the actual strategies used to teach expressive skills of music performance. Teaching strategies form the *how* of music teaching; they involve vocabulary usage, various forms of modeling, and management procedures (Tait, 1992).

The objective of this chapter is to illustrate how psychological research on emotional communication in music performance might contribute to the development of more efficient teaching strategies aimed at the expressive aspects of performance. First, we summarize relevant research. Then, we describe a framework for organizing the findings. Finally, we consider how theory and research on expression might inform day-to-day teaching practice.

Research on Emotional Expression in Performance

Performers and listeners often discuss and compare musical performances in terms of their expressive aspects, and there are many treatises on performance practices that can be used to enhance emotional expressivity (e.g., Hudson, 1994). Therefore, it may come as a surprise that it is only recently that researchers have began to study this phenomenon. This may reflect the dominant influence of cognitive science in psychology in general and music psychology in particular, which has led to a focus on cognitive aspects of performance, such as structural representation (for a review, see Gabrielsson, 1999). However, renewed interest in emotion has led to increased interest in musical emotion also (Juslin & Sloboda, 2001), even in performance research.

Emotions are difficult to define and measure. Yet most researchers would probably agree that emotions consist of many components: cognitive appraisal, subjective feeling, physiology, expression, and action tendency (Oatley & Jenkins, 1996). For example, we may appraise an event as harmful that evokes feelings of fear and physiological reactions in our body; we may express this fear verbally or nonverbally and may also act in certain ways (e.g., running away) rather than others. There are two major approaches to conceptualizing emotions. According to the *categorical* approach, people experience emotions as categories that are distinct from one another (Ekman, 1992). The categorical approach thus focuses on the characteristics that distinguish emotions from one another. In contrast, the *dimensional* approach focuses on identifying emotions based on their placement on a small number of dimensions like *valence* (positive/negative) and *activation* (high/low) (Russell, 1980).

What is emotional communication? We reserve this term for situations where the performer intends to communicate an emotion to the listener. Accurate com-

munication takes place to the extent that the performer's expressive intention is understood by the listener. This approach implies that expression and recognition of emotions should be studied in an integrated fashion. Accordingly, most studies in the domain have used the following procedure: The performer is asked to play a piece of music to express various emotions (e.g., sadness) chosen by the investigator. The performances are first recorded and later analyzed according to their acoustic characteristics. The performances are also judged by listeners to see whether they perceive the expression in accordance with the performer's intention. Thus, the focus in this research is on *perception* (rather than induction) of emotion.

Accuracy

The first question to face any researcher concerned with emotional communication in music is whether such communication is possible at all. In a pioneering study, Kotlyar and Morozov (1976) asked 10 opera singers to sing phrases from various pieces of music in such a way that they would communicate joy, anger, sorrow, and fear to listeners. Results show that the 10 musically trained listeners who judged the emotional expression of each performance were consistently successful at recognizing the intended expressions. Since then, several studies have confirmed that professional musicians are able to communicate emotions to listeners (Behrens & Green, 1993; Gabrielsson & Juslin, 1996; Juslin, 1997b, 2000; Juslin & Madison, 1999; Sundberg, Iwarsson, & Hagegård, 1995), but that there are considerable individual differences in expressive skill.

Few studies have reported the results in a manner that makes more precise estimates of communication accuracy possible. Juslin (1997c) used a forced-choice format to enable comparison with the results reported in studies of vocal expression of emotion. He found that the communication accuracy was 75% correct—about four times more accurate than would be expected by chance alone. This suggests—at least under ideal circumstances—that the accuracy of communication of emotion in music performance may approach the accuracy of facial and vocal expression (Johnstone & Scherer, 2000). Furthermore, the communicative process seems to be reliable regardless of the particular response format used to collect listeners' judgments (Juslin, 1997a).

Code Usage

A number of studies have attempted to describe the *code* (i.e., the acoustic means) that performers use to communicate emotions to listeners (Gabrielsson & Juslin, 1996; Juslin, 1997b; 2000; Juslin & Madison, 1999; Rapoport, 1996). One of the main findings is that the performer's expressive intention affects almost every aspect of the performance; that is, emotional expression in performance involves a sizable array of *cues* (i.e., pieces of information) that are used by performers and listeners. A summary of the code usage established in investigations so far is shown in Table 14.1. Included are the five emotions—happiness, sadness, anger, fear, tenderness—that have been studied most extensively. These emo-

tions represent a natural point of departure because all are regarded as typical emotions by laypeople (Shields, 1984) and as *basic emotions* (i.e., innate and universal emotions) by scientists (Plutchik, 1994). The same emotions also appear occasionally as expression marks in musical scores (e.g., *festoso, dolente, furioso, timoroso, teneramente*).

The expressive cues shown in Table 14.1 include tempo, sound level, timing, intonation, articulation, timbre, vibrato, tone attacks, tone decays, and pauses. Both the mean level of a cue and its variability throughout the performance may be important for the expression. For example, sadness is associated with slow tempo, low sound level, *legato* articulation, small articulation vari-

Table 14.1. Cue utilization in communication of emotions (based on material presented in Juslin, 2001).

Emotion	Cue Utilization	Activity, Valence
Happiness	fast tempo, small tempo variability, *staccato* articulation, large articulation variability, high sound level, bright timbre, fast tone attacks, small timing variations, increased durational contrasts between long and short notes, rising microintonation, small vibrato extent	high, positive
Sadness	very slow tempo, *legato* articulation, small articulation variability, low sound level, dull timbre, large timing variations, reduced durational contrasts between long and short notes, slow tone attacks, flat or falling microintonation, slow vibrato, final *ritardando*, phrase *decelerando*	low, negative
Anger	high sound level, sharp timbre, spectral noise, fast tempo, *staccato* articulation, abrupt tone attacks, increased durational contrasts between long and short notes, no *ritardando*, sudden accents, accents on tonally unstable notes, *crescendo*, phrase *accelerando*, large vibrato extent	high, negative
Tenderness	slow tempo, slow tone attacks, low sound level, small sound-level variability, *legato* articulation, soft timbre, moderate timing variations, intense vibrato, reduced durational contrasts between long and short notes, final *ritardando*, accents on stable notes	low, positive
Fear	*staccato* articulation, very low sound level, large sound-level variability, fast tempo, large tempo variability, very large timing variations, bright spectrum, fast, shallow, irregular vibrato, pauses between phrases, sudden syncopations	moderate, negative

Note: This is a simplified description of the relationships established in studies of performers' and listeners' cue utilization in expression of emotion via music performance. For information about the precise definition and measurement of each cue, see Juslin (1999). The rightmost column shows each emotion's position on two emotion dimensions: *activity* (high vs. low) and *valence* (positive vs. negative) (e.g., Plutchik, 1994, chapter 3).

ability, slow tone attacks, and soft timbre (for a detailed review, see Juslin, 1999). Also, different tones in the melodic structure may be emphasized depending on which emotion the performer intends to express (Lindström, 1999). It is possible to simulate emotional expression in synthesized performances based on the findings in the table in such a way that listeners can accurately decode the intended emotion (Juslin, 1997c; Bresin & Friberg, 2000).

While Table 14.1 is limited to a few emotion categories, one can easily imagine how these categories may be combined or mixed in different ways and also how emotional expression may be altered during a performance (Juslin, 2001). Some of the cues shown in the table may be common knowledge to most performers, whereas other cues (e.g., those that have to do with the microstructure of the performance) are less obvious. The number of cues available, of course, depends on the instrument used. Furthermore, cue utilization is not completely consistent across performers, instruments, or pieces of music (Juslin, 2000).

Most studies in the field so far have focused on cues that are applied in much the same way and to much the same extent throughout a piece. However, it would seem intuitively that much of music's expressiveness lies in the way cue use changes during the course of the performance. Indeed, there seem to exist certain *expressive contours* (i.e., patterns of changes in tempo and dynamics) that are characteristic of specific emotions. Listening tests that employed systematic manipulations of synthesized (Juslin, 1997c) or real performances (Juslin & Madison, 1999) have shown that expressive contours can be used by a listener to decode emotional expression.

Performer Insight

An important question is whether music performers have any insight regarding their own cue utilization. It seems generally agreed that performers are usually not aware of the details of how their musical intentions are realized in performance (Sloboda, 1996). In the case of emotional communication, performers are not normally conscious of how they use the cues listed in Table 14.1 (Juslin & Laukka, 2000).

However, there are large individual differences among performers in this regard. Some performers seem to imagine themselves being in the emotional state that their performance is intended to express and just let things happen (Juslin & Laukka, 2000; Persson, 2001). For example, the Russian violist Yuri Bashmet commented, "Identify with the emotions and the notes—fearful as they are—will look after themselves" (Seckerson, 1991, p. 26). Other performers take a more analytical approach, explicitly pondering how to vary different cues. But to the extent that cues are used *implicitly*, this presents a problem for the teaching of expression, which relies predominately on verbal instruction (Tait, 1992; Woody, 2000).

A Theoretical Framework

One reason for the neglect of emotion in both performance research and music education may be the lack of relevant theories. In the following, we describe the

only elaborated theoretical framework aimed specifically at emotional communication via performance, namely, the *functionalist perspective* (Juslin, 1997b; 2001).

Origin of the Code

Music performers are able to communicate emotions to listeners. What is it that makes this communication possible? Or, more specifically, what is the origin of the acoustical code used by performers? Arguably, the code reflects contributions from both nature and nurture.

Regarding nature, there is evidence for *innate brain programs* for vocal expression of emotion. Studies of the neurological substrates that underlie spontaneous vocalizations of emotion in monkeys and humans with brain lesions provide evidence of brain circuits that function to initiate innate affect vocalizations (Jürgens, 1992). We hypothesize that music performers communicate emotions to listeners by using the same acoustic code as is used in vocal expression. This hypothesis is supported by similarities in cue utilization between music performance and vocal expression (Juslin, 1999). For example, vocal expression of sadness involves slow speech rate, low voice intensity, and little high-frequency energy in the spectrum of the voice. Similar acoustic cues are used to express sadness in music performance (Table 14.1). Cross-cultural studies of vocal expression (Johnstone & Scherer, 2000) and music performance (Juslin, 2001) show that there are cross-cultural similarities. Thus there seems to exist an innate code for acoustical communication of emotion, which could explain why emotional expression is often regarded by music teachers as instinctive. If musicians are to apply this innate code to their performance, they need to understand the parallels between human voices and musical instruments and to learn sufficient technique to express emotions in accordance with the vocal code.

The second factor that governs emotional expression in performance is social learning or specific memories. This is a lifelong process that begins with the early interaction between mother and infant. When mothers talk to their infants, for example, if they want to calm their infant, they reduce the speed and intensity of their speech and talk with slowly falling pitch contours. If mothers want to express disapproval toward some unfavorable activity they employ brief, sharp, and *staccato*-like contours (Papoušek, 1996). Although the code used by mothers seems to be innate, the particular expressive style of the mother modulates the expressive style of the infant. This modulation of the expressive skills continues throughout life as one accumulates experience. Performers learn links between cues and extramusical aspects (e.g., motion, body language) through analogies (Persson, 1993; Sloboda, 1996; see also chapter 15 in this volume), which implies that extramusical life experiences are crucial in learning expressivity in performance (Woody, 2000).

Description of the Code

One way of capturing the crucial characteristics of the communicative process is to conceptualize it in terms of a variant of Brunswik's (1956) lens model. The

lens model was originally intended as a model of visual perception that described the relationship between an organism and distal cues. However, it was later used mainly in studies of human judgment where the goal was to relate the judge's judgment strategy to a description of the judgment task (Cooksey, 1996).

The modified lens model (Figure 14.1) illustrates how performers *encode* (i.e., express) emotions by means of a set of cues (e.g., variations of tempo, sound level, and timbre) that are *probabilistic* (i.e., uncertain) and partly *redundant*. The emotions are *decoded* (i.e., recognized) by listeners who use these same cues to infer the expression. The cues are probabilistic in that they are not perfectly reliable indicators of the intended expression. Performers and listeners have to *combine* the cues for reliable communication to occur. However, this is not simply a matter of pattern matching, because the cues contribute in an additive fashion to listeners' judgments: Each cue is neither necessary nor sufficient, but the larger the number of cues used, the more reliable the communication. The redundancy among cues partly reflects how sounds are produced on instruments (e.g., a harder string attack produces a tone that is both louder and sharper in timbre).

In Figure 14.1, *accuracy* refers to the correlation between the performer's intention and the listener's judgment. *Matching* refers to the degree of similarity between the performer's and the listener's cue utilization, respectively. For

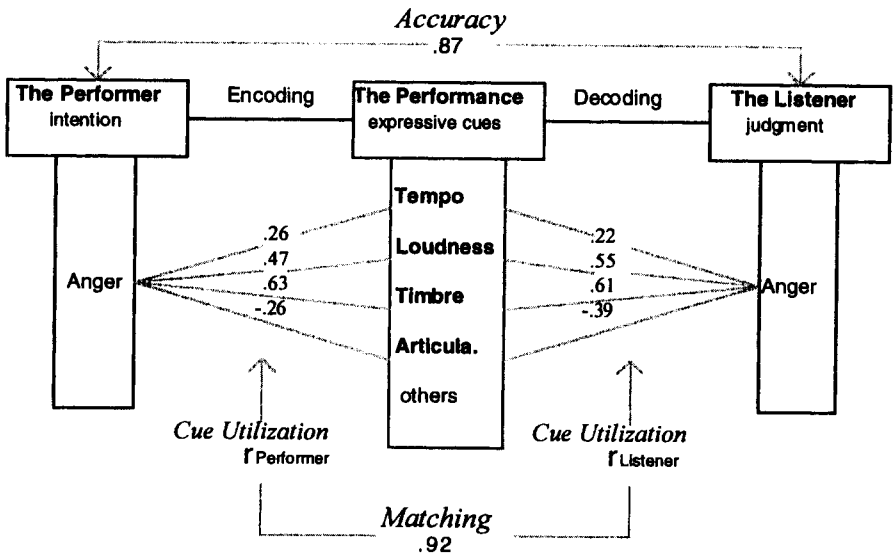

Figure 14.1. A Brunswikian lens model of emotional communication in music performance (adapted from Juslin, 1997b). The cue weights should be interpreted as follows: Positive (as opposed to negative) signs indicate, respectively for each cue, fast (vs. slow) mean tempo, high (vs. low) sound level, sharp (vs. soft) timbre, and *legato* (vs. *staccato*) articulation (for details regarding methodology, see Juslin, 2000).

successful communication to occur, the performer's cue utilization must be as similar as possible to the listener's cue utilization. For illustrative purposes, unpublished data have been inserted into Figure 14.1. As can be seen, there is a high correlation between intention and judgment, which means that the performer was successful in communicating anger to the listener. This is explained by the high level of matching between the performer's and the listener's cue utilization.

Brunswik's lens model has a number of important implications. First, we cannot expect perfect accuracy of communication. If cues are only probabilistic, that means that accuracy can only be probabilistic, too. Second, to understand why the communication is successful or not in a particular situation we have to describe both expression and recognition in terms of the same concepts. Third, because the cues are partly redundant, many different cue utilization strategies may lead to the same level of accuracy (Juslin, 2000). There is a virtue associated with this redundancy. Because there is no pressure toward uniformity in cue utilization, performers can communicate successfully with listeners without compromising their unique playing styles.

Applications in Music Education

Can Emotional Expression Be Learned?

Expertise in music performance is commonly seen as the synthesis of technical and expressive skills (chapter 7). However, technical aspects of playing are often regarded as learnable skills, whereas expressive aspects are regarded as being more instinctive. Many teachers view expression as something that cannot be taught—a view that is sometimes shared by their students: "There is no technique to perform expressively. You have to use your soul" (cited in Woody, 2000, p. 21).

This view probably stems from certain myths about artistic expression. One such myth is that expression is entirely subjective and passive in its genesis and has nothing to do with understanding (Howard, 1989). In this view, consistent with the romantic notion of art and artists as a kind of mystery, expression is seen as a hands-off affair that is best left alone. Hence, expression is wrongly believed to reflect a divine endowment—or talent—beyond learning and development (cf. Sloboda, 1996).

Although we often think of artistic expression in terms of individual talent, the criteria for what is regarded as high art ultimately reflect social construction. Nowhere is this more apparent than in an educational setting (Kingsbury, 1988). Part of the problem the music teacher faces resides in the tension between the subjective world of individual performers and the social and objective requirements of the educational setting. Hence, an important goal of any teaching strategy aimed at developing expressive skills should be to *relate* the subjective world of the performer (e.g., imagery, metaphor, emotion) to objective features of performance (e.g., articulation).

Emotional expressiveness in music is sometimes hard to describe in words, making it somewhat elusive to both research and teaching practice. Furthermore, it is probably true that expressive skills to some extent reflect the emotional sensitivity of the performer. But this does not imply that it is impossible to learn expressive skills through training. Studies that have addressed this issue have demonstrated that expressive skills *can* be improved by training (Marchand, 1975; Juslin & Laukka, 2000; Woody, 1999).

The idea that the learning of musical expression is best left untouched by conscious thought reflects a misunderstanding that pervades commonsense teaching (i.e., teaching that relies not on empirically derived models and knowledge but rather on tradition and folklore) and is typical of master performers who may never have received training on how to teach musicians (Persson, 1996). It is not realized that goal-directed strategies that initially are willfully applied normally undergo *automation* as a result of practice (Hallam, 1997). That is, although a performer may initially have to use cues in a conscious manner, soon the associations among cues and emotions become internalized by the performer and no longer require conscious control.

Traditional Strategies for Teaching Expression

Aural Modeling. Perhaps the most frequently used tool in conveying to students how something should be played is aural modeling. The teacher's performance provides a model of what is desired from the student, and the student is usually required to learn by imitating the teacher. Such strategies are usually achieved on the instrument or using the voice (e.g., singing a certain phrase). Although modeling is useful, it has some limitations. One is that the student is required to pick up the relevant aspects of the model. It may be difficult for a student to know what to listen for and how to represent it in terms of specific skills (Lehmann, 1997). Davidson and Scripp (1992) note that masterful performances are so compact and seamless that it is difficult to observe the subskills that support a fluent production.

Experiential Strategies. There are, however, a number of experiential teaching strategies also, which instead aim at conveying the subjective aspects of performing to a student. One such strategy is the use of *metaphors* to focus the emotional qualities of the performance by creating an emotional state within the performer (Davidson & Scripp, 1992). A teacher may, for example, say: "Well, I don't think the lover and his lass had much fun, do you? If a young girl and her boy go into the cornfields, they have other things in mind than playing cards surely!" (comment to a student singing Finzi's "It was a Lover and His Lass," in Persson, 1993, p. 328). Or a teacher may say: "Strange . . . myths . . . ghosts . . . dragons . . . eerie . . . the unknown . . . spine-chilling . . . a drama . . . Weber was an opera composer!" (comment to a student playing an instrumental piece by C. M. Weber, in Persson, 1993, p. 328). Although metaphors can be effective (Kohut, 1985), there are some problems with them. One problem is that metaphors depend on the performer's personal experience with

words and images. Since different performers have different experiences, metaphors are often ambiguous.

Another teaching strategy endorsed by some teachers is to focus on the performer's *felt emotions*, trusting that these emotions will naturally translate into appropriate sound properties (Woody, 2000). Felt emotion, however, is no guarantee that the emotion will be successfully conveyed to listeners; nor is it necessary to feel the emotion in order to communicate successfully. As observed by Sloboda (1996), students rarely monitor the expressive outcomes of their own performances. Instead, they monitor their own intentions and "take the intention for the deed" (p. 121).

The Problem of Feedback. Based on an extensive review of a century of research on skill acquisition, Ericsson, Krampe, and Tesch-Römer (1993) proposed three elements that are required in a learning task for it to qualify as *deliberate practice*: (1) clear task definition (2) informative feedback, and (3) opportunities for repetition and correction of errors. Our view is that traditional strategies for teaching expression are problematic mainly in that they do not provide informative feedback to the performer.

Technically, feedback can be defined as "the process by which an environment returns to individuals a portion of the information in their response output necessary to compare their present strategy with a representation of an ideal strategy" (Balzer, Doherty, & O'Connor, 1989, p. 412). It follows from this definition that many kinds of responses that teachers give their students (e.g., "put some expression into it!") do not actually constitute feedback. Thus we agree with Tait's (1992) astute conclusion that "teaching strategies need to become more specific in terms of tasks and feedback" (p. 532). Teachers need a pedagogical model that can guide the development of expressivity and emphasize its significance for successful communication with an audience.

Alternative Approaches to Teaching Emotional Communication

Teaching Theory of Emotional Communication. One fairly straightforward way of taking advantage of performance research would be to teach the code description shown in Table 14.1. This description could be used as a springboard for exploring different interpretations and reflecting on what makes for a stunning or lackluster performance of a specific piece of music. The value of reflection and adoption of multiple stances toward a piece of art is often emphasized. True enough, simple application of the expressive principles in Table 14.1 may not result in living expression, but these principles can serve as the core from which subtler interpretations are developed with knowledge about the particular instrument, piece, style, and composer.

We believe that the ultimate goal should be to provide performers with the tools they need to develop their own personal expression. The performer may wish the interpretation of a given piece to be clear or ambiguous, stable or variable, specific or general, depending on the composition. Knowledge about the

relationships between expressive cues and their emotional effects will help performers to reliably achieve desired listener responses. As in the visual arts, a performer may need to know the underlying principles and conventions in order to know how to vary them in an aesthetically pleasing manner.

Theory of emotional communication could usefully be taught to music students, based on the framework discussed earlier. A deeper understanding of the communicative process may be beneficial for the learning process. Rabinowitz (1988) argues that "knowledge about the how, where, and why of strategy use [is] important if students are to take control of their cognitive processing" (p. 234). Such knowledge about expressive skills makes it more likely that students retain the new knowledge and are able to apply it to new situations.

Cognitive Feedback. Recall that emotional communication in music performance involves a number of acoustic cues that are used by both performers and listeners. Both expression and recognition of emotions are made by *integrating* these cues. Such integration requires knowledge about the relationships among performers, cues, and listeners. The notion of *cognitive feedback* (hereafter, *CFB*) is to allow the performer to compare a model of his or her cue utilization to an *optimal* model of cue utilization. This is, of course, a fundamental feature of feedback as such. However, how this is achieved is crucial. CFB was originally developed in studies of cognitive judgment (Cooksey, 1996). To illustrate how CFB works in a musical context, we summarize a study that evaluated the efficacy of the CFB strategy (for details, see Juslin & Laukka, 2000).

In the first phase of the study, eight amateur guitarists were asked to play a piece of music in such a way that they would communicate four different emotions to listeners. Their performances were recorded and analyzed in terms of acoustic characteristics. Listeners also rated each performance on scales that corresponded to the intended emotions. Then statistical analysis was used to model the relationships between (1) performers' intentions and cues and (2) cues and listeners' judgments. Finally, the performer and listener models were quantitatively related to each other (by means of the lens model equation; Cooksey, 1996). This made it possible to directly *compare* how performers and listeners used the cues in the performances (cf. Figure 14.1).

In the second phase of the study, half of the performers returned to the laboratory to receive CFB. This consisted of a description of the performer's cue utilization, the listeners' cue utilization, and the degree of matching between performer and listeners. Instances of mismatching between performer and listeners were explained to individual performers. For example, a performer would be told that "you used *staccato* articulation in your sadness expressions, but the listeners associated *legato* articulation with sadness. You should therefore try to play your sadness expressions with more *legato* articulation." In other words, the performers were given specific directions on how to alter their cue utilization to make it more similar to the listeners' cue utilization. The other half of the performers acted as control group and did not receive any feedback.

In the final phase, all performers returned to the laboratory to repeat the first task once more. That is, they were once again asked to perform a piece of music

to communicate emotions to listeners. The goal was to see whether the performers who had received CFB had improved their communication accuracy more than the control group. Two kinds of criteria were used to evaluate the efficacy of CFB: (1) behavioral criteria (did CFB improve the performers' accuracy?) and (2) reaction criteria (how did the performers react to CFB?).

Figure 14.2 shows the results. As can be seen, *before* feedback there was no significant difference in accuracy between the groups. However, *after* feedback there was a significant difference in accuracy. CFB yielded about a 50% increase in accuracy after a single session. Furthermore, the performers reacted positively to the CFB and believed that it had really improved their skills. In contrast, the control group did *not* improve its accuracy, suggesting that simple task repetition leads to little improvement in this context. Improvement requires informative feedback.

There is often disagreement about whether teachers' instructions should address sound properties of the performance or experiential concepts. CFB resolves this problem because it *relates* the acoustical vocabulary to the experiential vocabulary. When using CFB, one is consensually establishing the extent to which a performance is successful in communicating a certain emotion, rather than relying on the judgment of a single person. The teacher's advice is provided automatically, as it were, from the statistical analysis of the communicative process. The analysis renders transparent much of the previously opaque process of communication—in particular, the combined and unique effects of the acoustic cues. Those effects are extremely difficult for a listener or performer to infer.

Applications of Cognitive Feedback

Among the benefits of CFB are that (1) its efficacy has been empirically demonstrated, (2) it is not subject to the changing ideals of individual teachers, and (3) it is consistent with empirically confirmed features of deliberate practice. Among the drawbacks of CFB—in the form described—are that CFB is complicated and time-consuming to carry out and requires special equipment for acoustic analyses. With both benefits and drawbacks in mind, there are various ways, present and future, of implementing CFB in teaching practice.

CFB as Computer-Assisted Teaching. Applications of computer feedback for music performance have been around for some time, concerning, for instance, piano technique and intonation in singing (Hallam, 1997). However, none of the applications concern the expressive aspects of performance. Through the use of algorithms for automatic analysis of acoustic cues in performances and statistical models that simulate emotion judgments of various listener populations, CFB could be applied in teaching more swiftly. User-friendly software for this purpose is currently being developed in a research project at the Uppsala University led by the first author of this chapter. Computer-assisted teaching could serve as a complement to traditional teaching, allowing performers to experiment freely with interpretive ideas.

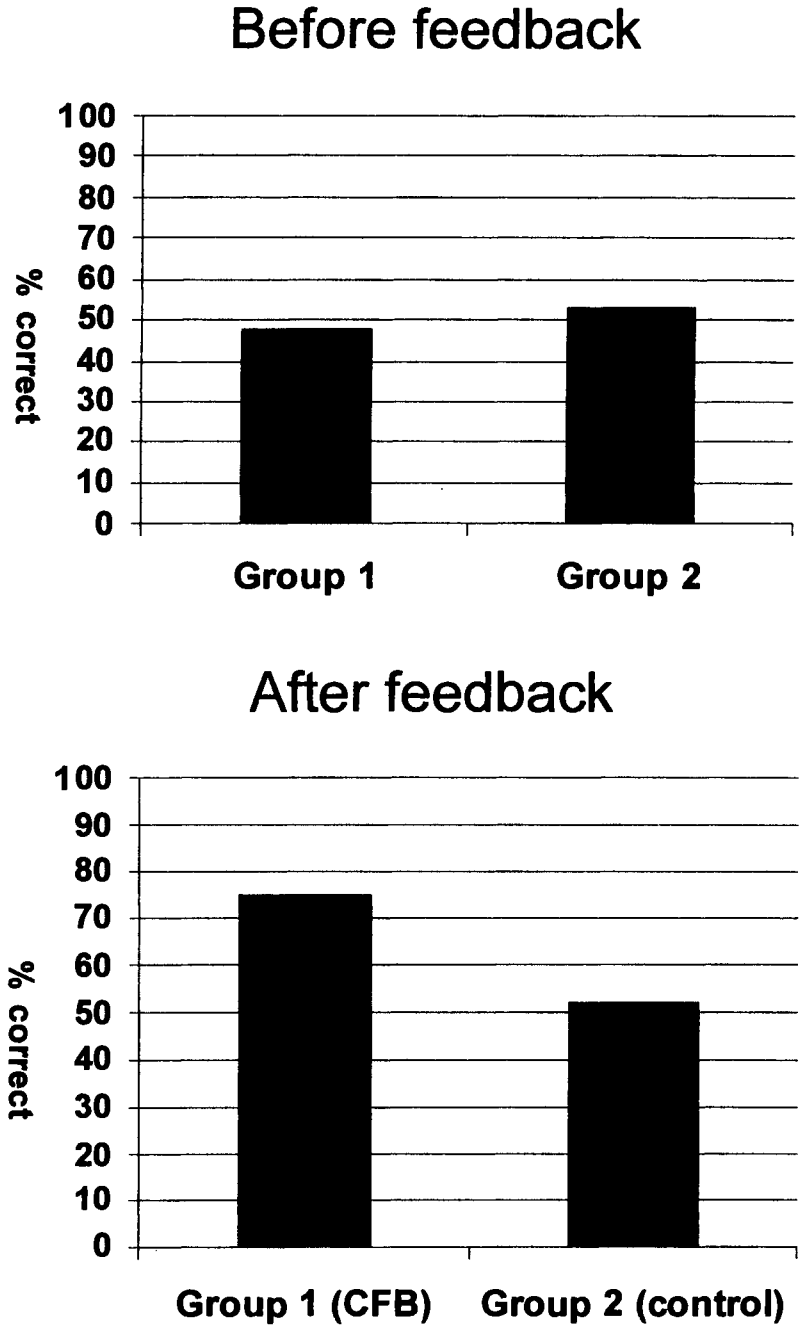

Figure 14.2. Between-subjects comparisons of communication accuracy (% correct) for Group 1 (cognitive feedback, CFB) and Group 2 (control) before and after feedback (from Juslin & Laukka, 2000).

CFB in a Noncomputerized Setting. Prior to the production of appropriate software, the CFB strategy can still serve as a pedagogical tool, although without the exact and objective feedback provided by computer-assisted procedures. No statistics or computer programs are required when simply asking a group of students to perform a certain piece of music with the intention of communicating a number of emotions to a group of listening students, and then asking the listeners how they perceived the different performances. A discussion could follow that highlights the possible reasons that some performers seemed more successful in conveying their intentions than others using the cue utilization list (Table 14.1). The purpose of this exercise could be to make students *aware* of the many possibilities of expressiveness.

Toward an Integration of Technique and Expression

The world of Western art music, in particular, has tended to preserve what Renshaw (1986) terms a "museum culture," which has prompted many educators to focus on the technical aspects of performance. But it is likely that uncovering the nature and function of expression by research will help to restore the balance between technique and expression. However, we must not forget that expression is also a matter of learnable technique. Some of the differences among individuals in expressive ability reflect technical differences, but it is technique that allows artistic flexibility and is not likely to alienate the performer from the subjective experience of the music studied and performed.

In this chapter, we have not only presented possible teaching strategies in relation to developing expressive skills, but we have also endeavored to show that science and arts are neither opposites nor contradictory. However, in regard to finding specific applications of cognitive feedback, further research is needed. We therefore propose that qualitative studies of the subjective world of performers and quantitative studies of the communicative process should be pursued in combination. To achieve this, psychologists, educators, and musicians will need to work in close collaboration. This book may itself contribute to this very goal.

Acknowledgment. The writing of this chapter was supported by the Bank of Sweden Tercentenary Foundation.

Body Movement

JANE W. DAVIDSON & JORGE SALGADO CORREIA

Body movement plays a role in the construction, execution, and perception of musical performances. We explore the interface between technical matters of physical control and the expressive components of physical gestures and discuss the bodily origins of musical meaning, expressive performance, and musical skill acquisition. For example, bodily gesture and rhythm in proto-musical mother-child exchanges influence the development of thought and knowledge, and expressive slowing in music (ritardando) corresponds to the deceleration of runners coming to a halt. Specific movement gestures in music performance function as illustrative and emblematic cues and clearly indicate the focus of the performer's attention, whether on the narrative content of a song or on showing off to the audience. Thus, through body movement thoughts and concerns are communicated to the audience. Performers, educators, and students can use this knowledge to enhance their performing, teaching, and learning capacities.

All musicians use their bodies to interact with their musical instruments when performing music. The intention of this chapter is to show that the body is not only essential to the physical manipulation of the instrument for the accurate execution of music, but it is also vital in the generation of expressive ideas about the music. In addition, the body seems to be critical in the production and perception of information about the performer's concerns to coordinate with coperformers and audience and to engage in extramusical concerns on stage, for instance, preening display movements.

To begin the exploration of musical performance and the body, it is important to recall that parents rhythmically pat, bounce, and caress their babies and melodically vocalize softly to them in *motherese* (infant-directed speech). In essence, the movements and sounds are based on exchanges that utilize varying elements associated with expressive musical performance. The motherese de-

velops into play and conversational turn taking (Papoušek, 1996). There is imitation, matching, elaboration, with all kinds of emotions being played out through pitch, rhythm, and movement variation for the giver and the receiver of the information. Trevarthen (1999–2000) has argued that these *proto-musical* experiences are critical in establishing physiological and emotional attunement so that the interactive patterns become salient and, therefore, meaningful.

Given Trevarthen's ideas, it may be that proto-musical behavior is vital for the general development of meaningful thoughts and actions. It would follow that a concrete and practical way of understanding music can be explored through bodily movement. To generate music, the formulation and execution of expressive ideas and qualities in movement is certainly necessary. By implication, this would suggest that the understanding of musical performance could be clarified or enhanced when the movements that produce the musical sounds are given due attention by both the performer and the audience.

In light of the preceding, it seems no accident that physical metaphors are commonly used in reference to music: "a punchy performance," a "flowing *legato*," for example. Johnson (1999), Clarke (2001), and Damasio (1999), from the disciplines of philosophy, music psychology, and neuroscience respectively, all concur that these metaphors are helpful in assisting us to relay how we experience music. For performers, teachers, and students, it seems that the movement metaphor may be a powerful tool in the development of a musical performance. We shall return to this and other points about strategies for developing meaningful performances later in the chapter when considering how musical expression may be taught through body movement. But after a brief presentation of a justification for the central importance of the body in the production and perception of musical performances it seems critical to examine both elements in detail.

Production of Body Movement in Performance

A motor program is conceived of as a hierarchical structure that translates information input into performed action. When we learn to play a musical instrument and then work on a specific piece of music, these programs are constructed and strengthened with rehearsal. It is now well documented that it takes in excess of 10,000 hours of technical and repertoire practice (see Ericsson, Krampe, & Tesch-Römer, 1993) to refine an instrumental technique to reach expertise (the professional standard to play in a symphony orchestra); and during this practice the development of motor programs interfaces with that of other cognitive skills such as memorization in order for the whole learning and playing process to become automated.

Examining different skilled performances made by typists and pianists, Shaffer (1982, 1984) explored how motor programs are organized. He discovered that in typing, sequences of key presses have definite timing profiles across performances of the same word sequences. He concluded that the movement control program elicits effects on the performance that are inevitable but expressive only

of the individual's production of words. In piano performance, Shaffer (1984) concluded that some of the timing deviations from the metric pulse of the musical rhythm are, similarly, the inevitable expression of features of the motor program. However, he went on to illustrate that other timing profile variations are flexible in tone production. Though these features are themselves integrated into the motor program, they are seen as timing modifications intended to enhance the musical effect. These intentional variations can be increased or diminished but never totally removed. Thus two elements of motor programming coexist in musical performance: timing profiles directly related to simple execution and timing deviations for musically enhancing effects.

In line with Shaffer's evidence, it is essential to recognize that dynamics, intonation, and timbre, as well as timing, are manipulated according to an individual's performance interpretation, and indeed, it has been demonstrated that differently intentioned performances contain different quantities of dynamic variation that are consciously used and recognized by performers as expressive devices (Nakamura, 1987). As stated earlier, it seems that the expressive effects applied to musical structures may be, in some part at least, related to bodily sources. For instance, a mathematical model produced by Todd (1985) indicated that phrase-related tempo changes—the acceleration and deceleration of tones in a musical phrase—are directly proportional to their position in the musical phrase. For example, slowing at a phrase boundary occurs in a systematic and seemingly rule-governed manner. Later Todd (1992, 1995) modified the proposal, basing the new model of deceleration toward a musical phrase end on velocity in physical motion. Recently it has been discovered that the expressive device of slowing toward a musical phrase end may be linked to the human movement properties found when adults slow down and stop after running (Friberg & Sundberg, 1999).

So, considering the body in the production of music, it is critical that motor programs are well established. However, the body is much more than a mechanistic source of input and output. There is a vast array of movements and gestures that serve many purposes. For example, one study tracked how individual points of the body move in space each 0.20 s during a piano performance, investigating the playing of the same piece of music with three different expressive intentions labeled deadpan, normal, and exaggerated (Davidson, 1994; in press). The study revealed a relationship between the movement size and the intensity of the musical sound expression—the more exaggerated the expressive intention of the music, the larger the movement. This suggested a direct correlation between the expressive movement and the production of musical intensity, since these performances were regarded as sounding as well as looking more expressive. In addition, it was revealed that the performer made a constant rocking movement when playing, though this movement was barely visible in the deadpan condition.

There are several possible accounts for the different types of movement used by pianists. First, they could be regarded as being responsive to the sounds produced—that is, reflecting the sounds. In the case of the rocking, there may even be movements analogous to those of self-stimulation observed in speech (Ekman

& Friesen, 1969)—movements used by the performer to make him- or herself feel at ease in the social context of the performance and/or enjoy the musical sounds being made. Support for this idea comes in the finding that although the rocking movement is allied to the timing and some structural features of the music (Clarke & Davidson, 1998), it seems to be not strictly bound to the musical structure, so it may be connected to the performer's individual concerns as well as a reaction to the music.

However, in line with research that suggests that the body provides a source for the generation of musical expression (see Friberg & Sundberg, 1999), it seems that the pianist's movements may be indicators of the mental and physical intentions necessary to generate the expressive performance. Although research on the origin of physical expression is scant, by drawing a parallel between the research on general locomotion (all kinds of traveling patterns from walking to running) and movement in musical performance Davidson (in press) was able to develop a theory of physical expression in playing. Although musical expression (that is, a specifically performed and intended communication) is not equivalent to locomotion, the locomotion research examined how the characteristics of gender and identity were displayed and used for communicative ends and thus expressed in the movement patterns. It is on these grounds that a parallel was made between the research findings and movements of musical expression.

Cutting, Proffitt, and Kozlowski (1978) and Kozlowski and Cutting (1977) were interested in how observers used the visual information available in the locomotion patterns. The researchers used bands of reflective tape attached to all the major body joints and filmed in highly contrasting light conditions to produce observation data that showed movement patterns only, avoiding surface information like dress, hairstyle, and so forth. From these movement displays onlookers were initially asked to identify the walker's sex. Then, in a series of studies where the onlookers knew all the walkers, they were asked to identify the walkers by name. Onlookers were very good at determining sex and naming individuals from these minimal visual displays.

The researchers showed that any part of the walking movement cycle and any body joint shown as a two-second excerpt provides similar information expressive of either gender or identity. The results were explained by demonstrating that there is a point within the walker's body referred to as the *center of moment* that acts as a reference around which movements in all parts of the body are organized, and this center is different for men and women (Cutting et al., 1978). Davidson proposed that such a principle may be in operation in musical performance, the description providing a framework from which we can begin to understand the importance of the rocking movement in the pianist's performances. The idea is that there is a physical center for the expression of musical information, the rocking being a critical part of the generation of the musical expression.

From the analysis of the pianist's movements, Davidson noted that the rocking emanated from the hip region. Given the sitting position of a pianist, the hips represent the fulcrum for the pianist's center of gravity and therefore provide the pivotal point for all upper torso movements. This center of gravity seemed

to be the central location for the generation of this overall physical expression: thus the hips may be the center of moment. Although only a single pianist was used in a detailed case study (Davidson, in press), previous studies had indicated that a range of individual performers make similar types of movements and modifications to them across different expressive interpretations, suggesting that generalizable findings can be assumed from the case-study material (Davidson, 1993, had studied the perception of violinists' movements).

Although some musicians appear to remain absolutely still when performing, data from many studies (Davidson 1991, 1993, 1994, 1997, in press) have shown that despite individual differences, when interviewed, many of the players said that the musical ideas they had were connected with the concept of a repetitive whole-body motion. It was an imagined sense of motion. Thus it could be that the movement may be internalized as well as externalized, and so it may be present to some degree. This idea links with that of Alexander Truslit, the German pedagogue:

> Musical motion is internal and encompasses the whole human being. It is not only an emotion [*Gemüts-Bewegung*] but also a true motion sensation. It must be distinguished from acoustic vibrations, from sympathetic resonance, from technical movements in playing an instrument, from the sequence of tones (which is only the outward manifestation of the inner process), and from conducting movements (though they merge partially with it). Musical motion can be likened to an invisible, imaginary dance. (Truslit, 1938, translated and presented by Repp, 1993, p. 51)

For Truslit, the movement metaphor for understanding and experiencing movement is of key importance. With the center-of-moment principle, the claim is that real or imagined motion is necessary to generate musical expression. This is a contentious idea, but nonetheless it brings together several allied propositions to produce a coherent theoretical proposal.

Related to the center-of-moment principle and in addition to the rocking motion, individually identifiable expressive locations have been discovered (see Davidson, in press). When these specific movements were closely examined in relation to the musical score, it was found, first, that they only occurred when a particular body part—the hand, for instance—was free to move, that is, when it was not tied to the technicalities of executing the music. Examples of these locations would be structural features like rests and sustained pedal notes. Second, the movements were all of a rotational nature—circling wrist movements and shoulder rotations, for instance. Third, these movements seemed to form a vocabulary of gestures in that they appeared across performances of different styles of music. They were not, however, allied in a one-to-one manner with musical features or pieces. There was a tendency for the performer to use the gestures in a variety of contexts and manners—sometimes small and slow, other times large and fast.

Further studies had refined the description of the center of moment by suggesting that different parts of the body convey similar expressive information at different hierarchical levels (Cutting & Proffitt, 1981). This finding could account

for results obtained earlier that indicated that more localized movement is of a similar expressive type to that of the overall rocking motion.

Gellrich (1991) has explored how specifically learned gestures can furnish a musical performance with an expressive intention. From his perspective, it is apparent that many of the gestures are culturally learned, as are their associated meanings. It is certain, in all forms of music, that some elements of physical gesture are learned from shared cultural codes. They may be picked up from teachers, peers, or even observation of someone on TV. Technically, the gestures may be *superfluous* to the production of the music—a surface level of movement or a kind of rhetoric that the performer adds to the performance. It could be that the deep-level source of expression is the rocking movement and that the local expressive gesture is a means of adding to that.

While Davidson's is case-study work, it does seem that the findings may be generalizable, since the growing research literature on nonverbal gesture in conversation and social interaction indicates that gestures often have particular purposes and these are commonly understood and used within a specific social and cultural context (see Ellis & Beattie, 1986; Argyle, 1988). For instance, *emblems* (such as a raising of the eyebrows or a shoulder shrug) are typically used to reinforce what is being said. The movement vocabulary of gestures used in music could have some similar functions. For instance, within the context of jazz performance saxophonists often raise the bell of the instrument and close their eyes as a symbol of intense expression, usually getting louder. Some saxophonists make the physical gesture even when they cannot actually play any louder.

So it seems that the bodily production of music involves general motion and specific localized culturally learned gestures for technical, musical, and socially communicative purposes. Beyond production, it would appear that from a perceptual perspective, body movements can assist the degree of coordination between coperformers and aid audience comprehension of the musical performance.

Perception of Body Movement in Performance

It is now well documented that audiences can detect finely grained information about musical expression (timing, pitch, and dynamics modifications to structural features of the music) and intention (the emotional mood of the performer and the piece) from a musician's body movements when he or she is playing (Davidson, 1993, 1994, 1995). So embodied musical meaning seems to be both perceptually available and comprehensible to audiences. In fact, when audiences are not skilled as listeners they rely entirely on the visual information they receive, not being able to differentiate between musical intentions and aural information (Davidson, 1994).

In an attempt to assess whether all or parts of the movements of a musical performance are meaningful, Davidson (in press, b) explored whether the movement information of a pianist was available to observers in a continuous stream or it was limited to particular moments within a performance. It was discovered,

on the one hand, that audiences reported the repetitive body rocking as being a continuously present and key source of expressive information, but on the other hand clips of only two seconds of visual material revealed that some moments were more obvious indicators of expressive intention than others, especially those moments that contained particular expressive gestures.

So it would appear that those movements used to produce a performance are informative of the musical meaning, as well as being generative of the musical intention itself. Consider the following anecdote about Glenn Gould (cited by Delalande, 1990) that explores the link between audience perception and the performer's use of his body. Gould's career fell into two distinct phases: an early period during which he gave concert tours as well as making sound recordings and a late period when he only worked in the recording studio. Looking at video footage from both periods, Delalande discovered that in the live performances Gould's movements had a degree of unpredictability but showed great fluency. In the sound-recording sessions, the movements were far more repetitive and fixed. It is possible that the earlier movements were for direct communicative intentions: literally demonstrating ideas to the audience. In the later performances, perhaps Gould was less socially motivated and was simply focusing on the best way to achieve a sound performance. Of course, this is only one possible interpretation of Gould's movements, but it nevertheless raises issues about the role of social interaction in shaping the production of the performance. Davidson and Good (1997; in press) discovered that when playing in small ensembles performers use their movement patterns to coordinate timing, dynamics and other expressive effects with their coperformers. So perception of coperformers has an influence on shaping the movement patterns, too.

The nature of the social mediation that goes on among performer, coperformer, and audience in the construction of the performance and the critical role of the body in shaping this have received very little attention in the psychology research literature. One relevant study is on the singer Annie Lennox (Davidson, 2001). Analysis showed that in addition to the specific movements related directly to the communication of the song—such as coordination signals and expressive gestures about the narrative content of the songs—some other types of movements were used purely for audience display or showing-off purposes. These involved a deliberate attempt to involve audience participation and had nothing to do with the song's narrative. For instance, there were moments when Annie Lennox danced playfully with her coperformers and came to the front of the stage, asking the audience members near the stage to clap along in time with the singing. Frith's (1996) analysis of pop singers' behavior showed that the pop singer constantly negotiates a communication of the song's narrative, a pop-star role with associated culturally defined behaviors, and his or her own individuality in the public forum.

Annie Lennox plays the role of a star in her use of showing-off or display gestures. She is a narrator-interpreter in her use of illustrative and emblematic gestures with the coperformers and audience. She is a coworker in her use of regulatory movements to coordinate musical entrances and exits. Internal self-concern also seems to be presented in Annie's adaptive gestures such as the self-

stimulation involved in touching her face or caressing her body with her arms as she sings. The particular illustrative, emblematic, regulatory, and display gestures are specific to Annie and her personal experiences and thus also indicate critical information about an unique individual. However, the adaptive gestures seem to display inner personal states or characteristics, whereas the display, regulatory, and illustrative (emblematic) gestures are more audience (externally) oriented.

Summary

Presenting the findings of the body movement work in summary, it seems that musical skills involve issues of fluency and technique, yet in the live performance critical concerns appear to be how the performer presents him- or herself as:

- A communicator interacting with coperformers to regulate the performance so that it remains unified
- An individual interpreter of the narrative or expressive/emotional elements of the work being played
- A self with individual experiences and behaviors
- A public figure with a clear aim to interact with and entertain the audience

All of these factors together highlight the tremendous range of skills involved in performance and undoubtedly provide important insights into understanding *what* information is being communicated in a performance.

The literature surveyed shows how critical gestural movements are in the production of and perception of a performance and particularly underscores the role of social interaction in the construction of a performance through the discovery that different types of gestures are used for specific coperformer and audience engagement. It could well be that the presence of others promotes the use of these communicative gestures.

Another issue to emerge from this research is the juxtaposition of movements connected with self and self-adaptation and those connected with pure social display. It seems that different aspects of self and self-projection are revealed in the movements.

Thus far, the work presented has demonstrated that musical performance movements are of the following types: purely biomechanical (they can only occur when the body is free and ready to use them), individual (each person has his or her own style), and culturally determined (some of the movements are learned through imitation of others' behaviors in specific contexts and so have common presentations within the cultural context). Many of these performance movements have clear functions and meanings: to communicate the expressive intention (for instance, a sudden surge forward to facilitate the execution of a loud musical passage or a high curving hand gesture to link sections of the music during a pause); to communicate directly with the audience or coperformers about issues of coordination or participation (for example, nodding the head to beckon the audience to join in a chorus of a song or exchanging glances for the coperformer to take over a solo in a jazz piece); to signal extramusical concerns

(for example, gesturing to the audience to remain quiet); to present information about the performer's personality, with his or her individualized characteristics providing important cues (muted contained gestures or large extravagant gestures, for example); and to show off to the audience.

In addition to the findings presented earlier, some performance movements with no specific value to the audience as interpretative cues are nevertheless the by-products of psychophysical, social, and cultural practices that surround performance—for example, standing rooted on both feet to be able to sing better. Although the audience may not read such cues in their assessment of the performance, taken together it is likely that such movements do add to the overall style and content of the performance.

A final point is that the body movements need to be presented at an optimal level. For example, it seems that too many movements might create an overly exaggerated performance and too few movements might make the performance appear stilted. Recall, for example, that although grand flourishing gestures were fashionable in nineteenth-century musical performance, Liszt was referred to by Glinka as an "exaggerator of nuance" (cited in Morgenstern, 1956, p. 129).

Bearing all of the findings discussed earlier in mind, the final section of this chapter considers their educational implications.

Working with the Body in Music Performance Teaching

Contemporary method books and study guides include diagrams of the correct positions and postures for holding musical instruments in order to play (see, e.g., Miller, 1996), but few of these texts provide information about how to use the body effectively to achieve a musically expressive performance or a charismatic and highly personalized interaction with the audience. However, there has been a historical interest in such matters. For instance, Pierre Baillot in his *L'art du violon* of 1834 (cited in Stowell, 1985) suggests that different types of movement are necessary to produce different musical tempi. For instance, the *adagio* tempo requires "more ample movements" than the *allegro*, where the notes are "tossed off," whereas in *presto* there is "great physical abandon."

Where an interest in the use of bodily gesture for musical interpretation has been expressed, it has typically been found when the author has an interest in the domain of dance and body alignment, with the most commonly cited source of inspiration for the practical being the teachings of Emile Jacques-Dalcroze (1865–1950), who points to body movement as crucial to the process of unifying the musical elements and focusing on musical expression. The Dalcrozian approach addressed the whole issue of musical meaning and musical communication:

What is the source of music? Where does music begin?
Human emotions are translated into musical motion.
Where do we sense emotions?
In various parts of the body.

How do we feel emotions?
By various sensations produced by different levels of muscular contraction and relaxation.
How does the body express these internal feelings to the external world?
In postures, gestures, and movements of various kinds. Some of these are automatic, some are spontaneous, others are the results of thought and will.
By what instrument does a human being translate inner emotions into music?
By human motion. (Jacques-Dalcroze writing in 1931, cited in Choksy, Abramson, Gillespie, & Woods, 1986, p. 31).

Some individual teachers may not agree with the Dalcrozian approach to teaching and learning music, but it does centralize the role of the body, connecting sounds to particular physical gestures. Recently Pierce (1994) has made a significant impact in the United States by adapting Dalcrozian principles for work with advanced musicians. Her approach involves teaching rhythm by experiencing the beat of pulse of music through pendular, swinging movements away from the instrument. The point of an exercise like this is to embody the full motion required to produce the attack point on the beat. That is, the student can feel the approaching downbeat and the surrounding moments in the body swing. So quite an abstract musical idea can be played out through the body. In another example, in order to achieve a *legato* line and to assist in the detection of a melody line that may be submerged in a harmony passage, students are asked to trace with the hand an analog to the shape of the melody, attending to weight and flow of the line to assist or draw attention to direction of melody and the surrounding harmonies and other textures.

Although we cannot comment on the efficacy of Pierce's work or, indeed, that of Dalcroze and others, we believe that these teachers draw on principles based on the human body and human nature that can assist development of a deeper base from which music technique and expression can be explored and understood.

In line with the range of ideas presented earlier, it becomes evident that there is not just one way to explore the body in music in order to improve technique, musical expression, and the presentation of self in performance, but rooted in the research discussed earlier in the chapter we now present some of our own methods for working with students to train their bodies. More detail about these practical ideas can be found in Correia (1999a, 1999b) and Davidson, Pitts, and Correia (2000), where experimental evidence that verifies the efficacy of the methods is presented.

Training Fluency of Movement. Without doubt, musicians need to be able to be aware of the muscular tensions or bad postural habits that may interfere with their playing. Thus, as a general principle, attempting to find the point of best equilibrium for head, neck, spine, pelvis, and legs is recommended as a good practical grounding for students to develop self-awareness in the overall posture of their bodies when preparing to play. These principles emerge out of the teachings of Alexander (1869–1943) and his principles on body alignment—the Alexander Technique.

Exploring Expressive Potential: The Narrative of the Musical Work. Based on drama-style exercises (see Boal, 1992), students are asked to express different characters, affects, or states of mind suggested by the narrative of the piece they are learning. They do this first through physical gesture and then in their musical sounds.

Working on the Intention of Each Musical Phrase. Once engaged and acquainted with the style and the overall atmosphere of the piece, the students are then asked to find *action metaphors* for each phrase or effect, trying to build up a nonverbal narrative in which every passage of the piece becomes meaningful and thus communicable through movement or physical gesture. Here the concepts of weight and flow are adapted from the movement analyst and choreographer Laban (1960), who attracted the student's attention to all the dynamic qualities of each movement as a means of understanding how forces act upon it and to give as broad an expressive palette as possible.

Directing an Interpretation: Conducting the Musical Expression of the Teacher. Another means of using the body to gain insights into the musical expression is for the student to conduct the expression in the playing of the teacher, using the body as the means through which to get the teacher to make expressive sound changes to his or her playing. Trials and discussion are used to explore all the expressive nuances by gestures and/or movement.

Finding the Inner and Outer Personality in Movement. Stategies to develop a sense of a public versus a private communication of one's self on stage has been central to the work of the actor (see Boal, 1992). It seems likely that some of the best performers are able to connect with the communicative principles necessary to achieve a good public presentation, while other individuals need to be aided. In music performance, teachers often ask their students to make their bodily gestures larger and more obvious to the audience so that the presentational component of the performance—its publicness—is clear. Difficulties in terms of both music production and perception seem to arise when the performer's behavior is either not sufficiently public for the concert environment or, on occasion, too large-scale and overt. Here issues of historical style and audience opinion can be explored.

Teacher's Body Movement Strategies to Develop Musical Expression in the Student. A wide range of verbal *metaphors*—especially for situations where the expression has to do with inner motions or reactions (like contraction or tenderness) can be used by teachers to stimulate the student's imagination and bodily meaning. These metaphors usually captured physical qualities. For instance, Correia (1999b) reported one teacher as having said, "Play it as if you were throwing pebbles into a pond, and feel the ripples pulsing out of the center of your body to the bow."

Concluding Comments

The evidence presented in this chapter has shown the significance of body movement in the development, performance, and training of musicians. Inter-

facing empirical findings, theory, and some practical applications, we hope to have inspired readers to reappraise their use of movement in the training of musicians and in their own performances. The work we have covered is in no way meant to be prescriptive, rather a starting point from which further developments can and we believe should be made.

Solo Voice

GRAHAM F. WELCH & JOHAN SUNDBERG

One of the principal challenges for the singer is to acquire an understanding of how to develop and maintain a particular set of culturally specific musical behaviors using an instrument that is not visible and in which the functional components change physically across the lifespan. The singer's instrument has three components. The respiratory system is responsible for variations in loudness; changes in the pattern and frequency of vocal fold vibration are perceived as variations in pitch and voice quality; and changes in the configuration of the vocal tract are linked to resonance and carrying power. Although often interrelated (particularly in the untrained vocalist), these three functional characteristics are susceptible through education to focused development and conscious control.

The ability to use the voice to express music through singing is a characteristic of all known musical cultures. Each culture tends to value particular vocal timbres in the performance of its art music, such as the vocal sounds commonly associated with classical opera in the West, with the throat music of Tuva, or with blues. These vocal timbres are a selection from a much wider potential variety, indicating the inherent plasticity of the human voice. So one of the central issues in any consideration of solo voice performance is the development and maintenance of a particular set of culturally specific behaviors that use an instrument that is not visible and in which the functional components change physically across the life span. This chapter will examine the basic design of the vocal instrument (its anatomy, physiology, and psychological correlates), its function in singing, and the pedagogical implications for both teachers and performers.

Structure and Function

The vocal instrument (Figure 16.1) consists of three essential components: the *respiratory system*, the *vocal folds* and the *vocal tract* (the cavity formed by the spaces above the larynx, namely, the pharynx and the mouth, which are sometimes complemented by the nasal cavity) (cf. Sundberg, 1996). Together, their combined action determines the characteristics of perceived vocal sound in speech and singing.

The respiratory system is the energy source for human voice production. This system compresses the lungs to provide an upward-flowing air stream that sets the *vocal folds* (situated within the larynx) into vibration. The vibrating vocal folds chop the air stream into a pulsating airflow (Figure 16.1; *transglottal airflow*) called the *voice source*. This consists of a complex of simultaneously sounding pure tones, or *partials* of different frequencies. Since the relationship between the partials in voiced sounds corresponds exactly to the harmonic series, the partials are also called harmonics and the lowest is called the fundamental. These partials decrease in strength with their ascending frequencies (see glottal source spectrum in the figure). However, the voice source is filtered by the spaces of the vocal tract above the vocal folds. Depending on its configuration, the vocal tract enhances or suppresses particular partials and so forms (shapes) the output sound (see the radiated spectrum in the figure). Consequently, these vocal tract resonances are called *formants* (see figure). The properties of the voice source, plus the frequencies of the formants, enable us to perceive and label particular output sounds as vowels. Formants also characterize consonants, both voiced (e.g., *d*) and unvoiced (e.g., *t*). The combined action of the vocal folds and the vocal tract also creates the distinctive personal timbre that we perceive in a voice.

The Vocal Tract

At the lower end of the vocal tract is the *larynx*. The two vocal folds are located inside the larynx and are made up of muscles shaped as folds. Their horizontal and vertical dimensions change in relation mainly to pitch. Covered by a mucous membrane, the folds are approximately 3 mm long in newborn infants and grow at an average rate of 0.4 mm per year for females and 0.7 mm per year for males. With a disproportionate growth during puberty in males, adult female vocal folds are about 9 to 13 mm, compared to 15 to 20 mm in adult males (Titze, 1994). Vocal fold length and vibrating mass are crucial to the pitch range of the voice: the longer and thicker the vocal folds, the lower the pitch range. Consequently, because their vocal folds are smaller, young children have a higher vocal pitch range than adults. Although boys tend to have slightly longer vocal folds than girls, this difference appears not to be reflected in customary pitch ranges, as these are very similar. However, once puberty begins (at around the age of eight in some girls) and the relative physical dimensions increase, voice pitch lowers and diverges between male and female voices. This results in adult male voices' being approximately one fifth to one octave lower than those for adult

females, depending on the singer's voice classification. (For example, the average spoken pitch of a typical soprano is near B_3 (247 Hz), a semitone below middle C or C_4, but the average spoken pitch of a typical tenor is about a fifth lower at E_3 (165 Hz), a sixth below middle C: Titze, 1994, p. 188.) Vocal fold length does not significantly depend on body height but is more related to the circumference of the neck (a function of body build). At the limits of vocal pitch range, there is an overlap between men and women in their sung vocal pitch ranges, and this is greater between altos and tenors than sopranos and basses (Titze, 1994, p. 187; see "Voice Source" later).

The vocal folds run horizontally from front to back within the *thyroid cartilage*. They are attached together at the front to the inside of the thyroid cartilage (Adam's apple) and at the back to two mobile cartilages (the *arytenoids*). When one is breathing silently, the arytenoid cartilages are moved apart (abduction) by the *opener* set of muscles (*posterior cricoarytenoid* muscles), allowing the air stream to flow freely. The gap between the two folds is known as the glottis. When one is speaking or singing, voiced sounds are produced when the *closer* muscles (the lateral *cricoarytenoid* and *interarytenoid* muscles) bring the arytenoid cartilages together and hence draw the posterior ends of vocal folds together (adduction), so that their edges vibrate in the air stream. The folds are abducted for unvoiced sounds (such as certain consonants) and adducted for voiced sounds (such as vowels). The muscles responsible for opening and closing the glottis are mainly located at the back of the vocal folds near the spine. As well as assisting in basic vocal fold vibration, this set of opener and closer muscles is also involved when changing the loudness of the voice.

The air pressure in the lungs is the main tool for varying vocal loudness: the higher the pressure, the louder the voice. The underlying mechanism is that a greater air pressure throws the vocal folds apart with a greater force, with the result that they then also close more quickly. If the closer muscles are fully activated and the opener muscles are relaxed, the vocal folds are kept tightly closed together. This requires much more effort from the air stream to push them apart. Eventually, even when the folds are firmly adducted, at high lung pressures it is usually possible to get some air between the vocal folds. The effort, however, bursts the folds apart and then snaps them back together, creating a bigger disturbance of the air, which is perceived as a louder voice and *pressed* phonation (also termed *hyperadduction* or overly tight vocal fold adduction: Harris et al., 1998).

The laryngeal *lengthener* and *shortener* muscles are essentially responsible for pitch change. The shortener muscles (the *thyroarytenoids*) are located within the vocal folds themselves. They have a horizontal orientation (front to back). When these contract, the result is a fatter, bulkier, shorter vibrating tissue that produces a lower pitch. In contrast, the lengthener muscles (the *cricothyroids*) have more of a vertical orientation and are attached near the front of the larynx, stretched between the thyroid and cricoid cartilages. The effect of the contraction of the lengthener muscles on the cartilages is to tilt and slide the thyroid cartilage forward and so stretch (lengthen) the vocal folds. In so doing, the fundamental frequency is raised.

Effective coordinated action of each of these shortener and lengthener muscles is required for skilled voicing. When a voice becomes louder, the activation of the closer muscles is increased, while the activation of the lengthener muscles is reduced. The reason is that the increased airflow creates the louder snapping together of the vibrating vocal folds and so the lengthener and shortener muscles have to work harder in combination to resist the pressure from the lungs, either to maintain or to change pitch as well as intensity (see "Voice Source" later and also Thurman & Welch, 2000, pp. 394–408).

A few millimeters above the vocal folds there is another pair of folds, also covered by mucous membrane. These are called the *false vocal folds* or the *ventricular folds*. Between the vocal folds and the ventricular folds there is a small cavity known as the *laryngeal ventricle* (sometimes termed *epilarynx*). This links into the much larger pharyngeal space above. The ceiling of the pharynx is the *soft palate* (*velum*), which also serves as the gateway to the nasal cavities. Narrow channels in the ceiling of the nasal cavity lead up to other cavities, the maxillary and frontal sinuses, which are located in the bone structure of the skull. The pharynx leads into the oral cavity. Both these cavities have their shapes altered by the movement of the tongue and the jaw. Thus the pulsating air stream flows through a tube that consists of a group of linked chambers to produce particular vocal timbres.

With regard to differences between the sexes, an adult female vocal tract is about 15% to 20% shorter than its adult male counterpart. In particular, the female laryngeal ventricle (the space between the vocal folds to the false folds) and pharynx are shorter (Story, Titze, & Hoffman, 1997) than those of the male, while the mouth length difference between the sexes is less marked (Nordström, 1977).

Breathing

The lungs are elastic, spongy structures suspended in a vacuum in a sac within the rib cage. Because of the vacuum, their volume is enlarged. They contain a great number of small cavities linked by a system of air pipes, which join in the trachea, a tube that leads up to the vocal folds. Inhalation and exhalation correspond to decompression and compression of the lungs, which is performed by the respiratory system through forces generated by muscles, elasticity, and gravitation. Through muscle contraction, we can expand and contract the rib cage. As most of the lung surface is covered by the rib cage, small rib cage movements result in substantial compression or decompression. A large inspiratory muscle sheet, the diaphragm, constitutes the boundary between the rib cage and the abdomen. It originates along the lower edge of the rib cage and is vaulted into it. When contracting, it lowers the bottom of the rib cage by pushing the abdominal content downward and forward, which in turn expands the abdominal wall. Conversely, by contracting the abdominal wall muscles the abdominal content can be pushed back into the rib cage, thus compressing the lungs.

After a completely relaxed sigh, lung volume typically reaches the *functional residual capacity* (*FRC*), generally near 40% of maximum lung volume in an

upright position. In singing and speech alike, we usually phonate at lung volumes above FRC, whereas phonating below FRC can feel uncomfortable. When trained singers learn new songs, they learn how to inhale and sing in order to avoid lung volumes below FRC. Small lung volumes are generally used in speech, whereas in classical singing phrases are often initiated at very high lung volumes. Moreover, classical singers tend to repeat their breathing patterns very consistently when they sing the same phrase. They seem to use the rib cage mainly for changing lung volume, though some singers appear also to make use of the abdominal wall (Thomasson & Sundberg, 1999).

The overpressure of air in the trachea generates an air stream through the *glottis* (the space between the vocal folds). The pressure just below the glottis, the *subglottal pressure*, provides the driving force of the voice and is the main tool for controlling vocal loudness: the higher the pressure, the louder the voice (as mentioned earlier). This pressure variation in singing needs to be quite accurate, as pressure affects pitch; failure to match a target pressure may result in pitch errors (singing out of tune). A classical singing exercise that involves *staccato* performance (short tones interleaved with short silent intervals) of ascending and descending triad patterns seems particularly appropriate to train the singer's subglottal pressure control in coordination with the control of the laryngeal muscles that regulate the fundamental frequency. During the silent intervals the vocal folds part, leaving the airways open, so lung pressure must then be reduced to zero to avoid a waste of air. In addition, high tones need higher pressures than low tones, so each tone usually needs a different pressure. Singers also use subglottal pressure variations to demarcate the tones in rapid sequences, as in legato *coloratura* singing. Then each tone receives its own pressure pulse, so that one pressure pulse is produced for each tone in synchrony with the fundamental frequency pattern. In quick tempi, these pressure pulses may be as short as 150 milliseconds (ms).

Voice Source

In voiced sounds, the voice source is a pulsating airflow (see waveform element in Figure 16.1). The voice source can be varied in several different ways with respect to fundamental frequency (perceived as pitch), amplitude of the spectrum partials (perceived as loudness), and dominance of the fundamental (perceived as type of voice production).

The perceived pitch corresponds to the frequency of vocal fold vibration. Thus when the pitch of A_4 is being sung, the vocal folds open and close the glottis 440 times per second ($A_4 = 440$ Hz). The main determinant of fundamental frequency is the length and vibrating mass of the vocal folds: the longer and thinner the folds, the higher the pitch (as mentioned earlier). These properties are controlled by the laryngeal musculature. The approximate ranges covered by the main singer classifications are as follows: bass singers, 80–330 Hz (pitch range E_2–E_4); tenors, 123–520 Hz (C_3–C_5); altos, 175–700 Hz (F_3–F_5); and sopranos, 260–1,300 Hz (C_4–E_6). Fundamental frequency is also influenced by subglottal pressure. So, to stay in tune while producing a *crescendo*, a singer needs to reduce the activation of

the laryngeal muscles that regulate fundamental frequency as the subglottal pressure increases. This may partly explain why less-skilled singers find it difficult to sing high tones softly. Their laryngeal muscles are not yet skillfully coordinated enough to ensure that the vocal fold tension matches the low subglottal pressure. Instead, they rely on increased subglottal pressure to raise pitch, resulting in loud and sometimes mistuned singing. As with all human control systems, the key to success is an awareness of the target in relation to possible means of achieving that target.

The voice source is also influenced by the degree of glottal adduction. Weak adduction results in a leaky or breathy voice, as in a voiced whisper. Overly strong adduction produces pressed phonation, or a tense or strangled voice, as when we phonate while lifting a heavy burden. In between these extremes is a range of adduction variations, with classically trained singers tending to have more consistent adduction across their pitch range. This enables such singers to produce a more even vocal sound across wide pitch ranges, whether singing softly or loudly. Adolescent voices tend to be rather breathier, reflecting this period of instability in vocal coordination during voice change. Untrained females tend to have breathier voices than untrained males across the life span (Linville, 1996). This may be because the gap between the female arytenoids cartilages is generally wider and their closure requires a larger gesture (cf. Södersten, 1994) or because of some underlying gender patterning of the vocal mechanism during childhood (Welch & Howard, in press) or both.

Another type of variation in the voice source corresponds to different patterns of vocal fold oscillation. These patterns are called *vocal registers*. There are at least three registers, generally referred to as *vocal fry*, *chest* (or modal), and *falsetto*. The modal register is sometimes further subdivided in singing into lower and higher subregisters (also termed as *chest* and *head* by singers because of the physical sensations involved) to create four registers.

As stated earlier, greater shortener muscle activity increases the mass of the vocal folds and lowers vocal pitch, while greater lengthener muscle activity reduces the mass of the vocal folds and raises vocal pitch. In vocal fry (pulse register), which frequently occurs at phrase endings in conversational speech, the vocal folds are thick and lax and vibrate asymmetrically; as a result, fundamental frequency is low, generally well below 100 Hz for male voices. By contrast, in the two components of the modal register (lower and upper) the folds are less lax and vibrate symmetrically. If there is a predominance of the shortener laryngeal muscles, there is more vertical tissue mass, creating a larger bottom-to-top contact area and more horizontal depth in the oscillating vocal fold tissues. The vocal folds tend to remain in contact with each other for longer in each cycle (Titze, 1994). The resultant tone sounds richer and full-bodied (often termed *chest voice*). However, if there is greater lengthener activity, the vocal folds are longer and thinner and vocal fold contact is confined only to their superior (upper) portion and outer layers. This reduced vertical mass, smaller bottom-to-top contact area, and less horizontal depth produces a vocal quality that generally sounds lighter and thinner (also termed *head voice*). In falsetto, the folds are thin and stretched and rarely close the glottis completely, unless the voice has been trained

in this register (such as that of the countertenor). The shortener muscles are assumed to relax completely, so that vocal fold length is determined by the action of the lengtheners. The vertical tissue mass and horizontal depth can still be varied such that, in a trained falsettist, it is still possible to produce a sung pitch range of approximately two octaves (E_3 to E_5).

Singers are trained to change registers gradually, so that no salient timbre differences occur, unless specifically chosen to add particular voice coloring in their performance. As much of singing principally involves the two elements of the modal register (lower and higher), register transitions (*passaggi*) may best be rehearsed by first practicing *descending* rather than ascending pitch patterns and utilizing quieter phonation. This reduces the potential overinvolvement of subglottal pressure that can occur when singing ascending pitch patterns. Descending pitches require a gradual increase in tension of the shorteners within the vocal folds and a concomitant relaxing of the lengtheners.

A voice source characteristic of the trained singing voice is *vibrato*. There seem to be at least two types of vibrato, which are produced and sound differently (Dejonckere, Hirano, & Sundberg, 1995; Titze, 1994, p. 290). The vibrato used in classical singing is normally produced by pulsations in the pitch-raising lengthener muscle (cricothyroid) and is a *frequency vibrato*. In various types of popular music, a different kind of vibrato is often used, which is generated by variations in subglottal pressure imposing an undulation of voice source amplitude. It corresponds to an amplitude modulation of the voice source and is really an *intensity vibrato* (Sundberg, 1987). Frequency vibrato corresponds to a slow, nearly sinusoidal fundamental frequency modulation. Typically, the rate is somewhere between 5.5 and 7 undulations per second, with the extent of the modulation varying from ±50 to as much as ±150 cents (where 100 cents = 1 semitone). Both rate and extent are important. If the rate goes below 5 undulations per second, which may occur in older or strained voices, no clear pitch can be perceived; it sounds as if the pitch is swaying around. If it is faster than 7 undulations per second, the tone sounds nervous. Also, the acceptable range of frequency modulation is limited. If the extent surpasses about ±100 cents, it tends to sound exaggerated. In choral and in pop singing, vibrato typically has a much smaller extent than in classical singing.

Formants

As mentioned at the beginning of this chapter, the spaces above the vocal folds are a series of connected resonating chambers that filter the sounds that emanate from the voice source. Voiced sounds are acoustically rich, having many harmonics above the fundamental frequency. The tract amplifies certain component harmonics but dampens others. Formants are vocal tract resonances that appear at certain frequencies, the *formant frequencies*. Because partials of various frequencies are transmitted through the vocal tract simultaneously, those that coincide with the formant frequencies are radiated from the lip opening with a greater strength than others. Therefore, formants appear as peaks in the spectrum of the radiated sound (see Figure 16.1).

There are generally five formants relevant to singing, and they are crucial in our perception and discrimination of voiced sound. In speech communication our perception and labeling of certain sounds as vowels depends on the relationship between the lowest two formants. The frequency of the first formant is particularly sensitive to the size and shape of the pharynx and mouth cavity, which is largely influenced by the width of the jaw opening. Likewise, the second formant is particularly sensitive to the shape of the tongue body. If, for example, the first and second formants are located at 600 Hz (around $D\#_5$) and 1,000 Hz (C_6: soprano top C) respectively, the perceived vowel quality is /a:/ (as in *hard*); if they are located at 300 Hz ($D\#_4$) and 2,000 Hz (C_7) the perceived vowel quality is /i:/ (as in *heed*). The formant frequencies depend on vocal tract length and shape, which are controlled by the positioning of the lips, jaw, larynx, velum (soft palate), tongue, and pharyngeal side walls, that is, by articulation. In speech, the coordination of the vocal tract is not conscious but is a product of basic anatomy and physiology interacting through socialization with a particular sociocultural linguistic soundscape. Formant frequencies are decisive for vocal timbre. As well as determining perceived vowel quality, formants are important (alongside temporal patterns) for the perception of personal *voice quality*, permitting us to identify individual voices, such as those of favorite singers on a CD recording or family members on the telephone.

There is a close relationship between vocal tract shape and formant constellation. For example, a shortening of the tract, caused by retracting the corners of the mouth or by raising the larynx, increases all formant frequencies more or less. Both a narrowing of the pharynx and a widening of the mouth cavity increase the frequency of the first formant. This will make the sound brighter. Conversely, expanding the pharynx, protruding the lips, and lowering the larynx will lower the first two formants and make the sound darker in timbre. Moreover, if the pharynx is lengthened by lowering the larynx, the second formant is also lowered in vowels produced by a forward position of the tongue, such as /i:/ (as in *heed*). However, vocal tract length (and hence the formant frequencies of a given vowel) varies somewhat both among and within men, women, and children. Such differences explain some of the voice timbre variations among individuals. For example, it has been shown that for a given vowel tenors tend to sing with higher formant frequencies than basses (Sundberg, 1987, p. 110).

In trained classical singers, a characteristic feature of bass, baritone, tenor, countertenor, and alto voices is an exceptionally high energy peak, normally occurring somewhere between about 2.5 and 3 kHz (i.e., over one octave above C_6). This peak has been called the *singer's formant* (Sundberg, 1974, 1987). The energy peak allows the trained singer's voice to be heard above the sound of a full orchestra in a large concert hall. It appears in all voiced sounds and is normally a consequence of a clustering of the third, fourth, and fifth formant frequencies in a frequency range where the ear is particularly sensitive. This effect can be produced without excessive vocal effort, even when the orchestra is loud. This distinctive ring to the voice, and the source of its carrying power, is generated by a particular configuration of the vocal tract; a wide pharynx is often

combined with a lowered larynx (as compared to the rest position). The amplitude of the singer's formant varies among vowels and also with vocal loudness, since vocal loudness affects the slope of the voice source spectrum, as mentioned earlier.

The center frequency of the singer's formant seems significant to voice quality. In bass voices, the center frequency is near 2.4 kHz, in baritone voices near 2.6 kHz, in tenor voices near 2.8 kHz, and in alto voices (female) near 3.0 kHz. These variations can be assumed to reflect differences in vocal tract length and pharyngeal shape. In addition, the wide pharynx needed for clustering the higher formants to create the singer's formant also brings changes to the first two formants. For example, the second formant in front vowels such as /i/ is considerably lower in classical singing than in neutral speech.

Another phenomenon of formants relates to the perception of vowels in singing. The frequency of the first formant varies between about 250 and 1,000 Hz (roughly C_4–C_6) depending on the vowel. So many of the sung pitches produced by tenors, altos, and sopranos can have their fundamental frequency above the typical value of the first formant for a particular vowel. In order to remain (or attempt to remain) intelligible, singers tend to adjust the configuration of the vocal tract in order to raise the value of the first formant under these conditions. In the vowel /a/, this is achieved by a widening of the jaw opening. In other vowels, the lip opening and/or the tongue constriction of the vocal tract is first widened up to a certain point, and after this possibility has been exhausted the jaw opening is widened.

Once again, singers do not deliberately set out to tune the formants per se; rather, they learn (and self-monitor) a set of vocal tract coordinations that produces the desired perceptual effect, namely, a range of vocal pitches and vowels that sound cohesive (cf. Miller & Doing, 1998). In singing pedagogy, for example, much use has been made of the vowel /u:/ (as in *too*) in training both child and adult aspiring soloists. In normal phonation of this vowel, the third formant is low, so formant clustering does not normally occur. However, a rearticulation of the tongue shape, with an anterior placement of the tip of the tongue, filling out the cavity behind the lower incisors, will raise this formant and increase the perceptibility of a singer's formant.

At high pitches in the soprano range, all vowels share approximately the same formant frequencies. If the first formant is near that of the fundamental frequency (corresponding to the perceived pitch), it has the effect of making the fundamental much louder. For classical sopranos singing at pitches above 700 Hz ($F\#_5$, top of the staff), for example, such loudness increases come with no increase in vocal effort. However, since vowel quality is determined mainly by the two lowest formant frequencies, vowel intelligibility at high pitches becomes problematic. Faced with a choice between inaudible tones with normal vowel quality and audible tones with modified vowel quality, singers generally choose the latter. The intelligibility of very high singing relies almost exclusively on consonants, not vowels.

Thus formants are the principal resonances of the vocal tract. Other resonances occur also in the subglottal airways and the nasal sinus system. From the

audience's point of view, there appears to be little significant contribution to perceptual voice quality in classical singers from either the chest region (except at low pitches for basses) or the nasal cavities and sinuses. Other vocal genres, such as certain folk singing, may make greater use of nasal resonance. For the singers themselves, any kinesthetic sensations during singing from these bodily parts may assist in their self-monitoring of how they feel the voice is placed during performance.

Choral singers show less evidence of the singer's formant. This probably reflects the need to ensure that individual voices do not stand out in the creation of a choral blend (see also chapter 17). Similarly, *country* singing is more similar to normal speech than classical singing. Thus when one is singing loudly at higher pitches, there is often greater vocal fold adduction. Likewise, vocally untrained and inexperienced singers tend to use habitual speech coordinations when they sing. With increasing pitch, such singers tend to raise their larynxes and change their tone production toward pressed voice. This adds an edgy quality to the voice, corresponding to a weak fundamental and loud high partials, which is a characteristic also of some *folk music* styles.

Another popular singing style is the *belt voice* (Estill, 1988). This is a term that was used to describe singing in the American music theater in the 1940s and 1950s by Ethel Merman but is now also found outside the theater in the performance of other musical genres, such as gospel, spirituals, and jazz. Some popular singers (such as Whitney Houston, Gloria Estafan, Alanis Morissette, and Anita Baker) exploit this quality to create a particular emotional impact at certain moments in a song. The sound is loud and the vowel quality is more similar to that used in very loud speech than in operatic singing. It is produced with a narrow pharynx, a raised larynx, and high lung pressures.

One particularly striking use of formants in a musical genre is found in the throat singing (overtone singing) of Tuva (or Tyva), an autonomous republic within Russia on its border with Mongolia. This type of singing involves producing two distinct pitches simultaneously. One is low and sustained (such as in a bagpipe) and corresponds to the fundamental, while the other is much higher, with a flute- or whistle-type quality, and corresponds to one of the harmonics. There are different styles of throat singing, but each involves a particular voice source behavior (keeping the vocal folds closed for longer in each vibratory cycle) and shaping of the vocal tract (manipulating the tongue tip and root and its midpoint to cluster the second and third formants, with a protrusion of the jaw and a narrowing and rounding of the lips and, in some cases, using the false folds to vibrate an octave below at half the rate of the vocal folds). The result is a low sustained fundamental and a finely tuned formant peak. Depending on the pitch of the fundamental, up to 12 harmonics can be isolated individually. Enhanced in succession, they can create a melody (Levin & Edgerton, 1999). Throat singing is not taught formally but learned in the same way as language. It can be mastered also by non-native singers. This type of singing is also found in Tibet, Japan, and South America (Klingholz, 1993), and elements from such musics have been incorporated into modern Western music performance (Schaefer, 2000).

Performance and Pedagogy

Voice is an essential element of self-identity. It helps to define who we are and how other people experience us. It conveys our inner feeling states, both to ourselves and to others (Thurman & Welch, 2000). Emotion and mood are central characteristics of voice production and reception. This is because of the integrated networking of the body's nervous, endocrine, and immune systems. Whether we are feeling elated, relaxed, stressed, or threatened, each inner state is likely to be reflected in voice behavior and to be communicated to others and to ourselves (Welch, 2000b). Hence, the voice is exceedingly useful as a musical instrument.

Solo singers in training often have vocal habits that are potentially challenging for the voice teacher for five main reasons:

- Much voice behavior is not conscious. It is habitual and not readily accessible to conscious processes. It is also typically influenced (as well as being a reinforcement) by how we feel at the moment of voice use (Thurman & Welch, 2000).
- We cannot physically see the sound source (vocal folds) or tongue shape; we have to rely on our proprioception (from muscle receptors) and auditory feedback to sense what our voice is doing.
- Highly skilled musical performance requires consistent musical behaviors. The moment-to-moment changes in articulation that are characteristic of normal conversation are often inappropriate and inimical to culturally derived classical music performance (Sundberg, 2000, p. 235).
- Vocal music is a highly complex sociocultural artifact. The words and music each present separate challenges to the performer, as does their combination (Welch, 2000a). The text is often a narrative that has its own internal rules, whereas the music makes physical production demands on the vocal system that might be contrary to those expected in normal speech articulation (Welch, 1985a).
- The grouping of tones in musical motifs and phrases is an important aspect of music performance (Gabrielsson, 1999). Changes in voice timbre are often used for marking boundaries in musical structures. This makes the elimination of timbral differences between different pitch regions in a voice an essential aspect of vocal pedagogy.

One of the first tasks for the singing teacher is to bring elements of voice production to conscious awareness, such as an awareness of the underlying anatomical structures and their function in skilled voice production. Major professional associations for singing teachers (such as the National Association of Teachers of Singing in the United States and the Association of Teachers of Singing in the United Kingdom) now include scientific articles in their journals (*Journal of Singing* and *Singing*) in order to assist singing teachers and performers to understand better the data from voice science.

For many centuries, one pedagogical strategy has been to utilize small musical building blocks (*solfeggi* patterns of pitches, such as scales, motifs, arpeggios). Such simple musical exercises allow the singer to focus on and memorize isolated or simple combinations of elements from the dominant musical culture. Solfeggi may

also help the singer to work toward a greater evenness of vocal timbre across the pitch range. In untrained voices, vocal timbre tends to automatically change with pitch. However, through the use of such exercises, a greater evenness of vocal timbre is likely, particularly if (1) consonants are reduced in time (although consonant duration is varied for expressive purposes in actual singing performance) and (2) vowels are modified from typical habitual speech patterns.

Although imagery plays an important traditional role in voice pedagogy, it has rarely been researched systematically. Callaghan's (1997) survey of Australian teachers of singing reported three different types of imagery evidenced in practice (visual, kinesthetic, and aural). However, such practices were based on teachers' craft knowledge rather than empirical data. The experiential evidence of the efficacy of imagery continues to need corroboration in terms of well-controlled formal experimentation.

The scientific study of vocal production in singing is a relatively modern phenomenon. The human voice's invisibility has required the application of new technologies to reveal its underlying activity. For example, MRI (Story, Titze, & Hoffman, 1996), X-ray photography, and high-speed imaging are just some of the more important techniques that have been adapted from clinical studies for the analysis of singing.

The basis for performance is a variety of practice and rehearsal strategies that allow the singer to shape the perceptual and physical systems toward the identified musical goal (cf. Welch, 1985b). The practice of constituent elements in isolation can facilitate conscious awareness and control of basic coordination, as well as permitting the conscious overlaying of musical stylistics according to the particular genre and narrative context. Furthermore, reaction time studies indicate that we need approximately 300 ms to make a conscious adjustment to our motor behavior (cf. Schmidt, 1975, p. 137; Welch, 1985a), yet this is rather slow in relation to the requirements of vocal musical performance (such as for rapid scalic passages or arpeggios).

Given the complexities of the voice production in (classical) singing, the implications of a sound knowledge of vocal structure and function for vocal pedagogy are that

- Feedback from the teacher should be related directly to shaping conscious awareness, such as in understanding the relationship between tongue shape and formant tuning.
- The more complex the vocal task, the greater the opportunity for the student to misinterpret teacher feedback (Welch, 1985a, 1985b). Simpler vocal tasks, therefore, are more accessible to focused change.
- The biological aging process changes structure and function, not withstanding the relative stability of voice production across four decades (ages 20 to 60: Titze, 1994, p. 182). For example, the laryngeal cartilages begin to ossify (become more bonelike) in the third decade of life, suggesting that younger voices are more suited to agile musical requirements, whereas older voices are more able to sustain vocally strenuous performance. Therefore, different musical demands are appropriate for different age groups.

In summary, successful solo singing across the life span is more likely if both teachers and performers have developed habitual singing behaviors that are underpinned by an understanding of their physical and psychological reality.

Choir

STEN TERNSTRÖM & DUANE RICHARD KARNA

Choir singers and directors frequently find themselves grappling with acoustical issues that appear to affect their ability to perform well. Hearing one's own voice, for example, is crucial. It improves with increased singer spacing and depends also on the room acoustics. Singer preferences are diverse but on average one's own voice needs to be about 6 dB stronger than the rest of the choir. In most rooms this implies a fairly spread-out formation. Precise intonation may be jeopardized by pitch perception discrepancies and by mechanisms inherent to voice control but it can also be facilitated by acoustically informed measures such as articulatory enhancement of common partials. Researching such issues necessitates decomposition while remaining aware of the true complexity of the situation: that of many people singing together and hearing each other in a room.

Many people who choose to perform music as a satisfying pastime do so as choir singers. Singing in unison or in harmony with other people is a low-cost, enjoyable activity, which at the beginner's level demands little more than one's time and a certain dedication to the task.

During the past couple of decades, research into the acoustics of choir singing has uncovered numerous interesting effects that are of potential relevance to choral performance. Some concern voice production, others have to do with the acoustics of the stage and the auditorium, while still others are related to our sense of hearing. Many of them are rather subtle and, if taken in isolation, of minor importance. When the acoustical circumstances combine constructively, however, choral singing is certain to become easier; conversely, when they combine destructively, choral performance is likely to suffer. For this chapter, we have chosen to describe in detail some phenomena that we expect and hope to be particularly interesting and useful to choral directors and singers who are curious about acoustics.

Fundamentals of Room Acoustics

We note first that choirs are particularly dependent on the acoustics of the room, a subject that is not covered by other chapters in this volume.

Sound waves are a form of energy. One adult singer emits about three milliwatts (mW) of acoustic power in *forte*. Most of the energy emitted by the singer will bounce around in the room as reverberation until it is absorbed (into heat) by the walls and furnishings. The greater the absorption, the quicker the sound energy disappears, and the shorter the reverberation time will be. A minuscule proportion of the radiated sound energy eventually reaches the eardrums of listeners. The sound that reaches the listener from the source has three components: the direct sound, the early reflections, and the diffuse field (or reverberation). The *direct sound* travels in a straight line from source to receiver; it arrives first and reveals the distance and the direction to the source. The nearer the source, the stronger the direct sound. *Early reflections* are sounds that arrive at the listener after only one or two bounces against nearby walls. At delays less than about 40 ms we do not perceive these as separate echoes, but they are still very important for our impression of the acoustical liveness of a room. The *diffuse field* is the sum of the thousands of all later reflections that rapidly die down as a small amount of energy is lost into the wall at each bounce. The *reverberation time* is defined as the time it takes for the diffuse field to become 60 decibels (dB) weaker once the sound source has been turned off. After that time, the reverberation is essentially inaudible.

The diffuse field is so called because the many reflections tend to merge into a practically uniform sound field with no direction of its own. For a given source, the intensity of the diffuse field is much the same throughout the room. (Analogy: when you have been swimming in a pool for a while, the slosh of waves won't tell you where in the pool you have been.) There exists a distance from the source such that the intensities of the direct sound and the diffuse field are equal; this is called the *reverberation radius* of the room. If we move out farther from the source, the diffuse field dominates and the total sound intensity does not diminish appreciably with distance. If instead we approach the source, the direct sound will dominate and become louder the closer we are to the source. Considering the situation inside the choir, in rooms typical for choir performance only the one or two nearest circles of neighbors in the choir are within one reverberation radius of each other; the rest of the choir is outside.

Physical Versus Perceptual Sound Properties

The loudness, pitch, and timbre of a sound are *perceptual* entities that can be measured only by asking listeners what they hear. Fortunately, these three entities correspond closely—but not exactly—to three measurable *physical* entities of sound: pressure level (SPL), fundamental frequency (F_0), and distribution of energy over frequency. The physical properties are the main entry points of the

acoustician, who can measure them, study their evolution over time and space, and subject them to statistical analysis.

All the physical parameters of a tone can to some degree influence any or all perceptual parameters (Fletcher, 1934). The study of these dependencies is the basis of psychoacoustics. For example, a tone that has a strong fundamental partial but weak overtones is perceived as dull. When presented at very different loudness levels, such a tone may also appear to change somewhat in pitch, even though its fundamental frequency remains the same. This so-called pitch-amplitude effect is not generally known to musicians, but it may influence choral intonation in certain circumstances.

Sound Properties and Mechanisms as an Organizing Principle

For any research project on choir acoustics it is convenient to constrain the issue to one or two of the measurable *properties*, usually adopting a perspective either of voice production, of room acoustics, or of hearing, which are all *mechanisms*. It must be stressed that such constraints are for practicality only, because the reality of choral performance is too complex to be studied all at once. In Table 17.1 we list some examples of topics related to choir acoustics, categorized along these lines.

The intricacy of possible topics means that there is no obvious, systematic path for us to follow in order to cover the subject of choir acoustics in this compact overview. Instead, we will state some acoustical problems commonly encountered by choirs and point to ways of understanding and negotiating these problems. In each case we will first list the relevant acoustical issues and provide some practical recommendations. This will be followed by an in-depth background discussion of the problem, with explanations of the recommendations and references to scientific research.

Balance of Loudness

Choral singers sometimes complain that they cannot hear their own voices. Why might this be, and what can be done about it?

Relevant Factors

1. The physical spacing between singers
2. The amount of reverberation in the room
3. The presence or absence of reflectors close to each singer
4. The vocal power of the complaining singers relative to that of their neighbors

Recommendations

1. Increase the spacing between singers, and/or have the choir stand in fewer rows. If this is not possible, mix the sections.

Table 17.1. A tentative categorization of topics in choir acoustics. Topics discussed in this chapter are indicated in italics.

	Loudness/ Balance	Intonation	Timbre	Multivoice Issues
Voice production	Diversity of singers' vocal power; directivity of the human voice	Breath support, vibrato in choirs; *articulatory perturbation of pitch*	Acoustic differences between S-A-T-B, between trained voice and untrained, singer's formant or not	*The role of flutter in ensemble sound*; placement of singers within the choir; does uniformity of vowels matter?
Room acoustics	Effects of choir size, formation, *singer spacing and room absorption on the self-to-other ratio (SOR)*; distances; risers, shells, and reflectors	Effect of the SOR on intonation ability; can the pitch of the reverberation seem to go flat?	Effects of room response on voice usage; effects of different types of absorbents; wall proximity for basses; where to hold the music folder	Choir placement relative to audience; trade-off between room reverberation and the number of singers; ensemble timing
Perception	*Reflection, occlusion and bone conduction of one's own voice; diversity of singer preferences as to the SOR*	The *pitch/ amplitude effect* as an intonation hazard; *the pitch can differ slightly in the left and right ears*	*Pitch is more salient with certain timbres; role of common partials*; why some voices fit together and not others	Blending ability of different voice types; differences between choirs and vocal groups; *combination tones and beats*; how close is unison?
Sound technology	Choir with instrumental combo; public-address systems; self-monitoring for the choir	*What devices are suitable for giving the starting pitch?*	Faithful reproduction or enhancement?	Placement of microphones and loudspeakers

2. Decrease the amount of reverberation in the room by introducing absorbents, closing curtains, admitting the audience, or opening several windows.
3. Encourage the singers to experiment with the sheet music and folder as a small personal reflector. There is a particular angle that noticeably improves the perception of one's own voice. Remove any shells or other large reflecting surfaces at close range, because these tend to exacerbate the problem.
4. Place the quieter voices near the ends of the choir and the louder ones near the center.

Scientific Background

Self and Other. Inside a choir we have a complex transmitters-receivers situation with many directional sound sources, all of whom are also listeners (Marshall & Meyer, 1985). Taking the perspective of an individual singer in the choir, we will refer to the sound of one's own voice as *Self* and to the sound of the rest of the choir as *Other*. The Self sound is dominated by *airborne* sound coming out through the mouth, but it also has a component of *bone-conducted* sound. The relative contribution of the bone-conducted sound is hard, however, to measure objectively (von Békésy, 1949). For example, it can vary dramatically with vowels: block your ears and sing to compare /u/ with /a/! An open mouth radiates more sound, leaving less energy to be coupled through the body's tissues.

The airborne part of Self is entirely dominated by the direct sound from the mouth. The room reflections of Self are typically 15 to 20 dBs weaker than the direct Self. This means that inside any choir they will be drowned out (*masked*) by Other.

The Self-to-Other Ratio. A choir singer hears the Self sound together with the Other sound; ideally these should both be discernible in some optimal proportion. The *Self-to-Other Ratio* (*SOR*) can be measured on location for any particular singer and can be expressed in decibels. When the ears of a singer are subjected to the sounds of Self and Other simultaneously, Self will usually be a certain number of decibels stronger, in which case the SOR is said to be positive. Clearly, the SOR is a predictor of how well a singer will hear his or her own voice. Typical SOR values in live choral performance range from +1 to +8 dB (Ternström, 1994).

The major factor to influence the SOR is the intersinger spacing (item 1 above). The farther apart the singers are standing (especially from their own section colleagues), the greater the SOR, and the easier it will be for them to hear their own voices–and, conversely, the harder it will be for them to hear the others. Daugherty (1996) found that both singers and auditors preferred the choral sound produced in spread formations over that produced in close formation.

The SOR is also inversely related to the amount of reverberation in the room: the less reverberation, the weaker the total sound will be, and so the easier it will be to make out the sound of one's own voice (B). For a given choir placement in a room with given physical properties, the SOR can be predicted with some accuracy. This is important because it gives the architect's acoustics consultant a tangible goal: to design for a SOR onstage in the vicinity of +6 dB (Ternström, 1999).

Singer Preferences. In a normal situation, the individual choir singer cannot do very much to change his or her hearing-of-self, other than to use the music folder as a personal reflector to increase SOR. The permissible loudness of one's own voice is constrained by the music's dynamics. Vocal artists who perform with adjustable amplification, however, can be very fussy about the exact amount of monitor feedback they require. Ternström (1999) did an experiment with 23 experienced singers to determine (1) whether choir singers are particular about

their preferred SOR in a choral context and (2) how large the preferred SOR might be. The singers were indeed quite precise about their personal preferences: they reproduced their individual preferred SOR to within ±2 dB, which is a remarkably close tolerance. The overall average preferred SOR was +6 dB. However, tastes varied wildly, from +15 dB down to 0 dB. In other words, some of these singers wanted to hear their own voice a lot, while others preferred the rest of the choir to be just as loud. This large variation may be due to different habitual placement within the choir (see later), to individual voice timbres, and even to certain hearing losses so small as to be unknown by the singer.

Loudness Issues. The choir director should be aware that singer placement is not just a question of how well or poorly different voices sound together but also one of how comfortable each singer is with the balance of loudness of voices in his or her vicinity.

Having the choir stand in many rows will cause large differences in SOR between the center and the periphery of the choir, since some singers will have many neighbors and others will have few. In single-row formations, the SOR varies less with position in the choir. Furthermore, the SOR will be lowest in the bass section and highest in the soprano section when all sections are singing (Ternström, 1995). This is because sopranos are loudest: the human voice radiates acoustic power more efficiently at high fundamental frequencies. In terms of SPL, the Other sound will thus be dominated by sopranos, except in very close choir formations.

The ability to monitor one's own voice is crucial for accurate singing. As an example, have some volunteer singers carry small tape recorders to record their own voices (without headphones!) at very close range in various choral performance situations. Ask them to assess their own performances from the tape a few hours later. If the tape reveals unexpected errors, chances are that they could not hear themselves well enough.

Unison singing—all voices in synchrony on the same tones—is the worst case for monitoring one's own voice, since Other masks Self most efficiently when the frequencies overlap. If the SOR is too low, the singers may be able to hear their own voices only by making mistakes, and the scatter in intonation is likely to increase. In very large choirs, therefore, sectional formation is likely to be problematic.

Intonation

We are working on a piece that often tends to go out of tune at a particular point. Why might this be?

Relevant Factors

1. The *intrinsic pitch* of vowels and consonants is an acoustical and physiological phenomenon known from phonetics. In speech, some sounds tend to have a slightly raised or lowered F_0 because of the way the voice organ must be configured to produce them.

2. The *pitch-amplitude effect* is a perceptual phenomenon that makes it possible for the perceived pitch of a constant-frequency tone to change slightly with changes in loudness. Some people are more susceptible to this effect than others. The effect is most relevant to high and loud soprano singing.
3. *Breath support* has a direct bearing on intonation, particularly on long sustained tones in the upper pitch ranges. This is not really a choral issue but one of vocal training, although the problem is very common in choral singers.
4. *Complex modulations* between tonally distant keys is a music theory issue that many others have described, although little of predictive use has been reported; see any text on scales and temperament.

Recommendations

1. Analyze the text for intrinsic pitch effects (see later). Temporarily change the lyric to something completely different and see whether the intonation is affected.
2. If some sopranos tend to sing sharp on high, loud tones, chances are that their ears are fooling them. In this situation, conductors sometimes accuse the singers of a poor sense of pitch; however, most of the time they are doing their best and have no way of knowing they are sharp. Instead, try to ascertain whether the pitch-amplitude effect is in fact the culprit. An individual test for the pitch-amplitude effect is suggested later.
3. Have the singers learn vocal technique. The term *breath support* refers to a singer's proficiency in controlling the subglottal pressure. The fundamental frequency of vocal fold vibration is regulated mainly by the subglottal pressure (coarse, slow control issued by many large respiratory muscles) (Titze, 1989) and by the pull of the rather small *cricothyroid* muscle (fine, rapid control). If the subglottal pressure is too low, as with insufficient breath support, then the cricothyroid muscle must exert a much larger force to achieve a high target pitch, and so it tires quickly (chapter 16).

Acoustical and Psychoacoustical Background

In speech, there is rarely a need for precise intonation of sustained tones; rather, it is *gestures* or *inflections* in pitch that carry important information. Pitch in speech is also closely related to vocal effort. Increased subglottal pressure will normally raise the fundamental frequency, or F_0 (e.g., Titze, 1989). Hence, we expect in speech a strong covariation of loudness and pitch: the louder, the higher. Singers, however, must learn to control loudness and F_0 separately. This is a task that requires considerable coordination.

From an engineer's viewpoint, the voice organ is an unruly and entangled conglomerate of cartilage, muscle, and soft tissue. For such a device to produce sound at a stable F_0, it must be controlled by use of a host of auditory and neuromuscular mechanisms with compensatory action, or *servo systems*, that continuously monitor the voice output and apply corrective signals until the out-

put is perceived to match the target. Voice research has shown that the servo-system paradigm is in fact a good model for F_0 control (Larson et al., 2000; Ternström & Friberg, 1989). Since the voice organ is driven mainly by lung pressure, is steered by minute muscular control in the larynx, and is monitored by hearing and other types of receptors in the body, there seem to be few aspects of vocal function and near-field acoustics that could *not* have some bearing on intonation.

Because the intonation precision needed for choral harmony is very high, even small disruptions to pitch can be significant. Here we will discuss two of these: *intrinsic pitch*, which is a voice production phenomenon; and the *pitch-amplitude effect* that was mentioned earlier, which is a pitch perception phenomenon.

Articulatory Perturbation of Pitch (Intrinsic Pitch). In a voice science context, the term *articulation* refers to the action of adjusting and positioning the jaw, tongue, and lips to produce a given sequence of sounds. To phoneticians it is well known that in running speech some vowels tend to be produced with a slightly lower or higher F_0 than the average for the speech as a whole (Ladd & Silverman, 1984). Front vowels such as /i:/ and /e:/ (with the tongue held forward) tend to receive a slightly higher F_0, and back vowels such as /a:/ and /e:/ tend to be lower, on the order of a semitone or two. Phoneticians call this *intrinsic pitch*. Despite its name (*pitch* normally refers to perception or experience), this is not a perceptual effect but rather a vowel-dependent bias on F_0 that is somehow exerted by the articulation. Several biomechanical and acoustic hypotheses have been advanced to explain these deviations, but the matter is not yet closed.

In addition, the articulation of consonants sometimes involves movements of the larynx or changes in the air pressure differential that drives the vibration of the vocal folds. This can cause the F_0 of voiced consonants to differ from that of the adjacent vowels. For example, say very slowly *ahdahdah* and notice how the pitch drops during the *d* consonants. In fact, this intrinsic drop in pitch is a strong cue for us to interpret the sound as the consonant *d*.

In singing, intrinsic pitch effects would presumably be compensated for, as the singer is striving to reach a target frequency for each note. But what happens if it is hard to hear one's own voice, as is often the case in a choir? Ternström, Sundberg, and Colldén (1988) asked choir singers to sustain tones over a change of vowel and measured the average F_0 before and after the vowel transition. The subjects wore closed headphones in which they alternately heard their own voice fed back and a masking noise that completely drowned out their own voice. Each vowel pair was sung in noise and was then immediately repeated without noise. Intrinsic pitch effects were found in *both* conditions, but they were larger in noise, as expected. On the average, the largest F_0 changes were observed between /i:/ (high) and /ɛ:/ (low). For this case the average effect was about thirty cents, larger in noise and smaller with normal feedback. Such a pitch change is certainly large enough to make a chord go out of tune. Figure 17.1 summarizes the *occurrence* of pitch changes for the different vowel pairs in this experiment. The vowel /a:/ was not included, but it is known to have an even lower intrinsic pitch than /ɛ:/.

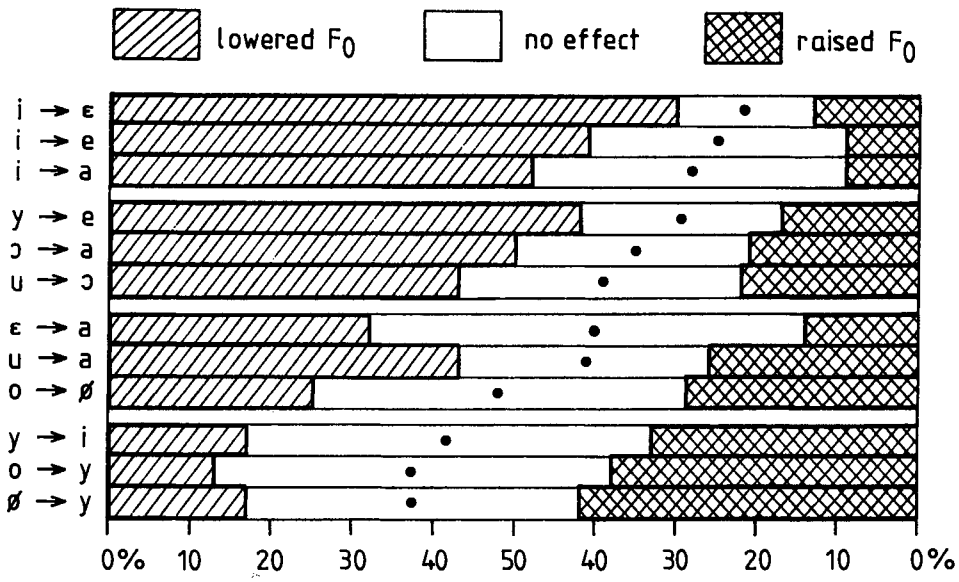

Figure 17.1. Articulatory perturbation of pitch over vowel changes. The bars show the relative occurrence of intrinsic pitch effects found when six subjects changed vowels on sustained tones (see text). The conditions with and without auditory feedback are pooled. For example, the top line is interpreted as follows: when the vowels /i:/ and /ɛ:/ were paired, /ɛ:/ was sung at a lower pitch in 70% of the cases and at a higher pitch in 13% of the cases, regardless of whether /i:/ or /ɛ:/ came first. (From Ternström, Sundberg & Colldén, 1988. Copyright American Speech-Language-Hearing Association, reprinted with permission.)

A practical consequence of this result is that intonation problems can sometimes be ascribed to a particular sequence of vowels and consonants (for example, *dies irae* or *kyrie eleison*) and that not hearing one's own voice will make things even worse.

The Pitch-Amplitude Effect. To test yourself for the pitch-amplitude effect, you will need a sound source that can produce a pure or nearly pure sine wave with stable loudness and frequency. Such a wave is best produced with a tone generator or a synthesizer with a Sine program or a very dull flutelike sound. Failing that, you can use a high-quality microphone and tape recorder to record somebody whistling a pure tone or have a soprano sing on a closed vowel. Try three or four tones that range from middle C (262 Hz) and two octaves up. Connect a pair of headphones to the sound source. Place the headphones on a table in front of you and adjust the volume so that you easily can tell whether the tone is playing or not, but no louder. Listen to its pitch, then put the headphones on without adjusting the volume and listen again. Many people will perceive a lower pitch when the tone thus becomes louder. To some, the drop will be large (a semitone or more); to others, it will be small or inaudible.

The pitch-amplitude effect is well known to psychoacousticians (e.g., Verschuure & van Meeteren, 1975). It is typically at its strongest in the region of 300 to 500 Hz, becomes insignificant at 1 to 2 kHz, and reverses at very high frequencies, where the pitch instead seems to increase with level. This explains why dull tones with only a few low partials are the most susceptible. The more high-frequency overtones there are in the stimulus sound, the less their combined pitch is perturbed, and the weaker the pitch-amplitude effect becomes. Ternström and Sundberg (1988) found a pronounced pitch-amplitude effect in some but not all male subjects who were attempting to sing in unison with a synthesized stimulus vowel /u:/, which is poor in high partials, but not with /a:/, which is rich in high partials. Ternström has also demonstrated the pitch-amplitude effect for soprano tones in syntheses of ensemble sounds (not published). For the effect to occur, the reference tone and the tone produced by the subject must be very different in loudness and the louder tone must have strong low partials and weak high partials. This situation is quite rare in choirs, but it does occur for sopranos who are singing high and loud. The effect will probably be more pronounced in venues with little reverberation, because then the difference in loudness will be large between one's own voice and the rest of the choir (the SOR will be high).

A soprano whose sense of hearing happens to have a steep pitch-amplitude dependency is faced with this problem: when singing high and loud she is likely to perceive her own voice as a little flat, because it is stronger than the other sounds around her and because high soprano tones are necessarily dominated by the fundamental partial (chapter 16). To compensate, she will probably produce a tone that is perceived as sharp by everyone else. Not knowing about the pitch-amplitude effect, she will feel unjustly accused of singing sharp and having a poor sense of pitch. Unfortunately, there is not much she can do to determine exactly at what pitch she should really be singing, other than gradually to learn how flat she should hear herself for the others to stop complaining. We believe choral directors should be aware that the pitch-amplitude effect exists, that it is an innate property of our auditory system, and that it has nothing to do with musical ability or talent.

A related phenomenon is the relationship between *timbre* and *pitch salience*, that is, whether the perceived pitch is clear or unclear (Terhardt, 1975). Listeners tend to agree less on the pitch of a tone if its spectrum is not balanced. For example, it is probably a bad idea to give the starting tone to the choir using a low flute stop on the organ, which has strong low-frequency partials and weak high-frequency partials, because different singers may perceive its pitch slightly differently. It is also risky to use small electronic beeper devices, which are rich in high partials but completely lacking in low partials. A voice or a piano should serve most singers well.

Singers sometimes try to hear their own voice better by blocking one ear with a fingertip. Blocking the ear does make the Self sound louder, but it also becomes muffled, while the Other sound becomes a lot weaker. This jeopardizes intonation, because such conditions increase the risk of the pitch-amplitude effect. Of course, closing one's ear would also look silly on stage. But wearing an earphone or hearing aid, for example, would have much the same effect.

Finally, we cannot even trust our two ears to perceive the same pitch. It is not uncommon to hear slightly different pitches from a tone generator—or tuning fork—that is held first to one ear and then to the other. A choir director giving pitch might need to know if one of his or her ears is slightly out of tune.

Overtones

In some long chords I can hear a tone that is not being sung by anyone in the choir. The tone typically sounds like a high-pitched whistle and is sometimes musically appropriate, sometimes not. What is going on?

Relevant Factors

1. One or more of the following circumstances may combine to make a particular partial tone especially loud: (a) the partial tone is a component of many of the constituent tones of the chord, (b) the formant frequency configuration of the vowel happens to enhance it, (c) many of the singers happen to agree very closely on the formation of that vowel, (d) vibrato is small or nonexistent.
2. The so-called *chorus effect* makes it easier for the ear to pick out the individual partial tones in ensemble sounds than in solo sounds.
3. In loud and/or pressed voice, in which the high-frequency partials are more intense than in soft voice, this phenomenon becomes more likely. This is in fact a strategy adopted for example by the Tuva throat singers (Levin & Edgerton, 1999).

Recommendations

1. If the unsung tone is a problem, sing in a softer nuance or experiment with a different vowel to see if the problem goes away. Modify open vowels to closed or vice versa. If the unsung tone is a desired effect, modify the vowel very slowly and carefully until the effect is maximized. Decide and explain to the singers which section is to act as the intonation reference at various points in the piece.
2. If the singers are having difficulty tuning a particular harmony and if different sections have different lyrics, try making them sing the same text. Change closed vowels to open; in particular, let the basses sing on *ah* for a while. More often than not, rich overtones will facilitate accurate intonation.
3. In practice, independently audible overtones are rarely a problem but rather an interesting curiosity that often goes unnoticed by the audience, unless the composer and the performers have taken extra pains to make the effect come across. In some traditions overtones are even cultivated as an instrument in its own right. Singers often wonder about overtones and how to enhance them, and the choral director can sometimes exploit overtone enhancement in the service of intonation.

Background

Combination Tones, Beats, and Harmony. When two stable unison tones of similar loudness are tuned slightly apart, they sound not like two tones but like one tone that *beats*. If the mistuning is gradually increased, the beating becomes too rapid to be perceived as such but rather invokes a roughness of timbre; at some point the ear will also start to resolve the two tones. Furthermore, for tones that are close in frequency to each other, distortion effects inside the ear can generate various audible *combination tones* whose frequencies are sums and differences of the frequencies of the two physical tones and their harmonics.

On instruments with stable pitch, so-called just or pure intonation sounds pure because it minimizes the beating and hides the combination tones by lining them up with the real partial tones. In choral sounds, however, things are rather different. Regular beats are never heard in a choir, for two reasons. The first and foremost is that the human voice is not stable enough in frequency for regular beats to occur. Even when singing an acceptably straight tone, most voices *flutter* up and down by 10 to 20 cents (Ternström & Friberg, 1989). This makes the beats irregular, and therefore they are not readily perceived. One interesting consequence of this is that there should be no inherent advantage of using just intonation in choir music (cf. Chapter 12). Ternström and Nordmark (1996) found that musically trained listeners who were asked to fine-tune major third intervals in synthesized sustained, nonvibrato ensemble sounds had diverse preferences but averaged between just intonation and equal temperament.

The second reason we do not hear the beats in the choir is that with more than two unison voices even the smallest F_0 differences between them will cause each voice to beat against each other voice, creating a great multitude of irregular beats. The beating is in fact so profuse and irregular that it sounds like something else. We might define the *chorus effect* or *ensemble effect* to be that character of sound that prevents us from hearing exactly how many voices are singing in unison. The minimum is three, which sounds distinctly different from both one and two voices (Ternström, Friberg, & Sundberg, 1988).

In vocal groups that perform close harmony with one voice to a part, the chorus effect is often intentionally avoided. Instead they strive to achieve harmonies that are so precisely tuned and so straight in pitch that the voices fuse together and we hear one instrumentlike chord rather than several part singers.

Reinforced Partials as an Aid to Intonation. We assume here that the reader is already somewhat familiar with the harmonic series of partial tones (fundamental plus overtones) and its relation to the musical scale.

In any sound from a single tone source, some partials will be stronger than others, but if they all vary together, the auditory brain centers will assume that they all derive from the same source and report only one percept to the listener. Therefore, we do not hear individual partial tones, unless one of them is markedly reinforced (see discussion of overtone singing in chapter 16). In ensemble sounds, however, the partial tones do not vary strictly together, as they do in

the sound of a single voice. Thus it can be easier to hear out individual partials in a sustained choral sound than in one voice.

Ternström and Sundberg (1988) did intonation experiments in which individual male singers sang fifths and major thirds together with both synthetic tones and with a prerecorded unison male choir. The experiment showed that when partial number three of the lower tone (which sounds like a fifth) was reinforced by the formant structure of the vowel, the subjects were more agreed on the intonation of fifths; similarly, when partial number five (which sounds like a major third) was strong, the subjects were more agreed on the intonation of major thirds. While the effect was not very large, it appeared even though the subjects were ignorant of the purpose of the experiment. The implication for choral directors is that accurate intonation of a particular chord can sometimes be facilitated by judiciously choosing a vowel that will emphasize (a partial tone at some octave of) the reference tone in the chord.

The formants of the vocal tract are only resonances and produce no sound of their own (chapter 16). Instead, they reinforce whatever frequencies are produced by phonation and frication. In most languages, the two lowest formants, F_1 and F_2, are sufficient to determine the identity of the vowel. The legend to Figure 17.2 discusses how this can be relevant to choral intonation. Read the words shown in Figure 17.2 in a loud whisper, without voicing, and you will probably hear the pitches of F_1 and/or F_2, albeit vaguely.

In the first example in Figure 17.2, with *who'd*, F_2 reinforces the tone B, which is common to the harmonic series of both the sung tones E and G; this is likely to facilitate intonation. In the *hood* example, F_1 emphasizes the G that is common to bass and tenor; again, this is probably good for intonation. In addition,

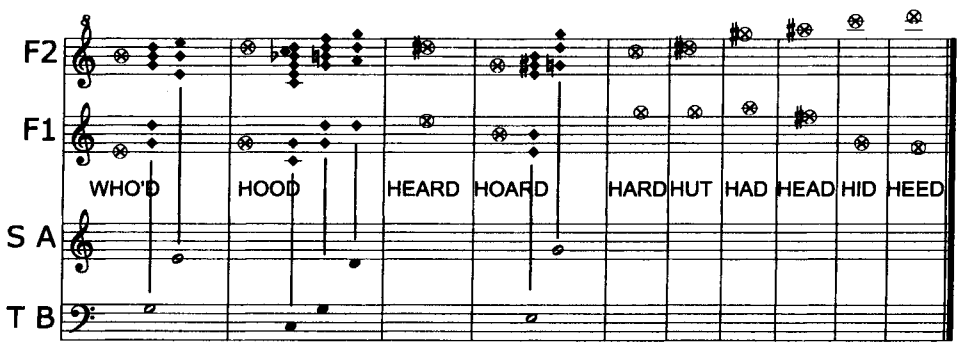

Figure 17.2. Some examples of possible interactions between formants and partials. The crossed circles indicate the approximate frequencies of the first and second formants (F_1 and F_2) for spoken English vowels as pronounced by adults (Peterson & Barney, 1952). These frequencies are vowel-specific and essentially independent of the sung pitch. Notice the *octava* on the clef for F_2; it needs to be notated an octave higher. The diamonds indicate the lowest few partial-tone frequencies of the corresponding sung tones on the S A and T B lines (soprano, alto, tenor, bass).

the F_2 of *hood* emphasizes the high D, which is common to all three voices; this is likely to reinforce the ninth of the chord. On *hoard*, however, F_2 might cause a problem by amplifying the clash between the $G_\sharp$ that is the fifth partial of the bass tone and the $G_\natural$ that signals the minor tonality.

A good place to learn more about intonation and overtones is at barbershop rehearsals and workshops. Because of their particular style requirements, barbershop singers usually take a keen interest in acoustical matters and often present lessons on the intricate relationship between the formant frequencies and the configuration of the common partials.

Conclusion

With this small sampler, we hope to have stirred the reader's interest in the field of choir acoustics, which of course encompasses many more topics, such as room and stage design, choral formations, the use of choral risers and reflecting shells, the deployment of sound equipment, and so on. More references to literature by others as well as ourselves can be found at www.speech.kth.se/~sten. While many issues are already addressed by the literature, there are still many more questions that remain to be answered. In anticipation of future research (Daugherty, 2000), let us close with some intriguing questions that have *not* been investigated at the time this chapter was written:

- Does a choral piece that tends to go flat generally stay in tune if it is sung a semitone higher, and if so, why?
- How is it that one or two key singers can seem to lead a whole section, while others seem to become expert at following the leader?
- How is it that some pairs of voices sound better together than others?

Piano

RICHARD PARNCUTT & MALCOLM TROUP

On the basis of research on the physics and physiology of the keystroke, the acoustics and perception of piano timbre, and the psychology of piano fingering, we explain observations such as the following, and investigate their practical implications. The timbre of an isolated tone cannot be varied independently of its loudness but depends on finger-key, key-keybed, hammer-key noise, and on the use of both pedals. The timbre of a chord further depends on the balance and onset timing of its tones, whereby louder tones tend to sound earlier (melody lead, velocity artifact). Both the sustaining pedal and *una corda* can enhance *sostenuto*. Leap trajectories are curved and asymmetrical. Optimal fingering is determined by physical, anatomic, motor, and cognitive constraints interacting with interpretive considerations, and depends on expertise.

Scientific thinking, methods, and results have influenced piano performance and piano teaching for well over a century, and innumerable piano-pedagogical publications have claimed scientific validity. On the one hand, artistic writers—often great pianists and piano teachers—have tended to fashion complex pseudoscientific theories post hoc to match their beliefs, so that such theories can be controversial and unreliable. On the other hand, scientific writers tend to focus on simple hypotheses and assumptions that are easy to demonstrate and explain but are of limited interest to musicians. It is little wonder, therefore, that modern piano students are often unaware of the basic findings (Parncutt & Holming, 2000).

Ortmann (1929/1981) successfully challenged influential but unfounded assumptions on touch and relaxation. Like him, we begin with observations that are easy to demonstrate scientifically and move gradually toward more complex ideas that are more likely to be of interest to modern pianists and piano teachers. We attempt a fresh approach by combining old and new acoustical

and psychological thinking and drawing upon our own performing and teaching experience.

Physics and Physiology of the Keystroke

Curved Versus Straight Fingers

The motor independence required to perform the complex sequences of finger movements that are typical of piano performance can only be acquired over many years of concentrated practice. Pianists must control not only the order and precise timing of keystrokes but also their force and the resultant key velocity (Parlitz, Peschel, & Altenmüller, 1998).

The force required to depress a key in the middle register varies by a factor of 100: to hold down the key requires about 0.5 newton (equivalent to 50 grams), and to play *fortissimo* requires about 50 newtons (5 kilograms) (Askenfelt & Jansson, 1991). One way to accommodate this wide range is to vary the curvature of the fingers (Ortmann, 1925).

Loud, scalelike passages are often better played with curved fingers. First, this allows force to be applied vertically and so most efficiently (Ortmann, 1929/1981; Gát, 1965). Second, this reduces the distance between the fingertip and the knuckle, increasing the available force at the fingertip for a given muscle force (lever principle).

Straight fingers are often preferred in softer, slower, single-line melodies, where the fleshy pads of flatter fingers allow a bigger skin area to touch the surface of the key, appropriate for *cantabile*. Extended fingers can also move through a larger horizontal arc than curved fingers and are appropriate when big stretches are required at a low to moderate dynamic level.

Fingers or Arms?

As a rule, *all* moving joints in the arms and fingers are involved to some extent in *all* piano playing; to try to prevent one joint from moving would cause unnecessary tension. Beyond that, basic physics predicts that small, lightweight limbs (e.g., the fingers) are suited for fast and/or quiet playing, while larger, heavier limbs (the upper and lower arm) are best for slow, loud playing (Ortmann, 1929/1981). According to this principle, movements of the hand (from the wrist) and forearm (from the elbow) are suitable for intermediate tempi and dynamic levels and for combinations like fast and loud (e.g., Liszt's Hungarian Rhapsody No. 6, with its right-hand presto octaves and left-hand chord leaps, all marked *sempre forte*). Similarly, scales in fast, lightweight octaves are best played from the wrist, moderately fast and loud octaves from the elbow, and loud, *bravura* octaves from the shoulder (cf. Gát, 1965), examples of all of which are also to be found in Liszt's Hungarian Rhapsody No. 6.

The underlying physical principle is Newton's second law of motion—force equals mass times acceleration (cf. Schultz, 1949)—which states that greater

masses require more force to accelerate them and exert more force when they decelerate (inertia). Thus the fingers can move back and forth more quickly, but the arms can exert more force.

This principle is mirrored in the historical evolution of keyboard technique (Gerig, 1974; Kochevitsky, 1967). In keyboard music of the eighteenth century, the fingertips did most of the work and the arms were held to the sides. In the nineteenth century, a heavier keyboard action, larger concert halls and orchestras, the new mass public, the emergence of the solo recital, and more elaborate writing for the keyboard made wrists and forearms more important (Kalkbrenner, Leschetizky). This led to Deppe's (1885) and Breithaupt's (1905) concept of arm weight and Matthay's (1903) emphasis on relaxation. Their basic idea was to relax the arm in free fall, then introduce minimal muscle tension to control the movement.

A similar pathway is still traveled by most pianists during their development from beginners to professionals. But advanced technical concepts such as arm weight can also be introduced quite early. For example, György Kurtág's *Jatekók*, a collection of children's pieces elaborated into a system of piano tuition by Kase (2001), introduces larger scale bodily movements from the start, delaying focused finger movements until later.

Leap Trajectories

Performers of pieces like Brahms's *Paganini Variations* and Second Piano Concerto are constantly confronted with high-speed leaps across the keyboard. Ortmann (1929/1981) observed that the optimal trajectory for a leap is not only *curved* but also *skewed* (asymmetrical): it departs close to horizontal and lands somewhere between horizontal and vertical. This minimizes the chance of missing the target and allows the force on the target key to be applied almost vertically.

During a leap, the hand and arm must accelerate from stationary to a maximum velocity and decelerate again before reaching the target. Since acceleration is a vector (with both magnitude and direction), leap trajectories cannot include sharp corners, which would require short bursts of high acceleration (Ortmann, 1929/1981). For similar reasons, it is widely held that rounded or curved movements are preferable in all areas of piano technique: "The shortest distance between two points is not a straight line but a curve" (Neuhaus, 1973).

In general, the likelihood of missing a target increases as the trajectory becomes longer, the time available becomes shorter, and the target becomes smaller (Fitts, 1954; Huron, 2001). For the piano, the margin of error at the target is the width of the key as seen from the approaching finger—greatest if the approach is vertical (from the air) and zero if horizontal (along the keyboard). When approached from the left or bass, the widest black-key targets are the tones C♯ and F♯; from the right or treble, B♭ and E♭. The optimal trajectory toward these keys is therefore flatter, and they can be reached more accurately. According to this logic, the falling leap at the start of Beethoven's Opus 111 (E♭ down to F♯ in left-hand octaves) may be more difficult than a slightly longer leap to a bigger target (e.g., D♭ to E♭).

While performing, pianists tend to be unaware of leap trajectories. The process seems highly automatic and intuitive, with the attention focusing aurally and visually on the target, not the trajectory, and relying on a combined tactile-auditory-visual memory of the keyboard. If unnecessary tension is avoided, an appropriately curved and skewed trajectory results automatically. The kinesthetic sense of joint, tendon, and muscle movements during the trajectory can be developed either by practicing leaps out of context without depressing the target tone (just preparing it) or by practicing leaps in the dark (without visual feedback). It is difficult to practice leaps at a slow tempo, just as high jumpers cannot practice in slow motion.

Tone Repetitions

High-speed repetitions are usually easier to perform by changing (alternating) fingers, because it is easier to move one finger horizontally off the key and drop another finger onto it, than to quickly move the same finger up and down. The latter requires more finger acceleration, which in turn requires more muscle force. Slow tone repetitions are often best performed *without* changing fingers, because at slower tempi the listener is more sensitive to the unevenness (variation in loudness) that can result from the differing strengths of the fingers. Moreover, at slow tempi there is less finger-key noise. Conversely, changing fingers can be useful if accentuation (i.e., *deliberate* unevenness) is required.

Fast repetitions were enabled by Sebastien Érard's *repeating action* of 1823 (Frey, 1933). The *let-off distance* (Askenfelt & Jannson, 1990) is the distance between the string and the top of the hammer after a key is slowly and silently depressed. Typically some one to three millimeters, it is also the distance traveled by the hammer in free flight after the jack is pushed away by the escapement dolly. The roughly corresponding *let-off point* of a piano key is found by slowly pressing the key until resistance is felt (as the jack escapes).

Depending on tempo and dynamics, fast repetitions may be best played *under the surface*, that is, by depressing the key to the keybed, lifting to the let-off point, and depressing again. The minimum time between repetitions is the time taken for the jack to return to its original position. A short setting of the let-off distance facilitates fast, quiet repetitions, as for example in the left-hand opening (*pp, très fondu, en trémolo*) of *Scarbo* from Ravel's *Gaspard de la nuit*. Playing from the let-off point also prevents the damper from reaching the string between keystrokes, so that a continuous sound can be obtained without pedaling.

Acoustics and Perception of Piano Timbre

Relationship Between Timbre and Loudness

We use the words *timbre* and *loudness* in the widely accepted psychoacoustical sense of how a sound is perceived or experienced by a listener (H. Fletcher, 1934). In general, the timbre of a sound–its perceived tone quality or color—depends

on at least two physical variables: its *spectral envelope* (relative amplitude of spectral partials at a given moment) and its *temporal envelope* (which rises suddenly as the hammer hits the string and then decays gradually). The critical importance of temporal envelope for piano timbre becomes clear when a piano tone is recorded and played backward. If the amplitude gradually increases instead of decreasing, with the hammer noise at the end instead of the beginning, the result sounds strangely like an organ (Houtsma, Rossing, & Wagenaars, 1987).

The experience of loudness may be distinguished from the physical measurement of *SPL*, measured in decibels, and from *dynamic level*, which is an instruction, recommendation, or suggestion from a composer to a musician. For practical purposes, loudness, SPL, and dynamic level are often the same, but they do diverge in everyday musical situations. Consider for example a thick bass chord marked *ppp*. The physics of the piano do not allow such a chord to be played with a very low SPL (as measured with an SPL meter). But a pianist playing as softly as the piano allows can manipulate other contextual variables such as timbre (pedaling, relative key velocity) and timing (tempo, delay) to enhance the impression of *ppp*.

Against the backdrop of these definitions, we may assert that the spectral and temporal envelope of an isolated piano tone cannot be changed independently of its SPL; hence, timbre cannot be changed independently of loudness (Baron & Hollo, 1935; Gát, 1965; Gerig, 1974; Hart, Fuller, & Lusby, 1934; Ortmann, 1937; Seashore, 1937). In a simple physical model of the piano action (Fletcher & Rossing, 1998, Figure 12.1), both the SPL and the spectral and temporal envelopes of a piano tone are determined uniquely by *hammer velocity*—the speed with which the hammer hits the string, which is determined in turn by key velocity (cf. Palmer and Brown, 1991). The crucial point is that the hammer hits the string in *free flight*: at (and just before) impact, there is no physical contact between the key and the hammer. Thus—apart from some interesting possibilities described later—the pianist cannot influence *how* the hammer hits the string, only the *speed* with which it does so.

Acousticians and psychologists have often wondered why, in spite of this evidence, so many pianists still believe that the timbre of a piano tone depends on *touch*—not only how fast but also *how* the key is depressed. A possible reason is that movements of a pianist's body and arms (smooth and round versus jagged and tense) seem to both performers and audiences to result in different timbres. But we cannot necessarily rely on this impression for the following reasons:

- Pianists almost never perform isolated tones without pedal, and the timbre of more complex textures clearly depends on a range of factors other than the way each individual key is depressed (see later).
- Movements that directly affect *control* may indirectly affect timbre. Consider the difference between *percussive* (or *staccato*) *touch* (when keys are hit from a distance above the surface) and *nonpercussive* or *legato touch* (when the key is depressed from the surface). Ortmann (1925) found that nonpercussive touch permits finer key control.
- Listeners can easily perceive timbral differences between piano performances but are not necessarily able to explain the origin of those differences (Heinlein, 1929b).

- Listeners cannot necessarily separate timbre from other perceptual variables. Timbre is often confused with pitch in ratings of performed intonation (chapter 12) and in other psychoacoustic experiments (Singh & Hirsh, 1992). Listeners regularly use the interdependence of timbre and loudness to deduce dynamic level in situations where sound intensity cues are lacking or unreliable, such as recordings. In most instruments (including the voice), louder tones have more jagged waveforms and hence relatively more high-frequency energy. In the piano, a sharper hammer blow produces sharper waveform peaks (Hall, 1991). The strongest perceptual cue to the original dynamic level of a piano recording is its timbre—regardless of how loudly the recording is played back.
- In general, auditory perception is influenced by visual perception (intermodal interference). Visual processing can affect the appraisal of piano performances (Behne, 1990; Shimosako & Oghushi, 1996), and an important part of the emotional and interpretive message sent from a performer to an audience is visual (chapter 15 in this volume; Rosen, 1995). For example, if an audience sees a pianist brutally hitting the keys, they may get an impression of a hard or brittle tone—beyond what the music actually sounds like.
- Pianists' perceptions of their own performances are multimodal (Galembo, Askenfelt, & Cuddy, 1998): the pianist's perception of timbre can be influenced by kinesthetic feedback from finger contact with the keys.

Askenfelt and Jansson (1991) suggested the possibility that *hammer-shank vibrations* at around 50 Hz might be greater in percussive touch and could theoretically affect piano string vibration—either by changing the angle of impact and thus shifting the striking point (only significant in the extreme treble: Galembo et al., 1998) or by allowing the hammer to rub along the string during contact. But Hart, Fuller, and Lusby (1934) and others (see Galembo et al., 1988) had already concluded that the influence of the hammer shank on the physical string motion is negligible, and when the matter was tested empirically Askenfelt and Jansson (1991) were unable to observe any rubbing motion between hammer and string. Even if effects of this kind are possible, the pianist can hardly manipulate them independently of finger-key noise (see later), so they cannot contribute *independently* to piano timbre.

Tone quality in piano performance is determined not only by the physics of individual keystrokes but also involves a complex and largely intuitive interaction among body movements, technical finesse, and musical interpretation (Kochevitsky, 1967). For example, it is possible that the exact timing of a *rubato* melodic phrase affects the global perception of timbre. The ability to produce a variety of timbres and to apply them appropriately to the interpretation of repertoire can only develop gradually over years of concentrated practice and careful listening.

Timbre of a Chord

The timbre of a piano chord depends on the timing and relative loudness of the tones (Baron & Hollo, 1935), because these affect both the temporal and the spec-

tral envelope. The attack portion of the temporal envelope can be manipulated by adjusting the timing of the tone onsets. An extreme case is an arpeggiated chord, whose timbre depends on the speed and direction of the arpeggiation—an expressive strategy employed by both performers (e.g., Glenn Gould's interpretations of Bach) and composers (e.g., Boulez's Sonate No. 3, *Constellations*). The spectral envelope can be manipulated by playing some tones louder and some softer. If the louder tone takes on a singing quality, it is either because its pitch becomes more *salient* (clear, prominent, audible, able to attract attention: Terhardt, Stoll, & Seewann, 1982) and/or because the timbre of the whole sonority becomes less rough (the roughness of a beating pair of pure tones falls rapidly as the difference between their amplitudes increases; cf. Terhardt, 1974). The technique of bringing out a tone is addressed later under "Melody Lead and the Velocity Artifact."

Sources of Percussive Noise

Percussive onset noise is as characteristic and integral to piano timbre as is the scraping of the bow of a stringed instrument or the breath activation of a wind instrument. This is clearly demonstrated when onset noise is electronically excluded from the tone, creating a drastic change in timbre. Normally, we hear holistically—we do not, and perhaps cannot, hear the onset noise separately. If the amount of noise increases, we hear the sound as increasingly harsh, dry, ugly, or forced and may be unaware of the physical source of the timbral change.

The three main sources of noise in piano timbre are *finger-key*, *key-keybed*, and *hammer-string*. Finger-key noise can be varied independently of string amplitude, but the biggest contributor to the noisy onset, hammer-string noise, cannot (Baron, 1958; Baron & Hollo, 1935; Hill, 1940), and, for practical purposes, neither can key-keybed noise.

Hammer-String Noise. The physical intensity of the hammer blow depends directly on its velocity, being most intense in *fortissimo*. For this reason, *cantabile* can sometimes be enhanced by limiting loudness. Perceptually, the situation is more complex, because the tone's partials mask the onset noise, so louder tones do not always *seem* more percussive. If higher tones seem more percussive than lower tones, it is because their noise component is more intense by comparison to the partials—not because the noise is more intense in an absolute sense.

Finger-Key Noise. This can contribute to the percussiveness of piano sound (appropriate, e.g., in many of Bartók's *Mikrokosmos*). It can also enhance an impression of *staccato* (Gát, 1965). Its audibility can be demonstrated by holding down a cluster of keys with one hand hitting them with the fingertips of the other hand. In practice, finger-key noise is not completely independent of hammer-string noise, because pianists tend to play louder when using percussive touch (Ortmann, 1925).

The impact between finger and key causes a sudden high acceleration and associated shock excitation (or thump) dominated by two flexing resonances of

the key at about 290 and 445 Hz (Steinway); this is transmitted through various structural parts of the piano to the soundboard (Askenfelt & Jansson, 1990, 1991). It is called *touch precursor* because it precedes the hammer blow by about twenty to forty milliseconds, depending on dynamic level (Askenfelt, 1993). Like early reflections in a concert hall (Hall, 1991; chapter 17 in this volume), the touch precursor can contribute to timbre but cannot be heard separately.

In a musical context, the tonal part of the piano sound may partially or completely mask finger-key noise, depending on dynamic level, texture, register, room acoustics, and position of the listener. Finger-key noise is more audible in higher registers, because it is less masked by the tone.

Finger-key noise may seem important to the performer but be irrelevant to the listener. Preliminary experiments suggest that listeners can discriminate percussive from nonpercussive touch, but only within some twenty centimeters of the string (Galembo et al., 1998; Koornhof & van der Walt, 1993). Pianists' perceptions of their own finger-key noise may also be influenced by the kinesthetic sensation of the finger hitting the key.

Key-Keybed Noise. This may be separately heard by holding the hammer against the string while pressing the key. In a musical context, key-keybed noise occurs almost simultaneously with hammer-string noise and so blends easily with it. Its low frequency gives it a deep timbre.

Theoretically, pianists can indirectly control key-keybed noise (Askenfelt & Jansson, 1991, Figures 4 and 5). In nonpercussive touch, the key velocity increases steadily during the key depression, reaching a maximum at the keybed. In percussive touch, the key velocity first increases, then decreases (as the energy is transferred to potential energy in parts of the action and kinetic energy in vibrations of the hammer shank), then increases again. So for a given dynamic level, key-keybed noise is greater in percussive than nonpercussive touch. In practice, due to limitations of sensory feedback to motor control, it is virtually impossible to vary key-keybed noise independently of the percussiveness of touch and dynamic level.

Cantabile and the Pedals

Cantabile means "singable" or "songlike." The sustaining pedal enhances the singing quality of a piano melody by improving the legato and enriching the timbre. The *una corda* pedal can also enhance *cantabile*, by increasing the effective tone duration.

The Sustaining Pedal

Banowetz (1985) regarded the sustaining pedal as "equivalent to the vibrato of the singer or the string player" (p. 13). Pianists do not simply depress and release the pedal but take advantage of a quasi-continuous series of intermediate positions that allow for more or fewer dampers to clear the strings in different

registers—part-pedaling (half, quarter, three-quarter, etc.), pedal squeezing, and flutter (or vibrating) pedal (K. U. Schnabel, 1950). The effectiveness of these techniques depends on a variety of physical factors (the instrument's make; wear and tear of the hammer heads; pre- and postrelease duration of tones in a given register; room acoustics), technical considerations (how many fingers are held down at a given instant), and interpretation (phrasing, tempo, dynamic and timbral shading, tonal relationships) and is controlled by highly intuitive auditory reflexes and responses (Heinlein, 1930; Repp, 1999)—which may explain the considerable differences in pedal usage observed even among expert pianists (Heinlein, 1929a).

Walter Gieseking considered that "just as one learns correct finger technique from the head and not the fingers, so one learns correct pedaling from the dictates of the ear and not the foot" (Banowetz, 1985, p. 231). The independent manipulation of pedal and fingers, as well as the ability to adjust to a variety of instruments and acoustic conditions, is one of the most difficult and important pianistic techniques to learn. This complexity makes pedaling hard to investigate scientifically.

Decay Time and Melody

Is the piano a suitable instrument for the performance of melody? Two of the perceptual factors that encourage a sense of melody (across cultures) are *sustain* (slow decay) and *pitch salience* (Huron, 2001). The piano best satisfies both conditions in the middle registers: high tones decay quickly, and both very high and very low tones have low pitch salience (cf. Terhardt et al., 1982).

By convention, the decay time of a sound is the time taken for its SPL to fall by 60 dB. This corresponds roughly to its perceived or effective duration. The decay of a piano tone before the finger is lifted is called *prerelease decay*, and varies from some 15 seconds in the deep bass to 0.5 second in the highest register (Hall, 1991; Repp, 1997; Martin, 1947). *Postrelease* decay times are roughly half a second in both treble and bass (Repp 1997, Figure 4), but they vary unpredictably from tone to tone, depending on the state of the dampers and their pressure on the string. The timbral effect of damping the string is more audible in the lower registers where the strings are heavier.

A sense of melody may be created in high registers by use of the sustaining pedal and by *legatissimo*, the overlapping of successive keystrokes (Repp, 1997). Legatissimo can be acoustically effective in all but the extreme high register where there are no dampers. Finger legato is important not only where the pedal is being changed frequently but also where part- or flutter pedaling is being used, which tends to damp the upper strings more than the lower.

Another way to create an impression of melody is suggested by Bregman's (1990) theory of *auditory streaming*. Successive tones are more likely to hang together as melody if they are close in pitch and time and similar in loudness and timbre. Thus a pianist can optimize *cantabile* by holding key velocity relatively constant, compensating for the piano's acoustic discontinuity in the higher registers. If a passage calls for metrical or structural accentuation (chapter 13),

other means may be used, such as agogic accents in the melody or dynamic accents in the accompaniment.

The Sustaining Effect of Una Corda

Casella (1936) considered that the *una corda* (soft) pedal "allows the executant to interpret a *cantabile* melody with greater depth of touch while never overstepping the mark" (our translation). Rubinstein (1980) remarked that he often produced his best *cantabile* by playing the melody *ff* with soft pedal.

The underlying physics was explained by Weinreich (1977; see also Hall, 1991; Fletcher & Rossing, 1998). The *una corda* pedal reduces the decay rate of the tone and so increases the effective duration. On a grand piano, the pedal shifts the mechanism sideways so that the hammer strikes only two (not one, as the Italian name suggests) of three unison strings. This reduces loudness, mellows the timbre, and modifies the hammer-string noise, because a different part of the hammer—the ridges between the grooves formed during normal playing—strikes the strings.

When the *una corda* pedal is *not* depressed, the three unison strings initially vibrate in phase, allowing them to transmit energy efficiently to the bridge and causing the sound level to fall rapidly. But the strings are never tuned to exactly the same frequency—and good tuners sometimes deliberately slightly mistune unison strings, for timbral reasons (Wead, 1921; Weinreich, 1977). So they soon get out of phase with one another, reducing the efficiency of sound transmission to the bridge. Once the phase relationship between the strings is effectively random, a second, slower decay phase—the *aftersound*—begins. With the *una corda* pedal depressed, one string begins almost at rest. Over the next few seconds, energy is transferred from the struck to the unstruck strings via the bridge. The overall decay rate is slower, because the struck and unstruck strings are out of phase from the start; the aftersound begins sooner and lasts longer (Hall, 1991, Figure 10.9).

We recommend experimenting with the sustaining effect of *una corda* in relatively quiet passages whose timbre is not adversely affected by the soft pedal. Melodic tones should be relatively long (say, a full second or more), to give the unstruck string time to start vibrating. The audibility of the effect will of course vary according to the instrument, chosen register, and room acoustics.

Melody Lead and the Velocity Artifact

Integral to piano technique is *polyphonic touch*, or the differentiation of dynamic levels within a chord, which enables melodies to be brought out of a contrapuntal context. Pianists have been doing this since the earliest clavichords and fortepianos allowed key velocity to determine dynamic level, allowing for example the entries of Bach fugal subjects to be projected. Sophisticated exercises and studies that addressed this technique appeared in the late nineteenth century. For a later generation, Artur Schnabel suggested that students play the

cluster CDEFG repeatedly with fingering 1-2-3-4-5, each time bringing out a different tone to create a melody, for example, 5–3–3, 4–2–2, 1–2–3–4–5–5–5 ("Hänschen klein," a German nursery tune) (Wolff, 1972, p. 177). In the eighth measure of his Klavierstück Nr. 2 (1) of 1954 (London: Universal), Stockhausen notated a widely spaced five-note chord for the right hand and labeled the individual tones *ff, fff, f, mf,* and *f*—a tall order for a human performer but something that the piano is at least physically capable of.

Vladimir Horowitz recommended that "in striking a chord, in which a single note is to be accented, the effect can be produced by holding the finger which is to play the melody note a trifle lower and much firmer than the fingers which are to play the unaccented notes. The reason for holding the finger a trifle lower is only psychological in effect; in actual practice, it isn't altogether necessary" (Eisenberg, 1928). Along similar lines, Schultz (1949, p. 176) suggested that "to accent the *C* in the chord *E-G-C* . . . fingered 1-2-5, the thumb and second finger show more joint-movement than the fifth, the muscles of which contract relatively strongly. The accented tone is actually played a fraction of a second before the unaccented ones, but the difference in time is too small to be readily observable."

The asynchrony referred to by Schultz is known in modern music-psychological literature as *melody lead.* In the piano, the time taken for a single key to fall from the surface to the keybed ranges from about 25 ms in *forte* to 160 ms in *piano* (Askenfelt & Jansson, 1991). When fingers strike the key surface simultaneously but descend at different velocities, the maximum possible asynchrony is around 100 ms (remembering that, in quiet percussive touch, the hammer reaches the string up to 35 ms before the key reaches the keybed but only 2 to 5 ms in *forte*: Askenfelt & Jansson, 1990, Figure 8). In practice, melody leads are typically in the range of 20 to 40 ms, which is short enough to be inaudible (again, like early reflections in a concert hall). They are observed in performances at all levels of expertise (Palmer, 1989, 1996; Repp, 1996).

Goebl (2001) found that melody lead times could be predicted accurately by calculating key and hammer travel times on the basis of their measured velocities, confirming that in one-hand chords his pianists were striking the key surfaces almost simultaneously, regardless of emphasis. This was consistent with the pianists' apparent lack of awareness of melody lead in interviews. Melody lead may thus be regarded primarily as an *artifact* of keyboard construction.

Melody leads of similar duration also occur in ensemble performance (Rasch, 1979). This could be an artifact of a different kind: those that lead an ensemble tend to do just that and play infinitesimally earlier than the others who follow—just as less-experienced piano accompanists sometimes tend to drag. Alternatively, the effect may be a deliberate or intuitive expressive device to help bring out the melody. Pianists, too, may *deliberately* anticipate melody tones by different degrees, depending on the expressive intention (Rasch, 1978; Henderson, 1936; Palmer, 1989, 1996). But this is difficult to confirm experimentally, as one must first subtract out the effect of the velocity artifact.

Melody lead (or lag) can render a tone more salient than other tones in a chord, independent of the associated intensity differences. The anticipated tone is ini-

tially not masked by the other tones; and according to Bregman's (1990) theory and experiments, a slightly asynchronous tone is more easily heard as part of a melody. Thus, from a perceptual point of view, it may be unnecessary or even inappropriate to develop a deliberate strategy to compensate for the velocity artifact—that is, to attempt to control the relationship between key velocity and synchrony.

A pianist who wishes to do this consciously and thereby widen the range of available interpretive possibilities is faced with a technical problem. Due to intrinsic motor and physiological limitations, it is extremely difficult to directly manipulate the timing of almost-simultaneous finger movements, because the time required by sensorimotor and aural-neurophysiological feedback between the fingers and the brain would be similar to the typical duration of melody lead times (some tens of ms). The first author of this chapter gets around this by raising the finger whose onset is to be delayed and setting all fingers in motion at about the same time, applying more force and velocity to the raised finger. That finger then hits the key surface slightly later than the others—not earlier, as suggested by Horowitz, and perhaps corresponding to the "diametrically opposed" method referred to by Eisenberg (1928). By adjusting the height of the raised finger and listening carefully, the asynchrony at the keyboard can be reduced. The technical and artistic effectiveness of this technique, which follows logically from the psychological findings but seems to contradicts much pianistic practice, is yet to be systematically investigated.

We have not addressed the tendency of some pianists—especially pianists from the early days of recording—to deliberately *delay* the melody (sometimes called bass lead: Goebl, in press; Repp, 1996; Vernon, 1936). This is technically relatively easy, since the asynchrony is between rather than within hands and may be regarded as a kind of agogic accent (chapter 13).

Psychology of Piano Fingering

> *To impose a fingering cannot logically meet the different conformations of hands . . . the absence of fingerings is an excellent exercise, suppresses the spirit of contradiction which induces us to choose to ignore the fingerings of the composer, and proves those eternal words: "One is never better served than by oneself." Let us seek our fingerings!*
>
> Debussy, *Douze Etudes*

How do pianists determine fingerings? What are the underlying criteria? How do fingerings differ among pianists? Only recently have questions such as these been regarded as amenable to psychological research methods.

In the following, we limit ourselves to psychological aspects of fingering and assume that pianists are free to choose their own. The question of whether

fingerings prescribed by composers such as Schubert, Chopin, Brahms, Liszt, Rachmaninoff, and Bartók should be followed (as, for example, Claudio Arrau has insisted) is a cultural, historical, and perhaps even ethical one and beyond our scope here.

Optimal Fingering

Optimal fingering emerges from a trade-off or compromise among various physical, anatomic, motor, and cognitive constraints, in conjunction with interpretive considerations. It depends on the relative importance of these different aspects for a given pianist or musical context. The complex interaction among these various constraints and their dependence on pianist and style mean that one can rarely speak of a single best fingering for a given passage.

Physical constraints on fingering include the horizontal and vertical arrangement of the black and white keys. In the determination of fingerings, these interact with *anatomic* constraints and associated individual differences: hand size and shape (measured by Wagner, 1988; see photos of pianists' hands in Gát, 1965) or the maximum comfortable stretches between pairs of fingers (included in the model of Parncutt et al., 1997; see also Jacobs, 2001).

Motor constraints can apply either within a single hand or between hands. Within a hand, they limit finger independence. According to Ortmann (1929/1981), such motor constraints can be reduced by practice but never eliminated. Between hands, motor constraints are involved in the coordination of tremolos, two-hand trills, and shakes; the execution of seamless transitions from one hand to another within Thalberg-style thumb melodies or accompanying figures; and the sharing of technically difficult figurations between the hands.

Cognitive constraints determine how well we can encode and retrieve complex finger patterns and their context dependencies. Fingerings that stay the same in different keys may reduce cognitive demands but are physically and anatomically more difficult. A change of fingering at a key change may be worthwhile if the anatomic and physical advantages balance the added cognitive load. To master these difficulties, many piano pedagogues, including Liszt (and, e.g., Frey, 1933), have recommended transposing difficult passages to all keys without changing the fingering.

Interactions between the two hands are primarily limited by cognitive constraints. In sight-reading unison passages (hands an octave apart), for example, two different fingerings must be planned and executed simultaneously (Parncutt, Sloboda, & Clarke, 1999). The cognitive load is reduced in mirror-image patterns in contrary motion, where fingerings can be identical in both hands—for example, in Messiaen's *Vingt regards sur l'enfant Jésus* (Troup, 1983, 1995).

By *interpretive* considerations we mean both communication of musical *structure* (chapter 13) and *emotion* (chapter 14). Fingering choices are often determined by matching a constraint to a given interpretive intention, for example, thumb on black at the start of a measure or phrase (Clarke et al., 1997) or second (index) finger at the end of a phrase. A more general interpretive consideration

is flexibility: pianists need a fingering that allows for changes of interpretation without changes of fingering that would increase the rate of errors (Sloboda et al., 1998).

Procedural Versus Declarative Knowledge

The knowledge (or memory) that underlies fingering choices may be described as episodic or semantic, or as procedural or declarative. These terms are defined in psychology (see, e.g., introductory texts) as follows. *Episodic* knowledge refers to a specific event: a pianist may finger a passage in a certain way because the passage resembles a previously encountered and fingered passage. *Semantic* knowledge is more generalized: here it includes rules and principles of fingering. Both episodic and semantic knowledge can be either declarative or procedural. *Declarative* knowledge can be verbalized (knowing *that*), but *procedural* knowledge (knowing *how*) typically refers to *automated* movements that underlie a skill, such as riding a bicycle or producing grammatically correct sentences: a five-year-old may be able to do both but is unable to describe the underlying physical or grammatical rules or principles.

All four aspects are important at all levels. Even the most experienced pianists try out fingerings at the keyboard (procedural) but can also explain their fingering choices (declarative: Clarke et al., 1997). Procedural knowledge of fingering may be acquired either by applying declarative knowledge (rules) to repertoire excerpts (episodic: see, e.g., technical methods of the 1920s and 1930s) or by improvising exercises to address specific fingering issues (semantic: e.g., Cortot, 1958; Gellrich & Parncutt, 1998).

Dependence on Task

Optimal fingering depends on whether a passage of music is improvised, sight-read, played from the score after rehearsal, or performed from memory. For example, marked differences were observed between fingerings spontaneously used by pianists in the sight-reading task of Sloboda et al. (1998) and fingerings written on scores of the same music by the same participants several months previously (Parncutt et al., 1997). Standard fingerings for scales and arpeggios are of course more useful in sight-reading (where they reduce the cognitive load) than in memorized performance, where the pianist has time to automate new fingerings (Clarke et al., 1997)—although this does not necessarily apply to professional sight-readers, who have usually seen the score in advance (chapter 9).

Differences between written and sight-read (or improvised) fingerings may be explained if we assume that writing primarily taps declarative knowledge and sight-reading (or improvisation) primarily taps procedural knowledge. Only during rehearsal does a pianist have the chance to allow declarative and procedural knowledge to interact, as new fingering patterns are deliberately learned and automated. Teachers and performers may therefore develop different fingering approaches and strategies for sight-reading as apart from rehearsed per-

formance, beyond merely learning standard fingerings for scales and arpeggios (cf. Deutsch, 1959).

Dependence on Expertise

Fingering depends on expertise (Clarke et al., 1997; Sloboda et al., 1998), because technique (finger independence, coordination of finger, arm, and hand movements, and so on) typically matures before interpretive ability and personal style. Beginners focus almost entirely on anatomic and physiological constraints but may not yet have the experience and knowledge necessary to choose the easiest variant. Young professional pianists (e.g., conservatory graduates) tend to use a fingering that is anatomically and physiologically optimal. Seasoned artists with consummate techniques usually focus on interpretive considerations; for example, Schnabel was famous for sacrificing digital expediency for interpretive integrity, regarding hand position ("handing") as more important than fingering (Wolff, 1972). Thus a teacher's best fingering is not necessarily best for a student, and while it is always advisable to extend the student's awareness of available fingerings, it may be unwise to expect rigorous imitation.

Acknowledgments. The first author of this chapter thanks Diana Weekes, his piano teacher from the University of Melbourne, for her copious, insightful, and challenging comments on this chapter, and another pianist and piano teacher, Patrick Holming, for ideas, discussions, and literature sources. For technical comments, we thank Anders Askenfelt, Alexander Galembo, Werner Goebl, Hans Christian Jabusch, and authors of other chapters. The second author acknowledges Alberto Guerrero, with whom he studied in Canada alongside Glenn Gould, and Walter Gieseking, with whom he studied in Germany.

String Instruments

KNUT GUETTLER & SUSAN HALLAM

Research on the physics of bowed stringed instruments can help the string teacher to explain the underlying acoustical phenomena and to develop corresponding pedagogical strategies. The first part of this chapter surveys current and historical acoustical research, focusing on information that can be related to technique. This section discusses not only the bowed attack with specific exercises to improve performance, but also other topics such as harmonics, rosin, timbre, and aspects of room acoustics during performance. An overview of psychological research relating to the distinctive aspects of playing a bowed stringed instrument and the characteristics of string players follows. This considers the importance of well developed aural skills, practice, and conscientiousness on the part of the player to develop high levels of expertise. The need for the teacher to demonstrate and provide opportunities to develop aural schemata, and give detailed constructive feedback is also discussed.

The first serious acoustical research on the violin can be dated back to the first half of the nineteenth century, when the French physicist Felix Savart borrowed from violin maker Jean Baptiste Vuillaume free top and back plates of violins crafted by Stradivari, Guarneri, and others, to examine how they vibrated at different frequencies (Savart, 1819, 1840). Contrary to popular belief, Savart discovered that the sound post does not function primarily to transmit the vibrations from the top to the back of the violin. Rather, its main function is to impose a nearly stationary point about which the top plate can rock.

The next major step toward an understanding of the acoustics of the violin was taken by Hermann von Helmholtz (1862/1954). Through acoustical filtering he was able to break tones down into pure tone components or partials (i.e., fundamental plus overtones), whose relative amplitudes influence timbre. In this

way, he could study each partial separately. Using a microscope, vibrating with nearly the same frequency as the string, he could watch the string in slow motion and show that bowing and plucking the string produced quite different patterns of vibration. With this method, he discovered the *slip-stick* action between the bow and the string, now called *Helmholtz motion*, which underlies the sawtooth-shaped force waveform acting on the bridge.

In the first part of the twentieth century, scientists from many countries contributed to research on the violin. While most of these focused on the instrument body and its vibrations, varnish, and wood, an Indian, Chandrasekara V. Raman, was particularly interested in the parameters of bowing technique: bow speed, bowing pressure (the correct physical term being *force*), and the bow-to-bridge distance, which together control the string wave form. Raman (1920) constructed a mechanical bowing machine that enabled him to measure the minimum required bowing pressure for any given pitch on the instrument, a value he found to be inversely proportional to the square of the bow-to-bridge distance. Interestingly, Raman found that particularly resonant tones required higher bowing pressure than less resonant ones. For resonant tones, more low-frequency wave energy is drained from the string through the bridge to the instrument's body, so the string will not maintain its fundamental-frequency oscillation with the same ease as for less resonant tones. In most cases, increasing the bow pressure can compensate for this energy loss. (String players normally adjust these bowing parameters intuitively, but if the sound is unsatisfactory, intuition does not always provide guidance as to what is wrong.) When the energy loss surpasses a certain magnitude, a steady-state oscillation is impossible at any bow pressure. Such tones are commonly termed *wolf tones* due to their (sometimes) howling character.

In the early 1950s, four Americans formed a group, jokingly calling themselves the Catgut Acoustical Society. Their ambition was "to increase and diffuse the knowledge of musical acoustics and to promote construction of fine stringed instruments" (currently used as their journal's cover-page motto). The organization now has worldwide membership comprised of scientists, luthiers, and musicians, who communicate through semiannual journals. Their publications provide a wealth of information for anyone interested in learning about string-instrument acoustics.

Research in the 1970s returned to the bow-string interaction. McIntyre and Woodhouse (1979) and Schumacher (1979) made the first computer simulations of the bowed string. This led to the discovery of the important role of *string torsion* (twisting or rolling under the bow) during the *attack phase* (defined as the first part of the tone, before it has settled into a steady vibration, or the transitional state between rest and the sustained tone). Without some torsion, strings would be much harder to bow. Computer simulations also increased the demand for quantification of physical string properties (Pickering, 1985) and knowledge about different string materials' effect on tone quality (Pickering, 1990). The results contributed to the design and manufacture of modern, well-responding strings.

Fundamentals of the Bow-String Contact

Helmholtz Motion

In a typical bowed tone, the string alternatively *sticks* to and *slips* against the bow hair. There is one *sticking interval* and one *slipping interval* per period of the tone (i.e., 440 times per second on an open violin A string). After the attack phase, the string takes the shape of two almost straight lines joined in a kink or corner, which follows a lens-shaped path (see Figure 19.1). On a violin A string, the corner travels along the string at a speed of approximately 290 meters per second. As the corner passes the bow in the direction of the bridge, the bow loses its grip (stick) on the string and begins to fly back (slip) along the bow hair. During the slipping interval, the corner reaches the bridge and is reflected back in the direction of the bow. At the instant the bow is passed again, the string portion under the bow starts moving much slower relative to the hair, allowing the string to stick again and stay stuck for the remaining, longest part of the cycle period (provided no other disturbance occurs). This particular string movement is called the Helmholtz motion.

In a violin upbow, the rotation along the string (relative to the player) is counterclockwise; in a downbow, clockwise. Thus a new rotational orientation has to be developed after each bow change. Bowing technique is primarily concerned with the creation and maintenance of Helmholtz motion.

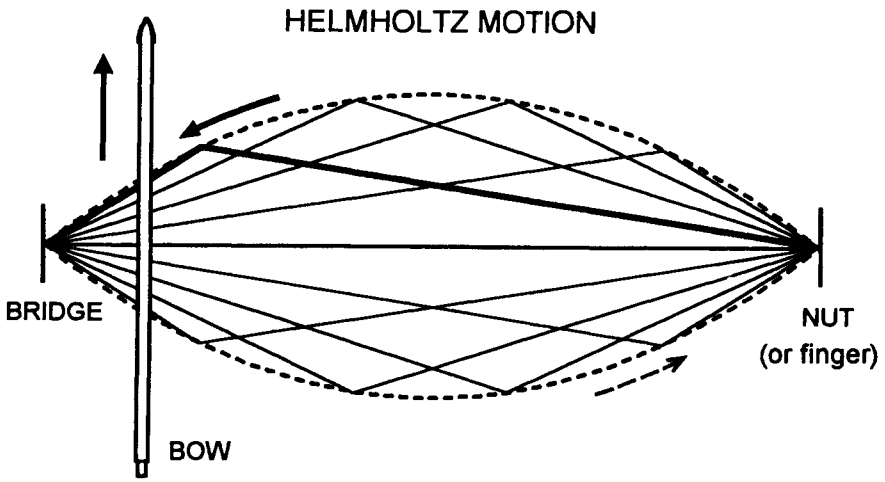

Figure 19.1. When the string is bowed in a steady state, the (idealized) string takes the form of two straight lines connected by a rotating corner. When the corner is traveling from the bow to the bridge and back, the string slips on the bow hair. In the remaining interval, the string sticks to the hair, if bowed properly.

Figure 19.2 (a) shows, in somewhat idealized form, the force exerted by the string on the bridge as a function of time. This force tries to move the bridge sideways and, as a result of the bridge's downward force shifting from leg to leg, causes the instrument body to vibrate, thereby creating sound.

Other Cyclic String Patterns

The Helmholtz mode is only one of several possible modes of vibration, and the one that produces the clearest pitch and the smoothest, fullest timbre. When more than one slipping interval occurs per cycle (producing more than one corner on the string at a given moment in time), the lower partials are weakened, and the sound becomes scratchy, with increased slipping noise (see "Hiss (Rosin Noise)" later). Figure 19.2 (b) shows the force wave with one extra slip per cycle. An easy way to recognize this mode is to look at the midpoint of the string, where its amplitude appears constricted during the attack phase. In most cases, a multislip pattern soon dies out as the corners are softened by string stiffness and the following energy absorbers:

- The compliant, not-totally-reflecting bridge (transferring energy to the instrument body)
- Damping by the soft finger pad
- The internal friction of the string (e.g., friction between windings, molecular friction)
- The drag of surrounding air

The faster some high-frequency wave energy is lost in these ways, the sooner the Helmholtz motion will form, provided that the bowing speed and pressure are in the right range. The concept of energy loss can explain why open strings, strings not yet broken in (having less internal friction), and strings with great ability to sustain *pizzicato* (ditto) are more susceptible to whistling and onset noise when bowed.

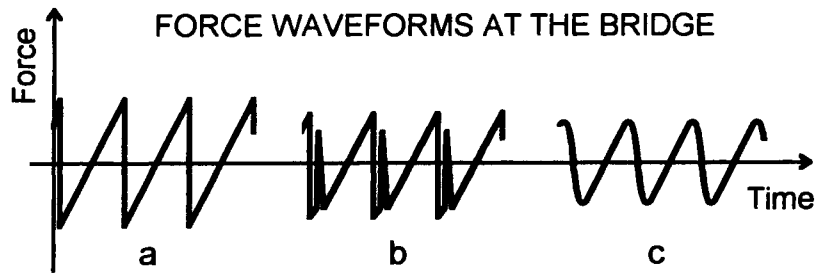

Figure 19.2. Different force waveforms acting sideways on the bridge in the plane of bowing (about three periods shown of each): (a) brilliant sound, (b) scratchy tone, (c) soft timbre that results from low bowing pressure and a rounded corner.

Rounding off the Helmholtz Corner

In practice, the string can never make a perfectly sharp corner. String stiffness and the losses mentioned earlier round it off. However, the bow will, to some degree, sharpen the corner every time it passes, depending on the bowing pressure. So as long as the player does not choke the string, a higher bowing pressure means a sharper corner and thus—according to the basic mathematical theory of Fourier analysis—a higher energy content of high partials. Correspondingly, lower bowing pressure encourages rounding and a softer tone color (see Figure 19.2 c).

Hiss (Rosin Noise)

During the slipping interval, an audible hiss or buzz is produced when the string slides on the rosined bow hair. Physically this consists of short bursts of noise (one per period of the fundamental frequency) and so is referred to as pulsed noise. This is an important contributor to the characteristic timbre of stringed instruments. In the scientific literature, the bow-to-bridge distance divided by the length of the vibrating string is termed β. (For example, if the bow is midway between the finger and the bridge, $\beta = 0.5$.) This ratio determines the duration of the hiss pulse relative to the cycle period. By bringing the bow nearer to the fingerboard (*sul tasto*), one increases β and the time proportion of hiss. Very low bowing pressure (as in *flautando*) lengthens the slipping period even further, adding even more breathiness to the sound.

Noise may also be generated during the sticking interval, especially on the violin, when bowed near the bridge. This largely undesirable spiky quality is particularly audible at high bowing pressure and is caused by minor local string slips across the hair-ribbon width (McIntyre, Schumacher, & Woodhouse, 1981; Pitteroff, 1995). Tilting the bow reduces the width and minimizes the effect.

Getting the String into Helmholtz Motion

So far, only the steady-state (postattack) oscillation of the string has been discussed. To get the string into Helmholtz motion quickly, a good strategy is to aim for a regular stick-slip pattern from the very onset. The violin body has a *response time* of the order of 5–15 ms, but the bowed string normally needs considerably longer to reach full amplitude (Melka, 1970). (Response time is here defined as the time required to reach 90% of full amplitude if a steady-state input signal is abruptly switched on.) The attack of bowed instruments is relatively slower than that of most wind instruments, making the string sound appear later than the wind, even when they start simultaneously. This delay is most noticeable at lower pitches (e.g., in the double basses), because transient duration varies inversely with fundamental frequency (so, for example, a tone an octave lower takes twice as long to sound fully). The string buildup time is, however, partly habitual (having to do with wrist action, etc.) and may, if desirable, be shortened through practice. We will return to this point later. First we will consider of the production of clean tone onsets.

During the attack phase, the motion of the string, for a given fundamental frequency and bow-to-bridge distance, is primarily determined by bowing *pressure* and *acceleration*. After the attack, when full amplitude has been reached, string motion is determined primarily by bowing *pressure* and *speed*. Based on computer simulations (Askenfelt & Guettler, 1998), Figure 19.3 shows schematically how the cleanness of the attack is influenced by bowing pressure and acceleration. For each relative bow-to-bridge distance (β), the noise-free region forms a (white) triangle in the figure, from which the following conclusions can be drawn:

- A certain minimum bowing pressure is required to start the proper slip-stick triggering directly (typically in the order of 0.1–0.2 Newton, comparable to 10–20 grams, for a violin).
- The required bow *acceleration* increases with the bow-to-bridge distance if the bowing pressure is kept unchanged (compare the positions of the rectangles drawn in the two panels of Figure 19.3).
- Near the minimum bowing pressure, the acceleration *tolerance* (i.e., the range of acceleration values that will produce noise-free attacks) is very small, but it increases with bow pressure, and with the bow-to-bridge distance (compare the widths of the rectangles drawn in the two panels of Figure 19.3).

In addition:

- For noise-free attacks with a given string, the required bow acceleration increases proportionally with the fundamental frequency and so does the acceleration tolerance.

The latter means that bowing can be varied more freely for high-pitched in-

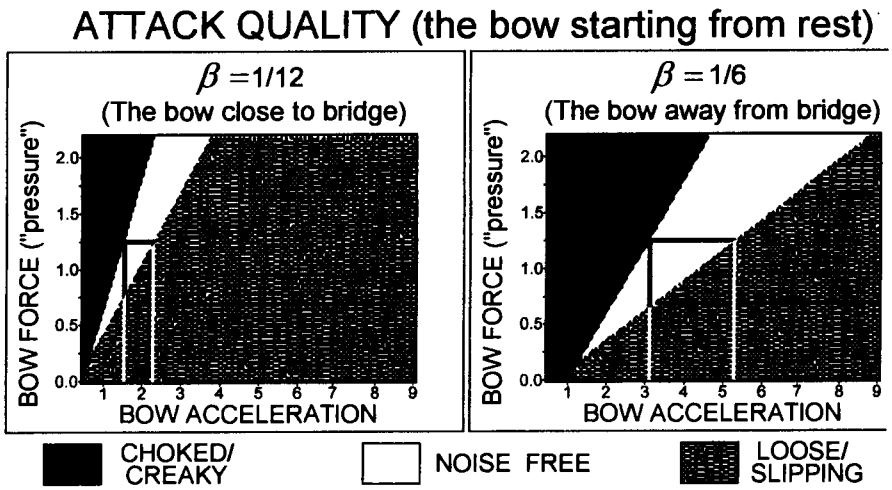

Figure 19.3. The combination of bowing pressure and acceleration (both scaled in arbitrary units) determines the quality of the attack. NOISE FREE means regular slip-stick triggering from the very onset. Within this (white) area, high acceleration gives the quickest tone buildup. Rectangle widths show the acceleration tolerances for a given bowing pressure.

struments than for their low-pitched counterparts. In order to make a quick tone buildup for a given bow pressure and position (i.e., reaching full amplitude as quickly as possible), the player must try to find the maximum (farthest to the right in the figure) acceleration within the noise-free (white) area. Only through practice and trial and error can this limit be found. The lower limit (i.e., the *lowest* noise-free acceleration) might also be practiced, as preparation for smooth bow changes.

If non-Helmholtzian waveforms are created, these will prevail for a number of *periods* before expiring, implying a longer lasting onset noise for low-pitched strings than for high-pitched ones (Guettler & Askenfelt, 1997).

How to Control Bow Acceleration in the Attack Phase

The generalizations outlined earlier need only be considered when the player is trying to account for problems in attack. For deciding what sounds best, the ear is always superior.

Many players prefer to start the stroke from the air, deliberately producing an onset with a certain airy or slippy sound. However, for low-pitched strings such an airy introduction may be too persistent, especially in *forte*.

In practice, acceleration is not an easy concept to grasp or to teach. Newton's second law, force equals mass times acceleration, suggests the following approach: When one is playing near the bridge, an almost constant acceleration can be achieved by adding mass to the bow, so that small deviations in the frictional force will have less effect on the bowing speed. This can be achieved by temporarily reducing the suppleness of one or more joints in order to add the mass of the fingers, hand, forearm, upper arm, and torso to the mass of the bow itself. (When one is doing this, bowing pressure should not be influenced!) For low-pitched tones and/or playing close to the bridge, this technique effectively reduces the influence of a rapidly fluctuating frictional force, which could otherwise make the acceleration uneven. The technique works best on heavier strings, where the magnitude of frictional fluctuations is greatest. A posture that allows for flexibility of the upper body is essential for a consistent and well-controlled bow-arm movement on any string instrument. For a double-bass player, it is particularly important not to let the instrument's body lock the chest in a fixed position.

Practice Suggestion: The student should learn the arm/finger action that produces noise-free attacks when making repeated attacks close to the bridge. The following should be varied: (1) the suppleness of the arm/finger joints, (2) the dynamic level, (3) the bow's starting point (frog-middle-tip), and (4) the pitch.

Control of String Vibration during the Steady-State Phase

As soon as a correct Helmholtz pattern is established, the player has a wide palette of timbres to choose from. For a given bow speed, different bow pressures may subsequently produce anything from "harmonics" and *flautando*, via "loose,"

"firm," and "pressed" timbres, to "raucous" and "creaky" sounds (Schelleng, 1970). As long as some kind of Helmholtz motion is present, the fundamental frequency will be well defined, so the pitch will be clear. When bowing pressure is far too high or the speed far too low, the sound may best be described as raucous or creaky. However, before raucousness appears, there is a point where the sound is pressed and the fundamental frequency is slightly reduced (flat), because the sticking rosin delays the string release (i.e., the transition from sticking to slipping phase) at excess bowing pressure. The effect is more pronounced for softer rosins, larger distances of the bow from the bridge, and shorter lengths of the vibrating strings, which increases the effective string stiffness (e.g., high positions on a violin G string). Moving the bow closer to the bridge hence reduces the flattening. As the bow-to-bridge distance becomes smaller, the palette of different timbres shrinks. Near the bridge, the bowing pressure must be held close to a single theoretically defined value (which depends on the chosen bow speed) if Helmholtz motion is to result. This means that when one is playing near the bridge fluctuations in bowing speed and pressure must be kept to a minimum.

Implications for Performance

When one is performing a *diminuendo*, both pressure and speed of bowing must be reduced simultaneously if a consistent tone quality is to be achieved—regardless of bow-to-bridge distance. Simplified, the ideal situation occurs when bowing speed is balanced against the combination of bowing pressure, relative bow-to-bridge distance (β), and fundamental frequency. Whenever one element is changed, compensation by one or more of the remaining three is normally required.

Example 1. If one keeps the bow pressure and distance to the bridge fixed, playing the same pitch on alternative strings will require a higher bow speed on the lowest tuned string. This is because the relative bow-to-bridge distance is greater for the string fingered in the highest position. (In some cases, this rule of thumb will not apply to a crossing between the third and the fourth string, because the lowest string is often disproportionately heavier in order to allow for a bigger sound in the instrument's lowest register. Such strings require lower bow speed and acceleration than others.)

Example 2. In double-stops that span large intervals, the highest sounding string should be given a relatively lower bowing pressure to prevent it from sounding pressed or flattened. (In these cases, both β and the fundamental frequency are higher for the upper tone, regardless of which string it is played on.)

Practice Suggestion: (1) Play several strokes, keeping two elements (e.g., speed and pressure) fixed while varying the third one (e.g., bow-to-bridge distance). After doing so, try to repeat the combination that gave the best sound, directly. Practice on different strings and at different pitches. (2) Play pairs of tones, two

low and two high, in intervals of an octave or larger. Notice the difference required in bow speed.

It is the bow speed that controls the string amplitude for a given bow-to-bridge distance and hence largely the physical loudness of a tone, which is mainly determined by the (loudest-sounding) lower partials. Increasing the bow pressure moderately may produce a slightly brighter sound but rarely increases the total sound level more than one or two decibels before the sound becomes pressed. However, bright sounds are usually *perceived* as loud. For example, when listening to the radio we are never in doubt of an orchestra's dynamic level, regardless of the listening volume. A change of bowing position toward the bridge increases the brilliance and may give the impression of a louder sound, even when compensated for by a lower bow speed.

The Smooth Bow Change

The rotational orientation of the Helmholtz corner is determined by the stroke direction. So when one starts a new stroke in the opposite direction, the whole transient process needs to begin again. Any release of the bow pressure during this phase implies a slower buildup of the new tone, as well as reduced brilliance. This type of temporary change in timbre is less noticeable in the violin than the double bass, due to the longer transient of the latter. If a brilliant, noise-free sound is to be maintained during the entire bow change, a stable bow pressure, combined with suitable bow acceleration, must be observed.

It is important to minimize the remains of the old corner rotation before developing a reversed one to avoid slipping noise caused by interference between two opposing corners. The bow *deceleration* that precedes the change of direction can be of considerably greater magnitude than the acceleration that follows. This has been confirmed by measuring the smooth bow changes of skilled players (Williams, 1985).

Practice Suggestion: Play bow changes at different dynamic levels and different bow-to-bridge distances. Experiment to find the wrist action, or suppleness, that works best in each case.

Spiccato *and* Ricochet

Computer simulations show that the requirements of bowing pressure and acceleration (as described in Figure 19.3) are met during clean *spiccato* attacks and that the bow quickly dampens the string prior to each new attack (Guettler & Askenfelt, 1998). If one places a small mark at the bow-stick midpoint, a horizontal figure of eight (∞) should be seen when one watches the mark during rapid *spiccato*. Any other figure is likely to produce some onset noise. In *ricochet*, where several strokes are performed in the same direction, the remains of the old Helmholtz pattern can easily be picked up and refreshed without any predamping, minimizing the buildup time. The same goes for other linked strokes

like *slurred staccato* and *portato*. This is why such attacks often sound cleaner than normal *spiccato* and *détaché*.

"Harmonics" (Flageolet Tones)

"Harmonics" are played by placing the finger at certain points of the string, thus filtering out the fundamental and some of its partials and allowing only some selected partials (overtones) to vibrate. (In physics, however, a *harmonic* means a frequency that is an integer multiple of the fundamental.) When harmonics are played, the string is almost motionless at certain points called nodes. Between these, the string behaves like several short strings, each of which exhibits Helmholtz motion (see Figure 19.4). The nodes are equally spaced along the string. This implies that on a string the stretch between the pressing and the touching finger in an "artificial harmonic" will remain the same whether it is performed as an octave, fifth, fourth, or major-third "harmonic" (see lower part of Figure 19.4). However, the highest position will give the shortest transient, due to earlier reflections between the bridge and the touching finger. A harmonic cannot be excited at the node and requires bowing pressure, speed, and acceleration comparable to that of a fingered tone of the same frequency. This is easily forgotten when combining harmonics with lower-pitched tones on the same string.

Rosins

Rosin temporarily melts in the near vicinity of a sliding string, increasing the difference in frictional force between stick at maximum hold, and slip. It is this difference (its span often referred to as the friction delta)—not the absolute friction values—that uniquely defines the harmonic spectrum for a given bow speed and position on a mounted string. Statements such as "You should be playing with the scales," ". . . barbs," or even ". . . teeth of good-quality hair, not the rosin"

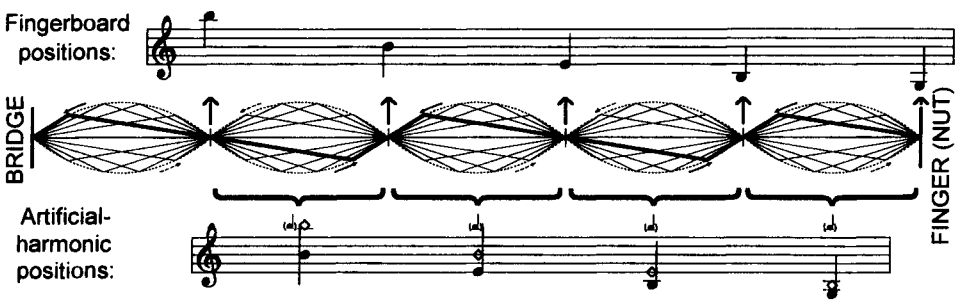

Figure 19.4. When one is playing harmonics, the string forms a series of Helmholtz figures separated by nodes. The distance between adjacent nodes equals one-half the wavelength of the harmonic frequency (here B_5).

are therefore scientifically unjustified. However, as advice to *limit the amount* of rosin such statements make some sense, since a thick layer of rosin tends to cause uneven friction characteristics. The hair should be judged from its ability to hold rosin evenly, rather than from its ability to cause mere friction, to which scale thickness of no more than 1/200 mm will not contribute much anyway (Rocaboy, 1990). The friction delta increases with the bowing pressure and with the softness of the rosin and decreases with increasing string weight (physical term: *wave resistance*). Because of this, soft rosins are often preferred for low-pitched instruments with heavier strings.

Pizzicato

Pizzicato and *arco* produce completely different string movements, as *pizzicato* involves no corner rotation, only a simple side-to-side movement, symmetrical over the string's midpoint. Although different, their spectra are both functions of the relative bow- (or finger-) to-bridge distance, with a large distance giving the highest proportion of fundamental-frequency amplitude and hence the longest sound-buildup time, while a small distance gives the brightest and most direct sound. High overtones tend to fade quickly. This depends, however, on both frequency and plucking *angle*, as the mobility, thus the individual overtone absorption, of the bridge varies with both. Test it!

Sound Radiation

The vibrating string does not produce any audible sound if not coupled to a body of adequate size. In fact, even the bodies of the violin family do not properly radiate the fundamental frequencies of their lowest tones. For the double bass and cello, a compliant floor sometimes comes to the rescue, as low-pitched vibrations are transmitted through their spikes much like tuning forks on a tabletop. Each string instrument has two groups of resonances: one dominated by the enclosed air and one by the wooden body parts. The main air resonance is for violin about 270 Hz ≈ C_4–$C\sharp_4$, viola: 240 Hz ≈ $B\flat_3$–B_3, cello: 115 Hz ≈ $B\flat_2$, and double bass: 65 Hz ≈ C_2, with their main body resonances a good fifth higher (Hutchins, 1962). (A wolf tone would most likely be situated near the latter, by which the top, and hence the bridge, moves considerably.)

The number of resonances per octave rapidly increases with frequency. In *vibrato*, many string partials temporarily coincide with body resonances and are thus well transmitted—while others fall between the resonances. This continuously varying timbre brings out a harmonic totality that is otherwise imperceptible. (One may compare it to viewing a landscape through a picket fence: unless moving, one cannot see it all.) Another interesting feature is the *directional dispersion* of high tones, by which a good instrument may produce an illusion of multiple sound sources in a reflecting room (Weinreich, 1997). In general, different-frequency bands have different radiation characteristics, which are important to bear in mind when positioning the instrument with respect to microphones or even an audience (Meyer, 1972).

When one is performing a solo in a large hall, an early first reflection increases definition and clarity. Instead of approaching the very front edge of a wide stage, stepping back might be better, because it will help to mirror the instrument for the audience in the acoustically reflective stage floor. Brilliance is crucial for perceptibility of rapid passages and should be slightly boosted, for example by bowing closer to the bridge in dark-sounding or reverberant halls. In addition, any view-obstructing music stand will also obstruct high frequencies.

Psychology of String Instrument Performance

Playing a Stringed Instrument

So far we have considered evidence that relates to how sound is produced on bowed stringed instruments and the relationship between this and acoustics. We now consider research evidence that relates to string players and what is distinctive about playing a stringed instrument. To date, research in the psychology of music has tended to neglect these issues, assuming that musicians are a relatively homogeneous group and that what applies to one musician will apply to all. Increasingly researchers are recognizing that there may be important differences between musicians, but as yet there is little research evidence.

What Is Distinctive about Playing a Bowed Stringed Instrument?

As the previous section infers, the technical requirements of the string repertoire are varied and demanding, requiring the acquisition of many skills that must become automated to enable fluent professional performance. To play a bowed stringed instrument requires sensitive motor control to enable secure intonation, clear articulation of bowing, and the coordination of two very different kinds of movements being undertaken by left and right hands. In addition, well-developed aural skills are required to monitor accuracy, as any finger can be used to play almost any note. The demands of the repertoire and professional work schedules also require high-level cognitive processing skills in relation to reading music, as the demands made on string players, particularly the first violins, tend to be greater than those made on other orchestral players. So what does the research evidence tell us about string players and the way they acquire their skills?

The Characteristics of String Players

Using psychometric techniques, Kemp (1995) found that orchestral string players tended to demonstrate more aloofness, conscientiousness, and considerable willpower than other instrumentalists. He suggested that these characteristics were necessary to maintain the level of practice required to master the complexity of playing a stringed instrument. In a further breakdown of the personality profiles into specific instruments, at the school and student level, Kemp found that

secondary school violinists emerged as having a tendency to be easily upset and emotional. In contrast, cellists emerged as both self-sufficient, shrewd, and aloof, demonstrating a greater social awareness not apparent in the other instrumentalists. The viola players at student level were more emotionally stable than their fellow string players, while the double-bass players presented a profile that was typical of the overall string profile. These findings must be viewed with some caution, as the number in each group was relatively small, but they are relevant to pedagogy to the extent that those who are learning to play stringed instruments may need a higher level of commitment to practice than those who are learning other orchestral instruments (see also chapter 1 in this volume).

Personality and Practice

How does the research on the personality of string players relate to what we know about their practice? Although there has been little research, such as there is supports the notion that string players, especially the violinists, undertake more practice than their orchestral peers (Jørgensen, 1997). This supports the findings outlined earlier. The reasons for the violinists' undertaking more practice may relate to the larger and more demanding repertoire. We know that there is a strong, if not perfect, relationship between the amount of time spent practicing and the level of expertise attained (Ericsson, Krampe, & Tesch-Römer, 1993; Hallam, 1998; Williamon & Valentine, 2000). Similarly, differences in practice patterns across instruments seem to reflect the demands of particular instruments. As practice draws on limited physical and mental resources, the amount of practice sustainable daily is limited by the individual's ability to recover. Four hours daily seems to be the maximum sustainable over long periods without burnout occurring (Ericsson et al., 1993; Hallam, 1995; Jørgensen, 1997). To accrue the additional hours of practice to achieve professional entry to a music conservatory, string players would need to start playing at a younger age than their wind- and brass-playing colleagues and violinists at an earlier age than other string players. While there is no formal evidence to support this, pianists (who undertake the most practice) and violinists who attain status as international soloists do tend to start playing at very early ages.

Learning to Play a Bowed Stringed Instrument

Given the lack of other cues to inform feedback, it is crucial for string players to develop accurate aural *schemata* (mental representations) against which to evaluate their performance. The evidence suggests that this does not occur until they have developed considerable expertise (Hallam, 2001). Teachers can provide aural representations through modeling, but they tend to spend little time in demonstration, although a large proportion of the variance in performance can be accounted for by their willingness to model aspects of their playing (Sang, 1987).

Feedback has an important role in learning to play any instrument. To be effective, it needs to be appropriate and relevant to the task. Conditions of restricted and unrestricted vision, for instance, had no differential effect on string

players' intonation, while verbal feedback produced more accurate intonation than recorded or model performance feedback in university-level string players (Salzberg, 1980). Violin posture can be improved through the teacher providing corrective feedback (Salzberg & Salzberg, 1981), and biofeedback techniques, where musicians receive through electronic monitoring direct feedback that regards muscular activity, have proved very useful in enabling string players to learn to relax specific muscles as they are playing (Irvine & LeVine, 1981; LeVine & Irvine, 1984; Morasky, Reynolds, & Clarke, 1981). These techniques can be used while students perform passages from the repertoire they are learning (Cutietta, 1986).

Practical Applications

What can we learn from the research findings in this chapter that will offer specific help to string players? Playing a stringed instrument is distinctive because of its relative difficulty and its particular reliance on well-developed aural skills. String players need to start playing young, undertake a considerable amount of practice, and be given numerous opportunities for listening to music and developing aural skills. Modeling and the provision of detailed verbal feedback are very important in teaching.

Wind Instruments

LEONARDO FUKS & HEINZ FADLE

In mouth-blown wind instruments, the energy provided by the respiratory system is converted directly into sound. In all cases a primary vibrating element, generically called *reed*, controls the airstream. The reed may be a piece of bamboo, the lips, a metallic tongue, or even the air jet (in flutes and recorders). Players control loudness, attack, intonation, and timbre by means of embouchure settings, blowing pressure, airflow, and length of the air column. The respiratory muscles perform complex and systematic movements, generating wide ranges of pressures, and coordinated oscillations that produce the vibrato effect. Intonation may be affected by the characteristics of the lung air. We address the associated sensory, physiological, and acoustical phenomena. Common controversial or misleading concepts among wind players are discussed and some simple experiments are proposed for pedagogical applications.

Mouth-blown wind instruments convert pneumatic energy, in the form of air pressure and velocity, into sound waves. They belong to the category that Sachs (1940) describes as *aerophones*. Other aerophones include the human voice, the pipe organ, and the accordion.

Wind players use their respiratory apparatus as an air compressor to supply energy to the instrument. At the mouth, air is delivered through a sophisticated interface with the instrument, which musicians refer to as their *embouchure*. Each subtle action from muscles of expiration and embouchure imprints the sound, forming part of the musical expression. The arms, hands, and fingers skillfully control a complex of tone holes, slides, rotating valves, levers, and other mechanisms. Inside the instrument, several phenomena take place, including reflection, diffraction, resonance, shock waves, damping, vortex generation, and chaotic oscillations. Body posture, respiratory techniques, and a psychological strategy to deal with stressful situations are additional key aspects of perfor-

mance. This rich environment challenges the abilities of players and educators to deal with a number of principles that are associated with performance on wind instruments. Some of the most important are described in this chapter.

The Reed

Every wind instrument has some mechanism that cyclically disturbs or interrupts the air stream. This mechanism can be generically called a *reed*. Therefore, rather than a component of bamboo or other elastic material, *reed* in this context stands for a valve that controls the air passing through the instrument, as shown in Figure 20.1. This concept has been consistently adopted by several authors in music acoustics (Campbell & Greated, 1987; Sundberg, 1991; Strong & Plitnik, 1992). The tongue, the lips, and the moving structures of the respiratory system may also be used to regulate the airflow, serving as additional valves.

Winds may incorporate a *mechanical reed* (reed woodwinds), *free reed* (mouth harmonicas), *lip reed* (brass instruments), or *air reed* (flutes and recorders), where one side is in contact with the player's mouth and the other attached to the instrument. Figure 20.1 shows four simplified models of reeds, each one representing a different type of oscillation. Because instruments such as the flute involve an air reed with no solid vibrating part, they are discussed separately.

As the air stream encounters resistance in passing the reed, a difference of pressure will be created between both sides. The pressure in the upstream (before the reed) is in principle higher than that of the downstream side due to friction losses. As the reed is flexible, it will tend to bend or move due to this pressure difference. In much the same way as a spring, a reed's elasticity will allow it to return to its original position and shape. The reed also contains mass that is distributed along its body. This defines a *spring-mass* system that has its own resonance frequencies.

In a similar manner to a tuning fork, a reed can be excited to oscillate at its own frequencies. This is the case in free reeds and, exceptionally, in clarinets

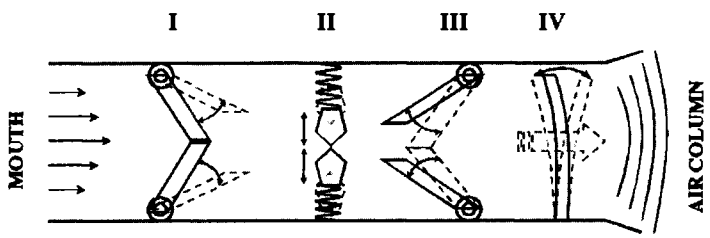

Figure 20.1. Oscillation types found in lip, mechanical, and free reeds: rest position of the reed (solid line) and extreme position during vibration (broken line). (I) outward-striking and (II) sideways- or upward-striking oscillations as found in brass instruments; (III) inward-striking oscillation, typical of reed woodwinds; and (IV) free-striking oscillations, which occur in free reeds.

that produce the so-called *squeak sounds* (Bouasse, 1929/1986). However, the tissue of the lips, forming a cushion pressed against the reeds, absorbs most of the reed energy in every cycle, with the oscillations being damped more than those of a tuning fork.

Another factor is the so-called *Bernoulli force*. When air passes through a narrow passage, the particles' velocity must increase in order to maintain a constant flow. This results in a drop in pressure past the narrow passage and a subsequent partial vacuum between air molecules. This negative pressure tends to suck the reed toward the closing position. If the closing reed blocks the air, this suction is immediately interrupted, releasing the reed to return to its original state.

In spite of being easily explained in general terms, the Bernoulli force is not important in all cases. It is certainly relevant in double reeds, especially the oboe, and for the higher range of brass instruments (Fletcher & Rossing, 1998). However, in the case of the clarinet its role is in most cases negligible, because it is not strong enough to make this instrument's reed vibrate (Worman, 1971).

The Air Column

The *air column* is the length of vibrating air in the instrument during sound production. The airflow that crosses the reed creates pressure waves that travel along the air column toward its end and are then reflected back to the reed. In lip and mechanical reeds, if the reflected wave pressure is strong enough it will make the reed reverse its direction. At this point, the system is ready for a new cycle, as it establishes a chain of *self-sustained oscillations*. In an air reed, the air jet flows alternately into the column and out into the ambient, as a result of the waves set up in the air column (Benade & Gans, 1968).

The connection between the air column and the reed, technically referred to as acoustical coupling, forces the reed to vibrate at certain frequencies. When producing a steady tone, the reed vibrates with a frequency close to one particular mode of the air column, so that reflected waves arrive precisely when the reed, depending on the oscillation type, closes or opens. Benade (1990) described this situation as the reed being "enslaved" by the air column. Each configuration of tone holes, keys, pistons, valves, or slide in a wind instrument determines the length and shape of the air column.

A given air column resonates at a set of frequencies that are possible inside it. Each of these frequencies corresponds to a resonance mode. The set of tones obtained with a fixed air column should ideally coincide with those of a harmonic series. However, instruments usually deviate from the perfect geometry of a cylinder or a cone, so that the real modes also deviate from the exact harmonics. Wind players must develop the skill of matching the embouchure and blowing controls to select the desired mode of the air column, which will result in particular tones. Whenever the reed and the air column achieve a pattern of self-sustained oscillations, a *playing mode* is defined. *Overblowing* happens when the instrument jumps from a mode to a higher one.

The four models in Figure 20.1 are *pressure-controlled valves*, as pressure is the main controller of the reed movement. Only air reeds such as the flute are directly controlled by airflow (Benade & Gans, 1968).

While the instrument is being played, the sound waves generated in the reed propagate both to the tube and to the mouth cavity, toward the player's airways. However, most of this energy propagated into the mouth is lost by absorption through the multiple branches and soft walls of the respiratory apparatus. Nevertheless, the vocal tract may respond to some frequencies, as it does for the formation of the vowel sounds. In such cases, the vocal tract can be considered as an internal air column that interacts with the reed and the instrument's air column.

Some skilled players attempt to master the control of the vocal tract to improve their sound quality and stability and to help in the transition between playing modes. While some authors consider that a player's vocal tract has a negligible influence on an instrument's tone (e.g., Backus, 1985, in reed woodwinds), others (Benade, 1986; Johnston, 1987; Fletcher & Rossing, 1998) claim a considerable influence of the vocal tract in instruments such as the clarinet, saxophone, harmonica, and brass.

Types of Reed Oscillation

Lip, mechanical, and free reeds perform characteristic types of oscillations according to their mechanical configuration, as shown in Figure 20.1. The airflow from the lungs crosses the reed, which is subject to forces provided by the embouchure. Helmholtz (1863/1954) referred to type I as an outward-striking and to type III as an inward-striking oscillation. Similarly, type II can be called upward- or sideways-striking and type IV a free-striking oscillation (Fletcher & Rossing, 1998).

In general, the playing frequencies in types II and III are lower than the resonant frequencies of the air column and of the reed itself, while in type I oscillations the playing frequency is higher than those of the air column and the reed alone (Fletcher & Rossing, 1998). Free reeds, corresponding to type IV, are not strongly coupled to an air column and essentially vibrate at their resonance frequencies.

The Embouchure

The *embouchure* can be defined as the constellation of forces and positions in the lips, mouth region, and face that act on the wind instrument (Porter, 1967). It consists of the muscles that form and surround the mouth, the teeth, the upper jaw and mandible, and muscles responsible for mastication. The embouchure controls the reed behavior, thus affecting tone color, articulation, dynamics, and other parameters. In defining the embouchure, it is possible to include the internal mouth configuration, such as the positioning of jaw and tongue. In this sense, the mouth cavity can be regarded as a secondary air column.

In reed woodwinds, the embouchure regulates the reed parameters, such as the stiffness, the aperture for the airflow, the degree of absorption, and, to some

extent, its effective mass (Nederveen, 1969). The embouchure also provides an airtight attachment of the lips to the instrument. In brass instruments, the lips obviously serve both as a reed and as an embouchure component and include the same functions cited earlier. In the flute, the embouchure must be skillfully shaped and managed to ensure proper generation and control of the sound. In spite of the importance of the embouchure in performance and sound production, these latter aspects seem to have been unexplored and therefore deserve more research interest.

Wind Instrument Families

Brass

Stroboscopic observations of the lip vibrations in a professional trombone player indicate that the upper lip vibrates with greater amplitudes than the lower lip in all frequencies and dynamic levels (Copley & Strong, 1996). This study also showed that on average, two-thirds of the mouthpiece diameter is covered by the upper lip and one-third by the lower lip. However, considerable variations of this proportion can be observed in the general playing population, which suggests that players tend to optimize their embouchure during the process of learning.

Lip reeds correspond to types I or II in Figure 20.1. In both cases air pressure tends to open the lips, but in type II the Bernoulli forces act alone to close the lips back. Usually, the type I occurs in the lowest playing modes, with type II being more frequent in the higher modes (Yoshikawa, 1995). It is also possible that both types of motion take place in combination, as observed across the whole compass in a trombone study (Copley & Strong, 1996). Not all studies, however, found the same behavior, probably due to differences in the measurement methods that were employed and particular techniques that were adopted by individual players (Chen & Weinreich, 1996).

A common warm-up practice among brass players consists of buzzing on the mouthpiece or with lips only. This exercise is also claimed to develop flexibility and control of lip vibrations. However, according to Yoshikawa (1995), the isolated mouthpiece represents a completely different acoustical system from the full instrument bore, supporting only type I oscillations but not type II. This finding suggests that exercises of this type do not develop lip flexibility in the way often assumed by brass teachers.

The vibration frequency of the lips increases with a combination of higher muscular tension and lower mass. This *mass* refers to the section of the lip that effectively vibrates. Also, raising the pitch requires higher blowing pressure (Bouhuys, 1964). Therefore, it could be expected that the player would tend to press the lips more firmly against the mouthpiece when playing higher tones. This was corroborated by Barbenal, Davies, and Kenny (1986), who observed that the compressive forces between lips and mouthpiece increase systematically with increasing pitch in professional players. Once again, this finding contradicts some

performers' claim that it is possible to develop a rather "loose" and "fixed" embouchure, regardless of pitch and dynamic level. However, the idea of a loose embouchure may work as a mental image that helps to achieve the goal of minimizing the effort and strain of the embouchure muscles in order to preserve the necessary sensory response of the tissues.

Reed Woodwinds

Mechanical reeds correspond to type III oscillations in Figure 20.1, where the airflow tends to blow them closed. In the oboe and in the bassoon, the reeds beat against each other almost all the time, completely interrupting the airflow in every oscillation. Similarly, in the saxophone, the reed tends to repeatedly beat against the mouthpiece. This occurs because the conical shape of those instruments creates comparatively high pressures where the reeds are located. In the clarinet, however, with its cylindrical shape, the reed does not necessarily beat against the mouthpiece for the relatively soft tones (Worman, 1971). This explains why softer tones of the clarinet have comparatively much stronger fundamentals than louder tones.

One major distinctive characteristic among mechanical reeds is their *hardness*, also referred to as heaviness or strength. Many players agree that harder reeds need higher blowing pressure and greater lip tension. Also, harder reeds are supposed to produce darker tones with less prominent high frequencies. In a study with oboe, bassoon, clarinet, and alto saxophone (Fuks, 1998a), two contrasting reeds were used in each, one rated as hard (heavy) and another as soft (light). In all reeds and instruments, louder tones required more airflow and higher blowing pressure. Among hard and soft reeds, the harder reeds always produced louder tones, needed more airflow, and involved higher blowing pressure.

Harmonicas and Similar Instruments

Free reeds correspond to type IV oscillations in Figure 20.1. The air tends to close the free reed until it reaches the vertical line and then starts to open it. The harmonica is the most typical instrument in this category. As mentioned earlier, its usual blown frequency is about the same as if it were plucked and left to vibrate alone.

As mentioned previously, the vocal tract acts as an additional air column. The effect of the vocal tract on the sound of a diatonic harmonica can be demonstrated just by moving the tongue back and forth inside the mouth while blowing, which produces clear changes in the relative intensity of the overtones.

Air Reeds: Flutes and Recorders

Air reeds contain a jet that is directed toward an air column, which generates airflow fluctuations inside the tube. In flutelike instruments, the airflow is guided through the player's lips toward a mouth hole. In recorderlike instruments, the flow is conducted through a *flue* channel that is directed toward a sharp edge called the labium.

Two different kinds of tone can be produced in such instruments: a *pipe tone* and an *edge tone*. A pipe tone results when the jet and the air column are acoustically coupled. All pipe tones coincide with the tube's modes, which roughly belong to a harmonic series and can be shifted by overblowing. However, when the jet is relatively distant from the resonant tube acoustical coupling to the pipe is poor and the jet interacts mainly with the labium. This produces edge tones with high frequencies that are proportional to the jet velocity. Therefore, they are not discrete as pipe tones but continuously varying. Edge tones may be important during the attack of a new tone. For example, if a flute player is starting a low C_4 (247 Hz), it takes a moment before the tone is actually initiated. During this period, the edge tones sound alone, contributing to the onset of the tone and to its sound quality. Edge tones are also generated when the pipe is damped (filled with cotton) and when the pipe is simply removed (Verge, 1995).

Air reeds are *flow-controlled* systems in which the pressure at both ends of the air column is close to the ambient pressure. For that reason, the air particles reach higher velocity close to these ends, so that they are directly affected by the airflow. Consequently, the player's vocal tract is usually weakly coupled to the flute and therefore has only a limited influence on the sound (Coltman, 1973; Fletcher & Rossing, 1998).

Boehm (1871/1964), the inventor of the modern flute, explains that the air stream strikes the sharp edge of the mouth hole and is broken (or divided) so that one part goes over or beyond the hole while the other part produces the tone. This is not a perfect description of what really happens, but it is still to be found in many textbooks. A flute can even produce a pipe tone when the edge of the mouth hole is dull. This can be demonstrated by applying a thin layer of wax or chewing gum to the edge of the mouth hole. If the wax or gum is placed in the right position, sound production might still be possible. In this case, however, the edge tones may be hampered, thus affecting the attack and overall sound quality.

Techniques

Using the Respiratory Muscles

The diaphragm is a large and thin muscle group located at the base of the lungs. It separates the thorax from the abdomen. Contrary to common belief, the diaphragm is solely an inspiratory agent that contracts when one breathes in by descending its central part, drawing the lungs downward, increasing the longitudinal dimension of the chest, and elevating the lower ribs (Roussos, 1995). These actions produce negative pressure around the lungs. During wind playing, blowing pressures range from almost 0 (e.g., *piano* low tones in the flute) to values that exceed 120 cm H_2O in *fortissimo* high-pitched trumpet tones (Bouhuys, 1968; Pawłowski & Zołtowski, 1987; Fletcher & Tornapolsky, 1999). If a player completely fills the lungs and closes the airways, without any expiratory effort, a pressure between 30 and 50 cm H_2O will be achieved. This is called relaxation pressure and is generated by the elasticity of the respiratory system.

Similarly, if the lungs are only partially filled—to 70% of their capacity, for example—the relaxation pressure will not exceed 20 cm H_2O (Agostoni & Mead, 1964).

Whenever pressures higher then the relaxation pressure are needed, the expiratory muscles (abdominal and internal intercostal muscles) will be used. However, if pressures lower than the relaxation values are necessary, the inspiratory muscles (external intercostal muscles and the diaphragm) will be used (Bouhuys, 1968). An example of the latter is playing the recorder at high lung volume, when the relaxation pressure is relatively higher than the required blowing pressure. This may also happen at some ranges of the flute and other instruments. Diaphragm activity in skilled flutists has been assessed in at least three studies (Gärtner, 1973; Cossette, 1993; Cossette, Sliwinski, & Macklem, 2000), and all of them indicate that some players make systematic use of the diaphragm, while others do not use it most of the time. These findings suggest that excessive emphasis has been given to the diaphragm in the description of wind performance.

Blowing Pressures

The pressure measured inside the player's mouth during performance is a major input parameter that has been documented in a number of studies. In reed woodwinds, blowing pressure is intimately related to airflow. Acoustical and aerodynamical considerations show that in reed woodwinds the oscillations initiate at a minimal pressure of approximately one-third of the pressure that completely closes the reed. In clarinets, for a fixed embouchure, the airflow and the sound power radiated by the instrument tend to decrease with increasing blowing pressure (Worman, 1971). If the player keeps a constant embouchure while increasing blowing pressure, the tone gets softer until eventually the reed simply closes. This apparent discrepancy explains why players must reduce the embouchure tightness when playing a *crescendo*.

Fuks and Sundberg (1999a) found that blowing pressures in the oboe, bassoon, clarinet, and alto saxophone are systematic in professional players. These authors measured the variation of blowing pressure with loudness and fundamental frequency at four dynamic levels: in isolated tones and musical arpeggios performed by two players of each instrument. Figure 20.2 displays part of the results, where each instrument presents characteristic curves, differing only slightly between players.

Vivona (1968) observed that nonprofessional trombone players use blowing pressures that increase with pitch and dynamic level. For tones $B\flat_2$, $B\flat_3$, and $B\flat_4$, the average pressures were 11, 16, and 39 cm H_2O in "soft volume level" and 24, 39, and 67 cm H_2O for "loud levels." This behavior is similar to reed woodwinds and should also apply to other brass instruments at different ranges.

A study of experienced trumpet players (Fletcher & Tornapolsky, 1999) showed that the minimal blowing pressure (i.e., threshold pressure) increased proportionally with the frequency of the tone played. In the first range, starting from threshold pressure, each doubling of blowing pressure caused the sound pres-

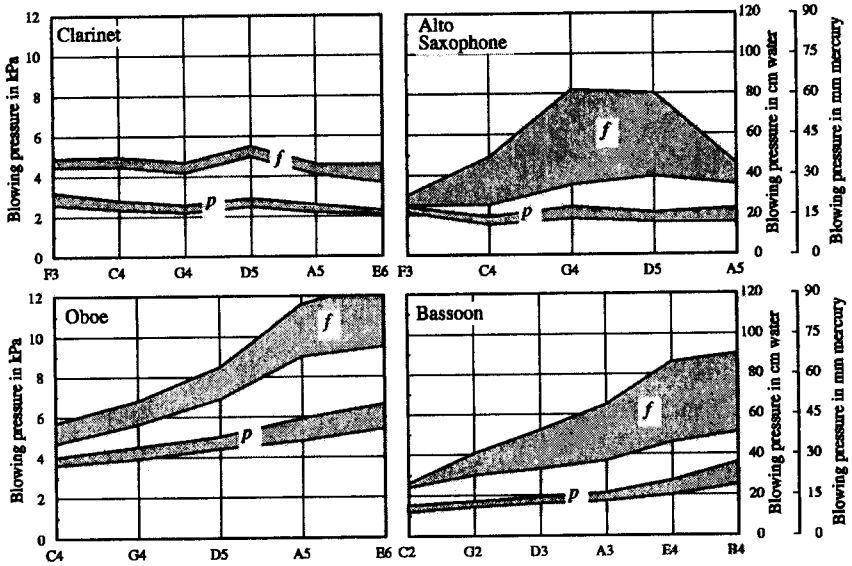

Figure 20.2. Blowing pressures in clarinet, alto saxophone, oboe, and bassoon tones, played at different dynamic levels by two professionals on each instrument. Pressure values are marked in kilopascal on the vertical axis on the left and in cm H_2O and mm of mercury on the right. In all instruments, blowing pressures increased from *piano* to *forte*. In the oboe and bassoon, the pressure systematically increased with fundamental frequency. In the clarinet, there was a slight decrease of pressure with fundamental frequency. In the saxophone, the pressure tended to increase with pitch in the first octave and followed the clarinet in the second octave. (From Fletcher & Rossing, 1998, after data from Fuks & Sundberg, 1999a. Copyright Springer-Verlag 1998, used by permission.)

sure level to increase by about fifteen decibels, whereas in a second and higher range, called the saturation region, doubling of blowing pressure increased the sound level by only three decibels. In some players, extreme pressures as high as 25 kPa (250 cm H_2O) were measured.

In reed woodwinds, there is also an important relationship between blowing pressures and intonation. As a rule, as the blowing pressure is increased, the fundamental frequency rises. This can be explained by an increase in the reed's natural frequency. Some clarinet players believe that playing tones louder makes the pitch go flat, because a player automatically reduces the embouchure tension to increase loudness (as discussed earlier) and thus decreases the reed's natural frequency (Bak & Doemler, 1987). In other words, the effect of lip relaxation on fundamental frequency is greater than the effect of pressure.

A rather linear relationship between blowing pressures and fundamental frequency has been found for flutes and recorders (Herman, 1959; Coltman, 1968; Fletcher & Rossing, 1998). This means that an octave leap by overblowing will require approximately twice the pressure.

In flutes, blowing pressure varies between 2 cm H_2O for C_4 and 20 cm H_2O for C_7, with little increase between soft and loud tones (Cossette et al., 2000). A crescendo is obtained by airflow velocity increase via the reduction of the oval lip opening, in both height and width. Interestingly, professional flutists tend to use the maximal blowing pressure that a given mode can take without overblowing. They do this to ensure steadiness and quality of tone. To control the dynamic level, a player needs to change the shape and dimension of the lip opening and also move the lips forward and backward. These maneuvers affect the embouchure, the jet length, and the proportion of mouth-hole covering (Fletcher & Rossing, 1998; Cossette et al., 2000).

Perception of Pressure

The results cited earlier suggest that the sensory functions in the abdominal, thoracic, and lung regions are important to effective wind instrument playing. Also, the ability of players to reach the required pressures quickly and systematically, to produce the target values with limited feedback from aural and other bodily senses, indicates that they have intuitively memorized the relevant parameters of their instrument. This assumption was confirmed by Smith et. al., (1990), who investigated the sensation of inspiratory volume and inspiratory pressure in wind instrument players. Their findings show that wind musicians have a considerably higher sensation for both inspiratory volume and pressure than nonmusical subjects. Fuks (1998b) applied a psychophysical production method to assess the sensation of blowing pressures in eight professional reed wind players. He found a proportional relationship between the measured blowing pressure and the estimated pressure level that expresses the players' perception. This approach showed that the subjects could judge quite accurately the multiplication of internal lung pressure, which seems to be a highly relevant sensory skill in wind performance. This particular ability may be trained by means of special exercises, for instance with the help of mechanical devices or a system controlled by a computer.

Lung Air Composition and Intonation

The temperature inside the instrument is related to intonation, so that an increase of 10°C (18°F) will raise the pitch by about a third of a semitone, or 31 cents (a semitone contains 100 cents).

Other factors may also affect intonation. Considerable variations in the concentration of carbon dioxide (CO_2) and oxygen (O_2) can be expected during playing. Fuks (1997) measured variations in the proportion of carbon dioxide in the air exhaled by players. This typically started at 2.5% and reached 8.5% at the end of long phrases. Meanwhile, the percentage of oxygen dropped from 21% to 12%.

The speed of sound depends on the gas properties and so proportionally affects the fundamental frequency of a wind instrument (excluding the free reeds). This can be demonstrated by having a wind player take a full breath of helium before playing: the tones may be transposed by an interval that exceeds nine semitones.

Under more realistic atmospheric conditions, the effect of the changes in gas composition, together with the change in air humidity, can produce a frequency decrease of up to 15 cents (15% of a semitone) during a long phrase. Trained players tend to compensate for this tendency for the pitch to fall by adjusting their embouchure and blowing pressure during their performance.

Vibrato

Vibrato consists of pulsations of pitch, usually accompanied by simultaneous pulsations of loudness and sound quality (Seashore, 1938/1967). Vibrato in winds can be produced by isolated or combined variations in blowing pressure or airflow, restrictions in the airways caused by the movement of the larynx and tongue, and movement and tension of the lips and jaw (affecting the reed vibrations). In the case of the trombone, mainly in jazz but also in some classical players, vibrato may be obtained by the variation of the instrument's length. On the trumpet, a common type of vibrato consists of a gentle shaking of the instrument, which affects the embouchure. This technique is called hand vibrato.

In general, vibrato seems to include blowing pressure oscillation, be it in flutes (Fletcher, 1975; Gärtner, 1973), reed woodwinds (Brown, 1973; Weait & Shea, 1977; Fuks, 1998a; Secan, 1997), or brass. Some studies have observed oscillations of the vocal folds during vibrato, suggesting that they play a role as a control mechanism. For intense vibrato tones produced on oboe, bassoon, and saxophone, wide pressure oscillations have been observed, on average 10 cm H_2O for the oboe and bassoon and reaching values of 20 cm H_2O in some cases (Fuks, 1998a). These wide undulations cannot be produced merely by the laryngeal mechanism, which otherwise would produce vocal sounds simultaneously, but require a great deal of expiratory force.

Vibrato is seldom taught, in spite of its ability to enhance the player's sonority and expressivity. Many educators consider that vibrato should be discovered by the student. Some others prescribe a series of respiratory maneuvers, most of which involve pulsation in the respiratory flow, thought to facilitate the acquisition of vibrato. A possible reason for this pedagogical attitude is that vibrato involves such a complex neuromuscular coordination that a simplified or step-by-step method for its production might produce an unsatisfactory, artificial effect.

Respiratory Movements

Much attention has been given in the teaching of wind playing to respiratory techniques. Instructions on how to breathe in and out during sound production are usually given by the teacher, often while he or she is examining the student's body posture.

A few physiological methods are available to assess respiratory movement during wind performance. The technique called body plethysmography involves confining the player in a closed box, with only the head outside. Any variation in the body volume is detected and registered by the equipment. In spite of the

rather clumsy setup, this technique has been successfully applied to both singing and trombone experiments (Bouhuys, 1968). Another technique employs magnets and sensors connected to the player's thorax. These accurately record the respiratory movements. Magnetometers have been used during the playing of sustained tones in the flute (Cossette, 1993; Cossette et al., 2000). The latter study with three professional flutists found that they used similar movements when inhaling but quite different patterns of expiratory movements during expiration and that these differences did not result in perceptible differences in sound quality.

Respiratory Inductive Plethysmography (*RIP*) is a technique that also employs electromagnetic technology. Elastic bands that contain electrical coils are wrapped around the chest and abdomen of the player. These bands permit indirect measurement of cross-sectional areas (Strömberg, 1996). The variations of chest and abdominal areas reflect the variations in lung volume and significant changes in body position. In a study with eight professional players of the bassoon, clarinet, oboe, and saxophone, all performing different musical and respiratory tasks, the musical phrases were initiated at 55 to 87% and terminated at between 14 and 52% of the players' vital capacity, depending on instrument, piece, and phrase length (Fuks & Sundberg, 1999b). Vital capacity is the maximal air volume that a person can exhale from full lungs. The players generally showed simultaneous and in many cases equally important contributions from rib cage and abdominal wall during playing. These findings often contradicted the players' own idea of how they used their respiratory apparatus. Some of the players even claimed that their rib cage was not moving at all during inhalations and playing, while the technical equipment demonstrated quite conclusively that their rib cage was responsible for more air displacement than the abdominal wall.

The studies mentioned earlier, undertaken with professional players of the flute and reed woodwinds, show that there is no single correct way to make expiratory movements in wind playing. We nevertheless recommend a relatively constant, systematic, and automatic expiratory pattern, as this allows the player to focus on other aspects of performance, such as blowing pressure and embouchure control.

Pedagogy and Winds

Wind playing imposes high demands in terms of learning and handling respiratory techniques, arm/hand/finger movement, tongue articulation, body posture, and embouchure control. Physiological aspects are therefore extremely important. However, it is also important for players to understand something of the acoustical behavior of the instrument they play, in terms of the function of the mechanisms and practical factors that produce the sound. In addition, psychological issues are involved, such as the aesthetic dimension of music and the emotional stress induced by intensive practice and public performance. Therefore, it is not uncommon that wind players inherit and develop an informal investigative attitude toward the physical, physiological, and psychological phenomena that they experience and try to apply these principles in teaching and

reasoning on the art. In some cases, these ideas are grounded in scientific knowledge but also include a combination of empirical conception and mental images. These images are supposed to represent an ensemble of complex tasks and sensations, which can hardly be expressed objectively (Kohut, 1985).

Physical, physiological, and psychophysical variables are continuously coordinated during performance and must be trained through systematic and repeated exercises, usually with the support of method books and under the supervision of an experienced teacher. The usual approach of most teaching methods is to combine the performance of musically significant studies with scales, arpeggios, and other drills that are used to hone the playing of complete works. Modern teaching tends to emphasize musical expression, even in studies that are relatively mechanical.

Many pedagogical methods briefly consider techniques for respiration and breathing for sound production and sometimes the underlying acoustical principles. In some cases, these methods review some basic anatomy of the respiratory apparatus, sometimes complemented by descriptions of the inspiratory and expiratory muscles, recommendations on posture during playing and on optimal inhalation strategy, and instructions on how to achieve "support" and "use the diaphragm." Some educators suggest that these terms may evoke an image of stressful playing that has led to a number of breathing and embouchure problems, even with experienced performers (Fadle & Kohut, 1999; Kohut, 1985).

Arnold Jacobs (1915–1998), a brilliant tuba player and teacher, spent his entire professional life studying respiratory and psychological aspects of winds. Jacobs was probably the most influential wind instrument teacher in the United States and other countries, particularly among brass players (Stewart, 1987; Frederiksen, 1996; Kohut, 1985). In his lessons and workshops, Jacobs used an ensemble of devices, developed for respiratory clinical purposes, to provide visual feedback to his pupils that regarded pulmonary pressure, airflow, and lung volume. Interestingly, Jacobs used a terminology that was more pedagogically oriented than based on physical facts. For instance, he emphasized *flow* as a key word for playing control, as opposed to *pressure*, which he deemed as a somewhat negative term. Because of their psychological effect, different terms tend to trigger different behaviors in players. There is another reason that Jacobs used the term *flow*. In brass instruments, a wide range of combinations of mouth pressure and lip resistance produce the same output level (Weast, 1965). If the player is able to use configurations that require lower pressures, such as lower embouchure resistance and/or stiffness, then the airflow should be maximized and the playing effort reduced (Nederveen, 1969/1998). These general principles are likely to apply also to other winds.

Final Remarks

Knowledge acquired through scientific research cannot replace, and should not challenge, the rich imagery that inspires and guides the artist. But it may help to question, consolidate, and fill the gaps left by individual observation, thus providing an objective background for education in wind playing. Without doubt,

some research results conflict with common practice and concepts among the profession, which are often based on obsolete hypotheses that have gained credibility among musicians over many generations.

However, because measurement methods and experimental procedures are still coarser than the musical subtleties involved in performance, it is important for researchers to understand the artists' reality and to take advantage of their skills and long-term experience when designing musically relevant investigations. Collaboration among areas such as physiology, acoustics, psychology, engineering, and musicology will help to enhance knowledge of music performance in winds. As a first step, there is a need to develop some consensus concerning the meaning of technical terms, in ways that promote a better understanding and effectiveness of their application to music teaching and learning.

Rehearsing and Conducting

HARRY E. PRICE & JAMES L. BYO

Conducting and rehearsal behaviors play a role in establishing an appropriate and effective rehearsal atmosphere. Situations in which conductors provide predominantly positive feedback result in better attitudes, attention, and performance. Fast paced rehearsals are usually the most effective, and comprise frequent and generally brief episodes of teacher talk and ensemble performance. Enthusiastic or dynamic rehearsing features stark contrasts of behavior at optimal times—loud and soft talk, expressive and neutral conducting, group and individual eye contact. Rehearsals should be structured to include processes of diagnosis, prescription, presentation, monitoring, and feedback, with brisk paced and clear directions. Essentially, a conductor should focus on making verbalizations efficient and keeping them to a minimum, while enhancing nonverbal behaviors to include large amounts of eye contact and clear and unambiguous conducting gestures.

"From the moment a conductor steps on the podium a special world is in the process of being constructed" (Faulkner, 1973, p. 149). By definition, conductors are leaders. Leadership requires competence, credibility, and charisma, and these qualities can influence musicians' attitudes and performances (Parasuraman & Nachman, 1987).

The current role of the conductor dates back to the late eighteenth century. Not until the mid-twentieth century, though, did a traditional focus on gesture or baton technique evolve to include issues of rehearsal technique. The application of scientific inquiry to rehearsing and conducting is a recent phenomenon, and the psychology of large ensemble leadership, even in a popular sense, remains insubstantially addressed.

One might consider conducting and rehearsing as distinctly separate acts, conducting being a nonverbal physical act, and rehearsing being conductor-led

ensemble preparation (largely verbalizations) for musical performance. It is our view that conducting and rehearsing are inextricably linked. When done well, they are complementary, even indistinguishable. In the school music environment, where the focus is on the nature of the rehearsal process with the concert serving to set a context (Reimer, 2000), rehearsing and teaching are analogous. One might argue that everything involved in rehearsing and conducting can be characterized via a teaching paradigm, even in a professional ensemble environment.

The Rehearsal

Rehearsal Atmosphere

Even actions that occur before the first words are uttered or downbeat given influence ensemble members' perceptions of a conductor's abilities. A hesitant approach to the podium, fumbling of materials, low levels of eye contact, and poor posture and hand position have a negative effect on perception of conductor competence, while the converse of these behaviors has a positive effect (Fredrickson, Johnson, & Robinson, 1998).

Conductor behaviors play a role in establishing authority. The likelihood that authority figures are persuasive is in part dependent on the extent to which they are viewed as decisive. Conductors who are inspiring and persuasive can be said to be exercising a form of domination over the performers (Faulkner, 1973). This domination, however, does not preclude the necessity of collaboration between conductor and ensemble. The rehearsal atmosphere must be such that the combination of conductor persuasiveness and collaboration results in an ensemble that is responsive and receptive to the conductor's verbal and nonverbal behaviors. Indeed, performances appear to benefit when ensemble members feel a part of the learning process rather than functioning as passive recipients of information (Hamann et al., 1990).

Feedback

Another aspect of conductor behavior that is relevant to rehearsal atmosphere is conductor feedback. Feedback is necessary in order to achieve the ultimate performance envisioned. Situations in which conductors provide predominantly positive feedback result in better attitudes, attention, and performance than ones in which conductors provide instruction without feedback (see Price, 1983). Indeed, positive rehearsal environments tend to result in better ensemble attentiveness and attitudes than do negative ones (e.g., Madsen & Yarbrough, 1985; Price, 1992). In contrast, there are accomplished conductors and teachers in instrumental music who use more negative than positive feedback, which results in successful performances and positive student attitudes (Cavitt, 1998; Duke & Henninger, 1998). It is important to consider that negative feedback delivered constructively is likely to function quite differently from that delivered angrily. Negative feedback is necessary and can function well if the combi-

nation of instruction and feedback, both negative *and* positive, leads to accomplishment of musical goals. If, however, the rehearsal is characterized by inordinate amounts of ensemble failures, the potential for negative feedback to be detrimental to attitude and attentiveness is increased.

Pacing

In general education, fast pacing of instruction has been linked to effective teaching, though it is recognized that in seeking an optimal pace one must consider the nature and complexity of the subject matter being taught as well as the sophistication of those being taught (e.g., Brophy & Good, 1986). Slow pacing is not necessarily an indication of ineffective teaching.

There is no unequivocal definition of rehearsal pacing nor of an optimal pace of activity. However, frequency and duration of ensemble performance episodes, conductor talk, lag time between cutoff and conductor talk, and conductor rate of speech are thought to be components of pacing. Experienced observers have been asked to view videotaped rehearsal examples and rate conductor pacing on a scale from very slow to very fast, and the responses correlated fast pace to fast rate of conductor speech (Single, 1990). This association is reinforced by findings in rehearsal settings, including a professional orchestra with Bruno Walter conducting that found most teacher/conductor verbal behaviors occurred in short bursts (Yarbrough, 1988).

In an attempt to describe pacing empirically, Duke, Prickett, and Jellison (1998) selected fast- and slow-paced videotaped examples of rehearsal conducting and music teaching, based on observers' personal perceptions of pacing, not on one prescribed definition. Fast and slow paces were then described according to the frequency and duration of conductor versus ensemble activities. They found that fast paced rehearsals comprised frequent and generally brief episodes of teacher talk and student performance.

In one of the few longitudinal studies of the rehearsal process, pacing was defined as change of focus of activity between director and ensemble (Yarbrough, Dunn, & Baird, 1996). An examination of rehearsals with the lowest and highest performance ratings found that the lowest performance rated rehearsal, which was the first rehearsal of a work, had a considerably slower pace than the higher rated and later rehearsal. These findings suggest that pacing should be examined as a change in activity and a function of the relative familiarity and difficulty of the literature being rehearsed.

A conductor might endeavor to quicken the rehearsal pace by speaking more succinctly, thus reducing the duration of talk episodes. While less-accomplished conductors stop and restart ensembles frequently, as is suggested by the preceding description of fast pace, they tend to do so without providing instruction (Goolsby, 1999). In addition, expert band conductors vary the rate of alternation between conductor talk and student performance episodes according to the issue being addressed (Cavitt, 1998). Thus advising a novice conductor to quicken the pace by working faster fails to acknowledge the fact that some performance errors and rehearsal conditions simply require more time to correct than others do.

Performance Error Detection

Related to conductor feedback and rehearsal pacing is the conductor's response to performance errors. How best to prepare prospective conductors to cope effectively with a "great confusion of sound" (Bruno Walter in Chesterman, 1976, p. 22) in rehearsal has been the object of study in performance error detection. There is no definitive hierarchy, by difficulty, across the different types of errors (pitch, rhythm, articulation, etc.) that may occur in rehearsals (Byo, 1997). A performance error is more or less audible depending on its type, its timbre, the texture and tempo of the music, whether the listener is conducting, and whether the listener opts for a focused or unfocused approach to the listening task (Byo & Sheldon, 2000). It may be advantageous for conductors to be aware of musicians' performance tendencies, such as rushing rather than dragging tempi and playing sharp rather than flat.

Conductors may improve their abilities to detect performance errors by practicing error detection (Byo, 1997). It is tempting to assume that tasks such as sight singing and harmonic dictation enhance skill in error detection. Research, however, shows that this may not be the case (Brand & Burnsed, 1981). It is likely that skill in error detection is most affected by practicing it directly. There seems to be pedagogical potential in structuring personal error detection practice experiences to begin with one line of music only. If one line of music is approached as the musically rich, comprehensive entity it can be (involving issues of tempo, pitch, rhythm, articulation, intonation, dynamics, and interpretation), it can present a formidable challenge to the intellect and ear of the conductor. The ability to detect errors effectively, in any context, begins with the ability to hear and evaluate one line of music completely and precisely. Further, there are indications that error detection skill increases when conductors go to rehearsal with a well-developed internal sound image of the score (Byo & Sheldon, 2000). This sound-based knowledge of the score can reduce or override aural distractions in rehearsal. Conductors should study scores in such a way that they are able to ask to what extent they hear from their ensemble what they expect to hear. Then, when the ensemble's performance fails to match their internalized images of the ideal sound, they will be able to begin the process of error detection.

Conductor Demeanor

In examining the effects of conductor enthusiasm on ensemble performance, attentiveness, and attitude, one might expect an enthusiastic conductor to be more interesting, if not more effective, than a dull one. However, the musicians in Yarbrough's (1975) study, in a statistical sense, did not perform better for, or pay more attention to, the enthusiastic conductor. This result caused the investigator to look more deeply at precisely what enthusiastic conductors do. A novice conductor who is not naturally dynamic might have the same concern. Yarbrough hypothesized that the enthusiastic rehearsal conductor is one who makes high levels of eye contact with the ensemble and varies it from group to individual, frequently approaches the ensemble by moving or leaning forward, manipulates

speech across a wide range of volumes, and gestures expressively with hands/arms and face (i.e., using a variety of movements and contrasts of facial expression).

Notice a recurring theme—that is, the behaviors of an enthusiastic conductor are not static; rather, they vary. Results of a detailed analysis that used an observation form designed to isolate these behaviors made apparent what was not readily seen through more casual observation—that *variation* in conductor behavior is perhaps more salient than doing *more* of a behavior (e.g., talking louder without contrast or conducting expressively without contrast). It appears that enthusiastic conducting (dynamic conducting, if you prefer) might best be described in terms of the conductor's ability to exhibit stark contrasts of behavior at optimal times—loud and soft talk, expressive and neutral conducting, group and individual eye contact (Byo, 1990). Much as music without appropriate variety and contrast is typically uninteresting, so is a rehearsal. By analyzing one's own conducting via videotape in combination with a conductor observation form, the aspiring conductor can apply a tested research procedure in order to see more clearly the behaviors related to enthusiastic rehearsing and conducting (Madsen & Yarbrough, 1985).

Of course, effective rehearsing and conducting extend beyond the mere delivery of information to include the accuracy of information conveyed by the conductor, both verbally and nonverbally, and the quality of the interaction between conductor and ensemble (Standley & Madsen, 1987). Conductors' abilities to create and sustain an intense rehearsal atmosphere hinge on their abilities to handle the subject matters of music, rehearsal, teaching, and group psychology accurately, appropriately, and in an engaging manner. This intensity can be reduced or lost by a conductor's mistake, slow or dull delivery, or casual demeanor (Madsen, 1990). For a conductor who lacks rehearsal intensity (or whose passion is not apparent to ensemble members), observation from analysis combined with videotape review can offer specific diagnosis of the problem and suggest corrective action (e.g., Cassidy, 1990; Kaiser, 1998).

Rehearsal Structure

Although originally it referred to the interaction of child with environment, Vygotsky's *Zone of Proximal Development* (ZPD) construct is pertinent to structuring rehearsals. ZPD, in the context of the rehearsal, can be thought of as the difference between what an ensemble can achieve without and with the direction of a conductor. It is the distance between what problems individuals can fix independently and the possible solutions that can be achieved in collaboration with peers or under the guidance of an authority (Vygotsky, 1978). As ensemble members become more sophisticated, they are increasingly independent of the conductor in their abilities to make appropriate decisions about the music and its performance. A group of students in a secondary school would require more basic direction about phrasing, articulation, and intonation tendencies than would a professional ensemble. It may be said that the conductor's task is to move the ZPD forward toward independence. Here the metaphor of scaffolding may be useful. It refers to establishing a situation in which musicians can achieve at

a higher level when provided external support. For example, a conductor might structure rehearsals and organize appropriate tasks so that an ensemble is better able to interpret and perform the music than if it were unaided. Studio teachers employ scaffolding strategies to help student progress across the zone by assisting students in moving from what they can accomplish dependently to reaching their potential to function independently (Kennell, 1989). With increased sophistication (independence), ensembles approach what may be comparable to self-regulation in individuals; thus less scaffolding is necessary to achieve a performance goal.

Rehearsing music is typically a process of successive approximations or small steps toward performance objectives. A rehearsal consists of any number of units or rehearsal frames in which the conductor identifies a problem in need of rehearsing, extracts it from the music, divides the problem into parts, rehearses the parts (by providing information, giving directions, asking questions, modeling, modifying a part for rehearsal purposes, providing feedback), and finishes with the problem being performed in context before the conductor moves on to other material (Duke, 1999/2000). "Accurate finger technique in the woodwind ostinato leading to letter D" might be considered a performance objective. A rehearsal frame would comprise all conductor and ensemble interactions as they relate to the development of accurate finger technique. A conductor's ability to clearly articulate and order instructional steps such that there is fairly constant improvement in the performance of this passage would likely be a major factor in an ensemble's perception of success—and perception of success by the ensemble is no trivial matter.

By viewing a videotaped rehearsal in these small units rather than as one complex whole, developing conductors are likely to see more clearly and with fewer distractions the elements involved in their decision-making processes. Knowledge of one's own sequencing of rehearsal instruction is possible through the use of formal observation tools designed to illuminate forward, failed, and repeated approximations of objectives (Duke & Madsen, 1991). Without structured videotape review of the rehearsal, it is difficult to obtain a precise evaluation of the conductor's ability to organize primarily in a forward or positive direction.

Basic to effective teaching in general education is a three-step sequence of instruction that involves (1) teacher task presentation, (2) student response, and (3) teacher feedback (Becker, Englemann, & Thomas, 1971). In music education, a parallel instructional model (conductor presentation of a task, ensemble interaction with the task, and conductor feedback) has been applied to and studied across many levels of ensemble sophistication (e.g., Arnold, 1995; Price, 1983; Tipton, 1996). Though many interaction patterns can be found in any rehearsal, the preferred complete sequential pattern is one that begins with the conductor providing a musical task for the performers, followed by the ensemble attempting to perform the task, and ending with descriptive, positive feedback from the conductor. In fact, experienced band conductors tend to use complete patterns more so than do less-experienced conductors (Goolsby, 1997). This three-step model holds promise for providing conductors with a scaffold on which to develop re-

hearsal structure. Again, videotape combined with relevant observation techniques helps one to see rehearsals in the context of these smaller units of instruction.

Rehearsing should be a process of diagnosis, prescription, presentation, monitoring, and feedback, with brisk-paced and clear directions. It can be characterized by frequent use of nonverbal communication, prioritization of rehearsal materials, task-related and contingent feedback, clear statement of rehearsal objectives, encouragement of ensemble-generated ideas, and, depending on the level of the ensemble, the teaching of musical in addition to performance skills (McCoy, 1985). Model secondary school choral conductors exhibit thorough preparation and maintain an appropriate atmosphere. Nonverbal communication tends to be positive. There is little sarcasm and a businesslike image is projected. Ensemble members talk little and disciplinary action is generally unnecessary (Fiocca, 1989).

Verbal Communication

Content

Verbal communication accounts for approximately 40 to 60% of ensemble rehearsal time (e.g., Single, 1990; Watkins, 1996; Yarbrough, 1988; Yarbrough & Price, 1989). While this is a large proportion of the rehearsal, it may be understandable, given some research evidence that indicates that ensemble members respond more accurately to verbal instruction than to conducting gestures (Skadsem, 1996, 1997).

In instrumental ensembles, conductors tend to focus on rhythm and tempo, although the sophistication of the conductor appears to have an impact on rehearsal emphasis. Experts tend to work more with overall ensemble sound, including more demonstrations, instruction on intonation, and guided listening, than do inexperienced conductors. Experienced conductors also address balance, style, and tone more than do novices (Goolsby, 1997, 1999).

Regardless of the content, less-experienced conductors tend to spend more time talking in rehearsals. They stop and restart ensembles more frequently without providing instruction and are less efficient, thus taking longer to prepare a piece for performance (Goolsby, 1999). Therefore, when conductors stop ensembles, they should make concise and substantive suggestions.

Experienced teachers not only talk less, but they provide more breaks between musical selections, spend more than half the rehearsal time performing, use more nonverbal modeling, and use less time getting started. They appear to be more proactive in that they use similar amounts of rehearsal time across pieces rehearsed, while less experienced conductors tend to spend more time on the first piece rehearsed, indicating that they are in a reactive mode. Evidently, inexperienced conductors get distracted from their rehearsal plans when responding to ensemble performance (Goolsby, 1996).

There is an evolution of focus over time as performance approaches, from fundamental issues of accuracy and precision to more general concerns of nu-

ance and interpretation. As the quality of performance increases or as a concert approaches, conductors tend to talk less and focus more on ensemble performing in rehearsals (Davis, 1998).

Aural Modeling

Aural modeling alone and in combination with language is among the most frequent verbal modes in rehearsals. It generally consists of a conductor providing a demonstration—vocal, acoustical or MIDI instrument, recording—followed by ensemble kinesthetic, vocal, or instrumental response. Models can be effective in demonstrating both appropriate and inappropriate performances and can be used to minimize verbalizations. Conductors pervasively use sung or quasi-sung sounds or other means of demonstration (e.g., clapping, tapping), both imitating salient features of what was previously performed and presenting examples of what they would like to hear (Weeks, 1996).

Ensemble directors' abilities to model have a strong relationship to the quality of instrumental music student performance, and strong modelers tend to spend more rehearsal time modeling than do less skillful modelers (Sang, 1987). Modeling is critical to a rehearsal, and experienced ensemble directors use more nonverbal instruction (e.g., modeling and demonstration) and talk less than do novices (Goolsby, 1996).

Conceptual Teaching

While considerable proportions of rehearsals are spent in verbal activity and modeling, principally on the part of the conductor, little of it elicits higher order or conceptual thinking on the part of the performers. General music and ensemble classes generally involve students in lower cognitive processes, emphasizing mechanics of performance almost to the exclusion of the application and accumulation of musical knowledge and the abilities to think about music (Goodlad, 1983). Conductors' efforts appear to be weighted toward providing guidance on how to make corrections or presenting exact solutions, by saying things such as "you need more air" or "the percussion need to play softer." This limits opportunities for self-correction on the part of the ensemble through slight hints or scaffolding (Weeks, 1996). In these situations, ensemble members function much like simple machinery, rendering only specific responses to specific instructions about a specific point in a specific piece of music.

Conversely, conceptual rehearsing reinforces or introduces concepts in ways that encourage the transfer of concepts from one passage to another passage or work. Statements can be as simple as "whenever you see a terraced dynamic, take care not to anticipate it with a slight crescendo or decrescendo" or as sophisticated as "this section is the recapitulation; what does that mean?" In secondary school choral settings, approximately 1% of rehearsal time is spent attempting to evoke higher order thinking, such as analysis, synthesis, or evaluation (e.g., Watkins, 1996). This same automatonlike approach to rehearsing has also been found in secondary school instrumental rehearsals, where less than 3% of

rehearsal time is spent in attempts to improve the grasp of musical concepts (Blocher, Greenwood, & Shellahamer, 1997). The literature, the bulk of which comes from the United States, is quite clear with regard to learning: unless one teaches for the transfer of ideas, there is no transfer.

Even though it appears that there is little encouragement of higher order thinking and the development of concepts in rehearsals, it would seem that planning and employing strategies to promote these throughout the rehearsal would be most effective in the long-term growth of performers and ensembles. Without these attributes, a conductor is condemned to reteach an idea every time a similar passage or concept is encountered, as opposed to musicians making connections cognitively and transferring knowledge and skills to new situations. More sophisticated performers have likely attained higher order music skills through inductive reasoning as a result of synthesis of many experiences; thus conductors of highly skilled ensembles are better able to attend to the performance nuances that help make music rapturous.

Nonverbal Issues

Facial Expression

The research in interpersonal communication indicates that the face is the primary nonverbal means of conveying six emotions—happiness, sadness, anger, fear, surprise, and disgust (Bull, 1983; Ekman & Friesen, 1975; Izard, 1997). Though it is tempting to assume that a conductor must somehow look like the music facially in order to achieve maximum effect, there is not a research base in music to support this notion. Research that isolates the conductor's face has only focused on approving, disapproving, and neutral expressions (e.g., Byo & Austin, 1994; Madsen & Yarbrough, 1985; Price & Winter, 1991). The face has been viewed as a means for conductors to respond approvingly (e.g., smile or nod) to appropriate ensemble performance or disapprovingly (e.g., furrowed brow) to inappropriate performance.

Seldom has the face been examined as a means to convey musical information (Berz, 1983; Mayne, 1993). In fact, one conductor-training technique involves mask work (covering the face) to prompt the conductor to focus on the expressive potential of the trunk and shoulders (Tait, 1985). This focus away from the face and toward the communicative power of the torso and breath in conductor training is a concept borrowed from theater and mime (Oertle, 1999). It appears that novice conductors should first develop a varied repertoire of nonverbal skills in gesture and body (see Conductor demeanor earlier). The area of greatest concern facially is eye contact.

Eye contact

The communicative advantages of eye contact are well documented in several research literatures (Burgoon et al. 1984; Fredrickson, 1992). Greater conductor

eye contact with an ensemble is associated with increased attentiveness by ensemble members (Yarbrough & Price, 1981). There is evidence, however, that directors of school ensembles look at the score more than the ensemble (Fredrickson, 1992; Sherrill, 1986).

Given the potential for conductor eye contact to interact with other nonverbal behaviors to result in an intensified message (e.g., Burgoon et al., 1984; Price & Winter, 1991), it is clear that conductors should look at the ensemble more often than not. One of the variables that separates accomplished and novice conductors is the tendency of accomplished conductors to combine expressive nonverbal behaviors (eyes, arm/hands, body movement) for optimal effect (Byo & Austin, 1994). By analyzing their own conducting via videotape and in combination with research-based observation techniques, conductors can formulate a clear picture of their eye contact tendencies and, if change is desired, create a plan of action (Byo & Austin, 1994; Madsen & Yarbrough, 1985).

While there is little research that examines ensemble member eye contact with the conductor, it is likely that the extent to which ensemble members are aware of their rehearsal and performance surroundings bears heavily on whether they are in a position to receive the full impact of nonverbal messages. Byo and Lethco (2001) examined musical events and conductor-related conditions during which student musicians tend to look at the conductor. High school band musicians looked up with much greater frequency during slow music than fast music where the demands of the music superseded effects of eye contact and expressive gesture. School-based conductors might promote watching the conductor by teaching ensemble members to look up for specific reasons at predetermined places in the music, for example, at entrances, releases, rehearsal numbers or letters, changes in meter, tempo, and dynamics, and the beginning and end of the piece or movement.

Conductors should be aware of two research findings that bear on issues of eye contact by ensemble members: (1) eye contact by ensemble members increases with musical sophistication, a result that is consistent with research findings in the recognition of specific conducting gestures (Mayne, 1993; Sousa, 1988), and (2) singers performed a dynamic change most successfully following concise verbal instructions from the conductor, despite having predicted that they would respond best by watching the conductor (Skadsem, 1997).

Gesture

Conductors must possess a large repertoire of nonverbal behaviors from which to choose in order to impart expressivity within the context of the structure and style of any composition. They must interpret and shape the elements that contribute to musical expression. Expressiveness/musicianship or musical effect is one of the primary factors in assessing performances (Bergee, 1995; Burnsed & King, 1987). The often-quoted statement by Seashore "beauty in music largely lies in the artistic deviation from the exact or rigid" (1938/1967, p. 249) would relate to both a conductor's interpretation and ability to demonstrate these "deviations." Otherwise, a metronome at varying tempi would serve as well as a person to lead an ensemble.

Employment of movement techniques by Rudolf von Laban, among the most influential figures in dance and movement education in the twentieth century, can result in superior performance than that achieved by typical verbal ensemble instruction (Holt, 1992). Laban characterized effort as having eight basic motions—thrusting, slashing, floating, gliding, wringing, pressing, flicking, and dabbing (Preston-Dunlop, 1980). Each of these and their permutations have analogues in conducting gestures and music performance. A conductor who has a physical command and understanding of these could draw upon them as needed; for instance, the appropriate employment of flicking, pressing, and thrusting may yield the exact representation desired of a specific *marcato* style within a passage. Given a lack of body movement coverage in conducting textbooks and traditional conducting courses, the application of principles of Laban to the pedagogy of conducting has been advocated. Laban Movement Analysis (Laban, 1975) is a framework within which conducting movement has been viewed and analyzed (Benge, 1996) and through which expressive gestures may be enhanced (Miller, 1988). A better understanding of movements and their possible interpretive meanings might well strengthen the communication between conductors and ensembles.

Whether individuals interpret other nonverbal behaviors consistently has been the focus of research on conducting emblems. Sousa (1988), adopting language from Ekman and Friesen (1969), applied the term *emblems* to conducting gestures whose meanings were interpreted reliably by musicians (e.g., changed conducting pattern size to indicate *piano*, *subito forte*, or *crescendo*; lowering of the left hand for *decrescendo*; or reboundless pattern for *staccato*). Among secondary school and college musicians, the ability to identify emblems on a paper-and-pencil test increases with years of instrumental music experience. With inexperienced musicians, even brief instruction in the recognition of emblems that reflect expressive musical characteristics such as *crescendo*, *staccato*, *legato*, and *tenuto* results in increased ability to derive meaning from gestures and perform accurately in response to them (Cofer, 1998; Kelly, 1997).

In studies that have examined the effects of conducting gestures on performance quality of high school musicians, investigators have found expressive gestures to elicit better performance quality than unexpressive ones (Grechesky, 1985; Laib, 1993; Sidoti, 1990). In research that involved young band students, however, expressive gestures did not result in better performance quality (Price & Winter, 1991). These results taken together are consistent with the positive relationship between performance experience and emblem recognition. It may be expeditious to specifically teach emblems of conducting to less-experienced musicians so they can better interpret them.

While conducting, a form of nonverbal communication, is a complex task, it can be learned outside the traditional apprenticeship and course modes. Basic conducting skills have been enhanced in research that focused on systematic self-observation of behavior—precise definitions of conducting skills, opportunities to practice, reinforcement through videotape feedback, and self-analysis (e.g., Madsen & Yarbrough, 1985; Price, 1983).

Conclusion

Everything conductors and ensemble members do in rehearsals should be of consequence, from the moment when everyone is assembled before the first passage is rehearsed to the concert performance. Conductors therefore need to establish their authority and expertise immediately and willfully decide on the rehearsal atmosphere to be created.

A conductor must engage the ensemble in such a way that an intense rehearsal atmosphere is established and then maintained. This will not happen if conductors fail to control the nature of their interactions with ensembles, lack overt enthusiasm for the task at hand, provide inaccurate information either verbally or nonverbally, or allow the pace of the rehearsal to be slow. It is the conductor's responsibility to bridge the gap between what the ensemble can do independently and what it could do with carefully crafted rehearsals under the guidance of an expert who uses well-ordered instruction. The rehearsal must be proactive, structuring scaffolding that will allow for successive approximations in which every effort will likely result in progress.

Rehearsal models must be accurate and need to address all learning styles and modalities by providing visual, aural, and kinesthetic experiences. Providing information in a multimodal (sensory) fashion is most effective, for example, conducting (visual) while providing a singing (auditory) model or having ensemble members move (kinesthetic) while singing their parts.

The conductor must have an arsenal of verbal and nonverbal skills. Instruction is most effective when it is substantive and delivered concisely, clearly, and without sarcasm. It should help move ensemble members beyond their current knowledge and conceptions to higher order musical thinking. Conductors need to maintain and elicit eye contact and have command of a large repertoire of facial expressions, conducting emblems and movements, and other means of communicating musical expression and precision.

In short, capable conductors must be remarkably prepared and have complete knowledge of the score and how to realize it. They need to know what they should be hearing, how it differs from the current rehearsal performance, and how to get to the level needed for concert performance. All aspects of the rehearsal should be planned. Components such as teaching conceptually and giving feedback are not done in isolation; the rehearsal should be imbued with these and other activities continuously.

Not only do aspects of conducting and rehearsing develop through experience and practice, but rehearsals also need to be audio- and videotaped and reviewed by conductors. There is a consistent theme in the literature that regards the benefits of systematic self-observation and feedback in enhancing podium skills. This helps us to see ourselves objectively or as others do.

It is an extremist perspective to suggest that either conducting or verbalization is unnecessary in an ensemble setting. There are those who hold the view that if a conductor could manage to present gestures that are perfect models, lacking in any ambiguity, there would be no need for talk. Conversely, there are

those who suggest that most of the productive work in a rehearsal is done when the conductor verbally and directly tells performers what is wanted. It is true that nonverbal and verbal forms of communication must be done exceptionally well; however, both are necessary.

Visual communication (nonverbal, inaudible, symbolic, or demonstrative behavior) alone is significantly less effective in improving ensemble performance than visual communication in combination with verbalization (oral use of meaningful words to convey information) and modeling (demonstration of behaviors). The combination of verbal and modeling communication is also more effective than visual communication alone. However, the combination of verbal, modeling, and visual communication is the most effective approach (Francisco, 1994). All must be done effectively, skillfully, and efficiently to have optimal rehearsals for excellent performances.

Contributors

RITA AIELLO is a visiting scholar in the psychology department of New York University. She is the editor of *Musical Perceptions* (Oxford University Press, 1994). Her research addresses the mental representation of music, the effect of musical training on the perception and cognition of music, and parallels between music and language. She has taught courses on the perception of music at the Juilliard School, the Manhattan School of Music, New York University, and Queens College of the City University of New York and has been a visiting honorary adjunct professor at Teachers College, Columbia University. She was trained as a classical pianist and has extensive teaching experience.

ECKART ALTENMÜLLER is professor at the Hannover University of Music and Drama and director of its Institute of Music Physiology and Performing Arts Medicine. He graduated in medicine (1983) and music (1985) and trained as a neurologist and neurophysiologist (Habilitation 1992). Since 1985 he has been researching brain processing of music and motor learning in musicians. He has published 46 scientific articles in peer-reviewed journals and 60 book contributions. Major awards include the Young Scientists Award of the German Physiological Society (1984), the Kornmüller-Award of the German Society for Clinical Electrophysiology (1992), and the Richard Lederman Lecture, Aspen (1999).

NANCY H. BARRY holds a Ph.D. in music education and certificates in computers in music and electronic music from Florida State University. She is currently professor and coordinator of graduate music education at the School of Music of the University of Oklahoma. She serves on the editoral boards of *Update: Applications of Research in Musical Education, Professional Educator,* and *Journal of Technology in Music Learning.* She has published numerous articles in journals such as *Psychology of Music, Update, Arts and Learning,* and *Journal of Music Teacher Education.* She has given over 40 presentations at conferences and seminars in the United States, Puerto Rico, Brazil, Germany, and Australia.

She is also an experienced studio teacher and frequent adjudicator of woodwinds and piano.

GIOVANNI UMBERTO BATTEL is director of the Conservatory of Music "B. Marcello" in Venice. He holds a degree and a postgraduate diploma from the Tartini Conservatory in Trieste and the Accademia di Santa Cecilia in Rome and a degree in musicology from Bologna University. His published articles address new methodologies of performance analysis. As a pianist, he has won six Italian national competitions and prizes at seven international competitions, including first prizes in Stresa and Enna and other prizes at the Viotti and Busoni competitions. He has given concerts throughout Europe and the United States, playing with chamber and symphony orchestras conducted by De Bernant, Gavazzeni, and Steinberg. Battel has also recorded for Italian radio and television (RAI).

ALICE G. BRANDFONBRENER received her undergraduate education at Wellesley College and her doctor of medicine from Columbia University. She is assistant professor of medicine at the Northwestern University Medical School and adjunct professor of performance studies at the Northwestern University School of Music. She directs the Medical Program for Performing Artists in Chicago and is editor of the journal *Medical Problems of Performing Artists*. She founded the Aspen symposium on medical problems of musicians and dancers in 1983 and was first president of the Performing Arts Medicine Association. A frequent lecturer to medical and musical audiences, she has written many articles for music education as well as medical journals on musicians' medical problems.

JAMES L BYO is professor of music education at Louisiana State University and editor of *Update: Applications of Research in Music Education* (published by MENC: National Association for Music Education). In 1997, he completed a six-year term as chair of the International Wind Band Education Committee of the World Association for Symphonic Bands and Ensembles. In this capacity, he presented research and presided over sessions in England, Spain, Japan, and Austria. His articles on issues relevant to music teacher/conductor effectiveness appear in all major U.S. research journals in music education. He is the recipient of two distinguished professor awards at LSU.

JORGE SALGADO CORREIA is lecturer at the University of Aveiro and a professional flute soloist. He graduated in philosophy from the University of Porto and studied flute performance at Porto Conservatoire and at the University of Amsterdam. His areas of research include the investigation of teaching and learning of performance skills from historical, analytical, psychological, sociological, and philosophical perspectives and reflexivity in musical performance: defining and developing practical music making as research. His specialist performance area is contemporary music, and he has given many world premieres and has had works specially commissioned for him. His publications include a recent article in *Psychology of Music* and a number of articles written in collaboration with Jane Davidson.

JANE W. DAVIDSON studied music, dance, and education at Newcastle-upon-Tyne and London before undertaking advanced vocal studies in Canada. She completed her M.A. in performance studies at City University (London) and after a period of time teaching in schools gained her Ph.D. in the psychology of music. She worked in the psychology department at Keele University and the music department at City University before taking up her current post as senior lecturer in music at the University of Sheffield. She is a former editor of the international journal *Psychology of Music*. Besides her teaching and research work, she performs as a vocal soloist and has appeared at the Queen Elizabeth Hall, St. Paul's Cathedral, and the London International Opera Festival.

HEINZ FADLE is professor of trombone at the Hochschule für Musik, Detmold, Germany. His publications include *Looking for the Natural Way* (Piccolo-Verlag, 1996) and *Musizieren* (Die Blaue Eule, 1999). He served as president of the International Trombone Association from 1996 until 1998. Invitations to teach and lecture have led him to the United States, Russia, Kazakhstan, Britain, and Hungary. He hosted the 21st International Trombone Workshop in Detmold (1992) and also served as a jury member at international competitions. For 22 years he was first chair of the Philharmonic State Orchestra Hamburg, also performing as a member of the Bayreuth Festival Orchestra, the Berliner Philharmoniker, Radio Sinfonie Hamburg, Münchner Staatsoper, and Deutsches Sinfonieorchester Berlin.

ANDERS FRIBERG is a research assistant in music acoustics at the Royal Institute of Technology (KTH), Stockholm. He holds a master's degree in applied physics from KTH. His doctoral thesis, *A Quantitative Rule System for Musical Performance* (1995), developed the computer-based music performance simulator *Director Musices*. His published research on the technology of music performance addresses phrasing, punctuation, intonation, synchronization, swing, and links with human motion and emotion and has appeared in *Computer Music Journal*, *Journal of the Acoustical Society of America*, and *Journal of New Music Research*. He plays piano in salsa and jazz groups and holds a piano performance diploma from Berklee College of Music, Boston.

LEONARDO FUKS is associate professor of music acoustics and voice physiology at Universidade do Brasil/UFRJ in Rio de Janeiro. His musical studies were undertaken at the Villa-Lobos Music School and Uni-Rio University. He has been a professional oboist in several Brazilian orchestras and chamber music groups and holds a degree in mechanical engineering, a master of science degree in design engineering, and a doctor of philosophy in music acoustics from the Royal Institute of Technology (KTH), Stockholm. His main research topics include wind instrument performance and vocal techniques in ethnic and contemporary music. He has created a number of low-cost wind instruments for music education and is the founder and director of a bicycle orchestra, the Cyclophonica.

JANINA FYK holds a master of arts in music education from the Paderewski Academy of Music in Poznan (Poland), a doctoral degree in music theory from the

Chopin Academy of Music in Warsaw, and a habilitation in musicology from the Institute of Arts of the Polish Academy of Sciences in Warsaw. She is now professor of musical arts at the Academy of Music in Krakow. Her areas of research interests include psychoacoustics, music psychology, and music education. She is involved in research that concerns the perception of pitch, vocal, and instrumental intonation as well as absolute pitch. She is author and coauthor of numerous articles and the monographic book *Melodic Intonation, Psychoacoustics, and the Violin.*

ALF GABRIELSSON graduated from Uppsala University and the Royal University College of Music in Stockholm. His Ph.D. thesis was titled *Studies in Rhythm,* and he has subsequently published numerous research articles on music performance and music experience. He teaches general psychology and music psychology and is the head of a research group on expressive performance in music, dance, speech, and body language. He is a member of the Swedish Royal Academy of Music and the Acoustical Society of America and a vice president of the International Association for Empirical Studies of the Arts (IAEA) and was president of the European Society for the Cognitive Sciences of Music (ESCOM) from 1997 to 2000.

MARTIN GELLRICH studied piano, violoncello, secondary teaching, psychology, and musicology and holds a Ph.D. from the Hochschule der Künste und the Technische Universität Berlin in music education and psychology. His research addresses instrumental teaching, developmental psychology of music, instrumental practice, group teaching methods, relative sol-fa, improvisation, history of music education, piano technique, and musical interpretation. His publications include *Üben mit Lis(z)t* (Frauenfeld, 1992), *Impulse zu einer Veränderung der Instrumental pädagogik* (Regensburg, 2002), and articles in the *British Journal of Music Education, Üben and Musizieren,* and *Bulletin of the Council for Research in Music Education.* As a freelance piano teacher he has given over 200 presentations on instrumental teaching, particularly on improvisation.

HEINER GEMBRIS studied music education at the Music Academy of Detmold and musicology at the Technical University of Berlin. From 1991 to 2001 he was professor of musicology at the universities of Münster and Halle. Since 2001 he has been professor of music and music education at the University of Paderborn and director of the Institut für Begabungsforschung und Begabtenförderung in der Musik. He is author of *Grundlagen musikalischer Begabung und Entwicklung* (Wissner, 1998) and coeditor of the series *Musikpädagogische Forschungsberichte* (Wissner, 1992ff). He has published numerous research articles on musical development and music listening. Currently he is the president of the Deutsche Gesellschaft für Musikpsychologie.

WILFRIED GRUHN is professor and head of the music education department at the Freiburg Academy of Music. He has published several books and many articles on the history of music education, on music perception and cognition, on teach-

ing methods, and on neurobiological learning theory. He was coeditor of *Musik und Unterricht* (1980–1998) and founded the first Internet *European Music Journal* (in 1999). He has participated as clinician and presenter at various international conferences and functions as national representative of ISME in Germany. A past president of the International Research Alliance of Institutes for Music Education (RAIME), he is currently a member of the editorial board of *Research Studies in Music Education* and of *Music Education Research*.

KNUT GUETTLER is professor of double bass at the Norwegian Academy of Music and also teaches at the Royal Conservatory of the Hague, the Netherlands. His main research focus is the computer modeling of the bow–string interaction. Another area is the physical properties of bows, in collaboration with the Royal Institute of Technology, Stockholm, He has published in the *Catgut Acoustical Society Journal* (*CAS Journal*), *Journal of the Acoustical Society of America*, and *Music Perception* and is a contributing editor for the *CAS Journal*. He is a former principal player of the Oslo Philharmonic, with international experience as a lecturer on string performance. He has solo recordings on Camerata (Japan) and Musica Viva (Germany), among others.

SUSAN HALLAM trained as a violinist at the Royal Academy of Music, after which she spent 10 years as a full-time professional musician working for the BBC. After completing a B.A. in psychology externally with London University and an M.Sc. and Ph.D. in the psychology of education at the Institute of Education, London University, she took a post in the department of psychology there. After a year at Oxford Brookes University as professor of teaching and learning, she returned to London Unviersity in 2001. She is chair of the education section of the British Psychological Society, and has acted as coeditor of the *BPS Education Section Review*, and editor of *Psychology of Music*.

PATRIK N. JUSLIN holds a Ph.D. in psychology from the Department of Psychology, Uppsala University, Sweden, and currently holds a position there as researcher. He has published extensively on music and emotion, and his research is concerned with developing and testing a new theoretical framework for studies of communication of emotion via musical performance, as well as methodological developments for the field of music education. He is a member of the International Society for Research on Emotions and received ESCOM" Young Researcher Award in 1996. He has edited a book on music and emotion for Oxford University Press together with John Sloboda. In addition to Juslin's work as a researcher, he has worked professionally as a guitar player and toured internationally with blues/jazz bands.

DUANE RICHARD KARNA is director of music ministry at the First Congregational Church in Eugene, Oregon. He was director of choral activities and associate professor of music at Salisbury State University (Maryland) from 1988 to 1996 and a member of the music faculty (voice/choral) at Central Washington from 1996 to 1999. He holds a bachelor's degree in vocal performance from the Uni-

versity of Puget Sound in Tacoma, Washington; master's degrees in vocal performance and in choral conducting from Southern Methodist University in Dallas, Texas; and a doctor of musical arts in choral conducting from the University of Arizona in Tucson. He is a member of the American Choral Directors Association, the International Federation of Choral Music, and the National Association of Teachers of Singing.

ANTHONY E. KEMP is emeritus professor at the University of Reading, where he supervises research students. Originally trained as a musician and teacher, he later studied at Sussex University, gaining his D.Phil. in psychology. He is a chartered psychologist and fellow of the British Psychological Society and also senior research fellow at the University of Surrey Roehampton. He is visiting professor at the Sibelius Academy, Helsinki, where he supervises doctoral students. He was chairman of the research commission and member of the board of directors of the International Society for Music Education and has written several books and articles on music psychology, and education. His book *The Musical Temperament: The Psychology and Personality of Musicians* was published by Oxford University Press in 1996.

BARRY J. KENNY studied music at Sydney University and the University of New South Wales and holds undergraduate degrees in English literature (Sydney University) and music (University of New South Wales). He has lectured and tutored in the School of Music and Music Education, University of New South Wales, in musical analysis and jazz history and is in the process of completing his doctoral studies. Barry's published work addresses the cognitive mechanisms involved in jazz improvisation and also discuss sociocultural issues that surround the interpretation and analysis of musical forms. His work has been published in *Research Studies in Music Education* and *Annual Review of Jazz Studies.* As a professional musician, he has been actively involved as a jazz pianist, teacher, and accompanist.

JAMES M. KJELLAND holds a bachelor's degree in music education, a master of music degree from the University of Wisconsin, Madison, and a doctorate in music education from the University of Texas at Austin. He is associate professor of music education and coordinator of string pedagogy at Northwestern University. He has also presented at numerous conferences in string and orchestra pedagogy throughout the United States and is a frequent guest conductor, adjudicator, and clinician for school orchestras. His publications include his coauthored *Strictly Strings: A Comprehensive String Class Method* (Highland/Etling) and numerous articles in journals such as: *American String Teacher, Instrumentalist,* and *Bulletin of the Council for Research in Music Education.*

ANDREAS C. LEHMANN researches and teaches music psychology at the School of Music in Würzburg, Germany. He holds a degree in music education and a Ph.D. in musicology from the Hochschule für Musik und Theater, Hannover, and

worked as a researcher in the psychology department at Florida State University, Tallahassee, and in the musicology department of the University of Halle, Germany. His research addresses the structure and acquisition of high-level instrumental music performance skills (sight-reading, memory, improvisation, practice). In 1997, he received the Young Researcher Merit Award from the European Society for the Cognitive Sciences of Music (ESCOM). With Harald Jørgensen, he is coeditor of *Does Practice Make Perfect? Current Theory and Research on Instrumental Music Practice* (Norges Musikkhøgskole).

VICTORIA MCARTHUR is program director of piano pedagogy and coordinator of group piano at Florida State University. She has published in *Psychology of Music* and *Bulletin of the Council for Research in Music Education*. She is a member of the editorial board of *Piano and Keyboard*, former senior editor for FJH Music Company, Miami, and currently keyboard editor for Alfred Publishing Company, Los Angeles. She has lectured extensively and authored and edited instructional books on sight-reading. Her other research areas are practice and motor memory. Her background in piano performance, piano pedagogy, music education research methods, cognitive and motor psychology, and biomechanics has formed her ideas and approach to the teaching of piano sight-reading.

GARY E. MCPHERSON studied music education at the Sydney Conservatorium of Music before completing a master of music education at Indiana University and a doctorate of philosophy at the University of Sydney. He is an associate professor of music education at the University of New South Wales and former treasurer for the International Society for Music Education and national president of the Australian Society for Music Education. His published research addresses visual, aural, and creative aspects of musical performance in young developing musicians. McPherson is currently on the editorial boards of all flagship journals in music education, as well as being editor for *Research Studies in Music Education*. As a trumpeter, he has performed with several of Australia's leading ensembles.

JANET MILLS gained her B.A. in music and mathematics from York University and her D.Phil. at Oxford University. She began her career as a secondary music teacher and then taught in higher education before becoming an H.M. Inspector of Schools in 1990. Currently she is a research fellow at the Royal College of Music in London.

STEVEN J. MORRISON is assistant professor of music education at the University of Washington, where he teaches courses in instructional methods and research. He is an instrumental music specialist whose research includes perceptual and performance aspects of intonation and the relationship of cultural context to music preference. He is currently investigating neural aspects of cross-cultural music comprehension in a joint research project with the University of Washington medical center. His articles have appeared in the *Journal of Research in Music Education*, *Bulletin for the Council of Research in Music Education*, *Up-*

date: Applications of Research in Music Education, and *Music Educators Journal*. He is chair of the Perception and Cognition Special Research Interest Group of the Society for Research in Music Education.

SUSAN A. O'NEILL is senior lecturer in psychology and Associate Director of the Unit for the Study of Musical Skill and Development at Keele University. Her research interests include motivation, identity, and gender issues associated with children's and adolescents' development of musical performance skills. She has published widely in the fields of psychology and music education. As a consultant for the Associated Board of the Royal Schools of Music she has presented seminars and workshops for professional development and teacher training courses throughout the United Kingdom. She is currently project leader for the Young People and Music Participation Project, which involves a longitudinal study of young people's motivation, identity, and engagement in music. She has taught flute and has performed extensively as a soloist and chamber musician in Canada and Europe.

RICHARD PARNCUTT holds undergraduate degress in in physics and music from the University of Melbourne and a Ph.D. in physics, psychology, and music from the University of New England, Australia. He is now professor of systematic musicology at the University of Graz, Austria. He is author of *Harmony: A Psychoacoustical Approach* (Springer, 1989) and research articles on the perception of harmony, tonality, rhythm, and piano performance, including psychoacoustic and cognitive theories and models. He is a member of the editorial advisory boards of *Psychology of Music*, *Music Perception*, *Musicae Scientiae*, *Journal of New Music Research*, *Jahrbuch Musikpsychologie*, *Systematische Musikwissenschaft*, *Contemporary Music Review*, and *Research Studies in Music Education*. He is an internationally experienced pianist, piano teacher, and accompanist.

ROLAND S. PERSSON holds a master of arts in music education from Ingesund College of Music (Sweden) and a Ph.D. in psychology from Huddersfield University (England). He is currently associate professor of psychology at Jönköping University and director of its center for psychology. He is editor in chief of *High Ability Studies* (Taylor & Francis) and a former piano performer, organist, and music educator. His research interests fall within the domain of social psychology, particularly talent and giftedness, gender issues, and psychometrics, where he has written numerous scholarly articles on the training of musical performers and their psychological health and education.

HARRY E. PRICE is professor and head of music education at the University of Alabama. In addition to his current research and teaching, he was a classical and jazz performer and secondary school and university band conductor and clinician. He is the former editor of the *Journal of Research in Music Education* and is on the editorial board of *Research Studies in Music Education* and the *International Journal of Music Education*. He edited *Music Education Research: An*

Anthology from the *Journal of Research in Music Education* and has over 50 research articles in publications such as *Journal of Research in Music Education, Bulletin of the Council for Research in Music Education, Research Studies in Music Education,* and *Boletin de Investigación Educativo-Musica.*

DAVID ROLAND is a consultant clinical psychologist and a classical guitarist. He completed an honors degree at the University of Sydney and a Ph.D. in clinical psychology at the University of Wollongong. His area of research interest is the management of performance anxiety and the application of mental skills to performing. He is the author of *The Confident Performer* (Currency Press, 1997) and has published in *Research Studies in Music Education.* He has presented his research to the International Society of Music Education (ISME Korea, 1992). He has been on the staff of the Canberra School of Music (Australian National University); guest-lectured for many universities and conservatories, and worked with a number of performing arts groups.

JOHAN SUNDBERG is a professor of music acoustics at the Royal Institute of Technology in Stockholm, where he led its music acoustics research group from 1970 to 2001. A prolific author of peer-reviewed journal articles, his main research interests are the singing voice and music performance. As president of the Music Acoustics Committee of the Royal Swedish Academy of Music, he edited 10 volumes of proceedings of public seminars. He is a member of the Royal Swedish Academy of Music and the Swedish Acoustical Society (President 1976–1981) and a fellow of the Acoustical Society of America. He has sung in the Stockholm Bach Choir (nine years as its president) and made his public solo debut with a lieder recital on his fiftieth birthday.

STEN TERNSTRÖM holds a doctoral degree from the Royal Institute of Technology (KTH), Stockholm, and is currently senior researcher and university lecturer there. He is the author of numerous research articles on the acoustics of choir singing and other topics in music acoustics and voice, often collaborating with Johan Sundberg. Ternström is associate editor of *Logopedics Phoniatrics Vocology,* board member of the Swedish Voice Society, and member of the scientific advisory board of the Voice Foundation in Philadelphia. A choir singer and arranger, he has performed extensively with leading a cappella vocal groups in Sweden.

MALCOLM TROUP is the founding (and now emeritus) professor of the music department of City University, London. He holds a D.Phil. in music from the University of York and honorary doctorates from City University, the Memorial University of Newfoundland, and the University of Chile. He is currently the European chair of the European Piano Teachers' Association and edits its *Piano Journal.* He is also chair of the Beethoven Society of Europe, president of the annual Oxford Philomusica Piano Festival, and vice president of the World Piano Competition, London. His research addresses performance practice, history of ideas, and aesthetics. As a solo pianist he has toured five continents, received the 1998 Liszt medal, and recorded for RCA Victor and the Continuum label.

GRAHAM F. WELCH (Ph.D.) is professor of music education at the University of London Institute of Education. He is a trained singer and semiprofessional performer for over 20 years whose research and associated publications include singing development across the life span, particularly in childhood and adolescence and including the trained chorister voice. Recent publications include *Bodymind and Voice: Foundations of Voice Education*, coedited and coauthored with Leon Thurman for the National Centre for Voice and Speech, and chapters on voice management, musical development and learning in the United Kingdom, and the teaching profession. He is currently chair of the Society for Research in the Psychology of Music and Music Education and cochair of the ISME Research Commission.

AARON WILLIAMON is a research fellow in psychology of music at the Royal College of Music. He completed his Ph.D. in cognitive psychology at the University of London (Royal Holloway), where his research centered on how skilled musicians learn, rehearse, and recall information when practicing and performing. In 1998, he was awarded the Hickman Prize by the Society for Research in Psychology of Music and Music Education (SRPMME) for his work on how audiences evaluate memorized performances. In addition to his continued interest in music cognition (particularly memorization and practice), he is currently researching the nature and effects of performance anxiety and how skilled musicians work together when learning and rehearsing compositions.

GLENN D. WILSON is reader in personality at the University of London Institute of Psychiatry and adjunct professor at the University of Nevada, Reno. He is author of some 200 scientific papers and 25 books, including *Psychology for Performing Artists* (Whurr, 2002) and (with Andrew Evans) *Fame: The Psychology of Stardom* (Vision, 1999). He makes frequent radio and TV appearances and has lectured widely abroad, for example, as guest of the Italian Cultural Association and as visiting professor at several U.S. institutions, including Stanford and California State University, Los Angeles. He is also a trained opera singer with an international freelance career.

PREFACE

On picking up a book with the title *Conceptualizing Music: Cognitive Structure, Theory, and Analysis*, one might reasonably assume that it deals with music cognition and how our knowledge of that discipline can be applied to music theory and analysis. This book does not do that, or at least not in a simple way. To begin, it does not have much to say about the fairly large body of research usually placed under the rubric "music cognition." This work, having been developed out of music psychology and informed by recent research in the brain sciences and mind sciences, proceeds by carefully crafted experiments, which are subjected to closely argued statistical and logical analysis. As practiced by such eminent and able researchers as Carol Krumhansl, John Sloboda, and David Huron, the study of music cognition has told us much about how humans process sonic and musical information.

But this book proceeds in a somewhat different way. Drawing on the same body of research from the brain sciences and mind sciences that shaped studies in music cognition, it explores how basic cognitive capacities are specified for understanding music. The project takes inspiration from recent work in linguistics and rhetoric by researchers like Ronald Langacker, Gilles Fauconnier, Mark Turner, and George Lakoff, and it is based on the assumption that musical understanding relies not on specialized capacities unique to the processing of patterned sound but on the specialized use of general capacities that humans use to structure their understanding of the everyday world. The methodology, in consequence, relies not on experimental design and data analysis but on using a broad and quite extensive body of research to interpret recurrent tropes of musical understanding. These tropes involve such things as the importance to musical understanding of relatively small and compact musical phenomena like "motives," "themes," and "chords"; the use of terms grounded in nonmusical domains—terms like "space" and "depth"—to characterize musical events; and the reliance on patterns of logical inference to reason about music.

The result of this investigation is a theoretical perspective on musical organization, but one rather different from what usually counts as "music theory." To make sense of this claim requires a bit of explanation about the intellectual context of music theory, for music theory is, within the rolling seas of humanistic studies, a

rather strange fish. Put bluntly, it is clear that much of what music theory does, as a discipline, does not count as any sort of theory in modern scholarship. This is exemplified by each of the two distinct but related and intertwined strands that make up contemporary music theory. One strand is occupied with pedagogy, the other with speculative and highly systematic approaches to musical organization.

Music theory, as it is presented in the classroom, is most often engaged with a careful and often relentless explication of what, for want of a better term, we can call musical grammar. Consider the following, from Edward Aldwell and Carl Schachter's *Harmony and Voice Leading*:

> Like VII^6, V$\frac{4}{3}$ has $\hat{2}$ as its bass. V$\frac{4}{3}$, in fact, resembles VII^6 so closely that they are almost interchangeable chords. The bass of V$\frac{4}{3}$ is a more neutral tone than that of V$\frac{5}{3}$ (or, as you will see, V$\frac{2}{}$) and can move convincingly either to $\hat{1}$ or to $\hat{3}$. Consequently, V$\frac{4}{3}$, like VII^6, forms a natural connection between I and I^6 and appears very frequently as a passing chord within an extended tonic.[1]

The prose and terminology are impressively dense. But one should not be misled into thinking that the authors are concerned only with abstruse compositional techniques, for immediately after this excerpt Aldwell and Schachter refer to a passage from an impromptu by Franz Schubert that illustrates the niceties of voice leading with which they are concerned. Their assumption is that the reader is familiar with the music and counts it as typical, and it is this familiarity that provides a phenomenological anchor for what might appear to be rather thick jargon. If you know Schubert's impromptu, or (better yet) can summon it in your sonic imagination when reading the example in score, Aldwell and Schachter's point about the harmonization of the second scale-step in the bass is not just clear but even obvious.

At the heart of pedagogical music theory are familiar or typical examples of music, the mysteries of which are revealed by a music theorist (or theorists) eager to share the secrets and wonder of this music with others. As elegant and persuasive as this approach might seem, it is, within our current cultural climate, more than a little unrealistic: music by Schubert and his contemporaries is often unfamiliar to the students who read Aldwell and Schachter's text (or any of a number of similar texts) and is not typical of the music that resonates through these students' digitized and hypercommercialized environments. That this should be so is often regarded as symptomatic of an illness of the late twentieth century, an illness that leads to an insufficient engagement with the great traditions of Western culture. For Classical music (as it is so styled), the antidote is music theory. Music theory, with its careful explication of the musical grammar of Mozart and Beethoven and Schubert, thus becomes the last redoubt against the dissolution of Western culture represented by a dwindling interest in the music of eighteenth- and nineteenth-century Europe.

If, for a moment, we step back from Aldwell and Schachter's text and generalize its intent beyond the specific repertoire relative to which it is framed, we might be able to avoid this rather sanctimonious stance. We could argue that music is a highly complex and idiosyncratic mode of human communication and that having a knowl-

1. Edward Aldwell and Carl Schachter, *Harmony and Voice Leading*, 2nd ed. (San Diego: Harcourt Brace Jovanovich, 1989), 112.

edge of the grammar of this mode of communication is essential to its deeper appreciation, no matter what form music might take. The argument is a familiar one to me, not the least because I often find myself making it. And yet, something rings hollow. The grammar that music theory teaches is unavoidably tied to the repertoire to which it refers, and just how this is generalized to apply to other repertoires is not immediately apparent: I know of no theory text that explains how the grammar of Schubert's musical discourse is manifested in the music of, say, John Coltrane or Prince. Given its isolation from contemporary culture, the music theory of the classroom appears to be little more than a ghost that haunts the echoing halls of a crumbling cultural empire.

The second strand of music theory partakes of the systematic quality inherent in grammars but generalizes it away from natural language and toward a free-standing intellectual construct. As an example of this sort of theory, consider the following brief passage from David Lewin's analysis of a section of the opening of Claude Debussy's piano prelude *Reflets dans l'eau*. In this excerpt, X, Y, and Z represent specific collections of musical notes, RI refers to the compound operations retrograde and inversion, RICH is a function that effects serial transformations, and T refers to transposition:

> In measure 10 the music of measure 9 is repeated and extended. The crescendo recurs. In the melody the repetition gives rise to a rotated form of Z_1, marked "rot Z_1" on figure 10.10. Rot Z_1 is B♭-A♭-F-E♭; it embeds serially the original form of Y, A♭-F-E♭, and precedes this Y by its overlapping inverse-RI-chained form B♭-A♭-F. (B♭-A♭-F is $RICH^{-1}$(A♭-F-E♭).) This relationship is more or less inherent in the derivations of X, Y, T(X), their repetitions, and Z_1.[2]

It is, of course, something of a challenge to evaluate this passage in isolation. Not only is it just one part of a larger analysis, but also it comes late in a book occupied with various and sundry applications of formal algebra and mathematical mapping theory to music. Nonetheless, what should be clear is that more than familiarity with Debussy's prelude is required to make sense of Lewin's interpretation of the passage. The reader must also be familiar with a style of abstract thought that is bound to appear cabalistic to the uninitiated, one in which the transformation of musical entities is at least as important as the entities themselves. For some, the inaccessibility of this mode of thought is one of its charms. For others, it is proof of the hermeticism and irrelevance of music theory.

Before continuing, I should make clear that I have deep respect for the theorists whose work I have cited. I use this work in my teaching and continue to be intrigued and stimulated by it. I also want to emphasize that these excerpts by no means reflect all that there is to music theory. I take them as representative of two strands of thought that are replicated and woven together in all sorts of different ways to create the texture of contemporary theoretical practice. What is important for my purposes here is that the practice of contemporary music theory is not like that of contemporary cultural or social theory. Instead of probing the cultural or historical

2. David Lewin, *Generalized Musical Intervals and Transformations* (New Haven, Conn.: Yale University Press, 1987), 234.

context for musical utterances, or the complex networks of social interaction that give rise to musical behavior, music theory continues to focus on details of musical discourse with an obsessiveness that is both maddening and quixotic to cultural and social theorists.

Given the impressive traditions of music theory and their influence on my own thought, I cannot guarantee that what I offer here is a great improvement on this situation. One of the things I want to do in the chapters that follow, however, is to develop a somewhat different view of music theory—one that sees music theory as a response to a problem. The problem is that of musical understanding: how it is that we can make sense of sequences of nonlinguistic patterned sound, that we can do so with amazing rapidity, and that (often as not) we can return to these or similar sound sequences and find continued reward. I will argue that our understanding of music relies on a play of concepts and conceptual structures that emerges from training basic cognitive capacities on musical phenomena and that music theory and music analysis derive from this play.

This mode of inquiry is not one common in the discipline of music theory, despite its similarities to work done by Leonard B. Meyer, Eugene Narmour, and Robert Gjerdingen. It does, however, share features with the approach to music evident in Susan McClary's recent *Conventional Wisdom*. That this should be so reveals a debt on my part, for it was Professor McClary who first suggested that I read Mark Johnson's *The Body in the Mind* back in the late 1980s, and this had a profound effect on my research. In her book, McClary explores the cultural and historical forces that have shaped genres like opera and the blues and compositional practices like tonality. My focus is on a somewhat different set of forces: those that shape the way humans think. It seems inevitable that these forces are in some sort of grand, if ill-defined, dialogue with cultural and historical agencies: it is, after all, human cognitive processes and human culture and history about which we are talking. That cultural and social theory have turned a deaf ear to this dialogue is not surprising: cognitive theory has had little room for and less patience with culture, and the detail of its investigative method is no match for the epic sweep of high theoretical practice at its best. And yet it seems we must, at some point, come to terms with cognitive structure, for if we do not develop an understanding of how cognitive processes shape the basic materials of thought, we risk accepting these materials as things given by nature, just as culture and history—and music, for that matter—were once assumed to be given by nature.

A glimpse of the problem can be seen in McClary's compelling analysis of Robert Johnson's 1936 "Cross Road Blues." McClary contrasts Johnson's blues with those of Bessie Smith, noting that the influence of Johnson's music on white British blues players of the 1960s was due in part to a misconception: the British musicians believed that the idiosyncrasies of Johnson's blues style represented "authentic" blues practice. Describing the unique sound of Johnson's "Cross Road Blues," McClary writes,

> An affect of dread and entrapment pervades this tune—partly the result of his strangulated, falsetto vocals and his uncanny replication of that timbre on the guitar. Moreover, Johnson's percussive guitar pulse, which locks in at the eighth-note level, allows almost no sensual movement: even though Johnson's singing constantly strains

> against that beat, the listener's body is regulated by those short, aggressively articulated units. The guitar thus seems to represent simultaneously both oppressive outside forces and a desperate subjectivity fighting vainly for escape.[3]

I have no quarrel with McClary's analysis—indeed, in this short passage, she has captured a number of the essential features of Johnson's performance style. The difficulty comes with the ultimate justification for the affect produced by the song. Why do Johnson's vocals and guitar work yield dread and entrapment rather than joyful anticipation and a feeling of liberation? Clearly, the rhythmic framework is important, but why is it that the rigidity of Johnson's beat constrains us rather than providing a secure foundation from which we can coolly regard his plaint? These are not easy questions, all the more so because of the relatively unique character of Johnson's recording when compared with other blues recordings of the period, and because hearing "Cross Road Blues" as something other than a moving, haunting song is to misunderstand it rather thoroughly. Cultural, social, and historical context cannot, by themselves, explain the origin of our affective response to the song, for our broad agreement on the effect of Johnson's music transcends these implements of high theory (even if they have a profound influence on what we do with "Cross Road Blues" once we have heard it). I propose that exploring the way cognitive structure informs our understanding of music gives us a way to account for the source of our broad agreement on the affect that pervades Johnson's blues and can help us understand better the ways culture, society, and history reshape musical practice.

Again, the way I want to accomplish this is by reconceptualizing what it means to theorize about music. This can be done by approaching music theory from the perspective provided by recent work in cognitive science. My intellectual guideposts include not only the wealth of work done in the mind sciences and the brain sciences but also contemporary and historical ways of theorizing about music. These theories of music—now with "theory" understood in somewhat more traditional terms—capture important aspects of how it is we structure our understanding of music. At their best, they represent a technical and systematic articulation of an accord on what matters in music that is similar in kind, if not terminology, to our accord on how Robert Johnson's blues move us: we agree on how music is put together and we agree on what music means because both are structured by basic cognitive processes through which we organize our understanding of the world. And so music theory—this rather strange fish in the seas of humanistic scholarship—may yet tell us some quite interesting things about the cultural and social construction of music. Understanding the way music theory instantiates cognitive processes will also help explain its continuing value. It will offer such help whether that theory be prosaic—as within the classroom or within critical discourse (since even the most radical of cultural or sociological theorists inevitably makes recourse to basic music-theoretical constructs)—or poetic, as with the elusive and allusive constructs of abstract theory.

3. Susan McClary, *Conventional Wisdom: The Content of Musical Form* (Berkeley: University of California Press, 2000), 51.

As should be apparent from the preceding, my intent here is to address not only music theorists but also musicologists and ethnomusicologists who find the challenges of theorizing about music intriguing. What follows will also be of interest to those with either a professional or avocational interest in cognitive science, for music presents a number of interesting problems for cognitive processing, not the least of which are its embeddedness in culture and the demands it places on real-time processing. In entertaining the thought of such an audience, however, I should briefly clarify a distinction I draw between sound and music and the cognitive abilities related to each, which is based on three suppositions. First, not all sound is music. Second, an account of how humans process sound is not the same thing as how they understand music. Third, phenomena relevant to musical understanding exist at a conceptual level—that is, at a level of cognitive activity at least potentially accessible to conscious thought. I should emphasize that I regard the conceptual level as occupying only a small part of our total cognitive activity, and I am not at all opposed to efforts by music psychologists and others who try to explain how structures at the preconceptual level connect with and motivate structures on the conceptual level. For me, however, it is at the conceptual level that I find the most profoundly interesting questions, for concepts are the tools that allow us to construct the complex notions essential to musical understanding. From this perspective, conceptualizing music is fundamental to inquiries about music, whether those be from the perspective of music cognition, or ethnomusicology, or musicology, or theory.

ACKNOWLEDGMENTS

In the course of writing this book I enjoyed the assistance of many people, all of whom improved the product immeasurably. Among the many colleagues who read drafts of material or responded to presentations I have given, are the following: Kofi Agawu, Holly Aksnes, Jeanne Bamberger, Larry Barsalou, Philip Bohlman, Candace Brower, Scott Burnham, Clif Callender, Thomas Christensen, Martin Clayton, Rick Cohn, Nick Cook, Arnie Cox, Bob Gjerdingen, Robert Hatten, Bob Holzer, Brian Hyer, Rich Janda, Carol Krumhansl, the late Jim McCawley, Marc Perlman, Anne Robertson, John Rothgeb, Janna Saslaw, Martin Stokes, and Mark Turner. Their comments, suggestions, and queries helped me strengthen and reformulate my arguments. Ben Brinner, Gilles Fauconnier, Douglas Hofstadter, Travis Jackson, Bobby Short, Sumarsam, and Susan Youens were generous in their response to questions I posed to them and provided me with information and insight I simply could not have gained elsewhere. Students in my classes and seminars at the University of Chicago listened to many of the ideas presented in this book, to which they responded with questions, challenges, and comments. Although it would be impractical to acknowledge all of them here, they contributed immensely to the shape those ideas have taken in this book.

Deborah Gillaspie of the Chicago Jazz Archive and Regenstein Library patiently endured my requests for obscure recordings and was indispensable in helping me find materials that I needed. The musical examples were expertly prepared by Jürgen Selk of Music Graphics International. Philipp Goedicke and Heinrich Jaeger helped me with the translation of difficult passages in German, and my brother Gene Zbikowski assisted in deciphering some of the more recalcitrant clauses in Rameau's and Proust's French. José António Martins and Aron Topielski served as my research assistants, ably tracking things down, organizing my sprawling files, and getting to know the photocopier, perhaps better than they wanted to. Maribeth Payne, when she served as Executive Editor for Music at Oxford University Press, listened to my ideas for the book (at least once at the risk of missing her train) and then provided valuable encouragement and assistance in the process of turning a proposal into a final manuscript.

Institutional support came through a yearlong fellowship at the Franke Institute

for the Humanities (formerly the Chicago Humanities Institute) at the University of Chicago and from the Department of Music of the University of Chicago. The latter provided not only a home for my research but financial support as well. Some of the recordings discussed in chapter 5 were made available by the Archives for Traditional Music in Bloomington, Indiana, and by the Bowling Green Sound Recordings Archives, Bowling Green, Ohio.

Finally, production of this book was facilitated by subventions from two scholarly societies. The Society for Music Theory provided a subvention to defray the costs of producing the musical examples, and the result of this assistance can be seen in the number and appearance of the examples I was able to include. The Publications Committee of the American Musicological Society was equally enthusiastic about the book and agreed to include it in its series, AMS Studies in Music. This decision not only made the book more affordable but also gave me an excellent and endlessly patient editor in Lawrence Bernstein.

My family—Vicky Long, Anna Katia, and Andrei Nicolai—had to put up with sharing me with this project, and I am afraid they got the short end of the deal more than once. Without their support, understanding, and uncritical companionship, this book would have been much the poorer.

My musical examples generally adhere to the readings of the following editions: the new *Beethoven Werke*; the Johannes Brahms *Sämtliche Werke*; the *Neue Mozart Ausgabe*; Casimiri's edition of the works of Palestrina; the *Neue Schubert Ausgabe*; Clara Schumann's edition of the *Lieder* of Robert Schumann; the new *Richard Wagner: Sämtliche Werke* (in conjunction with the C. F. Peter's score of *Tristan*); and the Collected Works of Giaches Wert for *Corpus mensurabilis musicae*. Some indications of editorial intiative in those editions—generally with respect to dynamic markings added on the basis of parallel readings—have been realized tacitly in my examples for the sake of clarity of appearance. The setting of Bernhard Klein's "Trockne Blumen" was prepared from the 1822 edition by E. H. G. Christiani in Berlin.

When dealing with historical sources written in languages other than English, I have generally followed one of two practices. Where there is no translation of the work, or where I think existing translations are not wholly satisfactory, I provide my own translation, with the original in a footnote. Where satisfactory translations exist, I use these and do not include the original in the footnote. In a few cases, I have thought readers might like to make reference to both the original and a translation and consequently have included citations for both in the footnotes.

Some of the material that follows has been previously published elsewhere and is used here by kind permission of the journals in which it originally appeared. This material includes the following: "Conceptual Models and Cross-Domain Mapping: New Perspectives on Theories of Music and Hierarchy," *Journal of Music Theory* 41/2 (© 1997, *Journal of Music Theory*); "Musical Coherence, Motive, and Categorization," *Music Perception* 17/1 (© 1999 by The Regents of the University of California); and "The Blossoms of 'Trockne Blumen': Music and Text in the Early Nineteenth Century," *Music Analysis* 18/3 (© 1999, Blackwell Publishers, Ltd.).

CONCEPTUALIZING MUSIC

CONCEPTUALIZING MUSIC

Early in the opening volume of *A la recherche du temps perdu*, Marcel Proust presents the first of a number of memorable accounts of listening to music. He describes Charles Swann's initial encounter with the andante of Vinteuil's sonata for violin and piano:

> Doubtless the notes which we hear at such moments tend, according to their pitch and volume, to spread out before our eyes over surfaces of varying dimensions, to trace arabesques, to give us the sensation of breadth or tenuity, stability or caprice. But the notes themselves have vanished before these sensations have developed sufficiently to escape submersion under those which the succeeding or even simultaneous notes have already begun to awaken in us. And this impression would continue to envelop in its liquidity, its ceaseless overlapping, the *motifs* which from time to time emerge, barely discernible, to plunge again and disappear and drown, recognized only by the particular kind of pleasure which they instill, impossible to describe, to recollect, to name, ineffable—did not our memory, like a laborer who toils at the laying down of firm foundations beneath the tumult of the waves, by fashioning for us facsimiles of those fugitive phrases, enable us to compare and to contrast them with those that follow. And so, scarcely had the exquisite sensation which Swann had experienced died away, before his memory had furnished him with an immediate transcript, sketchy, it is true, and provisional, which he had been able to glance at while the piece continued, so that, when the same impression suddenly returned, it was no longer impossible to grasp.[1]

What Proust summons in this lyrical, enchanted vignette is the awakening and initial consolidation of musical understanding. Swann's first impressions of Vinteuil's sonata are vague and unformed, his mind simultaneously struggling with and savoring the ineffability of the music. But then, with the aid of memory, patterns emerge. Although these are incomplete and subject to revision, they offer him a way to make sense of the music, even as it continues to play.

Conceptualizing Music provides an exploration of the process of musical under-

1. Marcel Proust, *Swann's Way* (vol. 1 of *Remembrance of Things Past*), trans. C. K. Scott Moncrieff and Terence Kilmartin (New York: Vintage Books, 1981), 227.

standing—that is, the process through which those liquid impressions spoken of by Proust are transformed into structures that make it possible to grasp music. In what follows, I argue that Swann's—or anyone's—understanding of music draws on the same cognitive processes that humans use to organize their understanding of the world as a whole. Confronted with musical sound, these processes create musical concepts, the things that enabled Swann to gain a grasp of the music. The act of conceptualizing music is the beginning of a whole chain of cognitive events that allow us to theorize about music and to analyze the things that populate our aural past, present, and future.

The notion that Swann's musings might give rise to musical concepts demands some further consideration. Concepts are often thought of as highly stable cognitive structures of considerable complexity, a view hardly commensurate with the ephemera attended to or produced by Swann. Recent work in the brain sciences and the mind sciences, however, has changed how we view concepts. There are now persuasive arguments that concepts are quite fluid, that they are not irrevocably wedded to words or to concrete representations, and that they are not even unique to our species.[2] In consequence, the provisional replicas of musical phrases that make it possible for Swann to secure a foothold in the unfamiliar terrain of Vinteuil's sonata need not automatically be excluded from the conceptual domain. In fact, they are very much like the concepts we use to structure our understanding of the everyday world.

This same work in the brain sciences and the mind sciences suggests a way to account for the apparent simplicity and immediacy of musical understanding, which seems incommensurate with the complexity of musical structure. For instance, the sonata by the fictional Vinteuil is intended to be a relatively complex contemporary work that has captured the fancy of the musical elite of the Paris salons. Nonetheless, Swann, whose connoisseurship does not extend to music, is able to gain a grasp of the work almost immediately. That he is able to do so is not simply novelistic license but is, in fact, thoroughly plausible: almost everyone has had the experience of listening to an unusual composition or exotic repertoire and being able to make *something* of it. This possibility has suggested to some a latent musicality in humans comparable to the sort of competence for language proposed by Noam Chomsky.[3] Competencies of this sort raise as many questions as they answer, however, particularly where cultural entities such as music are concerned. It seems more promising to follow the path of researchers who have rejected linguistic competence as a given

2. See, for instance, Douglas R. Hofstadter and the Fluid Analogies Research Group, *Fluid Concepts and Creative Analogies: Computer Models of the Fundamental Mechanisms of Thought* (New York: Basic Books, 1995), chaps. 5–6, 8–10; Gerald M. Edelman, *The Remembered Present: A Biological Theory of Consciousness* (New York: Basic Books, 1989), chap. 8; and Donald R. Griffin, *Animal Minds* (Chicago: University of Chicago Press, 1992), chap. 6.

3. The notion of musical competence has generated a range of commentary and scholarship. See John Blacking, "Music, Culture, and Experience," in *Music, Culture, and Experience: Selected Papers of John Blacking*, ed. Reginald Byron, with a foreword by Bruno Nettl (Chicago: University of Chicago Press, 1995), 228–31, on musical competence and culture; Steven Pinker, *How the Mind Works* (New York: W. W. Norton, 1997), 528–38, on musical competence and its relation to other competencies; and Allan Keiler, "The Origins of Schenker's Thought: How Man Is Musical," *Journal of Music Theory* 33 (1989): 273–98, on a nineteenth-century conception of musical faculties akin to musical competence.

and who have set about exploring the cognitive foundations of language.[4] Their task has been to discover what processes are basic to human cognition and then to determine how they are specified for language. For my part, I would like to explore how some of these same general cognitive processes are specified for music. By this means I hope to account for the apparent ease and real rapidity with which we can conceptualize a highly complex, completely unfamiliar music on our first encounter, without having to postulate the faculty of musical competence.

At a bit more of a remove, but no less important for a complete account of cognitive processing, is the way concepts come to be organized into the more extended cognitive structures with which our thought is usually occupied. This is where theories come into play, for theories are the cognitive tools that guide the way we reason about the things we experience. At first, this might seem to be a rather specialized use of the notion of "theory," for the theory with which much current literature is occupied—within and without music scholarship—is hardly the stuff of everyday experience. Recent research has countered this view of theory by demonstrating that the elegant and abstract theories of science have much in common with the tools for reasoning used by very young children.[5] Theories are the basic means by which we make our experience coherent and guide further action. The rough-and-ready transcript that guides Swann's listening thus has something in common with the more fully articulated and systematic structures we usually associate with the idea of "music theory."

That music theory might have alliances with everyday thought processes is a provocative claim. On the one hand, music theory often manifests itself as a relentlessly practical discipline: a codification of the scales, chords, and grammatical rules proper to a highly circumscribed portion of musical discourse, assembled with the intent of rendering music comprehensible to those who would become musically literate. On the other hand, music theory can reach into the far corners of abstraction to embrace complicated mathematical concepts or the arcane symbologies of voice-leading graphs, as any reader of the *Journal of Music Theory, Music Theory Spectrum*, or *Music Analysis* will quickly discover. Nonetheless, I want to argue that music theory, in all its diverse forms, reflects the same basic processes that guide our understanding of the everyday world. Theorizing about music is an activity specialized only in its domain, not in the cognitive processes it involves.

What might these cognitive processes be, and how would they manifest themselves? To answer these questions, let us begin at a beginning, with two theories of

4. For general introductions to some of the working assumptions of cognitive linguists, see George Lakoff, "The Invariance Hypothesis: Is Abstract Reason Based on Image-Schemas?" *Cognitive Linguistics* 1 (1990): 39–74; and Michael Tomasello, "Introduction: A Cognitive-Functional Perspective on Language Structure," in *The New Psychology of Language: Cognitive and Functional Approaches to Language Structure*, ed. Michael Tomasello (Mahwah, N.J.: Erlbaum Associates, 1998), vii–xxiii. In the field of cognitive linguistics, Ron Langacker's work is particularly notable for its thoroughness and its systematic approach. See Langacker, *Theoretical Prerequisites*, and *Descriptive Application*, vols. 1 and 2, respectively, of *Foundations of Cognitive Grammar* (Stanford, Calif.: Stanford University Press, 1987, 1992); idem, *Grammar and Conceptualization* (Berlin: Mouton de Gruyter, 2000).

5. See Alison Gopnik and Andrew N. Meltzoff, *Words, Thoughts, and Theories* (Cambridge, Mass.: MIT Press, 1997); and Alison Gopnik, Andrew N. Meltzoff, and Patricia K. Kuhl, *The Scientist in the Crib: Minds, Brains, and How Children Learn* (New York: William Morrow, 1999).

music from Greek antiquity. These theories, and the music to which they refer, are so unfamiliar that even many who make music theory the focus of their research have only passing knowledge of what they involve. But there is an advantage in this unfamiliarity, for the disorienting effect it can have also serves to loosen our notions about what a theory of music, or a theoretical construct, should be. Despite connections with music theory as it was practiced in Europe and (to a lesser extent) in the Arabic world, Greek music theory of antiquity is the theory of an alien society. Nonetheless, this theory was a beginning—one of the starting points for accounts of musical organization in the Western tradition. We can discern within it, therefore, the theorists of antiquity grappling with basic constructs equivalent to, if still different from, the sort of constructs taught in beginning music theory classes today. Both aspects will allow us to see the role basic cognitive structures play in our understanding of music.

ANCIENT MUSIC THEORY AND MODERN COGNITIVE SCIENCE

Those who wrote on Greek musical practice in antiquity concerned themselves with a wide variety of topics, including the place of music in society, musical aesthetics, the construction and nature of musical instruments, and the organization of pitch materials. Specific discussions of pitch materials—the usual topic of disquisitions more directly oriented to music theory—centered around the set of pitch relationships that has come to be called the Greater Perfect System.[6] As shown in figure I.1, this consisted of a set of four tetrachords (*hypaton, meson, diezeugmenon,* and *hyperbolaion*), which, together with one additional note (called *Proslambanomenos*), provided the framework for a two-octave system of pitches basic to Greek music. The end points of the tetrachords (the notes *Hypate hypaton, Hypate meson, Mese,* and so on), together with *Proslambanomenos*, were regarded as stable, unmovable pitches. There was, however, no fixed standard for tuning—the note-names given in figure I.1 are simply for the purposes of illustration. Within the boundaries marked by each tetrachord were two other pitches, whose placement varied according to which of three different genera was understood to be in play. (In the tetrachord *hypaton*, for instance, the variable notes above *Hypate hypaton* were *Parhypate hypaton* and *Lichanos hypaton*.) The diatonic genus located the movable pitches in a manner analogous to modern diatonic scales (for instance, given the reference pitches on fig. I.1, *Parhypate hypaton* in the diatonic genus would be equivalent to F3, and *Lichanos hypaton* would be equivalent to G3), but the chromatic and enharmonic genera situated the pitches in ways that have no comfortable analogue in modern scale construction. The result was a system in which the placement of movable pitches could vary widely and in which intervals between successive pitches could be smaller than a half step and larger than a whole step.

6. For a more detailed discussion of the Greater Perfect System and its place in Greek theory of antiquity, see Andrew Barker, ed. and trans., introduction to *Harmonic and Acoustic Theory* (vol. 2 of *Greek Musical Writings*), Cambridge Readings in the Literature of Music (Cambridge: Cambridge University Press, 1989), 12–13. For a more general overview of Greek music theory and a thorough discussion of the sources, see Thomas J. Mathiesen, *Apollo's Lyre: Greek Music and Music Theory in Antiquity and the Middle Ages* (Lincoln: University of Nebraska Press, 2000), part 4.

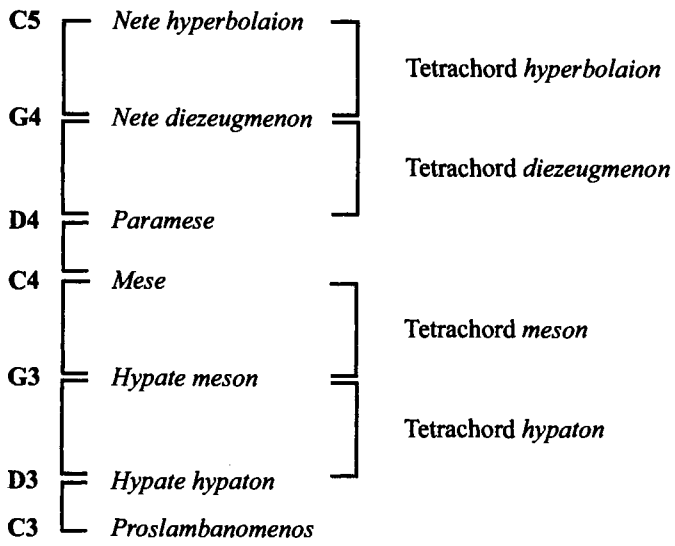

FIGURE I.1 Diagram of the Greater Perfect System of Greek music theory

There were two main theoretical approaches to presenting the elements of the Greater Perfect System. The Pythagorean approach derives from a metaphysics associated with Pythagoras of Samos, who lived during the sixth century B.C. Its hallmarks are a persistent interest in number and the deployment of numerical conceptions in cosmological contexts. In contrast to this, the Aristoxenian approach, associated with the Peripatetic school of the fourth century B.C., places little reliance on number, trusting instead in observation and reason as the means to knowledge about music.

Pythagoras and the Blacksmiths

Nicomachus of Gerasa, a mathematician and harmonist writing around the beginning of the second century A.D., described Pythagoras's discovery of the basic principles of music theory as follows:

> He [Pythagoras] was plunged one day in thought and intense reasoning, to see if he could devise some instrumental aid for the hearing which would be consistent and not prone to error, in the way that sight is assisted by the compasses, the measuring rod and the *dioptra*, and touch by the balance and by the devising of measures; and happening by some heaven-sent chance to walk by a blacksmith's workshop, he heard the hammers beating iron on the anvil and giving out sounds fully concordant in combination with one another, with the exception of one pairing; and he recognized among them the consonance of the octave and those of the fifth and the fourth. He noticed that what lay between the fourth and the fifth was itself discordant, but was essential in filling out the greater of these intervals. Overjoyed at the way his project had come, with god's help, to fulfillment, he ran into the smithy, and through a great variety of experiments he discovered that what stood in direct relation to the difference in the

> sound was the weight of the hammers, not the force of the strikers or the shapes of the hammer-heads or the alteration of the iron which was being beaten. He weighed them accurately, and took away for his own use pieces of metal exactly equal in weight to the hammers.[7]

Nicomachus continues the story by describing how Pythagoras used the weights to conduct further experiments. After suspending the weights from identical strings, Pythagoras plucked pairs of strings and discovered the same concords as he had heard produced by the blacksmiths. He further discovered that the interval of an octave was produced by weights in a 2:1 ratio, that of the fifth by weights in a 3:2 ratio, and that of the fourth by weights in a 4:3 ratio, as shown in figure I.2a. The one discordant interval—that of a second sounded by the middle two weights—was the product of a 9:8 ratio. Additional experimentation showed that the smallest weight sounded a fourth, with the next to smallest weight (8:6 ≡ 4:3) and a fifth with the next to largest (9:6 ≡ 3:2; see fig. I.2b). The octave could thus be viewed as the product of either a fourth plus a fifth (12:9:6; fig. I.2c) or of a fifth plus a fourth (12:8:6; fig. I.2d). According to Nicomachus, Pythagoras also discovered that these ratios held constant throughout the musical domain. It made no difference whether the constituent notes of the intervals were produced through string tension, string division, beating on pots, or blowing on tubes—the relationships between these notes always reduced to the self-same ratios.[8]

The Pythagorean view of music outlined by Nicomachus assumes that music has its origins in the natural world and that the natural world has a basic (if often unseen) order that can be expressed through number. It is thus important to Nicomachus's story that the ringing of the hammers is accidental and not contrived: their harmony has everything to do with the inherent order of the world and almost nothing to do with the blacksmiths. It is also significant that the concordant intervals are immediately apparent to Pythagoras and that he can discern them even amid the discordant clang of the major second. Not only is the basis of musical order natural, but also it is manifest to all who have ears to hear. The association of these intervals with the pounding hammers provides the computational tool for

7. Nicomachus, *Enchiridion*, in Barker, *Greek Musical Writings*, 2: 256–57. The *dioptra* was a rod that was used for the indirect measurement of the height of tall objects.

8. Nicomachus, *Enchiridion*, 258. It should be noted that Nicomachus's story is a complete fiction. There is no evidence whatsoever that Pythagoras ever conducted any empirical research on the acoustic origins of harmonic relationships, with or without blacksmiths. Perhaps more important, the ratios described by Nicomachus simply do not work. To sound the intervals described in the story, the values of the weights must be squared—that is, the weights must be in the ratio 4:1 to produce the octave, 9:4 to produce the fifth, and 16:9 to produce the fourth. The ratios given by Nicomachus only work when used to segment a string into different sounding lengths. One-half the length of a string will sound an octave with the entire length of the string; two-thirds the length of the string will sound a fifth with the entire length of the string; and three-fourths the length of a string will sound a fourth with the entire length of the string. The importance of Nicomachus's story lies in its influence: in the form Boethius gave it in the sixth century, it became the standard account of basic Pythagorean principles for the Middle Ages and Renaissance; see Ancius Manlius Severinus Boethius, *Fundamentals of Music*, ed. Claude V. Palisca, trans. Calvin Bower, Music Theory Translation Series (New Haven, Conn.:Yale University Press, 1989), 17–19. A somewhat different perspective on Nichomachus's story can be found in Mathiesen, *Apollo's Lyre*, 399.

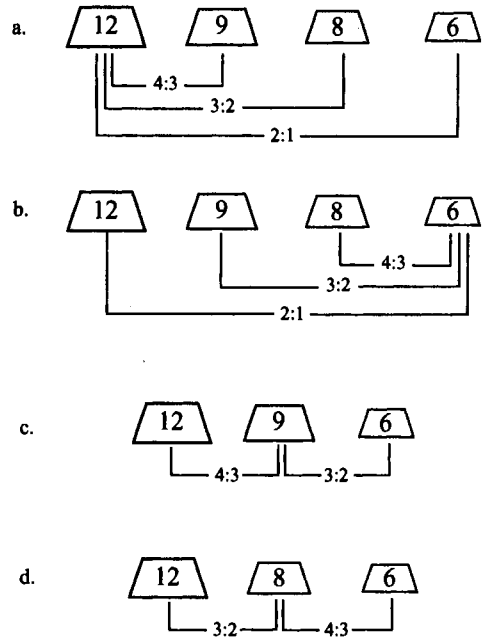

FIGURE I.2 Ratios of the octave, fifth, and fourth from Pythagorean legend

which Pythagoras had searched, for it allowed him to translate the constituent notes of the harmonic intervals into magnitudes—that is, into number.[9] These numbers then provide further proof of the order of nature, for the ratios of the concordant intervals (the octave, fifth, and fourth) are all simple (1:2, 2:3, and 3:4), while the ratio of the discordant second is relatively complex (8:9). Finally, the numbers involved in the ratios of the concords—1, 2, 3, and 4—were also those of the *tetraktys* of the decad, which Pythagoreans regarded as the "fount and root of ever-flowing nature."[10]

The account of musical organization presented by the story of Pythagoras and the blacksmiths is a model of concision. At its core are but three intervals: the octave, fourth, and fifth. The notes that make up these intervals are assigned magnitudes, the correspondence of which yields numerical ratios. These ratios come to stand for the intervals—the ratio 1:2 is the octave—and can also be used to describe relationships between them, leading to a precise account of the composi-

9. The notion of a computational tool I employ here derives from the work of Edwin Hutchins, especially that presented in the second chapter of his *Cognition in the Wild* (Cambridge, Mass.: MIT Press, 1995). Hutchins proposes that various of the navigational tools used by seafarers are in fact computational tools in that they facilitate computation by transforming analog information into digital information. This is exactly what the hammers did for Pythagoras: they transformed the analog information of sound into the digital information of hammer weights (with an intermediary stage occupied by the computational tool of a scale for measuring the weights).

10. Barker, *Greek Musical Writings*, 2: 30. A *tetraktys* is any coordinated group of four items; those of the *tetraktys* of the decad sum to 10, which is the basis of the base-10 number series used by the Greeks.

tion of intervals. The interval between the *Mese* and *Proslambanomenos* of figure 1.1 is an octave, a 1:2 ratio. This octave is made up of a fourth (from *Mese* to *Hypate meson*, a 3:4 ratio) and a fifth (from *Hypate meson* to *Proslambanomenos*, a 2:3 ratio). The fifth is in turn made up of a fourth (from *Hypate meson* to *Hypate hypaton*, another 3:4 ratio) and a tone (from *Hypate hypaton* to *Proslambanomenos*, an 8:9 ratio). With these components in place, a Pythagorean theorist could describe, through number, relationships between any of the fixed notes of the Greater Perfect System and eventually characterize the relationships that obtained among the movable notes of the various genera. The order of the cosmos, which was for Pythagoreans the order of number, thus found sounding expression in the domain of music.

Aristoxenus and Aristotelianism

Although the Pythagorean perspective on musical order was an influential one—for instance, it informed Plato's and Aristotle's writings on music—it was not the only one available to antiquity. The alternative offered by Aristoxenus in his *Elementa harmonica* (most likely written toward the end of the fourth century B.C.) starts with a definition of the science of harmonics:

> It is to be understood as the science which deals with all melody, and inquires how the voice naturally places intervals as it is tensed and relaxed. For we assert that the voice has a natural way of moving, and does not place intervals haphazardly. We try to give these matters demonstrations which conform to the appearances, not in the manner of our predecessors, some of whom used arguments quite extraneous to the subject, dismissing perception as inaccurate and inventing theoretical explanations, and saying that it is in ratios of numbers and relative speeds that the high and the low come about. Their accounts are altogether extraneous, and totally in conflict with the appearances. Others delivered oracular utterances on individual topics, without giving explanations of demonstrations, and without even properly enumerating the perceptual data. We, on the other hand, try to adopt initial principles which are all evident to anyone experienced in music, and to demonstrate what follows from them.[11]

This account of harmonics reveals Aristoxenus to be in conflict not only with the Pythagoreans (the unnamed antagonists who dismiss perception and explain pitch relations through ratios) but also with earlier harmonic theorists whose empirical work he found deficient because they did not explain their methods of proof or properly describe their observations.

Aristoxenus's alternative was to apply Aristotle's intellectual method to music more rigorously than did Aristotle himself.[12] This entailed restricting the account of music to terms and concepts that could properly be said to belong to the domain of music. It excluded descriptions that made recourse to ratios (which are in the domain of number) or to theories about the propagation of physical sound (which

11. Aristoxenus, *Elementa harmonica*, in *Harmonic and Acoustic Theory* (vol. 2 of *Greek Musical Writings*), ed. and trans. Andrew Barker, Cambridge Readings in the Literature of Music (Cambridge: Cambridge University Press, 1989), 149–50.

12. For commentary on Aristoxenus's approach, see Barker, *Greek Musical Writings*, 2: 66–69, 119.

are in the domain of physics). Once the definition of these basic musical concepts was accomplished, an explanation of the entire domain of music could then follow.

Aristoxenus's demonstration proceeds in three steps. First, he identifies two forms of vocal motion, the continuous and the intervallic. In the continuous form, which is associated with speech, the voice appears to traverse space without stopping, until the point of silence. In the intervallic form, which is associated with singing, the voice appears to stand still at specific points, and then pass over some interval of space before coming to rest at another point.[13] The various pitches upon which the voice pauses when singing constitute musical notes; the spaces between these notes are musical intervals.

Aristoxenus's second step is to draw distinctions among the various musical intervals. The first distinction is made with regard to magnitude, which reflects the amount of space between the two notes of the interval. That such a space exists is inferred from the difference between the two pitches that adjoin the interval; the size of the space can be reckoned in terms of how many other notes could be put inside it.[14] The second distinction is made with regard to concord and discord. Aristoxenus identifies the concordant intervals as the fourth, fifth, and octave (and their octave duplications). These are the only concordant intervals he accepts as determined by the intrinsic nature of melody—all other intervals are by definition discordant.[15]

The final step toward assembling the basic definitions and principles of harmonics is the derivation and division of the tone. Aristoxenus defines the tone as the difference between the first two concords (the fourth and the fifth) and explains that it can be divided in half (yielding the semitone), in thirds (yielding the least chromatic diesis), or in fourths (yielding the least enharmonic diesis, which is the smallest interval recognized as melodic).[16] These distinctions allow him to locate various notes within the tetrachords of the different genera and thereby to specify the scalar structure of each.

With these steps, Aristoxenus lays out the basic materials for his account of musical organization. Singing involves a specific way of using the voice that creates musical notes and musical intervals. Intervals can be distinguished according to size and whether they are concordant or discordant. Concordant intervals—the fourth, fifth, and octave—are accepted as axiomatic to melody and thus representative of the basic materials from which the various intervals of the Greater Perfect System can be developed.

13. Aristoxenus, *Elementa harmonica*, 133.

14. Aristoxenus, *Elementa harmonica*, 136.

15. Aristoxenus, *Elementa harmonica*, 139. Aristoxenus further distinguishes between composite and incomposite intervals (p. 137); however, this distinction is not necessary for a basic understanding of his theory.

16. Aristoxenus, *Elementa harmonica*, 140. The different *dieses* apply to the three genera mentioned above: the half-tone is used in the diatonic genus; the third-tone is used in the chromatic genus; and the fourth-tone is used in the enharmonic genus. For further discussion of Aristoxenus's *Elementa harmonica*, see Mathiesen, *Apollo's Lyre*, 319–34.

Greek Theory and Cognitive Structure

As mentioned, the music theories of Pythagoras and Aristoxenus belong to a world remote from our own. Not only did these theorists have to grapple with the most basic of principles, but also the music they would describe is a microtonal one that is primarily concerned with the successive notes of melody rather than the simultaneous notes of harmony. Despite this—or perhaps because of it—Pythagorean and Aristoxenian accounts of musical organization give us a glimpse into how theories are formed and, more important, the cognitive processes that are basic to these theories. In particular, three cognitive processes can be seen at work: categorization, cross-domain mapping, and the use of conceptual models.

CATEGORIZATION Our ability to categorize things is a cognitive process so basic and so pervasive that it can easily escape our notice. Were you to lift your eyes from this book and survey your surroundings, you might well see chairs, lamps, tables, and other books; were you outside, you might see trees, birds, clouds, cars, and bicycles. If you considered the other things that populate your day, you might think of friends and family members, facial expressions and gestures, actions and activities. Your recognition of these things reflects the categories through which we structure our thought: to recognize a book is to identify it as a member of the category *book*; to recognize a tree is to identify it as a member of the category *tree*. Categorization occurs in all sensory modalities and throughout the range of mental activities: we categorize smells and sounds, thoughts and emotions, skin sensations and physical movement.

Categories are not just basic to thought; they also give insight into our thought processes. At one time it was thought that categories reflected the structure of the real world, but recent research has shown that the categories humans use are shaped by their interactions with their environments. Our reasons for developing and employing a given category are part and parcel of the category itself: categories are not only *not* given by nature, but also they are subject to change and modification as our thought unfolds.

Two categories basic to Pythagorean and Aristoxenian music theory are those for consonant or dissonant intervals. Consonant intervals (such as the octave, fifth, and fourth) are fundamental to the conceptualization of Greek music: they mark the stable pitches of the Greater Perfect System and are the source of derivation for all further intervals, both consonant and dissonant. The process of categorization is also exhaustive: any interval that can be conceived belongs to one of these two categories.

This is not to say, however, that consonant and dissonant intervals are given by nature in any simple way, Pythagoras and the blacksmiths notwithstanding.[17] As one

17. I should note here that psychoacousticians distinguish between musical consonance, which is a cultural construct framed relative to a particular set of musical practices, and sensory consonance, which is a consequence of how sound waves are processed by the hearing mechanism (which involves the cochlea and the auditory cortex). Sensory consonance is thus a fairly straightforward product of nature. Although musical consonance has its basis in sensory consonance, there is some freedom in how the sensory data are interpreted.

example, consider the way Aristoxenians and Pythagoreans classified the interval of an octave plus a fourth. Aristoxenians considered the interval a consonance, since it was simply the combination of two smaller consonances. Pythagoreans, in contrast, classified intervals according to the numerical ratio formed by their constituent pitches. As explained by the anonymous (and thoroughly Pythagorean) author of the *Sectio canonis* (fourth century B.C.), consonant intervals are those whose ratios are either multiple (of the form $[mn]:n$) or epimoric (of the form $[n + 1]:n$). Dissonant intervals are those whose ratios are epimeric (of the form $[n + m]:n$, where m is greater than 1 and neither equal to nor a multiple of n).[18] Because the octave plus a fourth had the epimeric ratio 8:3, it was regarded as a dissonance.

Another example of how categories shape our understanding of phenomena is provided by Greek theorists' treatment of thirds and sixths. Although thirds and sixths sound fairly consonant, they were nonetheless categorized as discords. Two factors bear on this classification. First, forming thirds and sixths *requires* using the movable pitches of the Greater Perfect System—at best, a third or a sixth will involve only one of the stable pitches bounding the constituent tetrachords of the system. Thirds and sixths were intervals that necessarily varied in size, and so they were placed among the dissonances. Second, in the classification of intervals Greek theory followed a tradition of dichotomous categories: there was concord, discord, and nothing else. By contrast, neither of these factors played a part in the music theory of early India. Indian music theorists were consequently free to focus on the qualitative aspect of intervals rather than on their correspondence with the fixed notes of a tuning system and to construe intervallic relationships as concordant, discordant, or neutral.[19]

These two examples show that while the categories for consonant and dissonant intervals may be basic to Pythagorean and Aristoxenian theory, just how they are defined reflects the context and goals of categorization: consonance and dissonance are not naturally occurring properties, but ways of constructing an understanding of musical organization.

Of course, there are numerous other categories important for Pythagorean and Aristoxenian music theory, including those for pitches, intervals, and numerical ratios. These categories and others are basic to the sort of systematic account of musical phenomena provided by these theories—indeed, it is simply not possible to have a theory of music, or of anything else, without first having categories.

CROSS-DOMAIN MAPPING Cross-domain mapping is a process through which we structure our understanding of one domain (which is typically unfamiliar or abstract) in terms of another (which is most often familiar and concrete). For example, one way to think about the elusive concepts of electrical conductance is in terms of a hydraulic model: flipping the light switch turns on the *juice*, and elec-

18. *Sectio canonis*, in *Harmonic and Acoustic Theory* (vol. 2 of *Greek Musical Writings*), ed. Andrew Barker, Cambridge Readings in the Literature of Music (Cambridge: Cambridge University Press, 1989), 193.

19. Lewis Rowell, *Music and Musical Thought in Early India*, Chicago Studies in Ethnomusicology (Chicago: University of Chicago Press, 1992), 157–60.

trical current *flows* to the light bulb to light the room. By this means we take what we know about a fairly concrete and familiar source domain—the flow of water and other liquids—and map it onto a rather abstract and unfamiliar target domain: that of electricity. As a wealth of research on analogy and metaphor has shown, the process of mapping structure from one domain to another is basic to human understanding.

One place cross-domain mapping is evident is in the Pythagorean and Aristoxenian construal of interval. Because musical pitches are ephemeral and virtually intangible, relationships between pitches—musical intervals—represent something of a challenge to understanding. One way to meet this challenge is to map structure from the physical world onto music, a process evident in Nicomachus's story of Pythagoras and the blacksmiths. Pythagoras hears harmonious sounds, traces their origins to the blacksmiths' hammers, and then proceeds to conduct various experiments using weights equivalent to those of the hammers. These experiments lead, among other things, to a highly pragmatic objectification of musical pitch, as pitches are translated into physical objects that can be weighed, studied, and preserved. By performing a mapping from the concrete physical domain proper to the blacksmiths' hammers onto the domain of musical sound, Nicomachus's story allows us to structure the latter domain in terms of the former. Of course, musical notes are not physical objects that can be weighed, studied, and preserved—they remain ephemeral and virtually intangible. Nonetheless, we are so accustomed to the mapping between concrete physical objects and musical sound that we sometimes have to be reminded that notes are not enduring physical objects.

Aristoxenus's construal of musical interval involves a slightly different mapping. As we have seen, according to Aristoxenus, when the voice moves intervallically, it appears to stand still at a given place (a musical pitch) and then pass over an interval of space (a musical interval) before coming to rest at another place (another musical pitch). Underlying this account is a mapping from the familiar domain of two-dimensional space onto that of music. This mapping allows us to apply the methodology of measuring space to music. The difference between two linear measures yields a third measure; similarly, the difference between the intervals of a fifth and a fourth yields the interval of a tone. Since linear measures can be easily divided into equal halves or thirds or fourths, the musical tone can be similarly divided, something impossible from the Pythagorean perspective.

On closer inspection, the Pythagorean and Aristoxenian construals of interval are indeed incommensurate. From the Pythagorean perspective, pitches are physical objects, and an interval describes the relationship between these objects. From the Aristoxenian perspective, pitches are breadthless points that simply mark out an expanse of two-dimensional space, and an interval is the expanse itself. Each mapping gives an account of interval, but each leads to a different conceptualization of musical structure. This point can be generalized for music theory as a whole: mapping structure from a nonmusical domain onto music is a way of *creating* musical structure, and different mappings will lead to different accounts of musical structure.

CONCEPTUAL MODELS Both categorization and cross-domain mapping provide the basis for fundamental ontological assertions about musical materials: this

interval *is* a consonance; the pitches of an octave *are* physical objects. They can also lead to conditional statements: *if* the interval is an octave, *then* it is a consonance; *if* a pitch is an object, *then* its properties are measurable. Propositions like this are basic to conceptual models, which act as guides to reasoning and inference. In their simplest form, conceptual models consist of concepts in specified relationships, which pertain to a specific domain of knowledge.

For an example of a conceptual model, let us return to the classification of consonant and dissonant intervals presented in the *Sectio canonis*, according to which all consonant intervals have either multiple or epimoric ratios, and all dissonant intervals have epimeric ratios. This classificatory system relies on a conceptual model that organizes concepts related to interval, concord, discord, and the three classes of ratios. The simple pattern of inference that follows from this model is that if an interval has a multiple or an epimoric ratio, it is a concord; if it has an epimeric ratio, it is a discord.

Integral to this model are the products of categorization and cross-domain mapping. Two types of categories are involved in the model: those pertaining to music (the categories of concord and discord) and those pertaining to number (the multiple, epimoric, and epimeric ratios). Cross-domain mapping correlates the two types of categories by construing musical interval as a relationship between two objects (namely, musical pitches) to which magnitudes (in the form of numbers) can be assigned. Specific classes of ratios can then be used to distinguish between the musical categories.

The robustness of this particular conceptual model is reflected in the debate over the status of the octave plus a fourth that continued into the Middle Ages. In the second century A.D., Ptolemy showed the speciousness of the correlation of concord with multiple or epimoric ratios and argued for a classification of intervals based on empirical evaluation and the postulate that a concord added to a concord produces a concord.[20] Although Ptolemy still used ratios to describe various intervals, they were no longer part of the conceptual model through which intervals were classified into concords and discords. In the sixth century, Boethius presented both the Pythagorean and Ptolemaic models but took no position on which he preferred.[21] After Boethius, when an author wished to invoke the authority of the Pythagorean approach, the Pythagorean model of intervallic classification was cited; when an author wished for a more empirically satisfying classification, the Ptolemaic model was used.[22]

Conceptual models provide the first level of organization for concepts. They are too limited and localized, however, to provide the comprehensiveness we expect from theories of music. Theories achieve this comprehensiveness by integrating

André Barbera, "The Consonant Eleventh and the Expansion of the Musical Tetractys: A Study of Ancient Pythagoreanism," *Journal of Music Theory* 28 (1984): 191–223. Barbera's treatment of Aurelian's *Musica disciplina* on p. 210 is especially illuminating.

clusters of conceptual models. And as we shall see in the following chapters, conceptual models also play a role in categorization and cross-domain mapping. There, as in theories, they provide guides for reasoning and inference about specific and circumscribed domains of knowledge.

COGNITIVE PROCESSES AND MUSIC THEORY Much has been left out of this discussion of theories of music from Greek antiquity, with respect to both the theories themselves and the cognitive processes behind them. To be sure, these theories are of a different order than Swann's musings on Vinteuil's sonata. Nonetheless, the cognitive processes we have seen at work in Pythagorean and Aristoxenian theory are the same processes through which we organize our understanding of the world as a whole. Just how this occurs—how categorization, cross-domain mapping, and the use of conceptual models shape our theories of music and guide our analyses of musical works—is the subject of the remainder of this book.

OVERVIEW

I have divided the chapters that follow into two parts. In the first, I present a detailed overview of research on the three cognitive processes highlighted in this introduction. This overview is itself framed around specific musical topics, such as motivic transformation, text painting, and the ways in which we structure our understanding of a specific musical domain. The research that has been done in cognitive science over the past three decades has been extensive and far ranging, and one of the jobs of this portion of the book is to bring this work to bear on basic issues of musical understanding. Another objective is to show in some detail how these processes relate to one another and how they form the bedrock for our thought about music. The second part of the book moves from this foundation to analytical studies of specific musical issues. These issues include relationships between categorization and musical syntax, the problem of musical ontology, text-music relations, and conceptions of musical form and musical hierarchy.

Chapter 1 begins the overview of research in cognitive science with a close look at processes of categorization. For centuries, writers in the West regarded categories as fixed and immutable, and any variation in categorization was taken as evidence of the failure of the human intellect to deal with the structure of the real world. It took the pioneering work of Eleanor Rosch and others in the 1970s to show that category structure was not as simple as first believed. In particular, some levels of categorization are preferred over others, and some members of a category are regarded as better representing the category than others (a phenomenon known as *graded membership*).

The key to how this research can be applied to music is provided by the musical motive (or, as Proust would have it, the *motif*). Motives are generally reckoned to be one of the basic building blocks of musical works, but they are also a bit slippery: the "same" motive typically assumes a number of diverse shapes over the course of a work. Thinking of a motive as a cognitive category makes it possible to account for its identity, as well as its diversity, and reveals how aspects of categorization are embodied by musical materials. These preliminary applications of categorization to

music also show ways musical materials can be organized over the course of a work and offer an explanation of how it is possible to have musical concepts that are independent of language.

If categorization can be said to be the source of musical concepts, cross-domain mapping is the means by which these concepts are placed in correlation with others. Chapter 2 examines the process of cross-domain mapping in some detail, beginning with the work of cognitive linguists who, in the 1980s, proposed that metaphor was a basic structure of understanding. This proposal gained added weight when it was shown that metaphorical projection (which is one way to accomplish cross-domain mappings) was a general process not restricted to linguistic expressions but grounded in embodied experience.

One example of cross-domain mapping that involves music in a rather immediate way is the technique of text painting, a compositional device that aims to represent in music specific images summoned by the text of a vocal work. Text painting provides a point of departure for the exploration of how cross-domain mapping is manifested in our understanding of music, as it leads to an extension of cross-domain mapping called conceptual blending. In a conceptual blend, elements from two correlated domains are projected into a third, giving rise to a rich set of possibilities for the imagination. As I show in the latter part of chapter 2, text painting can lead to such blends, as can program music.

Chapter 3, which focuses on conceptual models and theories, gets to the heart of the perspective on cognition developed in part I. My point of departure is research by Jeanne Bamberger on children's representations of musical structure. In my analysis of Bamberger's study of one specific eight-year-old boy, I show the part played by categorization and cross-domain mapping in the conceptual models used by this boy to come to terms with a musical environment. I also show how these models are combined to form a theory of music and how this theory changes in response to changes in the task at hand. This close-up glimpse of the structure and role of conceptual models and theories leads, in the middle of the chapter, to a more generalized characterization of these knowledge structures, which I connect with work on similar structures in artificial intelligence, cognitive anthropology, ethnomusicology, and developmental psychology. In the latter part of the chapter, I return to music theory and explore the role of conceptual models and theories (that is, theories framed relative to a cognitive perspective) in analyses by Jean-Philippe Rameau and Heinrich Schenker, two of the best-known music theorists of the last three hundred years.

Although the features of cognitive structure discussed in part I might seem to be relatively detailed, in truth all are associated with relatively high-level cognitive processes. My reason for focusing on this level is quite simple: it allows me to engage in issues of immediate and occasionally central importance to music scholarship and to do so in a way that connects with extensive research in cognitive psychology and cognitive linguistics. Part II explores this possibility in greater depth by considering various problems of musical understanding from the perspective on cognitive structure and music theory developed in part I.

In chapter 4, I turn to the matter of how musical materials are organized within a work—more properly, the problem of musical syntax and, by extension, musical

semiotics. Although semioticians are usually quick to grant that music has a syntax, they are more doubtful about whether its semantic level has any depth. By taking a close look at how composers make use of categories of musical events—in this case, the way Mozart and Beethoven use motives in the opening movements of three string quartets—I am able to provide insight into how musical materials are organized in the service of musical discourse, as well as how features of this organization contribute to meaning construction as a whole.

In chapter 5, I confront a somewhat larger problem—one that may seem irredeemably abstract: the problem of what counts as a work of music. I view this problem, usually called the problem of musical ontology, as one of cultural knowledge and try to show that, as opposed to being hopelessly recondite, the problem is of immediate importance for understanding music. By approaching the entire work of music as a category—a category that includes all the scores, performances, representations, and such that are said to be "of" the piece—I develop a model for the cultural knowledge upon which judgments about musical ontology are made. Determinations of what counts as an instance of a particular musical work are thus one of the ways members of a musical community construct and negotiate their identity. My examples for this chapter are two songs taken from the traditions of popular music and jazz: "I Got Rhythm" and "Bye Bye Blackbird." The latter offers an intriguing case of how the cultural knowledge relative to which determinations of musical ontology are made can become complicated when implicated in the layered discourse structures Mikhail Bakhtin called "double-voiced discourse," and which were extended to African American culture through Henry Louis Gates Jr.'s notion of "Signifyin(g)."

Chapter 6 returns to the analysis of individual musical works by pursuing one of the entailments of text painting noted in chapter 2: under certain circumstances, combinations of words and music, through the process of conceptual blending, create worlds for the imagination well beyond those that spring from words or music alone. Where only a few fairly circumscribed instances of text-music relations were considered in chapter 2, here research on conceptual blending is applied to the whole of five Lieder from the nineteenth century. These analyses offer a way to flesh out the theory of conceptual blending as it applies to music and provide a further perspective on musical syntax. In these songs, we see words and music combining to create rich domains in which the imagination can play, as well as discover how musical syntax shapes our understandings of the words themselves.

The final analytical chapter (chap. 7) turns to music theory itself, specifically to the theories of musical form and hierarchy that go back to the eighteenth and early nineteenth centuries. Accounts of the form a musical work takes, or of how its elements relate to one another, are basic to theorizing about music—indeed, we can see these emerging in the course of M. Swann's ruminations on Vinteuil's sonata—but at times it seems that theorists are talking about quite different things. For instance, there are two common ways to talk about musical form: the first approaches form as deriving from the assembly of relatively static building blocks that are combined to create the finished work; the second approaches form as an emergent property of the work, which becomes manifest only as the music unfolds over time. The first approach yields a view of musical form that is quite static, the second a view rather

more dynamic. Using the analytical framework provided by cross-domain mapping, I discuss the source of these two models for musical form, as well as two models for musical hierarchy, and explore some of the ways these models interacted over the course of the history of music theory.

In the conclusion I return to M. Swann and to his final encounter with Vinteuil's sonata after a year in which it became thoroughly intertwined with his love affair with Odette, the courtesan with whom he had become acquainted around the same time he first encountered the andante. This will provide a frame for a review of the points made in the preceding chapters and an instrumentality for drawing conclusions from the whole.

COGNITIVE STRUCTURE, THEORY, AND ANALYSIS

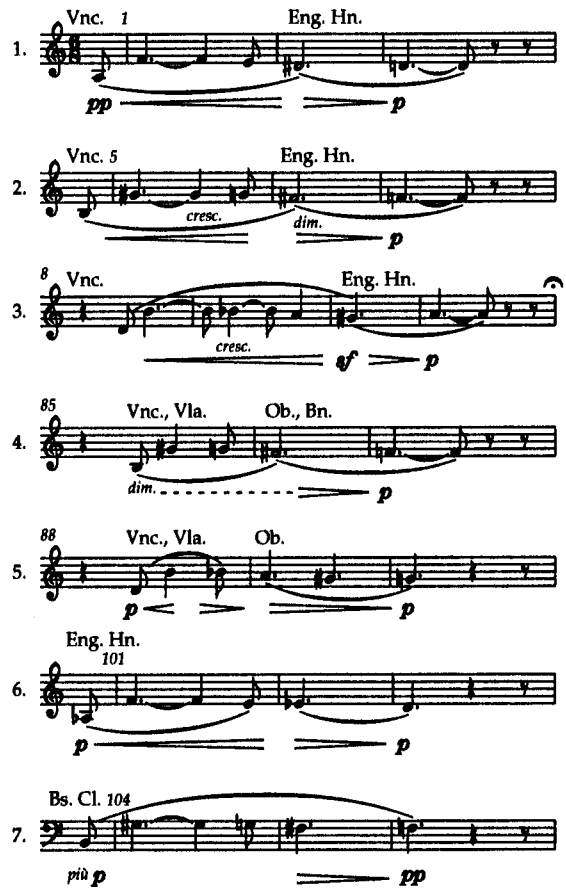
A central claim of this book is that through developing an appreciation of how aspects of cognitive structure shape our understanding of music we can better appreciate the active role of theories of music in that understanding. A further claim is that our analyses of musical phenomena—from the most mundane and localized of accounts to the most abstract and comprehensive—similarly reflect cognitive structure, in that every analysis is based on some sort of theory of music. Musical analyses are in truth dialogues, and not just dialogues between the analyst and an imagined audience: musical analyses are also dialogues between the analyst and some body of theoretical knowledge. Analysis rarely, if ever, simply corroborates a theory: analysis pulls theory and pushes it, extending and changing theory just as it also extends and changes our understanding of musical phenomena.

The analyses I present throughout this book are no different, except that they engage cognitive theory as well as music theory. The intent of the analyses is to show how our understanding of particular musical phenomena can be characterized in terms of specific cognitive processes and structures and thereby connect that understanding to research in cognitive science as a whole. The analyses are not intended as definitive statements about how we can account for such understanding; they are intended to be the initiation of a dialogue with cognitive theory, a dialogue whose purpose is to expand our knowledge of both music and cognition. Analysis is thus a central concern of what follows, but, unlike cognitive structure or theory, I have not treated it as a central topic for investigation. Instead, analysis will be a fundamental tool to explore both and to provide new insight into the conceptual worlds wrought by musical sound.

PART I

ASPECTS OF COGNITIVE STRUCTURE

CHAPTER ONE



CATEGORIZATION

In the opening eleven measures of the prelude to Richard Wagner's *Tristan und Isolde* there are three successive statements of a melodic motive that foreshadows, and then later accompanies, the tragic arc of the opera. Three times this motive emerges from silence, swells through the cellos and English horn, and then sinks back into the stillness from which it came. After the third statement, the motive disappears, then reappears a few long minutes later near the end of the prelude. Here it is stated first in the cellos and violas (and completed by the oboes and bassoons), then in the English horn, and finally in the bass clarinet. After the last of these, the prelude dissolves into the first scene of the opera. All of these statements are shown in example 1.1.

Although our first inclination is to treat these various statements as somehow the same—that is, all can be regarded as "statements of the opening motive from Wagner's *Tristan und Isolde*"—there are actually notable differences among them. There is, of course, the change in the instrumentation used for the statements at the end of the prelude, which contrasts with the distinctive timbral stamp put on the motive in the opening measures. There is a similar diversity in the pitches through which successive statements are given voice, since versions of the motive begin on either A3 (or A♭3), B3 (or B2), or D4. Although there are significant similarities in the rhythmic figuration used for the various statements, there is no pattern of duration and accentuation common to all. And there are also somewhat smaller variations: the first statement begins with a minor sixth instead of the major sixth used by the others, and the fourth is the only one shaped by both a diminuendo and a rallentando.

Despite their differences, these seven melodic fragments sound similar enough to one another to be regarded as functionally equivalent. Such equivalence was important to Wagner's compositional style, for it provided the material foundation for works uninterrupted by conventional forms. By recalling specific motives at crucial points within his musical and dramatic discourse Wagner was able to create a sense of shape and unity that seemed inevitable without being predictable. By the time of *Tristan*, however, such motives were no longer simple building blocks to be assembled and permuted but had become infinitely malleable constructs. Carl Dahlhaus, recognizing both the structural importance and mutability of these

EXAMPLE 1.1 Statements of the opening motive from Richard Wagner's *Tristan und Isolde*, Prelude

motives within the opera, likened them to woven threads that surface only to divide and then disappear from sight.[1]

To understand this music—to make sense of the sonic texture Wagner weaves—requires being able to assimilate these various musical phrases into a single cognitive construct and then recall that construct, often after an hour or more of Wagnerian effusion. Understanding Wagner—or most music, for that matter—requires being able to think in terms of categories of musical events. In this chapter, I explore what recent research into categorization can tell us about this process. First, however, I develop a slightly clearer picture of two basic aspects of understanding music, which will provide the groundwork for applying research on categorization to situations of the sort presented by the opening of Tristan. I do this by reviewing a theory of musical motive developed by one of the many students of Wagner. Not that Wag-

1. Carl Dahlhaus, *Richard Wagner's Music Dramas*, trans. Mary Whitall (Cambridge: Cambridge University Press, 1979), 63.

ner ever actually taught composition. But the influence of his music was enormous, and many lessons were taken away from his operas. Among these were lessons on compositional technique absorbed, refined, and retransmitted—in both treatise and score—by Arnold Schoenberg.

MUSICAL COHERENCE AND MOTIVE

Schoenberg thought of himself first and foremost as a Brahmsian, but, under the influence of Alexander von Zemlinsky, he also found a passion for Wagner. Schoenberg noted that his early works showed the influence of both masters: "In my *Verklärte Nacht* the thematic construction is based on Wagnerian 'model and sequence' above a roving harmony on the one hand, and on Brahms's technique of developing variation—as I call it—on the other."[2] Wagner was also known for his harmonic innovation, although Schoenberg took pains in one of his late essays to show that Brahms's harmonies were every bit as "progressive" as Wagner's.[3] Nonetheless, it was Wagner's harmonic language that was perceived as posing the most formidable challenge to composers of the late nineteenth century, for the free treatment of dissonance integral to this language loosened prevailing conceptions of tonal organization and called into question the "laws of tonality" that had formerly held sway.

From Schoenberg's perspective, Wagner's music presented few dangers for tonality. As Schoenberg had argued in his *Harmonielehre* of 1911, tonality had its origins in acoustic phenomena.[4] But shaping music in conformance with acoustic phenomena was not all there was to musical composition: composition also required insight into how the human mind worked. In an essay that attempted to sort out some of the problems raised by the "emancipation of the dissonance" Schoenberg wrote:

> Tonality's origin is found—and rightly so—in the laws of sound. But there are other laws that music obeys, apart from these and the laws that result from the combination of time and sound: namely, those governing the working of our minds. This latter forces us to find a particular kind of layout for those elements that make for cohesion—and to make them come to the fore, often enough and with enough plasticity—so that in the small amount of time granted us by the flow of the events, we can recognize the [musical] figures, grasp the way they hang together, and comprehend their meaning.[5]

In Schoenberg's view, the laws governing the workings of our minds require the composer to write in such a way that listeners can quickly recognize musical figures and the way they cohere. The listener, upon grasping this coherence, will then be able to comprehend the work.

Key to musical coherence and comprehension were musical motives. According

5. Arnold Schoenberg, "Opinion or Insight? (1926)," in *Style and Idea*, 259.

to Schoenberg, comprehension starts with recognition, and recognition starts with basic musical figures—that is, motives: "*Motive* is at any one time the smallest part of a piece or section of a piece that, despite change and variation, is recognizable as present throughout."[6] More specifically, motives consist of intervals and rhythmic patterns combined to produce a shape or contour that, once recognized, can be easily remembered.[7] A particularly striking illustration of Schoenberg's concept of motive is provided by his analysis of a subordinate theme from the first movement of Brahms's Sextet in B♭ major, Op. 18 (1860), shown in example 1.2.[8]

As Patricia Carpenter and Severine Neff have noted, rhythm is central to Schoenberg's concept of motive.[9] This centrality is clearly evident in his analysis of the Brahms sextet. Each family of motives is distinguished by a specific rhythmic pattern: all of the **a** motives use a ♩·♪♩♩ pattern; and all of the **b** motives use a ♩·♪♩ pattern. (Both patterns, of course, contribute to the marvelous waltz-like feel of the theme.) Contour also serves to distinguish the two families, although here some variation among the different motive forms can be noted. Motives $\mathbf{a}^1$, $\mathbf{a}^2$, and $\mathbf{a}^4$ all preserve the basic contour of motive **a**: the second note of the motive is lower than the first note, and the last note of the motive is higher than the first note. Motive $\mathbf{a}^3$ preserves only a portion of the contour of **a**: although the second note of the motive is lower than the first, so is the last note. In a similar fashion, motives $\mathbf{b}^1$ and $\mathbf{b}^3$ preserve the basic contour of motive **b** (the second note is lower than the first note, and the third note is lower than the second), while $\mathbf{b}^2$ preserves only a portion of the contour of **b** (the second note is lower than the first note, but the third note is higher than the second).

As this example shows, Schoenberg's concept of motive is broad and dynamic: a family of motives can be distinguished simply by rhythmic figure or contour; motive forms can be various and need have only some of their features in common. This conception is rather different from, for example, Heinrich Schenker's or Rudolph

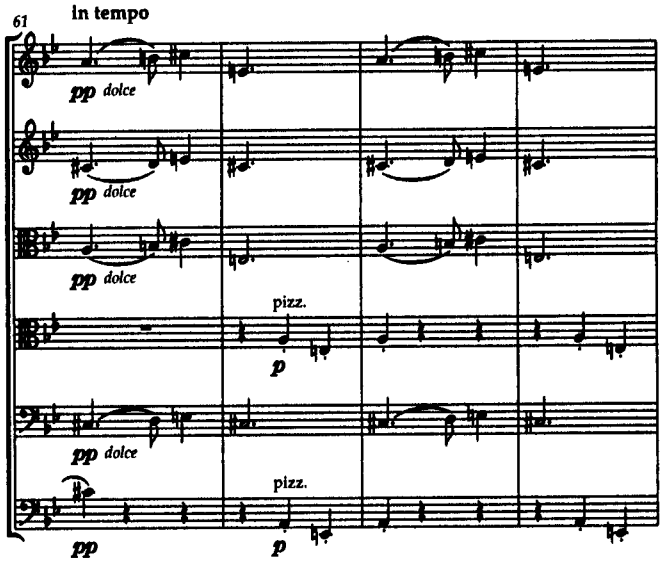
Réti's concept of motive. Both Schenker and Réti regard specific intervallic relationships as constituent of motive; rhythm and contour are regarded as secondary aspects of motivic organization.[10] The difference between Schenker's or Réti's conception of motive and that of Schoenberg lies with Schoenberg's notion of coherence and the role it plays in making music comprehensible. *Coherence* comes about when the various parts that make up a musical entity are connected in such a way that those parts similar to other entities become prominent. The work is most *comprehensible* to the listener when the arrangement of these parts is such that their relationship to each other and to the whole is manifest.[11] Thus there is no need to restrict the distinguishing features of a family of motives to specific intervallic relationships, nor is there a need to require that all motive forms share exactly the same features. All that is required of motive is recognizability and a potential for connection to other motive forms. This potential for connection contributes to coherence, which is, in turn, the basis for comprehensibility.

According to Schoenberg, then, the process of comprehension starts with recognizable bits (motives) that are easily remembered. Motives hang together not simply because their constituent parts are connected to one another but because these connections emphasize similarities to other motives. Coherence thus reflects properties shared by collections of motives; it is not, properly speaking, a property of any one individual motive. Motive forms are *of necessity* variable, for differences between forms reveal most clearly what is typical of the collection of motives as a whole. And, although attention to coherence is important to the composer who wishes to craft a convincing work, the apprehension of coherence is essential to the listener who would make sense of that work.

Many composers, working in the long shadow cast by Ludwig van Beethoven across the nineteenth century, relied on musical motives to make their works coherent. As Edward Cone has noted, the use of thematic transformation as a unifying device became increasingly important for composers of the later nineteenth century, composers whose lengthy movements often embraced stylistic extremes of tempo, meter, texture, and mood.[12] However, the prevalence of the device also poses problems for the listener, for it is often difficult to sort out relationships among various motivic entities. Consider the relationship of derivation, in which later motive forms are derived from earlier motive forms; thus motive $\mathbf{b}^3$ in example 1.2 is said to be derived from motive **b**. As straightforward as this might appear, tracing derivational relationships is rarely a simple task: motive **b** can itself be understood to be derived from one of the motives prevalent in the preliminary subordinate theme heard starting in m. 61 of Brahms's sextet (shown in ex. 1.3), which has the same rhythmic pattern but the reverse contour. Could $\mathbf{b}^3$ then be regarded as derived directly from this earlier motive form, or is it still to be regarded as derived from **b**?



Schubert's *Wanderer Fantasie*, Op. 15 of 1822 presents an even more complicated

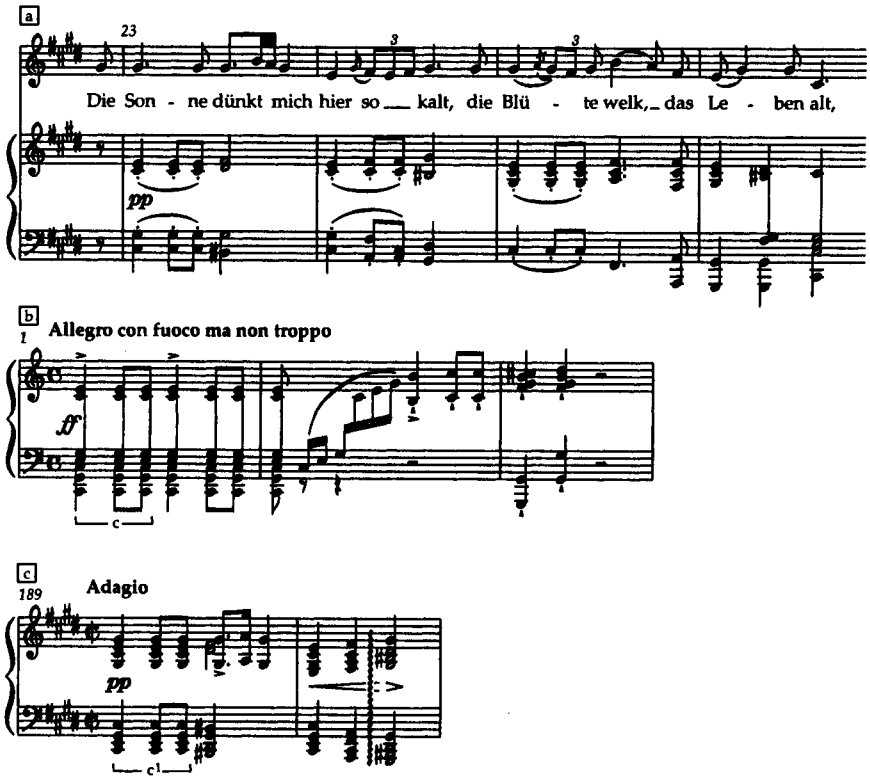
EXAMPLE 1.3 Johannes Brahms, Sextet, Op. 18, first movement, mm. 61–64



situation. The work is based on an arietta from Schubert's 1816 cantata "Der Wanderer," Op. 4/1, D. 489, which is quoted in the work's second movement Adagio; the relevant passage from the cantata appears in example 1.4a. If we have the arietta in mind, we can hear the motivic material of the first movement as derived from the arietta and then presented instrumentally in the subsequent Adagio (the motive from the first movement is labeled c in ex. 1.4b; its use in the Adagio is demonstrated in ex. 1.4c).[13] The temporal order of the process of derivation is thus reversed: c is heard as derived from c^1. If we are coming to the work fresh, we will most likely hear the Adagio as derived from the first movement: c^1 is thus derived from c. Finally, if we know the arietta but have temporarily forgotten it, its reprise in the Adagio, anticipated by the "derived" motives of the first movement, can be a moment of great rhetorical impact: the pianistic musings of the first movement have summoned forth the arietta that now stands before us.

It would seem that, as Cone argued, hearing relationships among motive forms is an ineluctably subjective affair. Following his argument still further, how we hear these relationships is important to how we respond to a work, for, as Schubert's fantasy suggests, it informs our understanding of musical rhetoric. The most dramatic case occurs in a work in which there are multiple derivations of motivic material. In the course of such a work we can lose our sense of how motive forms are connected, until the composer—often unexpectedly—reveals how the materials relate to one another by bringing them into rapprochement. The rhetorical aim of this sort of compositional strategy is what Cone calls "epiphany," and, when successful,

13. While the annotations in ex. 1.4 focus on the distinctive rhythmic figure common to each of the excerpts, it is worth noting that each passage also features a move to the dominant.

EXAMPLE 1.4 Franz Schubert, (a) "Der Wanderer," Op. 4 No. 1, D. 489, mm. 23–26; (b) *Wandererfantasie*, D. 760, mm. 1–3; (c) *Wandererfantasie*, mm. 189–90

it can compel the listener to realize a previously unsuspected—or at most unconfirmed—relationship among diverse motives.[14] Put another way, the strategy that leads to epiphany compels the listener to realize aspects of musical coherence that become evident only over the course of time.

Motives and motivic relationships are important for both the coherence and the rhetoric of music, but understanding the part they play in musical understanding poses some unique challenges. If the recognition of motives is central to the process of comprehending music, it must occur very rapidly. This rapidity has led some to argue for cognitive modules dedicated to the processing of such basic musical materials.[15] The theory of cognitive modularity, an adaptation of faculty psychology first proposed by the philosopher Jerry Fodor, bears some resemblance to the notion of competence discussed briefly in my introduction.[16] The coherence of musical

14. Cone, "On Derivation," 246.

15. See, for example, David Temperley, "Motivic Perception and Modularity," *Music Perception* 13 (1995): 141–69; and Eugene Narmour, *The Analysis and Cognition of Basic Melodic Structures: The Implication-Realization Model* (Chicago: University of Chicago Press, 1990).

16. Jerry A. Fodor, *The Modularity of Mind: An Essay on Faculty Psychology* (Cambridge, Mass.: MIT Press, 1983). According to the theory Fodor proposed in *The Modularity of Mind*, cognitive structure is organized into modules dedicated to specific processing tasks. There are thus modules for such things

materials, however, is an emergent property that is less well explained from a modular perspective since it involves the active comparison and evaluation of a number of motive forms.

One model that can rise to these challenges is offered by recent research into categorization, which has demonstrated that categorization is both extremely rapid and evaluative. From the perspective provided by this research, the coherence of music reflects our ability to group musical events into categories: the **a** and **b** motives of example 1.2 each constitutes a cognitive category, with five members in one category (**a**, $\mathbf{a}^1$, $\mathbf{a}^2$, $\mathbf{a}^3$, and $\mathbf{a}^4$) and four in the other (**b**, $\mathbf{b}^1$, $\mathbf{b}^2$, and $\mathbf{b}^3$). To describe the "laws of the mind" that Schoenberg noted—laws that force the composer to arrange musical elements so that they cohere—is to describe the process of categorization. In what follows, I shall review research on processes of categorization and show how it can be used to account for the role of motive as a starting place for higher-level cognitive processes and for relationships among diverse motive forms.

PROCESSES OF CATEGORIZATION

For the most part, the categories through which we structure our understanding of the world are not cause for a great deal of reflection. To all appearances, these categories are simply givens. A book is a book, a tree is a tree, and any equivocal cases are just a matter of insufficient knowledge. This commonsense view of categorization was the predominant view in philosophy and psychology at least since the time of Plato: categories, because they were constitutive of knowledge, were regarded as stable and universal. It was only in the 1950s that the adequacy of this view began to be called into question, most notably by Ludwig Wittgenstein in his *Philosophical Investigations*. There, in the midst of a discussion of language games, Wittgenstein paused to consider the category of "game" itself and found that category structure was far more complicated than it first appeared.[17] Research carried out in the 1960s and 1970s showed that numerous aspects of the way humans categorize could not be reconciled with the traditional view of categorization, and by the 1980s a new view of categorization had begun to develop. The categories through which humans organize their understanding of the world came to be seen as ways of *having* knowledge, rather than as reflecting what could be known.

The research crucial to developing this new view of categorization focused on two topics. The first concerns the relationship between the process of categorization and the taxonomic structures to which it gives rise. The second concerns the

---

as vision, hearing, language processing, and, presumably, the identification of musical motives. Fodor has since made arguments against modularity; see his recent *The Mind Doesn't Work That Way* (Cambridge, Mass.: MIT Press, 2000).

17. Ludwig Wittgenstein, *Philosophical Investigations*, trans. G. E. M. Anscombe (New York: Macmillan, 1953), 31–32. For summaries of the recent history of research into categorization, see Eleanor Rosch, "Categorization," in *Encyclopedia of Human Behavior*, ed. V. S. Ramachandran (San Diego: Academic Press, 1994), 1: 513–23; and George Lakoff, *Women, Fire, and Dangerous Things: What Categories Reveal about the Mind* (Chicago: University of Chicago Press, 1987), chap. 2.

internal structure of categories—that is, how members of a category relate to one another.

Most of the categories we use in daily life can be organized into hierarchically arranged taxonomies. The cat prowling around my feet is a *calico cat*, a *housecat*, a *feline*, a *mammal*, and a *living organism*. The levels in taxonomies of this sort are related by inclusion: *feline* includes all of the different sorts of *housecats*, a category that includes all of the different sorts of *calico cats*, a category that includes my particular cat. In categorizing things, it seems logical to work from the top of the hierarchy down, moving from the most abstract level to the most concrete. I note first that the thing before me is a living organism, and as I increase my level of discrimination determine exactly what sort of organism it is. In actually categorizing things in the world around us, however, we start neither at the most specific level ("the cat prowling around my feet") nor at the most general (*living organism*) but at a level in between; this level has come to be called the *basic level*. Research on the basic level tells us where, for practical purposes, the process of categorization begins. The first section that follows reviews research on the basic level and shows how it supports Schoenberg's contention that musical comprehension begins at the level of the motive.

It is similarly a commonplace to regard each level of a taxonomy as having clear, fixed boundaries: a creature either is or is not a *housecat*. Categories are thus unchanging anchors of understanding, their structure immutable and constant. The categories we actually *use* in daily life, however, cannot be so neatly characterized. These categories have a somewhat more complicated structure: membership is by degrees; category boundaries are relatively fluid and often hazy; and category structure can change over time. In these cases, the process of categorization is a highly dynamic one, requiring that we evaluate potential category members relative to existing category members which, together, define a standard of typicality. Categories with a variable membership are thus said to show typicality effects. The second section that follows reviews research on categories that illustrate typicality effects and shows how it can be used to model the coherence and variability of motive forms basic to Schoenberg's theory of motive.

Basic-Level Categorization

THE BASIC LEVEL The psychologist Roger Brown was perhaps the first to note that the categories we most frequently employ are not at the lowest level of a taxonomy (and concerned with individuals), nor are they at the highest level (and concerned with broad classes); instead, they are in the middle of a taxonomy, at a level of maximum utility.[18] For instance, we typically call the thing in our purse or pocket a *dime*, even though we might also call it *money* or a *metal object* (names at the superordinate level of the taxonomy), or *my favorite 1956 dime* (which would be at the subordinate level of the taxonomy).

TABLE 1.1. Sample Taxonomies Showing the Basic Level

Superordinate	*Basic Level*	*Subordinates*
Musical instrument	Guitar	Folk guitar
		Classical guitar
	Piano	Grand piano
		Upright piano
Fruit	Apple	Delicious apple
		Mackintosh apple
	Peach	Freestone peach
		Cling peach
Furniture	Table	Kitchen table
		Dining room table
	Lamp	Floor lamp
		Desk lamp

Adapted from Eleanor Rosch et al., "Basic Objects in Natural Categories," *Cognitive Psychology* 8 (1976): 388.

Subsequent research into ethnobotanical systems of classification by Brent Berlin and his associates supported the importance of mid-level classification and gave empirical evidence that this level is psychologically basic: at this level, people name things more readily, languages have simpler names, categories have greater cultural significance, things are remembered more readily, and things are perceived holistically.[19] Research directed specifically at mid-level classification was carried out by Eleanor Rosch and her associates in the early 1970s. In their report, this level was named the *basic level*, a term which has been generally adopted in the literature on categorization.[20] Examples of sample taxonomies showing the basic level are given in Table 1.1.

Rosch and her associates suggested that two contrasting principles influence the taxonomic level at which people prefer to categorize.[21] The first is the *efficiency principle*, according to which people prefer to minimize the number of categories they

must consider in making a categorization. For instance, if you were concerned with *things in my house*, categorizing at the level of *musical instrument* would yield the most efficient category, since the number of contrasting categories at this level (such as *furniture* and *fruit*) is significantly less than at the next level (*guitar, piano, apple, peach, table, lamp*). The second principle is the *informativeness principle*, according to which people tend to maximize the informativeness of their categorizations. Since the most information about any entity is found at the most specific level of a taxonomy, you would use *grand piano* to categorize the thing sitting in the living room. Rosch and her associates proposed that the intermediate level of a taxonomy (in this case, *piano*) optimizes both efficiency and informativeness and is thus the preferred level for basic categorizations. A number of empirical operations converge at the basic level. The basic level is the highest level whose members have similar and recognizable shapes; it is also the most abstract level for which a single mental image can be formed for the category. The basic level is also the highest level at which a person uses similar motor actions for interacting with category members. The basic level is *psychologically* basic: it is the level at which subjects are fastest at identifying category members, the level with the most commonly used labels for category members, the first level named and understood by children, the first level to enter the lexicon of a language, and the level with the shortest primary lexemes.[22]

In her initial work, Rosch assumed that the basic level depended on bundles of perceived-world attributes that formed natural discontinuities and that such attributes were inherent in the real world. She later came to doubt this assumption, and subsequent research has shown that the basic level is variable. It depends on cultural context and level of expertise and on whether one is dealing with categories that occur naturally, as humans interact with their environments, or with categories created for experimental ends.[23] Other research has indicated that the basic level is strongly determined by the ways in which humans interact with their environment and that it is highly dependent on the way humans perceive the spatial configuration of physical parts.[24] In all cases, however, Roger Brown's fundamental insight has held up: the preferred categorization for most of the things we encounter occupies a maximally useful level in the middle of a taxonomy.

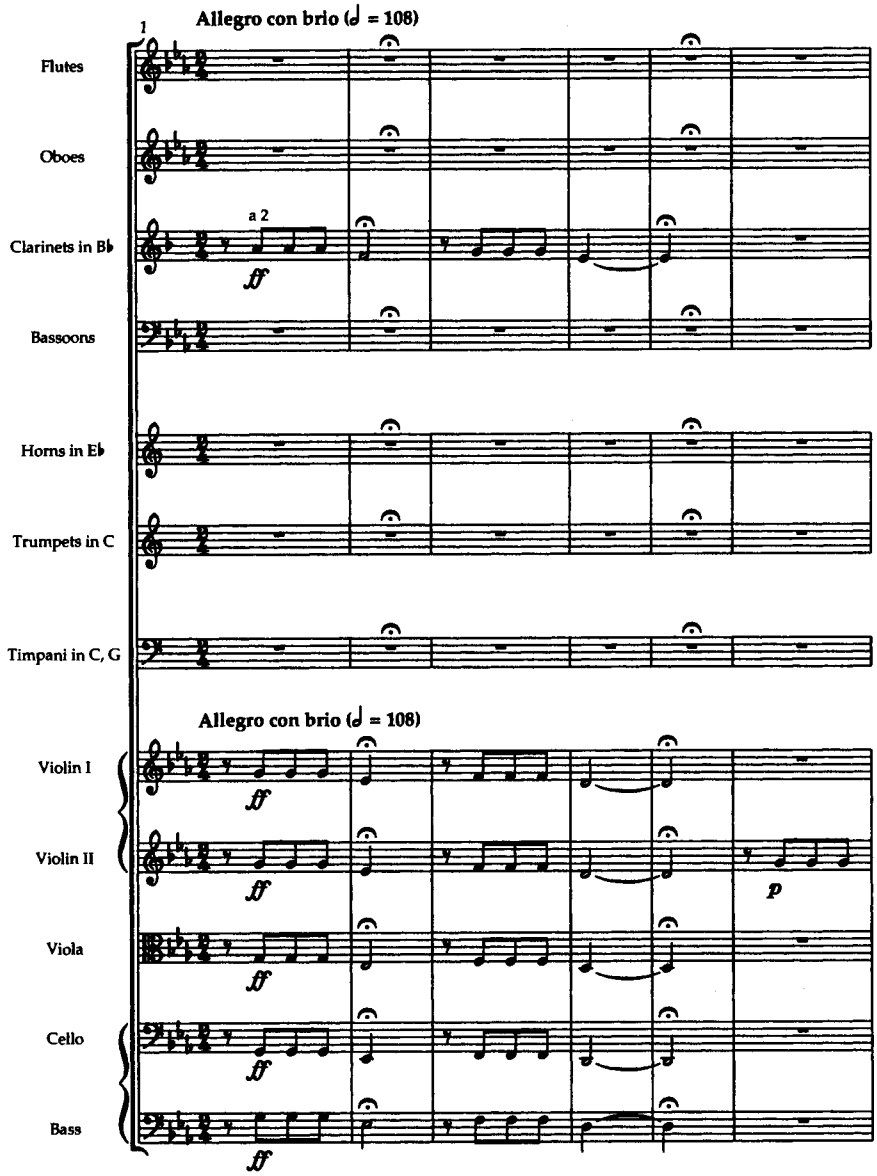
Barsalou, "Deriving Categories to Achieve Goals," *Psychology of Learning and Motivation: Advances in Research and Theory* 27 (1991): 1–64.

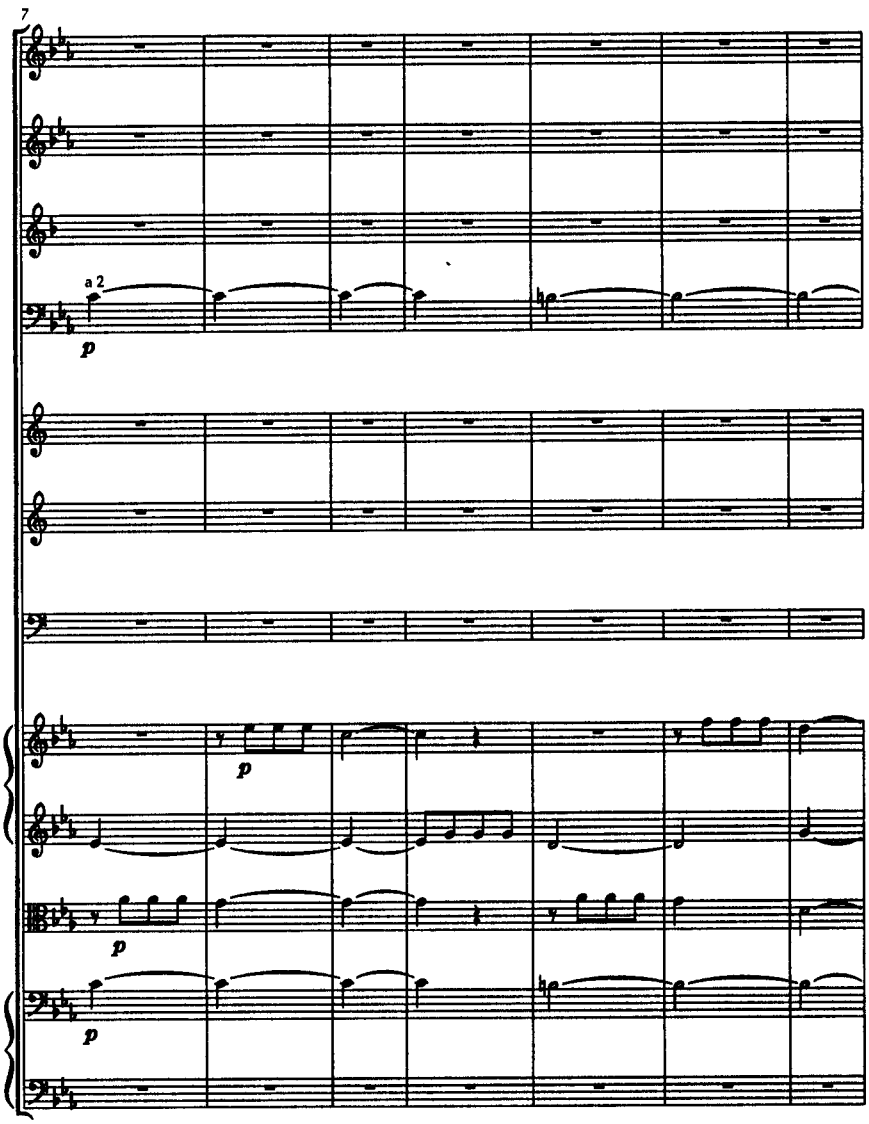
THE BASIC LEVEL AND MUSICAL MOTIVES In a close analogue to what are, perhaps, the most distinctive features of basic-level categories, Schoenberg's theory of musical coherence begins not with individual musical events or with four- or eight-measure phrases, but at a level somewhere in between. Although the motive is the smallest *recognizable* part of a musical work, it is in fact made up of still smaller parts—namely, its constituent pitches, intervals, and durations. The cognitive salience of the motive thus mirrors that of the basic level: in both cases, the focus is on the whole rather than on the parts. Each of Schoenberg's families of motives has a distinctive "shape" or contour that allows us to distinguish it from other motives. Similarly, the basic level is the highest taxonomic level at which category members have similarly perceived overall shapes and the highest level at which a single mental image can reflect the entire category. Finally, motive recognition is not something given directly by perception and can change with expertise: what counts as a motive, just as what counts as the basic level, is not immutable.



To illustrate correspondences between a musical motive and a basic-level category, let us consider the opening of Beethoven's Fifth Symphony, given in example 1.5. The passage is a familiar one, and it illustrates important matters of musical organization that we will later explore in Wagner's *Tristan*.[25] To the extent that we hear a "motive" in these opening gestures, we hear a figure that comprises four notes. The motive has a distinctive "shape" or contour that allows us to distinguish it from other motives (although such are in rather short supply in this particular example). Lastly, there is a certain minimal level of expertise involved in picking out mm. 1–2 and its ilk as "the motive." One can easily imagine an alternate hearing that would take mm. 1–2 and mm. 3–4 as the main thematic material for this section; the ensuing music would then represent a sort of fragmentation of this thematic material, rather than successive statements of various forms of the motive.[26]

SUMMARY Research on basic-level categories provides support for Schoenberg's proposal that musical comprehension begins at the motivic level, for such a level maximizes both efficiency and informativeness. In addition, there appear to be a number of correlations between musical motives and basic-level categories. Both are concerned with wholes, rather than the parts of these wholes; shape (whether as visual property or auditory analogue) is important to both; and both are subject to the influence of expertise. Finally, while entities such as "motives" may be basic to the process of comprehending music, they are actually relatively high-level cognitive constructs (as are basic-level categories). Although such constructs are fundamental to reason (and may even represent an important starting point for conscious

25. That a passage from Beethoven might be used to shed light on Wagner's compositional strategies is not accidental, for Beethoven's compositional style had a profound influence on Wagner. For discussion, see Klaus Kropfinger, *Wagner and Beethoven: Richard Wagner's Reception of Beethoven*, trans. Peter Palmer (Cambridge: Cambridge University Press, 1991); and Thomas S. Grey, *Wagner's Musical Prose: Texts and Contexts* (Cambridge: Cambridge University Press, 1995).



26. It is worth noting, however, the role of the fermatas in suggesting that mm. 1–2 are one entity and mm. 3–4 another, since these add time for the listener to process the musical information presented by Beethoven. This additional time may also play a role in what is considered the most "typical" form of the motive, a topic explored in greater depth later in this chapter.

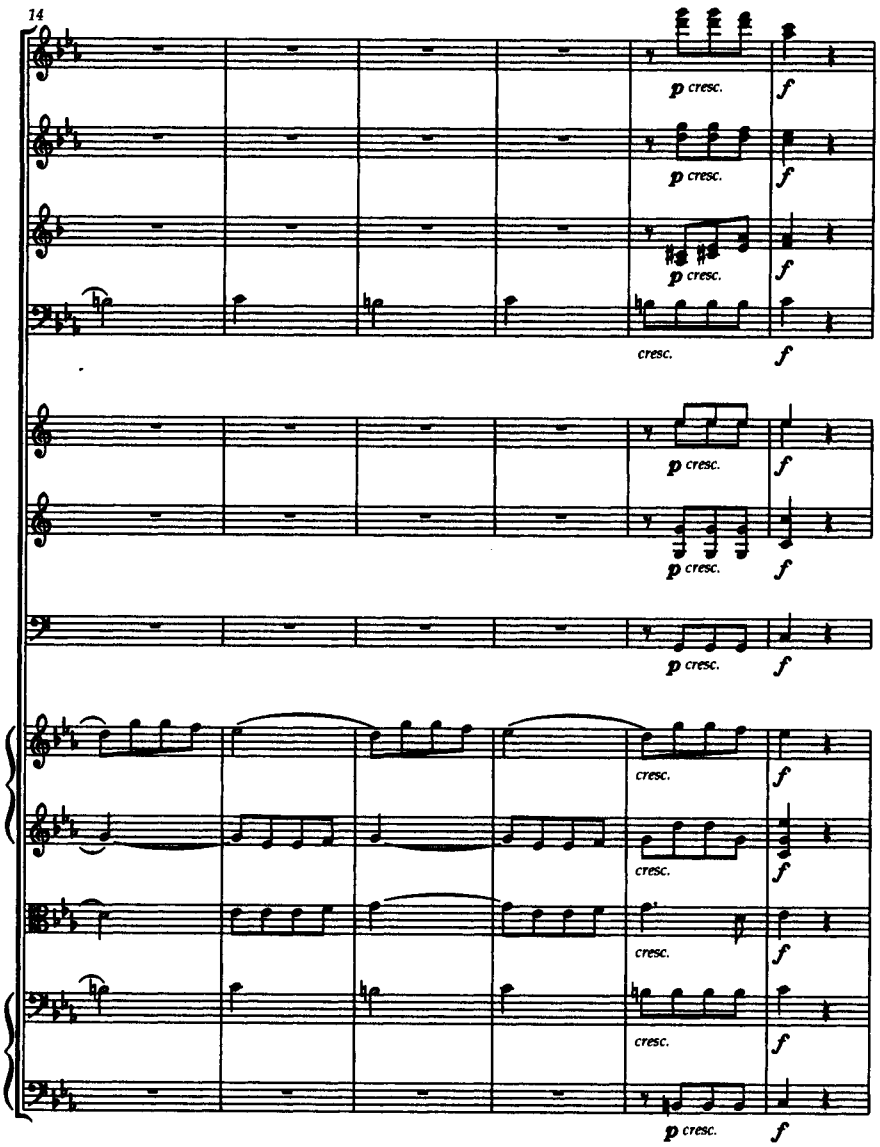
EXAMPLE 1.5 *(continued)*

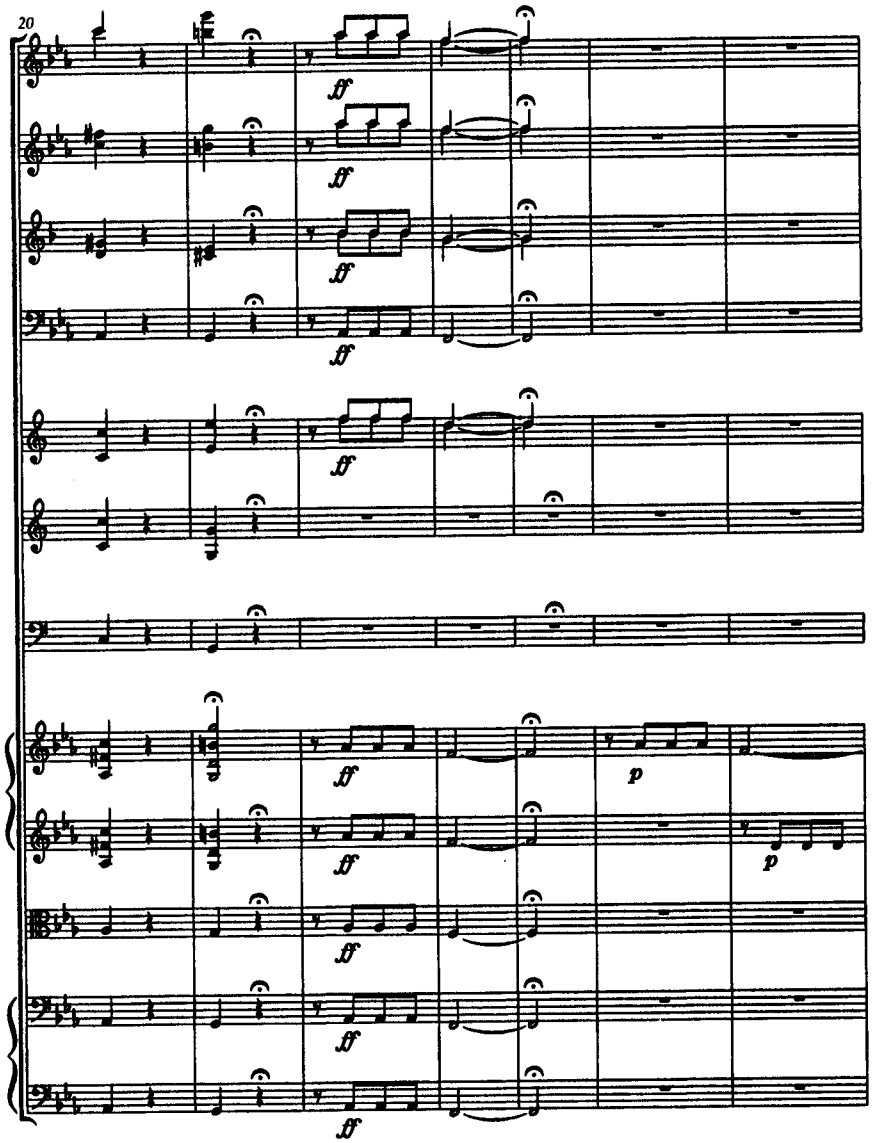


reasoning processes), they are the product of myriad other still more-basic processes that operate below the level of consciousness.

Typicality Effects

GRADED STRUCTURE AND A TYPOLOGY OF CATEGORIES As noted, the variability of motive forms was important to Schoenberg's notion of musical coherence, for this variability tended to emphasize how motive forms were similar to

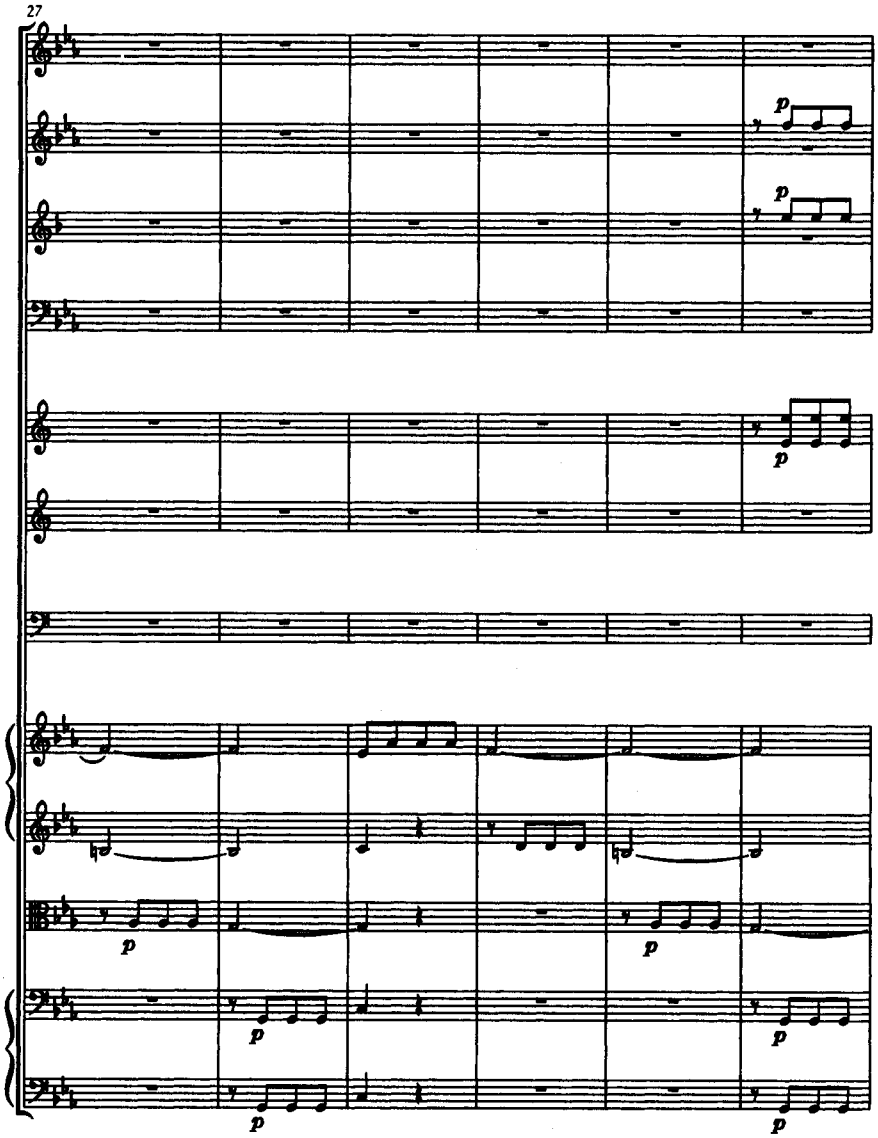
EXAMPLE 1.5 *(continued)*



(continued)

one another. Research on categorization has demonstrated an analogous structure for numerous categories. Membership in these categories is not fixed but is instead graded through a dynamic process in which the attributes of potential category members are compared with the attributes most typically found within the category.

As an example of such a graded structure, consider the category *bird*. Experimental rankings show that subjects view robins and sparrows as the best examples of birds, with

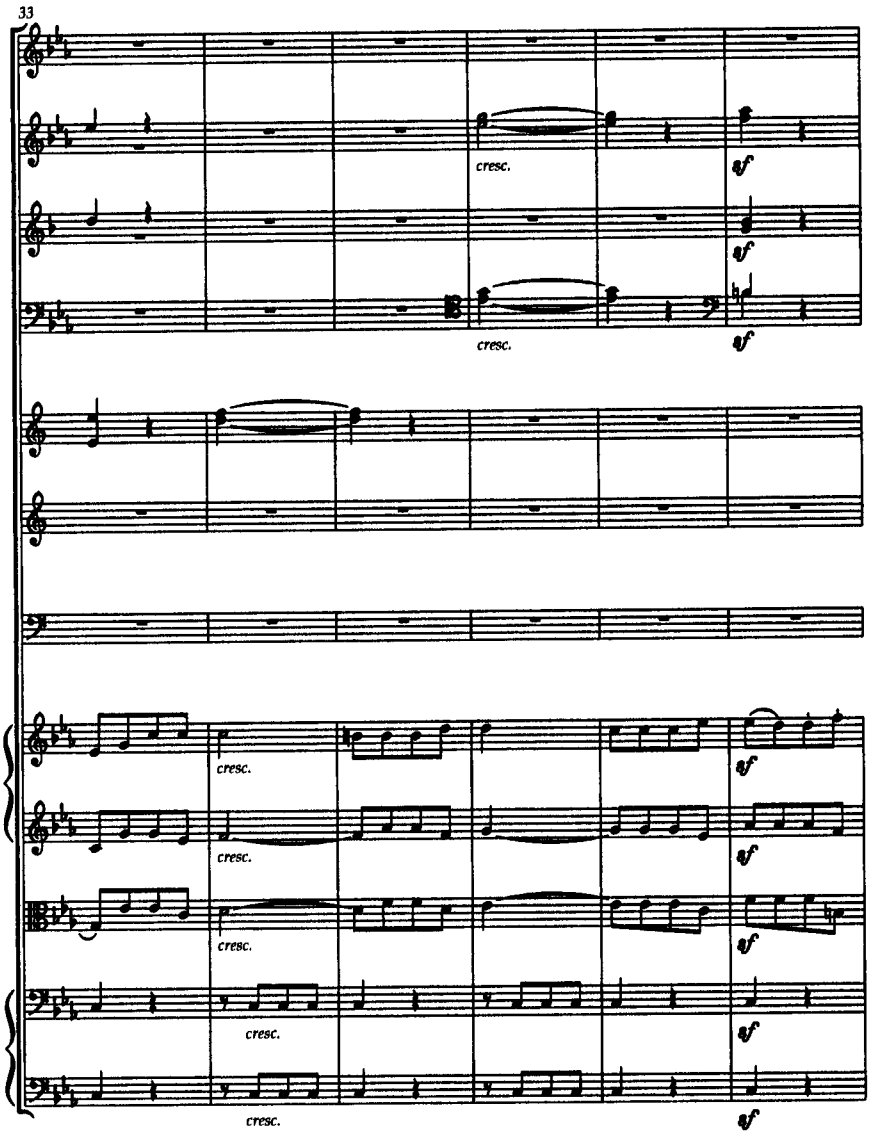


EXAMPLE 1.5 *(continued)*

owls and eagles lower down in the rankings, and ostriches, emus, and penguins among the worst examples.[27] All are considered members of the category *bird*, but some better represent the category than others. Consequently, category structure is graded according to typicality: category members range from the most typical to the least typ-

Moore (New York: Academic Press, 1973), 111–44; idem, "Cognitive Representations of Semantic Categories," *Journal of Experimental Psychology: General* 104 (1975): 192–233.

EXAMPLE 1.5 *(continued)*



(continued)

ical, with the former securely inside the bounds of the category (robins and sparrows) and the latter in danger of being excluded from the category (emus and penguins).

Graded membership has been shown to be pervasive among what are conventionally called *natural* categories, so named based on their emergence from the interaction of humans with their natural environments.[28] For the sake of clarity, and

28. On the pervasiveness of natural categories, see Lawrence W. Barsalou, "The Instability of Graded Structure: Implications for the Nature of Concepts," in *Concepts and Conceptual Development: Ecological and Intellectual Factors in Categorization*, ed. Ulric Neisser (Cambridge: Cambridge University Press, 1987), 102. On the term "natural" applied to certain categories, see Barsalou, *Cognitive Psychology*, chap. 2.

EXAMPLE 1.5 *(continued)*

to avoid certain of the associations summoned by the term "natural," I call this sort of category a Type 1 category.

Type 1 categories stand in contrast to categories in which membership is based on individually necessary and jointly sufficient conditions, such that the members of category x must have features y and z, and if something has features y and z it is a member of category x. Because the conception of categories of this latter sort is often traced backed to the work of Aristotle, such categories have been called *clas-*

sical categories; because the structure of these categories is not typically an analog representation of the natural world, such categories have also been called *artificial*.[29] I call this sort of category a Type 2 category. Most evidence indicates that Type 2 categories simply represent a specialized form of Type 1 categories—take a Type 1 category, specify limits for the category through the imposition of necessary and sufficient conditions for category membership, and you create a Type 2 category.[30]

PROTOTYPE EFFECTS AND FRAME STRUCTURE Eleanor Rosch and Carolyn Mervis, in their pioneering work on Type 1 categories, suggested that such categories were organized around a stable cognitive construct called a *prototype*, which encapsulated the statistically most-prevalent features of members of the category and against which potential category members were compared.[31] Type 1 categories were thus said to exhibit "prototype effects." It is clear, however, that the prototype offers more structure than simply a record of the attributes correlated with a particular category: although *wings* and *beak* are both highly correlated with *bird*, we know that *wings* are used for locomotion and *beaks* are used for eating. Relationships between attributes, as well as the values assigned these attributes, are thus important to the function of the prototype.

As a way of capturing the relational structure inherent in most categories, Lawrence Barsalou proposed using the notion of a *frame*, as developed in artificial intelligence research, to represent category structure.[32] As Barsalou has shown, the

29. On classical or artificial categories, see Edward E. Smith and Douglas L. Medin, *Categories and Concepts* (Cambridge, Mass.: Harvard University Press, 1981), chap. 1; Sharon Lee Armstrong, Lila R. Gleitman, and Henry Gleitman, "What Some Concepts Might Not Be," *Cognition* 13 (1983): 263–308; Lila R. Gleitman, Sharon Lee Armstrong, and Henry Gleitman, "On Doubting the Concept 'Concept'," in *New Trends in Conceptual Representation: Challenges to Piaget's Theory?*, ed. Ellin Kofsky Scholnick (Hillsdale, N.J.: Erlbaum Associates, 1983), 87–110; Lakoff, *Women, Fire, and Dangerous Things*, chap. 2; Barsalou, *Cognitive Psychology*, chap. 2.

30. Although the typology of categories I introduce here places a burden on those familiar with the traditional labels, it has two advantages. First, it avoids the complications caused if "natural" is interpreted as "given by nature"; while Type 1 categories result from humans' interactions with their environment, they are not given by that environment in any simple way. Second, the typology classifies categories on the basis of their internal structure. This is especially useful when considering research on categorization, since "artificial" categories (such as *things to pack in a small suitcase*, as discussed by Barsalou in his "Deriving Categories to Achieve Goals") often have the same basic structure as do "natural" categories (such as *bird*).

The exploration and implementation of frame structures in work on artificial intelligence is demonstrated in Marvin Minsky, "A Framework for Representing Knowledge," in *The Psychology of Computer Vision*, ed. Patrick Henry Winston (New York: McGraw-Hill, 1975), 211–77; Marvin Minsky, *The Society of Mind* (New York: Simon and Schuster, 1985); and Douglas B. Lenat and R. V. Guha, *Building Large*

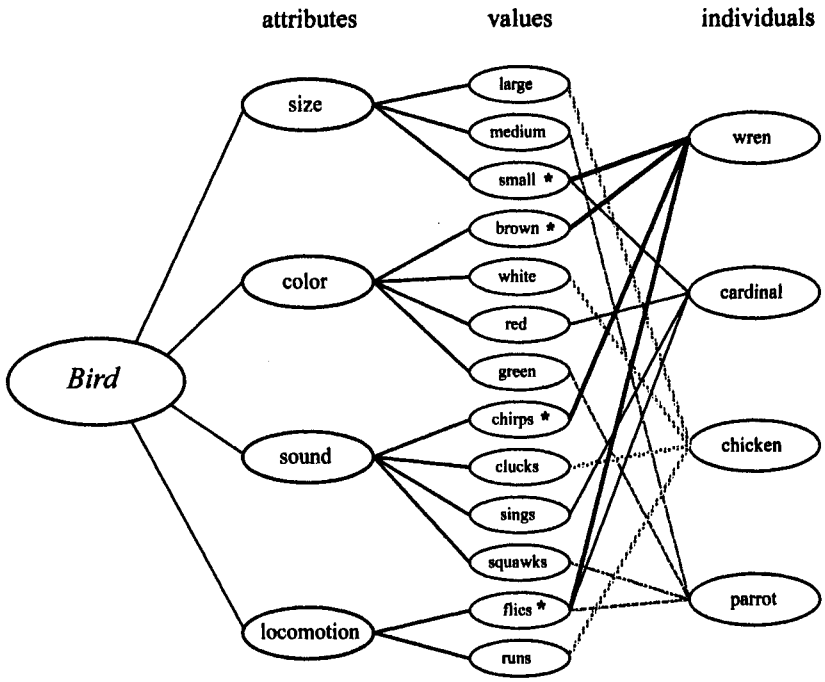

FIGURE 1.1 A partial frame for the category *bird* (asterisks indicate the values of the prototype that are stored in memory)

basic structure of a Type 1 category can be conceived of as a relational network made up of relatively abstract attributes, to which concrete values are assigned by each individual. For the category *bird*, for example, attributes might include *size*, *color*, *sound*, and *locomotion*, as shown in figure 1.1. For the attribute *size*, values might include *large*, *medium*, and *small*. Each member of the category exemplifies specific values for each of the attributes: a wren is *small*, *brown*, *chirps*, and *flies*; a chicken is *large*, *white*, *clucks*, and (for the most part) *runs*.

Of course, individuals with none of the attributes of the category would be excluded from it. Prototype effects arise from the comparison of the values represented by individuals with the values of the prototype for the category that are stored in memory (indicated with asterisks in fig. 1.1). If the values of the prototype for *bird* were *small*, *brown*, *chirps*, and *flies*, then a wren would be most typical of the category, a male cardinal (*small*, *red*, *sings*, *flies*) would be somewhat less typical, and a chicken (*large*, *white*, *clucks*, *runs*) would be least typical.

APPLICATIONS TO MUSIC Returning to the opening of the Fifth Symphony, we can see that, as suggested by Schoenberg's account of motive, there are a

---

Knowledge-Based Systems: Representation and Inference in the Cyc Project (Reading, Mass.: Addison Wesley, 1989).

number of different forms that Beethoven's motive takes in the first thirty-seven measures of the movement, and these vary with respect to contour, dynamics, and orchestration. Approached from the perspective of categorization, each motive form can be viewed as a member of the category *motive forms from the opening of Beethoven's Fifth Symphony*.[33] Attributes of this category might include things such as *orchestration*, *dynamic*, and *melodic profile*. In the following discussion, I show how these three attributes could play a part in determining membership in the category *motive forms from the opening of Beethoven's Fifth Symphony*; however, I should emphasize that, for present purposes, what is of concern is less the specific attributes and more the model of categorization they illustrate.

To characterize melodic profile, it is useful to account for intervallic relationships among motive forms in terms of diatonic intervals. That is, within the diatonic context of the movement, the descending third from G4 to E♭4 can be reckoned to be equivalent to the descending third from F4 to D4, even though the former is major and the latter is minor. Here I represent a descending third with **–3**, an ascending third with **+3**, and a unison with a **u**. With this in mind, the attribute-values for the first two statements of the motive would be *tutti*, *fortissimo*, and *u*, *u*, *–3*.

Although *rhythmic profile* is an equally important attribute of the category, it is not as useful for distinguishing among the various motive forms found in the opening measures shown in example 1.5. All the motive forms found there would assign the same value to this attribute: *short*, *short*, *short*, *long* (where *short* is equivalent to an eighth note and *long* varies between a quarter note and three tied half notes). In consequence, the attribute *rhythmic profile* is relatively transparent in the opening of the symphony, as is the attribute *played by instruments;* both will be omitted from the following account of category structure.

Figure 1.2 presents a frame diagram for the category *motive forms from the opening of Beethoven's Fifth Symphony;* it shows the values that thirteen instances of the motive assign to the attributes *orchestration*, *dynamic*, and *diatonic melodic profile*. The result is a rather dense diagram (owing in part to the number of individuals categorized), which gives an intriguing and rather counterintuitive picture of what is most typical of the various motive forms gathered there. Based on the evidence provided by these individuals, the most typical form of the motive would assign the values *solo*, *piano*, and *u*, *u*, *–3* to the relevant attributes. Although the last value is what we might expect, the first two are not: it is difficult to think of Beethoven's theme as anything other than *tutti* and *fortissimo*.

Were we to take into account a further fifteen instances of the motive, the profile

33. What follows is by no means the first attempt to use research on categorization to model variation among musical elements; notable are the studies of Robert L. Welker, "Abstraction of Themes from Melodic Variations," *Journal of Experimental Psychology: Human Perception and Performance* 8 (1982): 435–47; and Lucy Pollard-Gott, "Emergence of Thematic Concepts in Repeated Listening to Music," *Cognitive Psychology* 15 (1983): 66–94. The following extends this work by taking advantage of research done since the early 1980s and by endeavoring to give a more thorough account of the process of categorizing musical events. Mention should also be made of Robert O. Gjerdingen's discussion of typicality in *A Classic Turn of Phrase: Music and the Psychology of Convention*, Studies in the Criticism and Theory of Music (Philadelphia: University of Pennsylvania Press, 1988), 93–94, which anticipates many of the points made here.

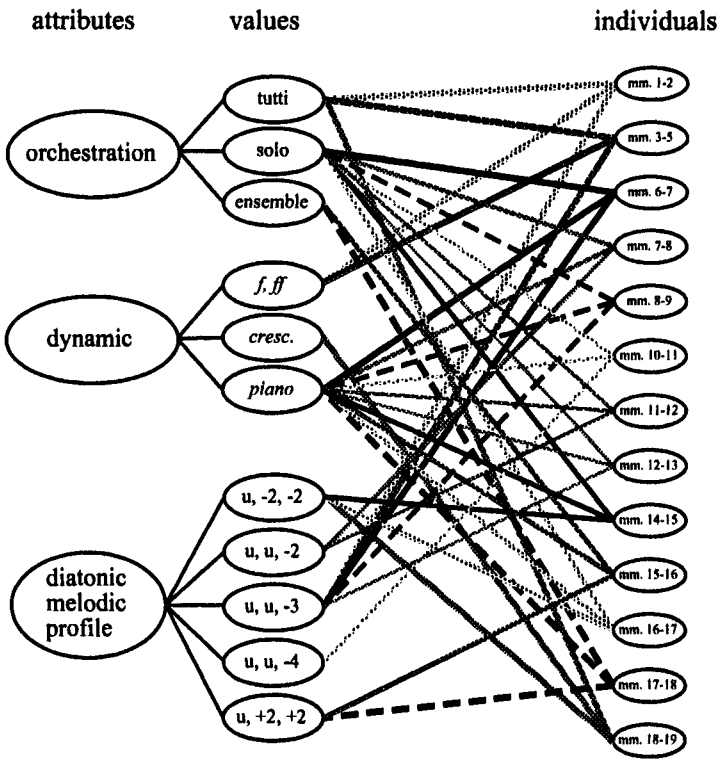

FIGURE 1.2 Diagram of the category structure for the category *motive forms from the opening of Beethoven's Fifth Symphony*, mm. 1–21

of typicality would be skewed even further away from what we might expect (this is shown in fig. 1.3, where the frame diagram has been rearranged somewhat in the interests of legibility). The difference between the evidence provided by figures 1.2 and 1.3 and our usual recollection of how Beethoven's theme sounds is due in part to a limitation of frame diagrams: they are essentially statistical representations of the most *common* values assigned attributes by individuals. They may not represent the most *important* attribute values for a given category, however.

BEYOND THE PROTOTYPE: CONCEPTUAL MODELS Recent empirical work on categorization has shown that category structure is even more variable than had been assumed by the researchers who first proposed the prototype theory of category structure.[34] In most Type 1 categories, some attributes are more important to category structure than others. As a result, some of the statistically most prevalent features of members of a category may be disregarded in formulating the

Barsalou, "Intraconcept Similarity and Its Implications for Interconcept Similarity," in *Similarity and Analogical Reasoning*, ed. S. Vosniadou and A. Ortony (Cambridge: Cambridge University Press, 1989), 76–121.

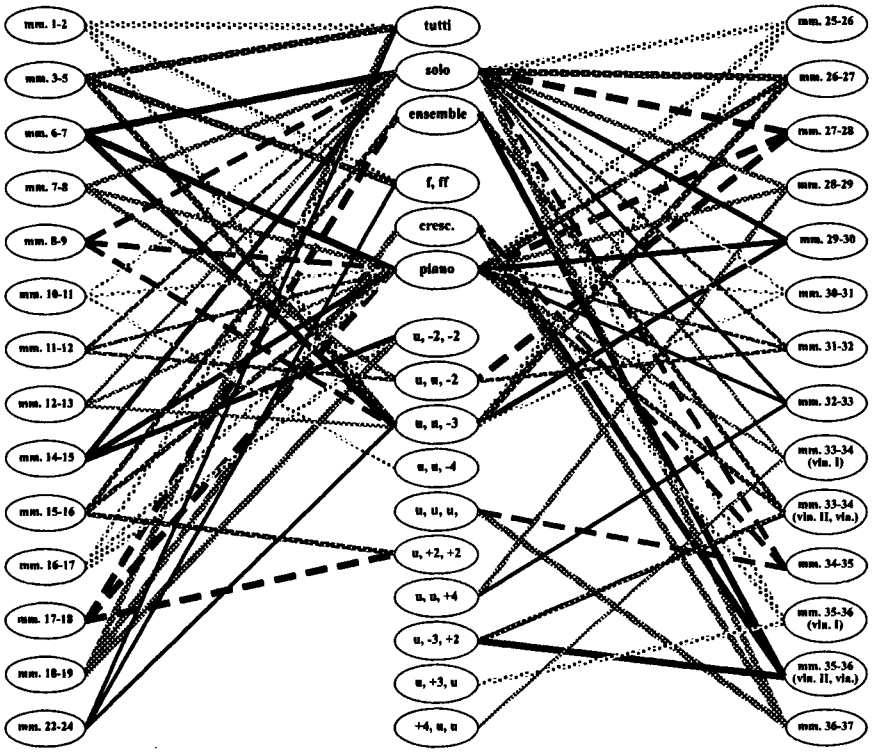

FIGURE 1.3 Diagram of the category structure for the category *motive forms from the opening of Beethoven's Fifth Symphony*, mm. 1–37

prototype. For example, attributes such as *natural environment* and *means of locomotion* have a strong influence on how we categorize whales, leading us to disregard such taxonomic attributes as *mode of respiration* and *means of reproduction*. In consequence, a whale seems closer to a prototypical fish than to a prototypical mammal, despite its proper Linnean categorization.[35] Research has also shown that judgments of typicality change over time, even when no new individuals are categorized. It appears that, rather than constituting a stable cognitive entity, the prototype for a category is actually fluid and variable and it changes with the circumstances of categorization.

An alternative view of category structure suggests that categories are organized around *conceptual models*. In brief, conceptual models consist of concepts in specified relationships; each model pertains to a specific domain of knowledge. Such models are central to reasoning and inference, and they will be discussed in greater detail in chapter 3; in what follows, the emphasis is on the role conceptual models play in categorization, rather than on the structure of such models. With regard to catego-

35. For a discussion of some of the factors involved in this particular categorization, see John Dupré, "Are Whales Fish?" in *Folkbiology*, ed. Douglas L. Medin and Scott Atran (Cambridge, Mass.: MIT Press, 1999), 461–76.

rization, the primary function of the conceptual model is to supply a guide for reasoning about accepted and potential members of the category. This is accomplished through a simplified representation of category structure that incorporates knowledge about what values are most typical for a select group of attributes for the given category. These attributes are selected according to the goals of categorization, which are themselves informed by more global conceptual models applicable to a broad range of categorization tasks.[36] The conceptual model for a given category thus reflects information of the sort summarized in frame diagrams but conditioned by knowledge about the overall goals of categorization.

As a means of developing a preliminary understanding of the concepts and relationships constituent of a conceptual model for a category, let us return once more to the opening of Beethoven's symphony and consider a conceptual model for the category *motive forms from the opening of Beethoven's Fifth Symphony*. The model, diagrammed in figure 1.4, consists of four correlated conceptual elements, characterized as the things necessary for a melodic fragment to count as an instance of the motive:

- the rhythmic pattern 
- a statement by the full orchestra
- a fortissimo dynamic
- an intervallic pattern consisting of three repeated notes followed by a descending diatonic third[37]

These elements give priority to select attributes of the motive (rhythmic pattern, orchestration, dynamics, and intervallic profile) and assign default values to these attributes—that is, they define what counts as a "typical" member of the category. This network of attributes and values then provides a guide for categorizing the various versions of the motive that occur in the opening measures. Accordingly, versions of the motive such as those of mm. 1–2 and mm. 22–24 (which instantiate all aspects of the conceptual model) would be judged most typical of the category; motive forms such as those of mm. 6–7 and mm. 29–30 (which instantiate only two aspects of the conceptual model) would be less typical; and motive forms such as those of mm. 7–8 and mm. 35–36 (which instantiate only the rhythmic aspect of the conceptual model) would be least typical of the category.

What, then, of the evidence provided by figure 1.3? That is, what can one make of the lack of correlation between the conceptual model and the individual category members, since most of these would be reckoned to be less typical members according to the conceptual model for the category? The answer to this question requires delving a bit deeper into the way conceptual models both reflect and shape our understanding of music.

36. Barsalou, "Deriving Categories to Achieve Goals"; Lawrence W. Barsalou, Wenchi Yeh, Barbara J. Luka, Karen L. Olseth, Kelly S. Mix, and Ling-Ling Wu, "Concepts and Meaning," in *Chicago Linguistics Society 29: Papers from the Parasession on the Correspondence of Conceptual, Semantic, and Grammatical Representations*, ed. Katharine Beals, Gina Cooke, David Kathman, Sotaro Kita, Karl-Erik McCullough, and David Testen (Chicago: University of Chicago, Chicago Linguistics Society, 1993), 23–61.

37. I should emphasize that the conceptual models I describe here are by no means the simplest elements of conceptual structure. Each conceptual cluster of the present model, for instance, could be represented by a still smaller conceptual model correlating the concepts that make up the cluster.

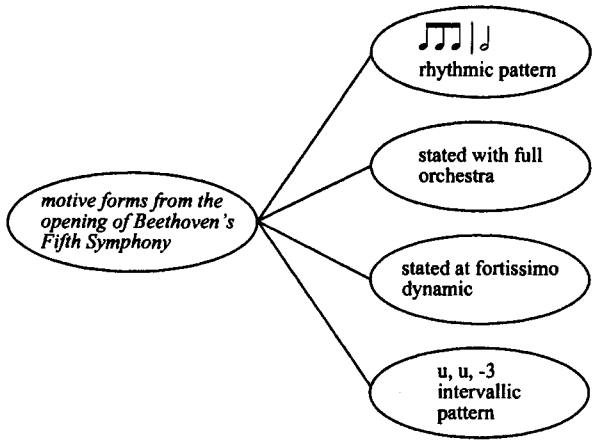

FIGURE 1.4 Conceptual model for the category *motive forms from the opening of Beethoven's Fifth Symphony*

The conceptual model shown in figure 1.4 gives undeniable priority to the statements of the motive that open the movement. The preference given the first statements of musical materials we encounter is not absolute—there are, of course, works in which the principal materials emerge only gradually—but it does reflect the fact that we must process musical materials in time and that it is often the case that significance accrues to the first events in any psychological process. Note that Beethoven departs from his opening materials only gradually; in particular, divergences from the intervallic pattern of the motive (the aspect of the typicality shown by fig. 1.3 that best matches the proposed conceptual model) occur somewhat later in the opening measures and correlate with the compositional strategies of development and transition.[38] The initial statements of the motive thus represent anchor points for the process of elaboration that Beethoven undertakes: the variations evident in figure 1.3 are variations *on* the musical materials summarized in the conceptual model of figure 1.4.

The conceptual model of figure 1.4 is also informed by our ideas about musical themes: that is, such themes should be strongly and clearly stated at privileged points within a movement (such as the beginning of the movement or after a change of key or tempo), after which they may be modified or embellished in conformance with compositional strategies. Our local model for the motive of Beethoven's symphony is thus shaped by a global model of what constitutes an appropriate musical theme. Such global models are developed through abstraction from any number of local models, and, perhaps more important, they are taken from the broader base of knowledge that constitutes culture.[39] For instance, in the case of Beethoven's symphony, the relevant global model for a musical theme reflects the influence of nineteenth-century German and Austrian musical culture and, in particular, the efforts

38. Relationships between processes of categorization and compositional strategy are developed more fully in chap. 4.

39. This perspective on culture is explored more fully in chaps. 3 and 5.

of the nineteenth-century critic and theorist A. B. Marx and others to come to terms with Beethoven's compositional style.[40]

Our global model of what counts as a theme (which applies to any number of works by any number of composers) is thus in rapport with the local models through which we organize our understanding of specific musical works. Without a global model, it can be difficult to decide what aspects of a phenomenon are relevant for categorization. Without local models, there is no way to anchor global models to specific phenomena.

It should be emphasized that the conceptual model sketched here and diagrammed in figure 1.4 represents limited features of a network of interrelated propositions that might be used to guide reasoning about how motive forms in the opening of Beethoven's symphony relate to one another. The model does not represent, in a simple way, what someone "has in mind" when confronting this music. The simplicity of the model (which reflects in part the global models relative to which it is framed) contributes to its efficiency. It is specific enough to allow for clear distinctions between the motive of the opening measures and other thematic materials in the symphony (such as the new theme that enters in m. 63). It is general enough, however, to accommodate the wide range of different forms the opening motive takes. The model also reflects our intuition that there is just one main form of the opening motive, despite evidence to the contrary. Intuitions such as this contribute to the plausibility of Type 2 categories, with their crisp boundaries and clear definitions. Features of the conceptual model for a given category will often be transformed into the necessary and sufficient conditions characteristic of Type 2 categories: take a Type 1 category and specify limits for it by regarding the constituent elements of the conceptual model relative to which it is structured as necessary and sufficient conditions for category membership, and you create a Type 2 category. In descriptions of music, this process yields "textbook" definitions of the sort that often lead to considerable debate among music theorists. Although such debates appear to be about music, they are in fact about how to define the categories through which we organize our understanding of music.

SUMMARY: TYPICALITY EFFECTS AND MUSICAL MOTIVE Categories that show typicality effects offer a way to model both the coherence and the variability of motive forms basic to Schoenberg's theory of motive. The property of coherence is analogous to the shared attributes of category members—that is, our

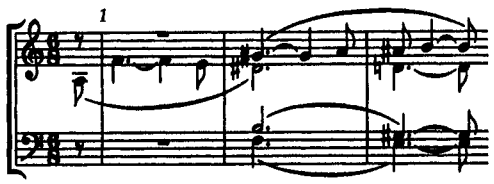
40. Marx's is perhaps the most important nineteenth-century voice within the tradition of analyzing the thematic aspects of Beethoven's music. Although Marx did not restrict himself to a definition of "theme" as such, preferring a broader and more organic account of musical organization, he did offer the notion of the *Satz*. Formed from motives, the Satz is a complete self-sufficient musical idea and represents the first coherent unit of musical organization. See Adolph Bernhard Marx, *Musical Form in the Age of Beethoven: Selected Writings on Theory and Method*, ed. and trans. Scott G. Burnham, Cambridge Studies in Music Theory and Analysis, 12 (Cambridge: Cambridge University Press, 1997), 68. The Satz is roughly comparable to Schoenberg's notion of a *Grundgestalt*, as discussed in Schoenberg, *The Musical Idea*, 169. It is no accident, of course, that Marx's formal theories reflect his efforts to make explicit Beethoven's compositional strategies. That is, to the extent that our notion of what constitutes a theme resonates with Marx's definition, that notion is informed by works such as the Fifth Symphony. Further discussion of Marx's notion of a motive is taken up in chap. 7.

sense that a collection of things coheres as a category reflects the attributes shared by those things. The variability Schoenberg noted is analogous to the variation among members of a Type 1 category. Just as certain motive forms are taken as the source for the derivation of further motive forms, so certain category members will be regarded as more typical of the category than others. While typicality effects reflect, to a certain extent, statistical invariances among the attribute-values demonstrated by category members, they are also a function of the goals of categorization. These goals shape the category's conceptual model, which represents what is regarded as most typical of the category and which also provides a guide for reasoning and inference about potential category members.

An important difference between collections of musical motives and cognitive categories is that the former must be processed under the temporal constraints of musical performance. Under most circumstances, these constraints will inform the conceptual model for a category of motive forms, with priority given to those forms that occur early in a work. As the example of Schubert's *Wanderer Fantasie* suggests, however, other factors may cause our concept of what constitutes the central motive of a work to change as the piece unfolds.

CATEGORIZATION AND WAGNERIAN LEITMOTIVEN

Wagner's Leidensmotiv



Approaching the seven statements of the opening motive from *Tristan und Isolde* given in example 1.1 as a cognitive category offers a way to explain why it is that we consider them "the same" even when they are manifestly different, and it gives some insight into their role as a point of entry into Wagner's sonic fantasy. Knowing something about the structure of cognitive categories also gives us a way to glimpse features of Wagner's compositional strategy, which both exploits and challenges our ability to categorize.

Before we explore the motive as a category, let us first situate the motive in its original context. As shown in example 1.6, the motive is accompanied by harmonies (provided by the clarinets and bassoons) and a rising chromatic line in the oboes. Hans von Wolzogen, in his classification of the motives from *Tristan und Isolde* (which he referred to as *Leitmotiven*), called the main motive the *Leidensmotiv* (the suffering motive) and the rising chromatic line the *Sehnsuchtsmotiv*, or the yearning motive.[41] The harmony on the downbeat of m. 2 is traditionally known as the "Tristan chord." As Carl Dahlhaus has noted, all of these elements are intertwined to such an extent that taking any one of them out of context distorts the whole.[42] Nonetheless, it is the

Hans von Wolzogen, *Thematischer Leitfaden durch die Musik zu Richard Wagner's* Tristan und Isolde*: Nebste einem Vorworte über den Sagenstoff des Wagner'schen Dramas* (Leipzig: Feodor Reinboth, 1890), 15. This work was also published in an English edition as *Guide through the Musical Motives of Richard Wagner's* Tristan and Isolde*: With a Preface on the Legend and the Poem of Wagner's Drama* (Leipzig: Feodor Reinboth, 1889).

42. Dahlhaus, *Richard Wagner's Music Dramas*, 63.

EXAMPLE 1.6 Opening motivic group from Richard Wagner's *Tristan und Isolde*

changes to the Leidensmotiv that are the most noticeable (not the least because it is the first sounding element of the ensemble), and so in the following I will focus on it, with the understanding that it is but one part—if a rather prominent one—of a larger whole.[43]

With these thoughts in mind, let me propose that the category *statements of the Leidensmotiv* is organized around a conceptual model consisting in two correlated elements, characterized as the things necessary for a melodic fragment to count as an instance of the motive:

- an ascending sixth, followed by three descending half-steps
- the rhythmic pattern 𝄋 ♪|♩.‿♩ ♪|♩.‿♪[44]

Again, this model is greatly simplified, for in addition to ignoring the materials that invariably accompany the Leidensmotiv, nothing is said of dynamics or orchestration, and the notion of a "motive" or "theme" is simply assumed (as part of the global model that frames this local model). The model is sufficient, however, to distinguish the Leidensmotiv from other motivic materials in Wagner's music drama and to evaluate the typicality of different versions that appear over the course of the work.

Turning to the versions of the motive given in example 1.1 we can note the following range of typicality: statements 1, 2, 6, and 7 are in complete conformance with the model (they are typical of the category), but statements 3, 4, and 5 conform rather less well (they are less typical of the category). Viewed from the perspective of compositional strategy, Wagner begins with two thoroughly typical members of the category and then follows them with a markedly less-typical member that adds a note and changes the rhythmic profile. After a considerable span of music, he returns to the motive, but again in a less than typical form—indeed, the two temporally compressed versions of mm. 85–90 enact the sense of reminiscence they are meant to evoke by presenting to our ears a distillation of the most salient aspects of

43. Robert P. Morgan has recently offered an analysis of the *Tristan* Prelude which focuses more on harmonic structure than on the appearance of motive forms and which offers an intriguing alternative to what I present in the following. See Morgan, "Circular Form in the *Tristan* Prelude," *Journal of the American Musicological Society* 53 (2000): 69–103. A selection of analyses of the Prelude spanning the twentieth century can be found in Robert Bailey, ed., *Prelude and Transfiguration from* Tristan and Isolde (New York: W. W. Norton, 1985).

44. The actual duration of the concluding note of the motive is variable; in all cases, however, its duration is of moderate length relative to that of the other notes that make up the motive.

the motive. Ten measures further (beginning in m. 100) there are two final appearances of the motive before the curtain goes up, each a thoroughly typical form. Wagner's compositional strategy thus falls into three stages. In the first stage (associated with statements 1 and 2), he establishes the motive. In the second stage (associated with statements 3, 4, and 5), he presents less typical forms of the motive; these are correlated with a larger set of "developmental" strategies, with which the central portion of the Prelude is concerned. Finally, in the third stage (associated with statements 6 and 7), he returns to more typical forms of the motive, preparatory to concluding the Prelude and beginning the music drama proper.[45]

Two things emerge from this initial sketch. First, in the different versions of the Leidensmotiv that appear in the Prelude, we have a category that develops over time. Because categorization is an active response to the environment, it always has a temporal dimension: a comparative categorization of birds, for instance, demands that we evaluate each in turn. With music the temporal aspect is slightly more prominent, since musical entities are thoroughly ephemeral: not only must we evaluate each musical entity in turn, but also this evaluation is practically the only evidence that the entities ever existed at all. Wagner is clearly conscious of the way the Leidensmotiv functions through time and uses it to give shape to the Prelude as a whole. Second, the view of Wagner's compositional strategy derived from comparing the versions of the motive in the Prelude, fascinating as it might be, is also misleading: the sort of circularity that it suggests is fundamentally at odds with his goal of perpetually progressive music. By looking at further instances of the Leidensmotiv over the course of *Tristan und Isolde* we can develop our understanding of both of these things and refine our interpretation of Wagner's treatment of the motive in the Prelude.

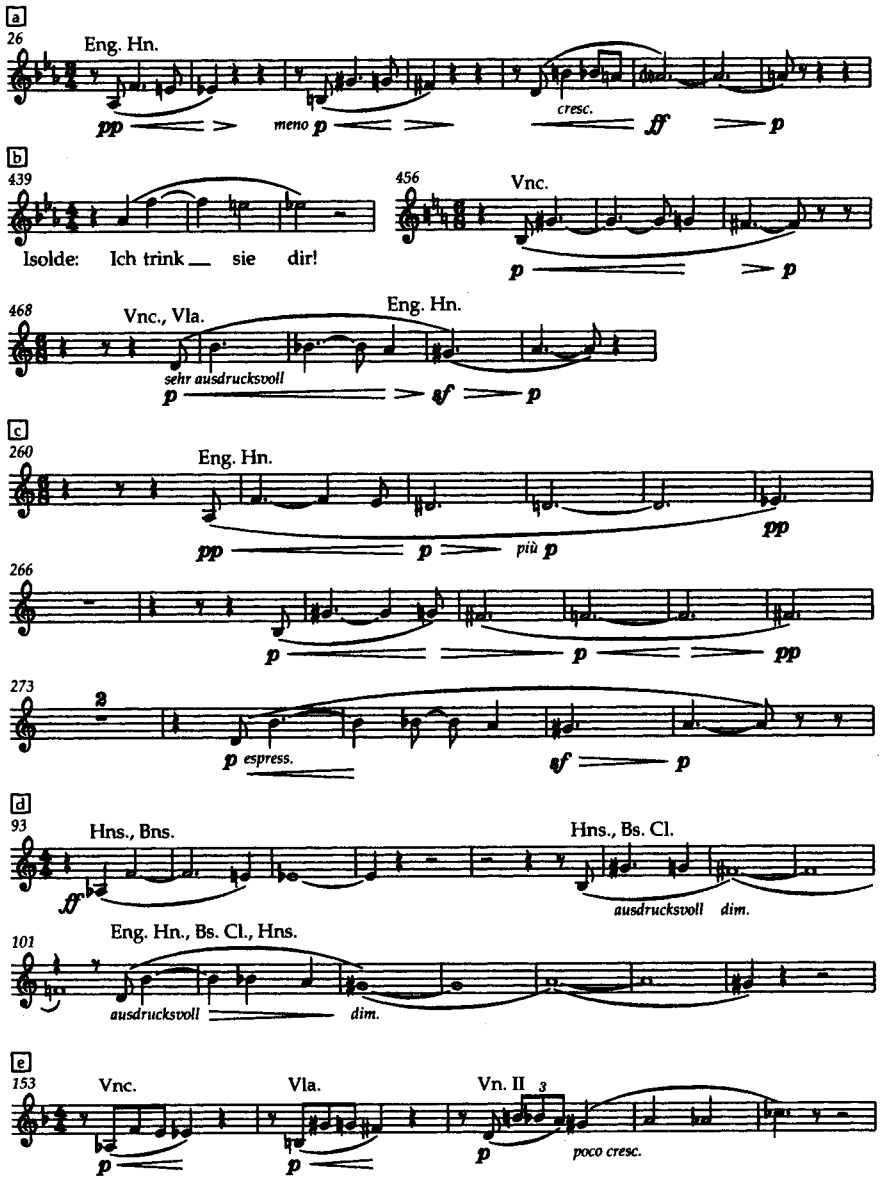
The Leidensmotiv and Musical Syntax

The Leidensmotiv is prominent at five moments in *Tristan und Isolde*: in act 1, scene 2, mm. 26–33 (p. 36; see ex. 1.7a) and scene 5, mm. 439–41, 456–58, and 468–72 (pp. 175–78; ex. 1.7b); in act 2, scene 3, mm. 260–78 (p. 448; ex. 1.7c); and in act 3, scene 2, mm. 93–107 (pp. 594–96; ex. 1.7d) and scene 3 (near the conclusion of the opera), mm. 153–57 (p. 630; ex. 1.7e).[46] In each case, there are three entries of the motive, beginning (as did those in the opening of the Prelude) on A (or, in the case of the first entry in act 3, scene 2, A♭), B, and D.

Each group departs from the conceptual model proposed above in various ways. The versions of act 1, scene 2 have one less pitch (and, of course, one less interval) than the model and a different rhythmic profile. Those of act 1, scene 5 have a different rhythmic profile. In act 2, scene 3, the versions of the motive are quite close

45. This syntactic pattern is analogous to the Beginning–Middle–End paradigm discussed by Kofi Agawu, but here it is expressed purely in terms of categories, rather than in terms of tonal organization. See Victor Kofi Agawu, *Playing with Signs: A Semiotic Interpretation of Classical Music* (Princeton, N.J.: Princeton University Press, 1991), chap. 2.

46. Measure numbers are given by scene; page numbers refer to the Dover reprint of the C. F. Peters 1911 edition of the score: Richard Wagner, *Tristan und Isolde* (New York: Dover Publications, 1973).



to the model, but the first two have extended endings, while those of act 3, scene 2 have an altered rhythmic profile, so that their overall duration is greatly expanded. Finally, the versions of the motive in act 3, scene 3 are greatly compressed (as are those of act 1, scene 2). Within each group, however, the versions of the motive are relatively consistent (with the exception of those of act 1, scene 5, about which more in a moment), although the last statement (beginning on D) is always a bit different from the preceding two. This consistency suggests that each group of three statements of the Leidensmotiv forms a syntactic unit, which represents its own local standard of typicality. These units are themselves members of a superordinate category (to which we could give some sort of cumbersome name like *successions of the Leidensmotiv beginning on A/A♭, B, and D*) whose members span almost the entirety of Wagner's music drama.[47]

For the most part, the statements that make up these syntactic units are conjunct, and, although they may stretch across a number of measures, the connection between the successive statements is quite obvious. The one exception comes with the three statements of act 1, scene 5, which occur at a climactic moment in the drama. Tristan has just drunk what he believes is a death potion. Isolde wrests the cup from him, sings "Verräther, ich trink' sie dir!" ("Betrayer! I drink to you!"), and then empties what remains in the cup. Unbeknownst to either, the draught they have consumed will lead not to death but will instead cause them to fall even more deeply in love. The melody for Isolde's unintentionally ironical "Ich trink' sie dir!" is the version of the Leidensmotiv that begins example 1.7b. For the fifteen measures of music that follow, the stage directions read: "She drinks, then throws the cup away. Both [Tristan and Isolde], seized with awe, in the greatest excitement but motionless, look fixedly into each other's eyes, in which the expression of defiance of death soon gives way to the glow of love." The cellos then enter with the second statement of the Leidensmotiv, beginning on B. Further stage directions follow, to accompany another ten measures of music: "Trembling seizes them: they clutch convulsively at their breasts and pass their hands over their foreheads." Unison cellos and violas then bring in the last statement of the Leidensmotiv, beginning on D. In this instance, what draws the three versions of the motive together into a single category is not so much their similarity to one another (although this is still quite audible) or their temporal proximity, but the way Wagner privileges them within his musical discourse. Not only is there nothing else to compete with them at the moment of their appearance, but also their participation in this pivotal moment suggests that they are autonomous agents within the drama itself.

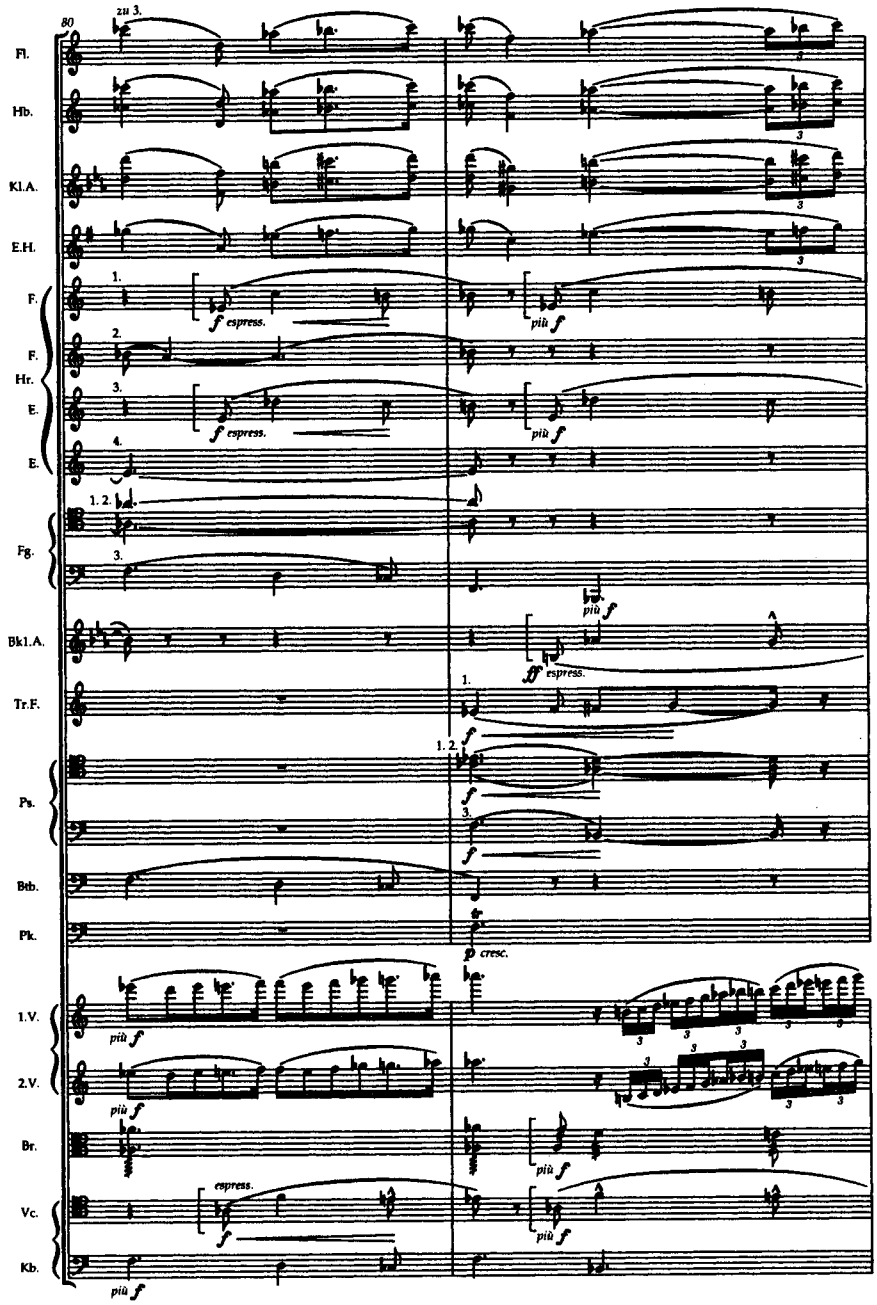
We should, if but briefly, consider the notion of syntax developed in the preceding paragraphs. First, the basic idea of syntax that I employ here is what Webster's calls "a connected or orderly system." I flesh out this idea further in chapter 4; for now, it is enough to say that this appears to be how at least some music theorists

47. Robert P. Morgan has also pointed out that each successive phrase within these units takes up the same notes outlined in the top voice of the preceding one, making it seem that each phrase emerges from the one just before; see Morgan, "Circular Form in the *Tristan* Prelude," 95, 102.

EXAMPLE 1.7 Statements of the Leidensmotiv from Richard Wagner's *Tristan und Isolde*: (a) act 1, scene 2, mm. 26–33 (*Richard Wagner: Sämtliche Werke* [*WSM*], vol. 8, part 1, mm. 313–20); (b) act 1, scene 5, mm. 439–41, 456–58, 468–72 (*WSM*; vol. 8, part 1, mm. 1754–56); (c) act 2, scene 3, mm. 260–78 (*WSM*, vol. 8, part 2, mm. 1890–1908); (d) act 3, scene 2, mm. 93–107 (*WSM*, vol. 8, part 3, mm. 1301–15; (e) act 3, scene 3, mm. 153–57 (*WSM*, vol. 8, part 3, mm. 1581–85)

construe the notion.[48] Second, the structural integrity of the syntax associated with the Leidensmotiv emerges only over time. Although all of its elements are present from the opening moments of Wagner's music drama, confirmation of the syntax must wait until well into the opera. Third, this syntax is specific to *Tristan und Isolde*. Not only would we expect a different motive to be used for another work, but this motive would almost certainly be deployed in different ways. Musical syntax, at least with regard to this example, is thus created over time and is idiosyncratic to one particular composition. Finally, semantic value may become associated with syntactic structure, something evident in Wagner's manipulation of the three statements of the motive in the climactic moment that occurs in act 1, scene 5. By disrupting or modifying his musical syntax, Wagner can create a type of meaning that is thoroughly—and exclusively—musical.

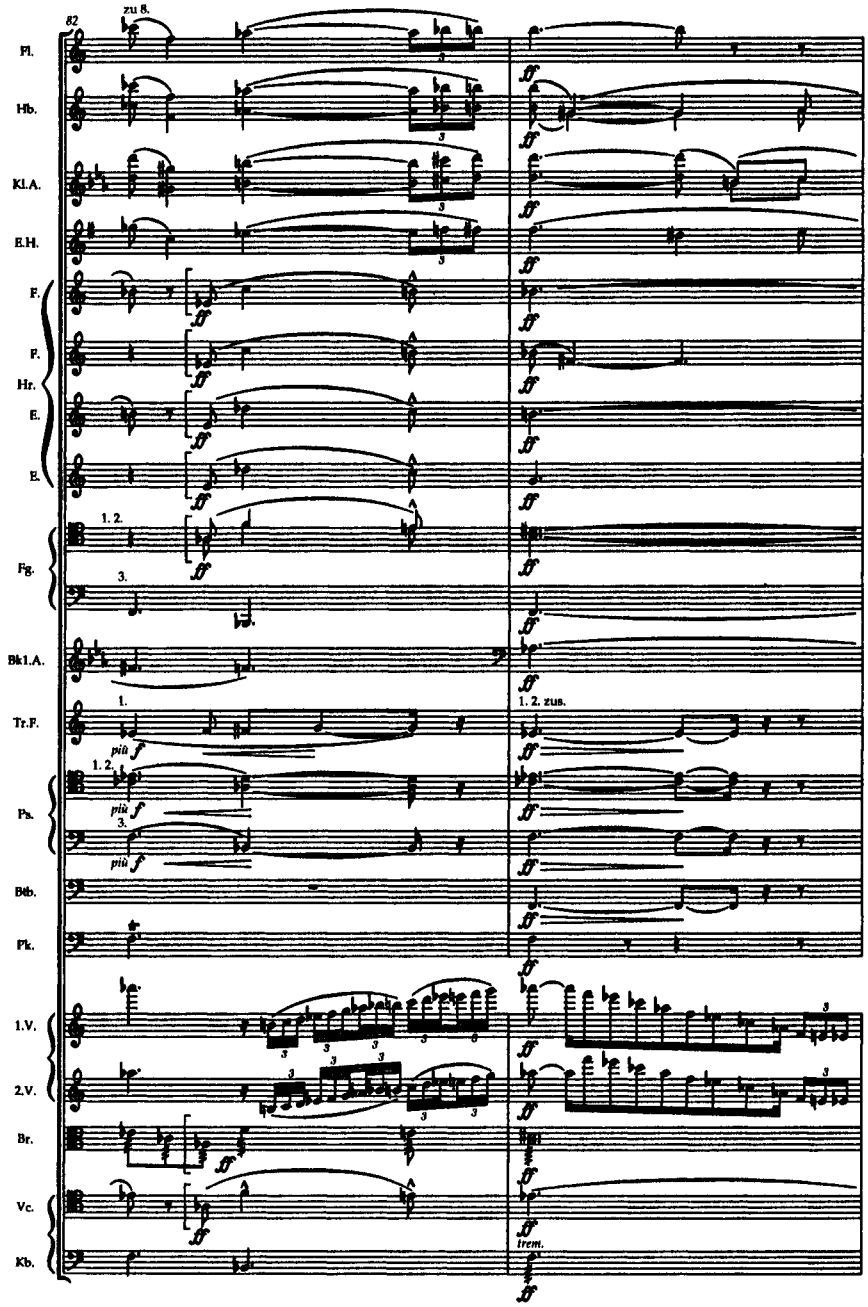
Syntactic Structure and Compositional Strategy



As a general type, the category *statements of the Leidensmotiv* has a temporal span coextensive with that of *Tristan und Isolde*. More specifically, Wagner carefully articulates the category over the course of the drama, with the motive appearing in syntactic units of three successive statements so that, with each entry of the motive on A (or A♭), we expect to hear two further entries, replicating the pattern set in the opening measures. Wagner relies on this expectation in act 1, scene 5 to underline both the tragedy and passion of Tristan's and Isolde's love. From this perspective, the further appearances of the Leidensmotiv in the Prelude after the initial three seem somewhat anomalous, for here they are only in pairs: statements on B and D in mm. 85–90, and on A♭ and B in mm. 100–106. But Wagner is playing a deep, even subliminal, game: buried beneath the overheated music in mm. 80–83 are three rhythmically displaced versions of the Leidensmotiv, all beginning on A♭ (as shown in ex. 1.8). Although little more than wraiths appearing in the midst of a fury of motives, these statements have their continuation—indeed, their consequence—in the entrances on B and D in the measures that follow. This hidden syntactic unit implies that the next round of statements, which start with the entrances on A♭ and B in mm. 100–106, should be followed by one additional entrance of the Leidensmotiv on D. Wagner withholds the third statement, however, and instead calls for the curtain to go up: in response to our anticipation of a third statement of the motive, Wagner gives us an entire opera.[49]

The shadowy appearances of the Leidensmotiv in mm. 80–83 of the Prelude and the somewhat less-typical versions that follow in mm. 85–90 suggest that Wag-

48. Cone, in "On Derivation," pairs the organizational system of syntax with the expressive tools of rhetoric. As another example of this sort of approach, Robert P. Morgan, in a recent essay, describes tonality as comprising "not only the abstract collections of diatonic pitches (plus their chromatic alterations), which have significant symmetrical properties of their own, but various asymmetrical *syntactical* functions, harmonic and linear, that transform these collections into a full-fledged compositional language" (Morgan, "Symmetrical Form and Common-Practice Tonality," *Music Theory Spectrum* 20 [1998]: 2, emphasis added).

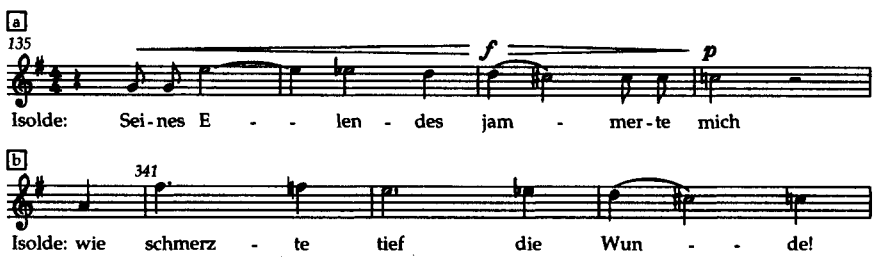


49. Morgan points out that the harmonic syntax for these final statements is also incomplete; see "Circular Form in the *Tristan* Prelude," 83.

EXAMPLE 1.8 Statements of the Leidensmotiv from Richard Wagner's *Tristan und Isolde*, Prelude, mm. 80–83

(continued)

EXAMPLE 1.8 *(continued)*



ner is both playing with and relying on our capacity to remember the motive (a capacity directly related to our ability to categorize it). But what Wagner wants is not the sort of recognition that calls attention to itself, distracting us from the flow of his drama as we become aware of its artifice, but something much more subtle. In consequence, the motive undergoes continual change, as the different versions collected in example 1.7 show, the only constant being the opening sixth and descending half steps. (Contrary to Schoenberg's concept of a motive—admittedly developed with reference to Brahms—rhythmic figuration is only weakly linked to the identity of the Leidensmotiv within the opera.) At the same time, the repetitions of the motive proper to each syntactic unit—which set up local, if ephemeral, standards for typicality—give each unit the illusion of stability and thus of properly representing the Leidensmotiv. What results is a syntax that is in constant transformation.

Further proof of Wagner's attention to musical memory can be seen in the relative atypicality of two of the rare isolated statements of the Leidensmotiv within *Tristan und Isolde*. One such statement occurs in the third scene of act 1. Isolde, recounting to Brangäne how her wrath against Tristan was turned to pity in her first encounter with him, sings "Er sah' mir in die Augen. Seines Elendes jammerte mich!—Das Schwert—ich ließ es fallen!" ("He looked into my eyes. His anguish touched my heart! The sword—I let it fall!"). As shown in example 1.9a, the middle phrase is sung to a modified version of the Leidensmotiv. This statement begins, unlike any other, on G4, and the chromatic passage that leads away from the E5 extends to four descending half-steps. And, relatively early in the long dialogue with Tristan that makes up scene 2 of act 2, Isolde sings "Wie schmerzte tief die Wunde!" ("How deeply the wound smarted"), again using a less-typical version of the Leidensmotiv (as shown in ex. 1.9b). The statement is doubled and ornamented by the strings, and its chromatic descent continues unhindered through six half steps. Both of these atypical appearances of the Leidensmotiv—atypical in their form relative to the conceptual model of the motive, and atypical in their isolation—function as remembrances of the motive rather than statements of it.

Carl Dahlhaus, in comparing the treatment of themes in the first movement of Anton Bruckner's Sixth Symphony to Brahms's method of developing variation, noted Bruckner's use of a similar strategy. When Bruckner returns to a theme, the

EXAMPLE 1.9 Isolated statements of the Leidensmotiv from Richard Wagner's *Tristan und Isolde*: (a) act 1, scene 3, mm. 135–38 (*Richard Wagner: Sämtliche Werke* [*WSM*], vol. 8, part 1, mm. 672–75); (b) act 2, scene 2, mm. 341–43 (*WSM*, vol. 8, part 2, mm. 886–88)

correspondence with the original version is often only approximate. Dahlhaus comments,

> That the one version is able to substitute for the other means, aesthetically, that instead of developing variation, where each variant represents . . . a consequence of the preceding one and a prerequisite for the next one, Bruckner makes use of an analytically elusive but clearly perceivable similarity by association, which makes the later version seem like a written-out memory of the earlier one. The logic of discourse, as conceived by Brahms, gives way to a system of approximate correspondences.[50]

The preceding analysis of transformations to the Leidensmotiv suggests that a more apt comparison would have juxtaposed Bruckner to Wagner rather than to Brahms, for it is "written-out memories" such as those shown in example 1.9 that contribute much to the power of Wagner's music dramas: we respond to such memories not with our intellect but in a way that seems far more intuitive and thus far more deeply felt.

Wagner, of course, could have had no explicit knowledge of how humans structure their understanding through categorization, since empirical evidence for this cognitive process did not begin to accumulate until a hundred years after the 1865 premiere of *Tristan und Isolde*. And yet Wagner almost assuredly had an implicit understanding of what Schoenberg called "the laws that govern the working of our minds." Wagner's music shows that he knew how to lay out his musical materials—to make them come to the fore, often enough and with enough plasticity—so that his listeners could comprehend their meaning. His music also shows that he knew how to challenge this ability, to modify the structure of categories of musical materials so that these same materials seemed new, or to have an entirely different ontological status (changing from a theme into a remembrance of a theme). An account of the way Wagner transformed the Leidensmotiv cannot exhaust his inexhaustible music, but it can give a glimpse into the processes through which we come to understand his music, as well as the way Wagner's compositional strategies both exploit and challenge that understanding.

CATEGORIZATION AND CONCEPTUALIZING MUSIC

Schoenberg's theory of motive, shaped by his understanding of the constraints on musical composition imposed by human cognitive processing (his "laws of the mind"), offers insight into how we organize our understanding of music in terms of categories of musical events. Motives were, for Schoenberg, where musical recognition started, and the coherence of musical motives was what made musical comprehension possible. As we have seen, these two functions are replicated in cognitive categories. Our preferred level of categorization is at a level in the middle of a taxonomy—the basic level—which, like the motive, strikes a compromise between efficiency and informativeness. The categories we use most often in everyday life

50. Carl Dahlhaus, *Nineteenth-Century Music*, trans. J. Bradford Robinson (Berkeley: University of California Press, 1989), 273.

are not defined in terms of individually necessary and jointly sufficient conditions. Instead, they have variable membership: some members are more typical of the category than others, and membership in the category is graded rather than an all-or-nothing affair. Musical motives show a similar amount of variation, and it is through developing a notion of what they have in common—a conceptual model for what is typical of the category—that we begin to comprehend the musical organization of works like those that fascinated Schoenberg.

As the analysis of Wagner's use of the Leidensmotiv shows, Schoenberg's conception of a motive is not adequate for all circumstances (especially in its reliance on rhythmic figuration), nor are composers always content to establish a single model for a motive and stick with it. Indeed, they may vary it constantly (as did Wagner in the case of the Leidensmotiv), or they may combine the models for different motive forms in any number of ways (as Cone's work on the problem of motivic derivation shows). Although focusing on motives offers a place to start, it is on the more general notion of a musical category—free as it is from associations with Beethoven's compositional process, fascinating as that is—that I want to focus. While a collection of assorted motive forms is a good example of a musical category, categories can be much more various and structured around whatever set of musical relationships seems best to account for what is salient about a particular repertoire. The relevant units may be harmonic (as in a chaconne), involve a repeated bass pattern (as in a passacaglia), or combine the two (as in the linear cadential patterns that Susan McClary has shown provide a structural framework for music of the sixteenth century);[51] music of the twentieth century suggests an even greater number of possibilities. And music (construed as patterned sound) may be just one of a number of contributing factors: one could also envision musical categories informed by the text being set (of particular importance for liturgical music) or the affect that is to be summoned (a concern for some types of dramatic music). In all cases, the choice and structure of the relevant musical categories will be guided by the global conceptual models relative to which the local models for each category are framed.

My proposal, then, is that categories are where our conceptualization of music starts. If to think is to think in terms of categories, then to think of music is to think in terms of musical categories. Viewed this way, categories constitute an analogue—or perhaps replacement—for the notion of a group as it has been developed by Fred Lerdahl and Ray Jackendoff. For Lerdahl and Jackendoff, musical understanding begins with the process of segmenting a musical work into contiguous sequences of pitch-events, drum beats, or the like.[52] Each such segment constitutes a group, and groups are arranged into a strict hierarchy that ultimately yields the entire work of music.[53] Musical categories

51. Susan McClary, *Conventional Wisdom: The Content of Musical Form* (Berkeley: University of California Press, 2000), 14–16.

52. Fred Lerdahl and Ray Jackendoff, *A Generative Theory of Tonal Music* (Cambridge, Mass.: MIT Press, 1983); the process of grouping is described on p. 13; the definition of a group is given on p. 37.

53. By "strict hierarchy," I mean a hierarchy in which the boundary points at each superordinate level conform to boundary points at the level immediately subordinate. Lerdahl and Jackendoff define this sort of organization as "hierarchical"; see Lerdahl and Jackendoff, *A Generative Theory of Tonal Music*, 13, 37. Conceptions of hierarchy as they are applied to music are discussed in greater detail in the latter part of chap. 7.

can absorb many of the functions of groups—specifically, the role of the group as the first level of organization for musical phenomena—but do not require absolute contiguity or strict hierarchical organization. As a result, a theory of musical categories can easily account for the multiple strands of polyphonic music in a way that grouping theory cannot. Each of the overlapping entries of a work in canon, for instance, could be regarded as a member of a category; this sort of analysis is simply impossible with grouping theory, since overlaps between groups are not permitted.

If categories are where our conceptualization of music starts, they must be closely linked to concepts themselves. At the risk of some confusion, I would like to go further and suggest that musical categories are concepts. Now, to attempt any definition of a concept is to (at least potentially) embroil myself in a long-standing debate within philosophy and cognitive science.[54] To skirt this debate, I concentrate on a definition of "concept" that reflects recent work in the mind sciences and the brain sciences, and that can be applied to music. Although I think this definition can inform the larger debate on "concept," I shall leave the substance of the debate for another time.

The definition of "concept" I develop here is influenced by the work of Gerald Edelman, who has been interested in developing a biological approach to consciousness. Edelman's definition of a concept is developed as a description of the capacities necessary for the control of complex interactions between an organism and its environment:

> An animal capable of concepts is able to identify a particular thing or action and control its future behavior on the basis of that identification in a more or less *general* way. It must act *as if* it could make judgments based on recognition of category membership or integrate "particulars" into "universals." This recognition rests not just on perceptual categorization (although a concept may have a highly sensory content) but, to some degree, *must also be relational.* It can connect one perceptual categorization to another even in the absence of the stimuli that triggered these categorizations.[55]

Thus to have concepts involves not only the process of categorization but also recognizing relationships *between* categories.[56] What is also important is that having concepts is a capacity that is not limited to humans, a point also made by Donald Griffin.[57] Concepts are thus not necessarily tied to language.

54. For a recent and stimulating sally in this debate, see Jerry A. Fodor, *Concepts: Where Cognitive Science Went Wrong* (Oxford: Clarendon Press, 1998).

55. Gerald M. Edelman, *The Remembered Present: A Biological Theory of Consciousness* (New York: Basic Books, 1989), 141.

56. Other works that either make a strong connection between categories and concepts or assert their equivalence include James Hampton and Danièle Dubois, "Psychological Models of Concepts," in *Categories and Concepts: Theoretical Views and Inductive Analysis*, ed. Iven van Mechelen, James Hampton, Ryszard S. Michalski, and Peter Theuns, Cognitive Science Series (London: Academic Press, 1993), 11–33; Barsalou, "Flexibility, Structure, and Linguistic Vagary in Concepts"; Barsalou et al., "Concepts and Meaning"; Smith and Medin, *Categories and Concepts*; and Gregory L. Murphy and Douglas L. Medin, "The Role of Theories in Conceptual Coherence," *Psychological Review* 92 (1985): 289–316.

57. Donald R. Griffin, *Animal Minds* (Chicago: University of Chicago Press, 1992), chap. 6. A similar approach can be seen in the work of Douglas Hofstadter and his associates, which has resulted in a number of computer programs that deal with relatively compact bundles of information they call "concepts"; see Hofstadter and the Fluid Analogies Research Group, *Fluid Concepts and Creative Analogies: Computer Models of the Fundamental Mechanisms of Thought* (New York: Basic Books, 1995).

With this perspective in mind, let me propose that a musical concept has three characteristics. First, it is a product of the process of categorization. A musical category, then, is quite literally where our conceptualization of music begins. Second, a musical concept is an essential part of the means through which we guide present and future actions. These actions thus constitute a sort of indirect evidence for a cognitive structure almost as ephemeral as music itself. Third, a musical concept can be related to other concepts, including concepts associated with bodily states (both physical and emotional), perceptual categories (including sound, which, after all, is not necessarily music), and linguistic constructs.

From the perspective provided by this definition, language—in the sense of natural language—is not required in order to have musical concepts. I have, of course, used language to characterize musical categories, as well as the conceptual models around which musical categories are organized. But we could imagine a listener—perhaps a particularly astute listener, but perhaps one no more skilled than Proust's M. Swann—who develops a musical category without recourse to language. While language is still nearly indispensable for communicating features of musical concepts and for developing such concepts in richer contexts, it is not required.[58] The notion of concepts independent of language is more than a little provocative, and with consequences that extend beyond music and the general debate on "concept" noted above. Where some authors have excluded music from the conceptual realm (because, by their definition, concepts require language),[59] music can join dance, the visual arts, and any of the other nonlinguistic modes of human expression as a properly conceptual activity.

This perspective on musical understanding also offers a new way to think about musical syntax. Music theory has traditionally (if not explicitly) characterized syntax in terms of relationships between categories of musical objects or events. For instance, a perfect authentic cadence, as it is usually defined, consists (in part) of a dominant chord followed by a tonic chord, with bass motion from $\hat{5}$ to $\hat{1}$, and with the soprano concluding an octave above the bass. The definition involves categories like scale step ($\hat{5}$ and $\hat{1}$), harmonic function (dominant and tonic), voice (bass and soprano), and interval (the octave). Members of these categories, when placed in specific relationships (succession and "above"), produce a component of musical syntax (the perfect authentic cadence).[60] Musical syntax can also be conceived of

58. The idea that language was not required for musical analysis was one of the ideas behind Hans Keller's wordless analyses. See Keller, "Wordless Functional Analysis no. 1: Mozart, K. 421," *The Score and I.M.A. Magazine* 22 (1958): 56–64; idem, "The Musical Analysis of Music," in *Essays on Music*, ed. Christopher Wintle (Cambridge: Cambridge University Press, 1994), 126–28; idem, "Functional Analysis no. 9a: Mozart's Piano Sonata in A Minor, K. 310," in *Essays on Music*, ed. Christopher Wintle (Cambridge: Cambridge University Press, 1994), 129–38.

59. Ray Jackendoff, *Consciousness and the Computational Mind* (Cambridge, Mass.: MIT Press, 1987); Mark DeBellis, *Music and Conceptualization* (Cambridge: Cambridge University Press, 1995).

60. It is worth noting that Type 2 categories are chiefly involved in this definition: within a given context, something either is or is not an example of $\hat{5}$; something either is or is not a dominant chord; and so on. Such categories are typical of the sorts of taxonomies established by formal music theory. However, note that at least one category (for voice) is less explicitly defined and functions more like a Type 1 category. For instance, the soprano is, by convention, the highest sounding voice within a multivoice texture, but in instrumental works it may actually sound well below the range of human sopranos (and thus be a somewhat atypical example of a soprano voice).

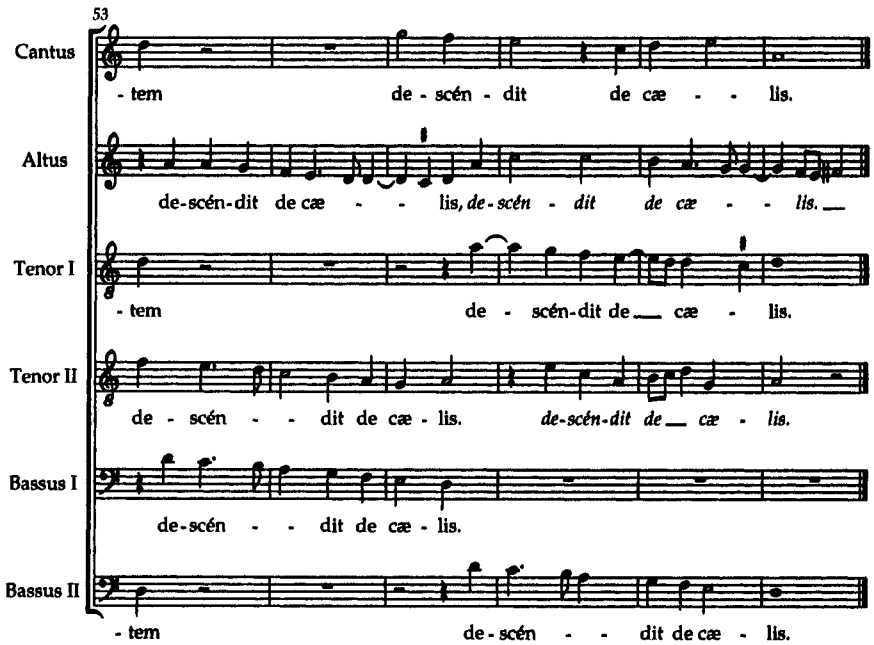
as an emergent property of sequences of musical events. Wagner's treatment of the Leidensmotiv offers one example of this, but the same can be said of most of the musical works that interest us: it is through the development of local levels of syntax that musical works become distinctive, and it is the multivalence of this syntax that makes repeated listening to the same work a rewarding experience. Of course, syntactic structure that is shared between musical works is also important, and in most music there is a dialogue between the two analogous to the dialogue between the local and global models relative to which musical categories are framed.[61] Elaborating this approach to musical syntax is the main goal of chapter 4. There we will see how composers rely on syntactic conventions to provide a framework for the development of more local patterns of syntax specific to individual works.

Before we can more fully investigate the role musical concepts play in understanding and the way musical syntax comes about, we need to consider two important issues. First, there is the issue of how relationships between concepts are established. This will be taken up in chapter 2, which explores how conceptual domains such as music and language are correlated through the process of cross-domain mapping. This process allows structure from one conceptual domain to be brought to bear on another and for relationships among concepts to be established. Second, there is the issue of where conceptual models come from and how they are used to guide reasoning. Chapter 3 shows how concepts and conceptual relationships are combined into conceptual models and how conceptual models are connected together to create theories of music.

61. My perspective on musical syntax owes a debt to Eugene Narmour's construal of musical style. Narmour distinguishes between intraopus style (which is specific to a given work) and extraopus style (which can be seen across a number of works). See Narmour, *The Analysis and Cognition of Basic Melodic Structures*; and idem, *The Analysis and Cognition of Melodic Complexity: The Implication-Realization Model* (Chicago: University of Chicago Press, 1992).

CHAPTER TWO

CROSS-DOMAIN MAPPING



About a quarter of the way through the Credo of his *Pope Marcellus Mass* (printed 1567), Giovanni Pierluigi da Palestrina indulges in a marvelous bit of text painting with telling effect. The text Palestrina sets here is "Qui propter nos homines et propter nostram salutem descendit de cælis" ("Who for us men, and for our salvation, came down from heaven"). As shown in example 2.1, with the first statement of the word "descendit," each voice begins a scalar descent. Christ's descent from heaven is thus represented with a cascading fall through musical space, a series of overlapping movements "down" the musical scale.

Palestrina's text painting is a striking embodiment of the conventional construal of pitch as "high" and "low." This way of thinking about pitch relations has a venerable tradition. Its basic elements can be seen in Aristoxenus's description of pitch relations in terms of two-dimensional space, which was discussed in the introduction to this volume. Pitches are understood as points in space, and musical intervals are reckoned in terms of distances between these points. However, the spatial orientation crucial to Palestrina's text painting—the correlation of the "up" and "down" of physical space with specific pitch relations, such that a musical scale can "descend"—was seldom used in Greek music theory. As Andrew Barker has noted, the standard Greek for what would now be called "high-pitched" is *oxys*, which meant "sharp," "pointed," or "keen-edged"; its musical opposite was *barys*, which meant "heavy" (but not, in opposition to *oxys*, "blunt").[1] Just when "up" and "down" consistently came to be correlated with musical pitch is unclear, but the linkage was in place at least by the beginning of the tenth century, a good six hundred years before Palestrina wrote his Mass. From around the tenth century, thus, musicians in the West began writing about and depicting pitch in terms of "high" and "low," mapping structural relations from the domain of vertically oriented, two-dimensional space onto the domain of music.

Perhaps more remarkable than the long tradition of construing pitch relations in terms of "up" and "down" are the ready reminders of how arbitrary a construal it is.

1. Andrew Barker, ed., *Harmonic and Acoustic Theory* (vol. 2 of *Greek Musical Writings*), Cambridge Readings in the Literature of Music (Cambridge: Cambridge University Press, 1989), 69, n. 2.

EXAMPLE 2.1 Giovanni Pierluigi da Palestrina, Credo of the *Pope Marcellus Mass*, mm. 53–58

Consider, for instance, "up" and "down" on the piano: how can D4 be "above" C4 on the piano when they are both on the same horizontal plane? Think of playing the two notes on the cello—to play the "higher" D4, we have to move our left hand "down," so that it is closer to the ground. In fact, there are countless reminders of the artificiality of describing pitch in terms of "high" and "low." And yet Palestrina's text painting seems anything but arbitrary—there seems to be an aptness to his portrayal of the descent from heaven that goes beyond mere traditions of depiction.

In this chapter, I explore the function of cross-domain mappings of the sort that underlie this small bit of text painting in the Credo of the *Pope Marcellus Mass*. Cross-domain mapping plays two important roles in musical understanding: first, it provides a way to connect musical concepts with concepts from other domains, including those associated with language; second, it provides a way to ground our descriptions of elusive musical phenomena in concepts derived from everyday experience. Both of these contribute to the establishment of relationships between concepts, relationships that are fundamental to the prospect of theorizing about music. In the first section that follows, I provide an introduction to the theory of cross-domain mapping as it has been developed in recent work by cognitive linguists and others. This introduction provides a framework for explaining what makes mappings possible and why some mappings are more effective than others.

Cross-domain mapping also makes it possible to correlate the musical domain with others, such as the domain of physical space or of gesture. Under certain circumstances, such correlations provide the basis for rich worlds of the imagination.

Correlating musical pitches with vertically oriented, two-dimensional space, for instance, leads quite naturally to an imaginary world in which pitches become things that move through space: the successive notes of a scale gradually descend and ascend; in other passages, some notes leap, while still others fall. Within this imaginary world, each traversal of space has a specific and unmistakable sound—that is, descent sounds one way, ascent another. And this is not something limited to text painting of the sort demonstrated by Palestrina, as any number of cartoon soundtracks confirm. Never mind that actual traversals of space sound nothing like those of the hyperkinetic Roadrunner or the hapless Wile E. Coyote; if the correlation between the domains is properly established, elements from each will blend together to create novel relationships and elements. In the second section that follows, I describe the process that leads to this sort of blending and show the role conceptual blending plays in text painting and program music.

AN INTRODUCTION TO CROSS-DOMAIN MAPPING

Cross-Domain Mapping and Metaphor

The theory of cross-domain mapping is a product of a generalized approach to linguistic metaphor first taken by George Lakoff and Mark Johnson in 1980. Perhaps the most common conception of metaphor is of a literary device, a manifestation of the figural use of language to create colorful if imprecise images. Lakoff and Johnson accumulated a substantial body of evidence demonstrating that metaphor was not simply a manifestation of literary creativity but was, in fact, pervasive in everyday discourse.[2] As an example, consider the way *up* and *down* are used to characterize emotions, consciousness, and health:

EMOTIONS

I'm feeling *up*. My spirits *rose*. I'm feeling *down*. I *fell* into a *depression*. My spirits *sank*.

CONSCIOUSNESS

Get *up*. I'm *up* already. He *rises* early in the morning. He *fell* asleep.

HEALTH

He's at the *peak* of health. She's in *top* shape. He came *down* with the flu.

Each characterization suggests not a literal representation of the spatial domain implied by the orientation *up–down* but, instead, uses our knowledge of physical space to structure our understanding of emotions, consciousness, or health.

Based on evidence provided by a large number of similar examples of the

2. George Lakoff and Mark Johnson, *Metaphors We Live By* (Chicago: University of Chicago Press, 1980). Their work has recently been extended in Lakoff and Johnson, *Philosophy in the Flesh: The Embodied Mind and Its Challenge to Western Thought* (New York: Basic Books, 1999).

appearance of metaphorical constructions in everyday discourse, Lakoff and Johnson proposed that metaphor was a basic structure of understanding through which we conceptualize one domain (the target domain, which is typically unfamiliar or abstract) in terms of another (the source domain, which is most often familiar and concrete). Further study has provided a wealth of empirical evidence for this proposal and contributed to the development of the field of cognitive linguistics.[3]

Fundamental to the theory of metaphor that sprang from Lakoff and Johnson's work is a distinction between conceptual metaphors and linguistic metaphors. A conceptual metaphor is a cognitive mapping between two different domains; a linguistic metaphor is an expression of such a mapping through language. For instance, the conceptual metaphor STATE OF BEING IS ORIENTATION IN VERTICAL SPACE maps relationships in physical space onto mental and physical states.[4] The cross-domain mapping wrought by this conceptual metaphor then gives rise to innumerable linguistic expressions. Some of these expressions are commonplace, such as "Maxwell seems a bit down today." Others summon a rich imagistic world, such as that of John Keats's "Ode to a Nightingale":

> My heart aches, and a drowsy numbness pains
> My sense, as though of hemlock I had drunk,
> Or emptied some dull opiate to the drains
> One minute past, and Lethe-wards had sunk.

Here the descent to the mythical river gives a physical correlate to the narcotic state of the narrator: the act of sinking is mapped onto a melancholy emotional state. Thus the same conceptual metaphor (STATE OF BEING IS ORIENTATION IN VERTICAL SPACE) is behind both linguistic metaphors, one commonplace ("Maxwell seems a bit down today"), the other poetic.

With respect to music, the "high" and "low" used to describe pitches reflect the conceptual metaphor PITCH RELATIONSHIPS ARE RELATIONSHIPS IN VERTICAL SPACE. This metaphor maps spatial orientations such as *up–down* onto the pitch continuum. The mapping yields a system of metaphors replete with possibilities for describing musical pitch. We can speak in terms of pitch contour (meaning successions of pitches, which are located at different places in pitch-space), gesture (mean-

3. For a review of the empirical evidence supporting metaphor as a basic cognitive process, see Raymond W. Gibbs, Jr., *The Poetics of Mind: Figurative Thought, Language, and Understanding* (Cambridge: Cambridge University Press, 1994). For discussion of the link between the study of metaphor as a cognitive process and the central concerns of cognitive linguistics, see George Lakoff, "The Invariance Hypothesis: Is Abstract Reason Based on Image-Schemas?" *Cognitive Linguistics* 1 (1990): 39–51.

4. By convention, conceptual metaphors are represented in capital letters. Thus LOVE IS A JOURNEY designates a conceptual metaphor of general application, and "Love is a journey" a specific linguistic expression based on that metaphor.

The conceptual metaphor STATE OF BEING IS ORIENTATION IN VERTICAL SPACE is a variant of the STATES ARE LOCATIONS conceptual metaphor discussed by George Lakoff and Mark Turner in *More Than Cool Reason: A Field Guide to Poetic Metaphor* (Chicago: University of Chicago Press, 1989). On cross-domain mapping as a general phenomenon, see Lakoff and Turner, *More Than Cool Reason*, 4; George Lakoff, "The Contemporary Theory of Metaphor," in *Metaphor and Thought*, 2nd ed., ed. Andrew Ortony (Cambridge: Cambridge University Press, 1993), 202–51; Gibbs, *The Poetics of Mind*; and Gilles Fauconnier, *Mappings in Thought and Language* (Cambridge: Cambridge University Press, 1997).

ing successions of pitches with a specific directionality and contour), and musical space (meaning a three- or four-dimensional extension of the basic two-dimensional mapping).[5] This system is given graphic representation in traditional musical notation: notes that are the result of more rapid vibrations of the sounding medium are placed higher on the page than notes that result from less rapid vibrations (with the exception of sharps and flats). The two-dimensional space of the musical page thus correlates with the spatial orientation ascribed to pitch.[6] The systematic quality that results from mapping spatial orientations onto the pitch continuum thus leads to an entire vocabulary for describing relationships among pitches that provides a rich set of possibilities for furthering our conceptualization of music.

As common as conceiving of pitches as "high" or "low" seems, not all cultures describe pitch relationships in purely spatial terms. As I noted here, Greek theorists of antiquity used *oxys* ("sharp" or "pointed") and *barys* ("heavy") to characterize pitches. And traversing historical distance is not the only way to discover alternative conceptualizations of pitch relations. Consider three examples in which it is culture, rather than time, that creates distance:

1. Steven Feld's research has shown that the Kaluli of Papua New Guinea describe melodic intervals with the same terms they use to characterize features of waterfalls. For instance, in Kaluli *sa* means "waterfall," and a *mogan* is a still or lightly swirling waterpool; *sa-mogan* is the flow of a waterfall into a level waterpool beneath it. *Sa-mogan* is also used to describe a melodic line that descends to a repeated note, the contour of which replicates that of a waterfall flowing into a pool. In contrast, there are no specific names for ascending intervals, which nonetheless do occur in Kaluli song.[7] Behind this account of musical intervals is the conceptual metaphor PITCH RELATIONSHIPS ARE WATERFALL CHARACTERISTICS, which provides the basis for a rich set of descriptive terms that capture some aspects of melody but not others.
2. In Bali and Java pitches are conceived not as "high" and "low" but as "small" and "large."[8] Here the conceptual metaphor is PITCH RELATIONSHIPS ARE RELATIONSHIPS OF PHYSICAL SIZE, a mapping that accurately

5. For further discussion of mappings between the spatial and pitch domains, see Arnie Walter Cox, "The Metaphoric Logic of Musical Motion and Space" (Ph.D. diss., University of Oregon, 1999).

6. It is worth noting that the spatial domain of the musical page is itself metaphorical, since the way the page is oriented in physical space—that is, whether it is propped on a music stand or lying flat on a table, turned right side up or upside down—does not change what we regard as the top and bottom of the page. Two factors, each independent of the actual orientation of the page in physical space, help establish the spatial domain of the page: the conventional orientation of the symbols on the page (either "rightside up" or "upside down") and the relative distance of the symbols on the page from the reader. Rightside up symbols that are farthest from the reader are at the "top" of the page; rightside up symbols that are nearest the reader are at the "bottom" of the page.

reflects the norms of acoustic production: small things typically vibrate more rapidly than large things. This acoustic fact is represented throughout the numerous parts of the gamelan, the collection of instruments central to the musical practice of Bali and Java.

3. The Suyá of the Amazon basin do not have an extensive vocabulary for describing pitch relationships. When they are described, however, it is in terms of age: pitches are conceived not as "high" and "low" but as "young" and "old." The conceptual metaphor that guides this mapping is PITCH RELATIONSHIPS ARE AGE RELATIONSHIPS, which accurately reflects the Suyá's beliefs that the pitch of the voice becomes deeper with age.[9]

With each of these conceptions of pitch relationships it is easy to focus on what they lack rather than what they offer. That is, it is natural (if not quite excusable) to reckon difference in somewhat chauvinistic terms: that the Kaluli do not have terms to describe ascending intervals, where we do; that the way pitch relationships are characterized in Bali and Java does not transfer into graphic representations with the same ease as do "high" and "low." It has to be remembered, however, that mapping "high" and "low" onto music has its own limitations: "high" and "low" cannot reflect the subtle play of flowing water, nor do they provide much of an explanation for how acoustic features correlate with pitch relationships. Such differences show that each mapping between domains makes some conceptualizations possible, while it disables others.

Image Schema Theory

The variety of conceptual metaphors used to characterize pitch relations leads to the question of the ultimate grounding of the process of cross-domain mapping. Even if we grant that we understand a target domain (such as pitch relationships) in terms of a source domain (such as orientation in vertical space), how is it that we understand the source domain in the first place? Mark Johnson answered this question by proposing that meaning was grounded in repeated patterns of bodily experience.[10] These patterns give rise to what Johnson called *image schemata*, which provide the basis for the concepts and relationships essential to metaphor. An image schema is a dynamic cognitive construct that functions somewhat like the abstract structure of an image and thereby connects together a vast range of different experiences that manifest this same recurring structure.[11] Image schemata are by no means exclusively visual—the idea of an image is simply a way of capturing the organization inferred from patterns in behavior and concept formation.

As one example of an image schema, consider the VERTICALITY schema, which might be summarized by a diagram of the sort given in figure 2.1. We grasp this structure repeatedly in thousands of perceptions and activities that we experience every day. Typical of these are the experiences of perceiving a tree, our felt sense of standing upright, the activity of climbing stairs, forming a mental image of a flagpole, and

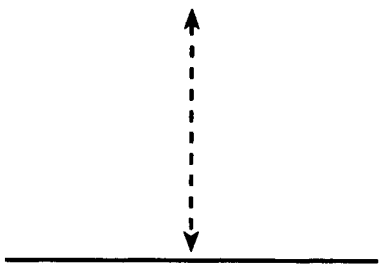

FIGURE 2.1 Diagram of the VERTICALITY schema

watching the level of water rise in the bathtub. The VERTICALITY schema is the abstract structure of the VERTICALITY experiences, images, and perceptions. Our concept of verticality is based on this schema, and this concept is in turn invoked by the various conceptual metaphors that use vertical space as a source domain through which to structure such target domains as emotions, consciousness, health, and musical pitch.

By definition, image schemata are preconceptual: they are not concepts, but they provide the fundamental structure upon which concepts are based. In consequence, it is important to emphasize that any diagram used to illustrate an image schema is intended to represent the key structural features and internal relations of the schema; it is not meant to summon a rich image or mental picture that we somehow have "in mind" and use actively to structure our thought. More directly, whatever actually occupies our thoughts is not, by definition, an image schema. We can conceive *of* image schemata, just as we can conceive of any of a number of nonconceptual or preconceptual cognitive processes. We can also note general patterns in the way concepts are structured, which can be attributed to image schemata. However, there are, by definition, no "image-schema concepts."

The relationship between the VERTICALITY schema and our characterization of musical pitch with reference to the spatial orientation *up–down* is fairly immediate: when we make *low* sounds, our chest resonates; when we make *high* sounds, our chest no longer resonates in the same way, and the source of the sound seems located nearer our head. The "up" and "down" of musical pitch thus correlate with the spatial "up" and "down"—the vertical orientation—of our bodies. The VERTICALITY schema offers a straightforward way to explain why we characterize musical pitch in terms of *high* and *low* even when the actual spatial orientation of the means through which we produce pitches either does not reinforce the characterization or runs directly counter to it.

At present, the image schema remains largely a theoretical construct. Work across a variety of fields, however, has made strong arguments for the importance of such a construct, including that by Leonard Talmy in linguistics, Gerald Edelman in neuroscience, David McNeill in psychology, and Raymond W. Gibbs Jr. and Herbert L. Colston in psycholinguistics.[12] Recently, Lawrence Barsalou and his associates have

Gibbs, Jr., and Herbert L. Colston, "The Cognitive Psychological Reality of Image Schemas and Their Transformations," *Cognitive Linguistics* 6 (1995): 347–78.

developed a comprehensive theory of mental representation based on perceptual symbols (which are analogical structures similar to image schemata) and have begun to provide empirical work to support the theory.[13] Antonio Damasio, working from a neurophysiological perspective, has made compelling arguments for the importance of the body to consciousness and thought.[14] Although research on image schemata and similar structures is still preliminary, it is also highly promising and offers some of the best prospects for solving some of the problems of the relationship between mind and body that have dogged cognitive research throughout this century.

The Invariance Principle

The theory of image schemata provides a way to explain how conceptual metaphors are grounded. It does not, by itself, explain why some conceptual metaphors seem intuitively better than others. For instance, the conceptual metaphor PITCHES ARE FRUIT could provide the grounding for such expressions as "You must play the first note more like an apple, the second more like a banana." Although such mappings are possible, they are certainly not common. Pitches and fruits just do not seem to be a good match.

To account for why some metaphorical mappings are more effective than others, George Lakoff and Mark Turner proposed that such mappings are not about the *imposition* of the structure of the source domain on the target domain, but are instead about the establishment of correspondences between the two domains. These correspondences are not haphazard, but instead preserve the image-schematic structure latent in each domain. Lakoff and Turner formalized this perspective with the Invariance Principle, which Turner states as follows: "In metaphoric mapping, for those components of the source and target domains determined to be involved in the mapping, preserve the image-schematic structure of the target, and import as much image-schematic structure from the source as is consistent with that preservation."[15] According to the Invariance Principle, mapping the spatial orientation

A preliminary discussion of a similar sort of topographical invariance, with applications to music, can

up–down onto pitch works because of correspondences between the image-schematic structure of components of the spatial and acoustical domains. Both space and the frequency spectrum are continua that can be divided into discontinuous elements. In the spatial domain, division of the continuum results in points; in the acoustic domain, it results in pitches. Mapping *up–down* onto pitch allows us to import the concrete relationships through which we understand physical space into the domain of music and thereby provide a coherent account of relationships between musical pitches. Mapping various fruits onto musical pitches works less well because fruit does not (in any ordinary way) constitute a continuum. To employ this mapping is to highlight instead both the discontinuity among musical pitches and how they are *unlike* one another (an emphasis on difference suggested by the idiomatic phrase "like apples and oranges").

Cross-Domain Mapping and Conceptual Models

According to current theory, cross-domain mappings are grounded in repeated patterns of embodied experience called image schemata. These schemata provide the basic structure employed in the mappings: the VERTICALITY schema is thus fundamental to our understanding of two- or three-dimensional spaces as having directionality and of musical pitch as "high" and "low." Image schemata also constrain the possibilities for mapping between two domains, a constraint reflected in the Invariance Principle. Because the VERTICALITY schema can be applied to both the spatial and the musical domains, we can use our understanding of the former to structure our understanding of the latter. It remains to be explained why one mapping would be preferred over another—why, for instance, we tend to describe pitch relations in terms of "high" and "low" rather than "small" and "large."

On the face of it, both of these mappings are equally viable. Both draw on aspects of our embodied experience: on the one hand, countless experiences with the seeming origin of our own voices; on the other hand, countless experiences with the sounds given out by physical objects in the world around us. Both mappings allow us to describe musical pitches as elements within a continuum. And each mapping can be easily understood from the perspective provided by the other. For instance, in Camille Saint-Saëns's *Le Carnaval des animaux*, the music for the elephant is played by the contrabass (*large* is *low*), that for the birds by the flute (*small* is *high*).[16] Although musicians educated in the West sense the novelty of the mapping, they can nonetheless understand it perfectly well. In a similar fashion, musicians from Bali and Java, when confronted with Western conventions for notation, have few if any problems translating "small" and "large" into "high" and "low."[17]

17. Personal communication from Sumarsam, 10 April 1998.

The reason we prefer one mapping over another has to do with the global conceptual models we absorb from culture and that supply crucial support for the preferred mapping.[18] In the West, the description of pitch relations in terms of "up" and "down" arose around the same time musicians began to develop ways of notating polyphonic compositions. These notational systems often relied, either directly or indirectly, on the physical placement of symbols on the page.[19] The attribution of "high" and "low" to musical pitches is thus correlated with a system of notation that permitted both the visualization and the preservation of musical works. In turn, this notation relied on a global model that made three important assumptions: first, pitches could be regarded as objects that were independent of the sound source that produced them; second, graphical symbols could be used to represent these pitch-objects; and third, the surface on which these symbols appeared was analogous to physical space. In Bali and Java, the performance of music was associated with the rich palette of instruments through which the music was effected. Thus the attribution of "small" and "large" to pitches correlated with characteristics of the musical instruments intrinsic to musical performance. The conception of musical pitches as physical objects relies on a global model that does not, at some fundamental level, disassociate a pitch from the sound source that produces it.[20]

As noted earlier, the characterization of pitch relations can be informed by mappings other than "high" and "low" and "small" and "large." In each case, the basic mapping relies on embodied knowledge and on the correlation of the musical domain with a more concrete domain. The specific mapping chosen within a tradition of discourse about music reflects not so much absolute musical structure as it does the broader cultural practice within which music and its understanding are embedded: mappings reflect the conceptual models that are important to culture. The cross-domain mappings employed by any theory of music are thus more than simple curiosities—they are actually key to understanding music as a rich cultural product that both constructs and is constructed by cultural experience.

18. These models and the relationship between global and local models will be discussed in greater detail in the next chapter.

19. With regard to an indirect reliance on physical placement, it was often a part of the pedagogy of *daseian* notation (developed in the ninth century, apparently with an eye toward accommodating the needs of *organum* at the fourth) to place "high" notes higher on the page, even though no such discrimination was required by the notation (since it relied strictly on a limited repertoire of letter-like symbols to indicate different pitches). See *Musica et Scolica enchiriadis una cum aliquibus tratatulis adiunctis*, ed. Hans Schmid, Veröffentlichungen der Musikhistorischen Kommission, Bayerische Akademie der Wissenschaften, 3 (Munich: Verlag der Bayerische Akademie der Wissenschaften, 1981); and the *Musica enchiriadis* and *Scolica enchiriadis*, ed. Claude V. Palisca, trans. Raymond Erickson, Music Theory Translation Series (New Haven, Conn.: Yale University Press, 1995). These treatises are currently thought to have been written no later than the tenth century and possibly as early as the middle of the ninth. For further discussion of the history of this notational convention, see Marie-Elisabeth Duchez, "La Représentation spatio-verticale du caractère musical grave-aigu et l'élaboration de la notion de hauteur de son dans la conscience musicale occidentale," *Acta musicologica* 51 (1979): 54–73.

20. It should be observed that a disassociation of pitch from sound does not obviate an image-schematic basis for understanding pitch relations. It only bears witness to a reification of pitch after its initial conceptualization.

Cross-Domain Mapping, Music, and Music Theory

PALESTRINA'S TEXT PAINTING The theory of cross-domain mapping outlined in the preceding discussion provides a relatively simple way to account for the effectiveness of Palestrina's text painting. According to this theory, we use the VERTICALITY schema, the product of countless bodily experiences, to give physical space an "up" and a "down" analogous to the "up" and "down" of our bodies. This orientation is then mapped on to a metaphorical musical space made up of pitches and the relations (or distances) between them. Pitches that result from more rapid vibrations of the sounding medium are regarded as "higher" than pitches that result from less rapid vibrations of the sounding medium. As each of the voices in Palestrina's six-part texture takes up the word "descendit," it begins to "descend" through musical space. The notion of descent summoned by the text is thus given sounding image by a specific series of musical events.

Of course, we could also hear (through the ears of a Javanese musician) the pitches growing larger, or hear (through the ears of the Suyá) the pitches growing older, or hear (through the ears of a Greek theorist) the pitches growing heavier. Distinct from these ways of hearing, Palestrina's text painting relies on a conceptual model that characterizes pitches as objects in two-dimensional, vertically oriented space, in which "up" and "down" describe specific pitch relations. This model is strongly associated with the conventions of musical notation as developed in the West: as pitches get "lower" in sound, they are also written "lower" on the musical staff.

There is an additional reason why Palestrina's text painting is as convincing as it is, however. The image of descent created by Palestrina relies on more than just the general notion of descent, which could have been evoked in a variety of ways: by a downward leap of a single interval; by a short sequence that alternated descending thirds with ascending seconds; or through having each voice enter in turn, beginning with the highest voice and ending with the lowest. The scalar descent chosen by Palestrina, however, provides a striking analogue for the descent of our bodies through physical space (when this descent is unaided by artificial means). Such a descent involves a lessening of potential energy and a continuous action in one direction, articulated by the regular transfer of weight from one leg to another.[21]

21. Most of us find descent—especially scalar descent—well represented by the thought of walking down a staircase, but I think it could be argued that walking down a hillside works as well. The reason is that it is not so much the neat, two-dimensional image of stairs that is operative but the regular transfer of weight from one leg to another. Indirect evidence is provided by a striking anecdote related by John Hockenberry, from a time when he was a reporter for National Public Radio. In order to get to a group of Kurdish refugees on a remote edge of Iraqi Kurdistan during the aftermath of the 1991 Gulf War, Hockenberry, a paraplegic since 1976, had to abandon his wheelchair temporarily and ride on a donkey. He comments on the effect of becoming reacquainted with a non-wheeled mode of transportation through the rhythm of the donkey's gait: "It was walking, that feeling of groping and climbing and floating on stilts that I had not felt for fifteen years. I had long ago grown to love my own wheels and their special physical grace, and so this clumsy leg walk was not something I missed until the sensation came rushing back through my body from the shoulders of a donkey." Hockenberry, *Moving Violations: War Zones, Wheelchairs, and Declarations of Independence* (New York: Hyperion, 1995), 2–3.

The act of singing a descending scale correlates well with the basic structure of this event: the relaxation many singers feel as they sing a descending scale matches the lessening of potential energy; the temporary pauses on each note of the scale match the regular transfer of weight, which articulates a physical descent. The text painting of "descendit" is thus supported by our embodied knowledge of descent, as well as by the conventions of ascribing "high" and "low" to musical pitches.

In its exploitation and enrichment of a mapping between the domains of physical space and music, Palestrina's text painting also gives us a glimpse into a process of meaning construction. Conventionally, text painting is understood to operate through a crude sort of mimesis: physical descents are represented by musical descents. By contrast, I have argued that hearing a succession of musical events as a descent is an act that is thoroughly mediated.[22] What mimesis there is is highly conditioned by the choice of cross-domain mappings through which discourse about music is structured; in turn, these mappings reflect the global models of a given cultural perspective and historical moment. Palestrina's text painting is not just woven into this web of meaning construction; it also spins its own threads. Some result from specific features of physical descents summoned by the passage, some from the point within the larger musical and dramatic discourse at which this striking moment occurs, and some from the sonic attributes that get mapped back onto the notion of physical descent. The meaning constructed is not, in the final analysis, simple or direct but multivalent and contingent, and it reflects the rich set of correspondences activated by mapping between the two domains.

CROSS-DOMAIN MAPPING AND MUSIC THEORY Because it provides a way to bring an integrated system of terms and structural relations to bear on problems of musical understanding, cross-domain mapping plays an important part in theories of music. Indeed, every theory of musical organization employs cross-domain mappings of one sort or another. Often, the appeal of such mappings is strong, and the mappings seem intuitively correct (much as "high" and "low" seem intuitively correct for the characterization of pitch relations). Further investigation, however, reveals that these mappings are every bit as mediated as those that are less systematically developed.

Rudolf Louis and Ludwig Thuille's characterization of tonality in their *Harmonielehre* provides a case in point. The relevant passage, which appears at the beginning of the first chapter, runs as follows:

> The unity within the diversity of all harmony is ensured through the law of *tonality*. This asserts that any succession of harmonies can become musically understandable only when each (independently appearing) *chord* is perceived to be in a specific relationship of dependence with respect to the *principal chord* that underlies the entire harmonic context. Both melodic and harmonic succession require a *center*, a point of repose, around which everything twists and turns. For *melodic* relationships, this stationary middle point is the *tonic note*, the Tone, whose central place in the scheme of the scale is made manifest by the melodic motions that we direct away from tonic and

22. This same argument, mutatis mutandis, applies to McClary's analysis of Robert Johnson's blues mentioned above in the preface.

> then back toward it again. The same role of a fixed middle point and resting place that, within melodic unity, falls to the tonic note, is played, with respect to harmony, by the *tonic chord*: the *consonant triad* that has the tonic note as its *root*.[23]

The view set forth by this characterization is that musical organization is analogous to that of the physical world. Music consequently obeys laws that are independent of human beings—"tonality" is, as it were, a natural force.[24] Musical understanding relies on apprehending the harmonic dependencies that reflect these immutable laws. The focal point of these dependencies is the center of the system—either the tonic note or the tonic chord—which acts as both a center of gravity and an axis of symmetry.[25] To support this perspective, Louis and Thuille appeal to the empirical evidence provided by actual melodic and harmonic progressions, which they believe show that every properly constructed melody turns around a single tonic note, and that every properly constructed harmonic progression turns around a single tonic chord.

Louis and Thuille's characterization of tonality does a marvelous job of capturing the compelling coherence wrought by well-composed tonal music. Given the evidence of ethnographic and historical studies of musical cultures, however, the idea that Western European tonality is a naturally occurring force seems doubtful, as would be the notion of a science aimed at discovering the laws behind this force. Also implicit in Louis and Thuille's theory is the concept that tonality exists apart from musical syntax: successions of musical events do not give rise to the law of tonality but serve only to provide evidence of its existence. According to this perspective, successions of musical events that do not provide evidence of tonal relations cannot be understood as music. Of course, such a view places rather profound restrictions on what counts as music.

Theorizing about music requires that we bring order, even if of a tenuous sort, to an ephemeral and often intangible domain. Cross-domain mapping aids this process by bringing systems of relationships to bear on the musical domain and by

23. "Die Einheit in der Mannigfaltigkeit aller Harmonie wird gewährleistet durch das Gesetz der *Tonalität*. Dieses sagt aus, daß irgendwelche Folgen von Harmonien nur dann musikalisch verständlich wirken können, wenn jeder (selbständig auftretende) *Accord* in einem bestimmten Verhältnis der Abhängigkeit von einem dem ganzen harmonischen Zusammenhang zugrunde liegenden *Hauptaccord* aufgefaßt wird. Wie die melodische Folge, so bedarf auch die Accordfolge eines *Centrums*, eines ruhenden Pols, um den sich alles 'dreht und wendet.' Für die *melodischen* Beziehungen ist dieser feststehende Mittlepunct die *Tonica*, der Ton, dessen centrale Stellung im Schema der Tonleiter dadurch zum Ausdruck gebracht wird, daß wir deren melodische Bewegung von ihm ausgehen und zu ihm wieder zurückkehren lassen. Dieselbe Rolle eines fixen Mittle- und Ruhepuncts, die innerhalb der melodischen Einheit der Tonica zufällt, spielt in *harmonischer* Hinsicht der *Tonica-Accord*: der *consonierende Dreiklang*, der Tonica zum *Grundton* hat." Rudolf Louis and Ludwig Thuille, *Harmonielehre*, 7th ed. (Stuttgart: Carl Grüninger Nachf. Ernst Klett, 1920), 7.

24. I should point out that Louis and Thuille are not concerned with tonality as it might be broadly defined, but with tonality as it is represented in Western European music of the eighteenth and nineteenth centuries. This is made all the more clear by their characterization of tonality in harmonic terms, something that has limited applicability to a fairly wide range of music currently recognized as tonal.

25. In the pages that follow this excerpt, Louis and Thuille explore in greater detail the idea that tonic is at the center of a symmetrical scheme of pitches and harmonies. See Louis and Thuille, *Harmonielehre*, 8–10.

correlating rich, if at times complicated, images with essential musical concepts. Such mappings are a way to both structure our understanding and extend it—indeed, much work in music theory is devoted to exploring the ramifications of these mappings. Nonetheless, each mapping reflects the cultural values and imperatives relative to which it is framed, not the verities of absolute musical structure. Tonality is not, in a simple way, a centric and symmetrical system, any more than it is a reflection of logic (as Hugo Riemann would have it), psychological energetics (as Ernst Kurth would have it), or gravity (as Arnold Schoenberg would have it).[26] Instead, tonality is a way of understanding musical organization. The cross-domain mappings through which notions such as tonality are articulated are not simply essential to theories of music; in fact, they constitute what counts as music in the first place.

Summary

Cross-domain mapping is a general cognitive process through which we structure an unfamiliar or abstract domain in terms of one more familiar or concrete. Cross-domain mapping plays two important roles in musical understanding. First, it provides a way to connect musical concepts with concepts from other domains. As we saw here, pitch relations within the domain of music have been connected with concepts associated with vertical space, waterfalls, physical size, and human aging. Each such mapping made possible systematic accounts of the ways pitches related to one another. Second, cross-domain mapping allows us to ground our descriptions of elusive musical phenomena in concepts derived from everyday experience, since the structural relations basic to cross-domain mapping have their source in repeated patterns of bodily experience—that is, in image schemata.

As we have seen, the mappings we use to structure our discourse about music are not accidental but reflect two constraints. One constraint is the Invariance Principle, which proposes that the best cross-domain mappings are those that preserve as much of the image-schematic structure of both target and source domains as possible. The other constraint is provided by the global conceptual models relative to which cross-domain mappings are framed. Taken together, these constraints suggest that cross-domain mappings not only provide a way to structure our understanding of music but also shape our ideas about what we include under the rubric "music." For an element to count as musical, it must be able to serve as a target for the cross-domain mappings that guide our discourse about music.

Because cross-domain mapping offers a way to connect what are often elusive musical concepts with concepts from more concrete domains, and because these connections give rise to integrated systems of terms and relations, cross-domain mapping is essential to our theorizing about music. Indeed, as we shall see in the

Kahnt, 1874); Ernst Kurth, *Die Voraussetzungen der theoretischen Harmonik und der tonalen Darstellungssysteme* (Bern: Akademische Buchhandlungen von Max Dreschel, 1913); Arnold Schoenberg, *Harmonielehre* (Leipzig: Verlagseigentum der Universal-Edition, 1911); trans. as *Theory of Harmony*, by Roy E. Carter (Berkeley: University of California Press, 1978).

next chapter, the concepts derived from processes of categorization and the relations created by cross-domain mapping provide the basic materials for music theory.

CONCEPTUAL BLENDING

Palestrina's text painting relies on our understanding of pitches as "high" and "low" and on our experiences with physical descents down staircases, slopes, and hillsides to create a vivid aural representation of the text. However, the imaginary world summoned by Palestrina also extends beyond the immediate bounds of text and music. Using the basic correlation between text and music as a point of departure, we can enter an imaginary domain in which the pitches to which "descendit" is sung become objects descending through musical space. Within this domain, every physical descent is accompanied by sounds that result from a smooth transition from very rapid to less rapid vibrations of the sounding medium. This extension of Palestrina's imaginarium cannot be predicted simply from linking the domain of text with the domain of music. It results instead from blending elements and events from these two domains to create a new one with its own structures and relations, a domain populated by such things as pitch-objects and the sound of descent.

It must be admitted that an imaginary domain populated with pitch-objects moving through musical space is a somewhat rarefied one. Even so, the process of conceptual blending through which it comes about is itself exceedingly common. For instance, concepts about humans and concepts about animals are often brought together in children's stories to produce talking animals. Such creatures are powerful devices in storytelling, for they offer narrative possibilities beyond those offered by characters with only human or animal attributes. In a like fashion, the combination of musical concepts with those from other domains creates possibilities for meaning construction that reach far beyond those of music alone. As an introduction to a methodology for exploring such conceptual blends in greater detail, let us turn to one of the talking animals from recent literature and discover what he can tell us about the process behind the imaginary world summoned by Palestrina's text painting.

Talking Animals and Conceptual Integration Networks

> The Old Grey Donkey, Eeyore, stood by himself in a thistly corner of the forest, his front feet well apart, his head on one side, and thought about things. Sometimes he thought sadly to himself, "Why?" and sometimes he thought, "Wherefore?" and sometimes he thought, "Inasmuch as which?"—and sometimes he didn't quite know what he *was* thinking about. So when Winnie-the-Pooh came stumping along, Eeyore was very glad to be able to stop thinking for a while, in order to say "How do you do?" in a gloomy manner to him.[27]

Thus A. A. Milne introduces a new character into the stories he crafted for his son, in this case a character built around a stuffed toy donkey Christopher Robin had

27. A. A. Milne, *The World of Pooh: The Complete Winnie-the-Pooh and the House at Pooh Corner*, illustrated by E. H. Shepard (New York: E. P. Dutton, 1957), 45–46.

received as a Christmas present. Eeyore is, unquestionably, a donkey, fond of thistles and content to stay outside in all sorts of weather. But Eeyore is also endowed with human characteristics: he is able to talk, to be perversely gloomy, to work his own convoluted chains of logic, and, on occasion, to be capable of exquisite irony. In fact, Eeyore is a blend of some of the concepts associated with donkeys and with humans.

In order to study conceptual blends such as that represented by Eeyore, the rhetorician Mark Turner and the linguist Gilles Fauconnier developed the notion of *conceptual integration networks* (CINs).[28] Each CIN consists of at least four circumscribed and transitory domains called *mental spaces*. Mental spaces temporarily recruit structure from more-generic conceptual domains in response to immediate circumstances and are constantly modified as our thought unfolds.[29] For instance, Milne's sketch of Eeyore sets up two closely related mental spaces. The first is that of the Old Grey Donkey—solitary, graceless, and phlegmatic. The second is that of a somewhat morose and plodding intellect, tangled in its own thoughts and happy enough to leave them behind at the first opportunity for social interaction. Aspects of these two spaces are combined in a third space, producing the character of Eeyore. Turner and Fauconnier use CINs to formalize the relationships between the mental spaces involved in a conceptual blend, to specify what aspects of the input spaces are imported into the blend, and to describe the emergent structure that results from the process of conceptual blending.

The CIN for the conceptual blend used by Milne is diagrammed in figure 2.2. Its network involves four interconnected mental spaces, which are shown as circles. Central to the network are two correlated *input spaces*, the "donkey" space and the "human" space. The solid double-headed arrow linking these two spaces indicates

28. Research on conceptual blending and conceptual integration networks is discussed in Gilles Fauconnier and Mark Turner, "Conceptual Projection and Middle Spaces," UCSD Department of Cognitive Science Technical Report 9401 (San Diego: University of California, San Diego, 1994); idem, "Blending as a Central Process of Grammar," in *Conceptual Structure, Discourse, and Language* [based on papers presented at the First Conceptual Structure, Discourse and Language Conference, San Diego, 1995], ed. Adele E. Goldberg (Stanford, Calif.: Center for the Study of Language and Information, 1996), 113–30; idem, "Principles of Conceptual Integration," in *Discourse and Cognition: Bridging the Gap: [Second] Conceptual Structure, Discourse, and Language Conference, Buffalo, 1996*, ed. Jean-Pierre Koenig (Stanford, Calif.: Center for the Study of Language and Information, 1998), 269–83; idem, "Conceptual Integration Networks," *Cognitive Science* 22 (1998): 133–87; Mark Turner and Gilles Fauconnier, "Conceptual Integration and Formal Expression," *Metaphor and Symbolic Activity* 10 (1995): 183–204; idem, "Conceptual Integration in Counterfactuals," in *Conceptual Structure, Discourse, and Language, II*, ed. Jean-Pierre Koenig (Stanford: Center for the Study of Language and Information, 1998), 285–96; Turner, *The Literary Mind*; Fauconnier, *Mappings in Thought and Language*; Seana Coulson, *Semantic Leaps: Frame-Shifting and Conceptual Blending in Meaning Construction* (Cambridge: Cambridge University Press, 2001), 115–202. The most comprehensive study of conceptual blending as of this writing is Gilles Fauconnier and Mark Turner, *The Way We Think: Conceptual Blending and the Mind's Hidden Complexities* (New York: Basic Books, 2002).

29. The theory of mental spaces is developed in Gilles Fauconnier, *Mental Spaces: Aspects of Meaning Construction in Natural Language*, 2nd ed., with a foreword by George Lakoff and Eve Sweetser (Cambridge: Cambridge University Press, 1994); Fauconnier, *Mappings in Thought and Language*; Gilles Fauconnier and Eve Sweetser, eds., *Spaces, Worlds, and Grammar* (Chicago: University of Chicago Press, 1996); see also Turner, *The Literary Mind*.

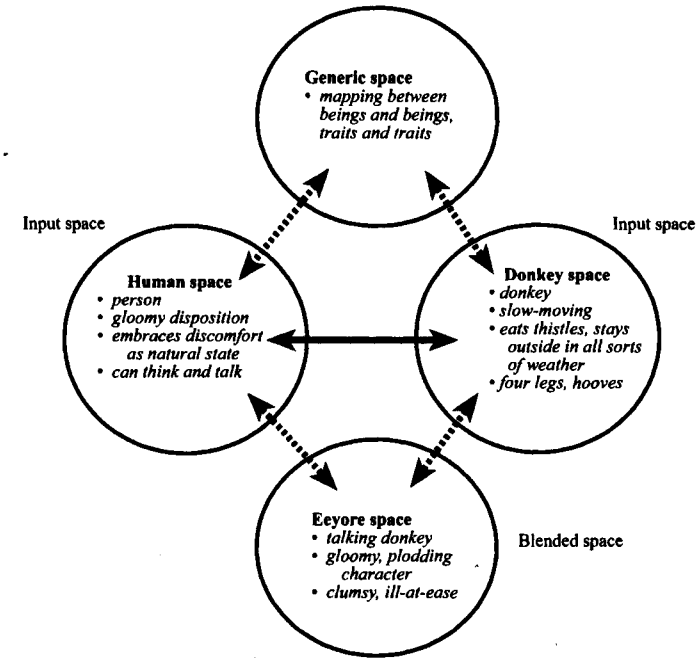

FIGURE 2.2 Conceptual integration network (CIN) for the anthropomorphic blend used for A. A. Milne's Eeyore

that elements within them serve as structural correlates: *person* is correlated with *donkey*, and *gloomy disposition* is correlated with *slow-moving*. Guiding the process of mapping between these domains is the *generic space*, which defines the core cross-space mapping and basic topography for the CIN.[30] Throughout this network, beings are mapped onto beings, and character traits onto character traits. Guided by the conceptual framework provided by the generic space, structure from each of the input spaces is projected into the fourth space, called the *blend*, which results in the anthropomorphic character of Eeyore. The mapping is only partial, however, reflecting the limitations imposed by the generic space. Since the generic space does not map between physical characteristics, we do not expect Eeyore to be of human appearance or to be human-sized.[31]

The dashed arrows linking the generic space to the input spaces, and the input spaces to the blended space, indicate the directions in which structure is projected:

30. The topography of a domain consists of the elements that populate the domain and the relations that hold between them. By definition, all of the domains in a CIN must have a uniform topography, which is represented in its abstract form by the generic space. The requirement of uniform topography within the correlational structure of a CIN can be seen as another manifestation of the Invariance Principle discussed earlier in this chapter.

31. Inasmuch as a number of the characters in Milne's stories originated as stuffed toys, they are easy to imagine as rather diminutive in size; in fact, this is how they are rendered in E. H. Shepard's illustrations. In his text, Milne is relatively silent on this matter, although various contextual clues suggest that the "animals" with which he deals are of the stuffed variety.

from the generic space to the input spaces, and from the input spaces to the blended space. The arrows are double-headed because, under certain circumstances, structure may also be projected from the blended space back into the input spaces, and from the input spaces back into the generic space. The idea of anthropomorphic animals that emerges in the blended space may thus influence the way we think about "regular" animals, leading us to talk to them and act toward them as though they had human characteristics. Similarly, our experiences with actual animals and people give life to the abstractions of the generic space. The double-headed arrows also serve as a reminder of the limitation of all of the diagrams of CINs I shall use: mental spaces are dynamic structures, as are the CINs that are built from them. Thus figure 2.2 represents a sort of analytical snapshot of this particular network, framed with the intent of capturing its essential features, but making no claim to exhausting the possibilities for description. Hints about how the CIN and its spaces may develop can be gleaned from the diagram, but a full account would require a series of such snapshots.

Although the diagram given in figure 2.2 is standard in the literature on mental spaces, it can lead to two misunderstandings. First, since the blend is at the bottom of the diagram, it gives the impression that concepts precipitate down into the blend. Second, the function of the generic space can be a bit confusing, since it does not seem to be directly involved in the blend. In the interests of clarifying these points I offer figure 2.3, which represents the essential components of a four-space CIN in a slightly different format. Here the generic space is properly represented as both the background and the foundation for the entire network. The two input spaces are concrete representations of the abstract structure represented by the generic space, and the conceptual blend is a further projection from these.

An important aspect of the topography of CINs is the basic logic established by the generic space. For the CIN of figure 2.2, the assumption is that beings visibly manifest their character traits. Old donkeys are slow-moving and balky; morose humans are given to gloomy pronouncements on the state of the world; and Eeyore talks and acts like the clumsy, gloomy character he is. The topography of the network also guides three operations—composition, completion, and elaboration—that produce emergent structure unique to the blend.

Composition puts together elements from the input spaces to create new entities in the blended space, yielding the character of Eeyore: although donkeys cannot actually think and talk, and humans do not have four legs or hooves, Eeyore has all these traits. *Completion* extends the image suggested by the initial mapping from the input spaces, drawing on our background knowledge of the circumstances summoned by the CIN. For instance, we know that gloomy characters expect the worst of situations. Eeyore can thus be relied on for solemn pronouncements of impending disaster on even the sunniest of days, to greet each calamity as confirmation of his estimation of the world, and to eat his thistles with little sign of relish. *Elaboration* is a more extensive operation than completion is; it develops the structure of the blended space by building on the principles and logic evinced by the blend. In effect, the input spaces decrease in importance and the focus is directed toward the rich imaginary possibilities of the blended space. At this point, we can start to write

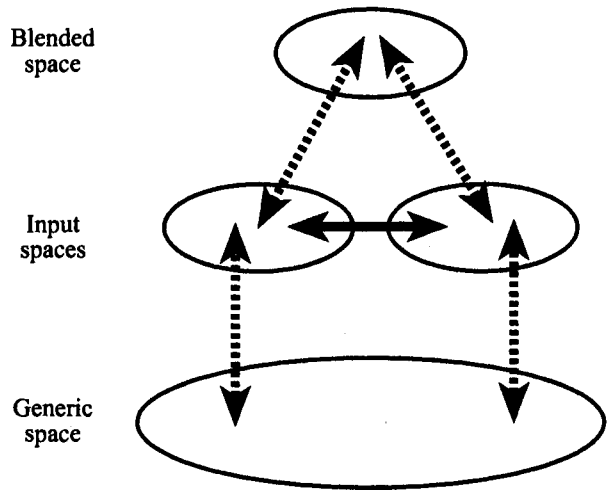

FIGURE 2.3 Alternative representation of a four-space CIN

our own stories about the Old Grey Donkey. Were we to place Eeyore aloft in an airplane, we could be sure he would profess no enjoyment of the view but would instead focus on the various aeronautical catastrophes that, from his perspective, were almost certainly imminent. Given Eeyore's clumsiness and the awkwardness of his hooves, we would be much less likely to imagine him flying the plane, leaving this to the more dexterous animals or to Christopher Robin.

Although the conceptual blend that yields anthropomorphic animals is important to Milne's story, it is not the only blend in evidence. Because Eeyore originated as a stuffed animal, he retains some of the characteristics of the species. Accordingly, in the story in which he is introduced, he loses his tail only to have it recovered by Winnie-the-Pooh and nailed back on by Christopher Robin, a sequence of events unlikely were he based solely on real donkeys. This points to yet another conceptual blend, in which one of the input spaces is structured around stuffed, rather than real, animals (and one that I shall not pursue in the present discussion).

A. A. Milne's Eeyore and most of the other characters from the Winnie-the-Pooh stories provide clear examples of conceptual blending. As indicated, however, the process of blending is not restricted to children's stories. On the one hand, conceptual blending is also common in everyday discourse. Witness statements such as "The car is being stubborn today—I just can't get her to start," which blends concepts related to the physical properties of inanimate objects and those related to the behavior of humans. On the other hand, conceptual blending also has its place in literature. Consider Proust's description of one feature of the springtime walks along the "Méséglise way" in Combray:

> We would leave town by the road which ran along the white fence of M. Swann's park. Before reaching it we would be met on our way by the scent of his lilac-trees, come out to welcome strangers. From amid the fresh little green hearts of their foliage they raised inquisitively over the fence of the park their plumes of white or mauve

> blossoms, which glowed, even in the shade, with the sunlight in which they had bathed.[32]

Here Proust blends features of the lilac trees with actions of which only animals or humans are capable, thus creating a memorable image that perfectly captures the intense sensual engagement prompted by spring.

Conceptual blending is a pervasive and often transparent cognitive process. A given situation or story may involve any number of conceptual blends, as the character of Eeyore—constructed from the attributes of both stuffed and real animals—shows. Each such blend can be described through a conceptual integration network, which permits a systematic description of specific features of the blend. Finally, the CIN associated with the character of Eeyore can be used to explain why the Old Grey Donkey has some, but not all, of the features of humans, and why we can easily imagine him taking part in some activities but not in others.

Conceptual Blends and Text Painting

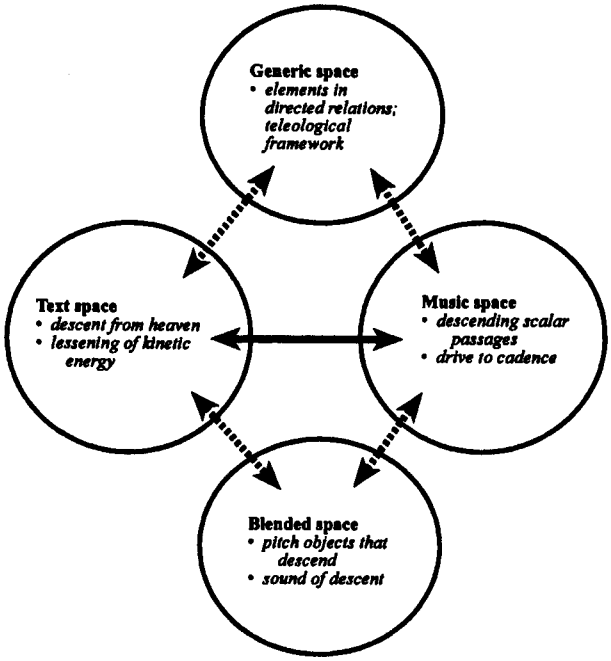
In the conceptual blends just discussed, the input spaces for each CIN were summoned by language. As Fauconnier has noted, however, mental spaces are very general and are constructed for many cognitive purposes; language is but one way to prompt the construction of a mental space.[33] Under certain circumstances, music can also prompt space construction. In the case of Palestrina's text painting, the mental space is relatively circumscribed and focuses on an orderly progression of pitches that lead resolutely toward a cadence. This space is in correspondence with that set up by the text, which focuses on Christ's movement from the heavenly to the mundane and the lessening of potential energy associated with physical descents.

Correlations between the musical and textual spaces involved in Palestrina's text painting set up the CIN shown in figure 2.4. The generic space for the CIN is structured around the notion of elements that are in directed relations conceived with respect to a teleological framework. Within the network, motions through physical and musical space are *directed* motions. As with the conceptual blend associated with the character of Eeyore, the emergent structure of the blended space can be described in terms of the operations of composition, completion, and elaboration.

Composition puts musical pitches together with the act of descent to yield pitch-objects that descend. Composition also associates descent with a specific sound, which actual descents may or may not produce. Completing this image, we might infer that the lower the pitch, the closer it is to the ground and to the mundane. We could also infer that, since descent can be given a sound, ascent can also be given a sound. Palestrina in fact confirms the latter inference in mm. 92–93 of the

32. Marcel Proust, *Swann's Way* (vol. 1 of *Remembrance of Things Past*), trans. C. K. Scott Moncrieff and Terence Kilmartin (New York: Vintage Books, 1981), 147–48. Further blends in Proust are discussed in Turner, *The Literary Mind*, 91–92, 120–23; see also my concluding chapter.

33. Personal communication from Gilles Fauconnier, 8 September 1998. This perspective is also represented, somewhat less explicitly, in Fauconnier and Turner, "Conceptual Integration Networks"; and Fauconnier, *Mappings in Thought and Language*.



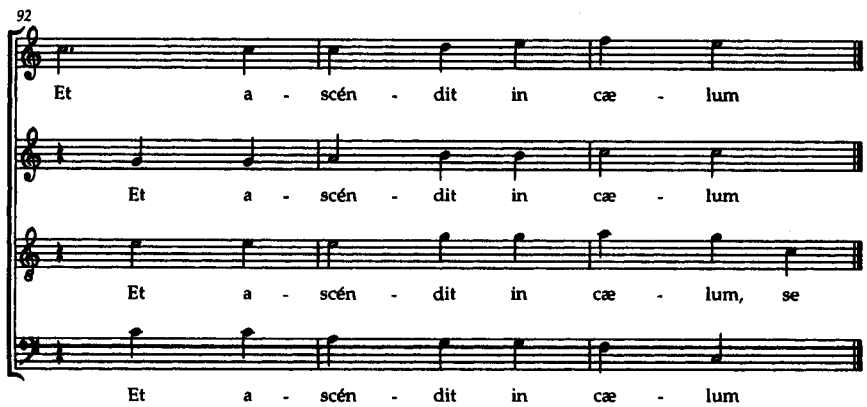


FIGURE 2.4 CIN for Palestrina's text painting

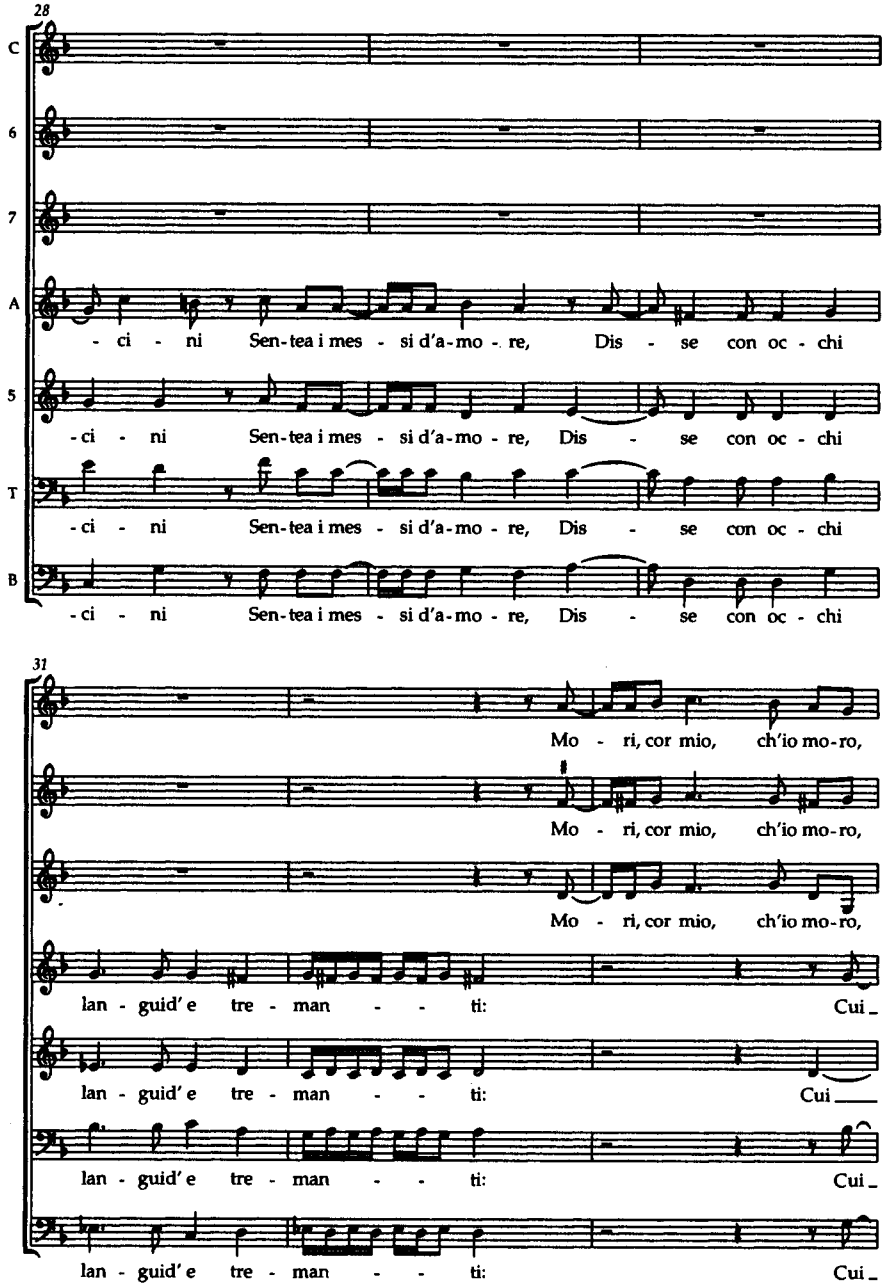
Credo, when, as shown in example 2.2, he sets "ascendit" with steadily rising pitches. Elaborating the blend, we might imagine pitch-objects doing all sorts of things, not just ascending and descending. Something like this is behind Louis and Thuille's characterization of tonality as a system of forces operating on pitches distributed throughout the field of musical space.

The extension of the conceptual blend suggested by mm. 92–93 of the Credo

EXAMPLE 2.2 Giovanni Pierluigi da Palestrina, Credo of the *Pope Marcellus Mass*, mm. 92–94

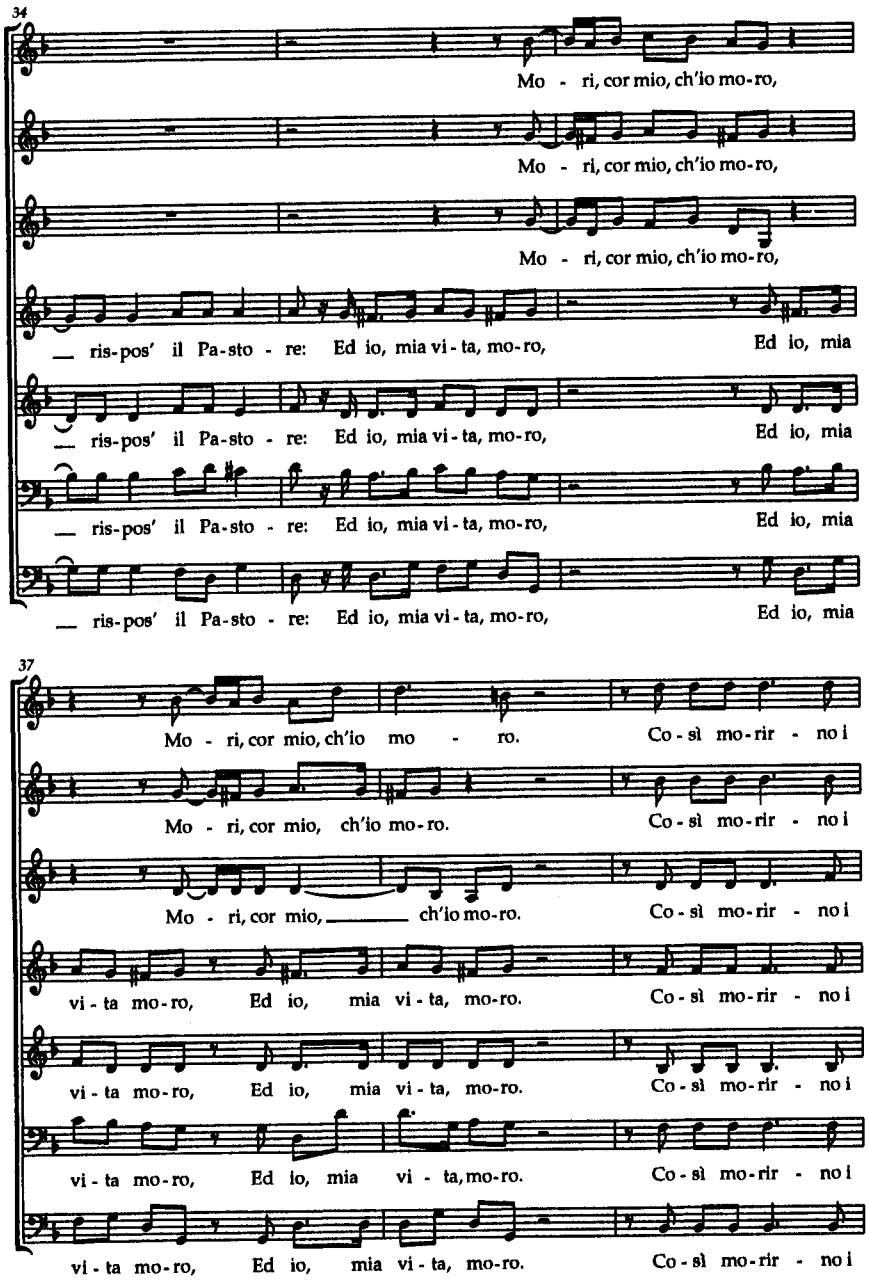
notwithstanding, Palestrina's text painting is a relatively isolated instance of meaning construction involving music and language. Indeed, text painting is usually regarded as a clearly circumscribed compositional technique, most often restricted to a single word or image. Under certain circumstances, however, music and language can combine to create rather more extended possibilities for meaning construction, as is shown by an instance of text painting in Giaches de Wert's seven-part madrigal "Tirsi morir volea," first printed in 1581.



The text for Wert's madrigal is from a poem by Giovanni Battista Guarini that is probably the most popular madrigal text of the late sixteenth century. It recounts a sexual encounter between a shepherd and a nymph.[34] The passage relevant to discussion here appears in example 2.3; the text for the entire poem, with the verses that appear in example 2.3 underlined, is as follows:

TIRSI MORIR VOLEA	THYRSIS WISHED TO DIE
Tirsi morir volea,	Thyrsis wished to die,
Gli occhi mirando di colei ch'adora,	gazing at the eyes of his beloved,
Quand'ella, che di lui non men ardea,	when she, whose ardor equaled his,
Li disse: "Ahimè, ben mio,	said: "Alas, my love,
Deh non morir ancora	do not die yet,
Che teco bramo di morir anch'io."	since I long to die with thee."
Frenò Tirsi il desio,	Thyrsis curbed the desire,
Ch'ebbe di pur sua vita allor finire,	which by then had almost ended his life:
E sentea morte, e non potea morire;	he felt death near, yet could not die;
E mentre il guardo suo fisso tenea	and while he kept his gaze
Ne' begli occhi divini,	fixed upon those eyes divine,
E'l nettar amoroso indi bevea,	and drank from thence the nectar of love,
La bella Ninfa sua, che già vicini	his pretty Nymph, who felt
Sentea i messi d'Amore,	Love's heralds near,
Disse con occhi languid' e tremanti:	said with languishing and trembling looks:
"Mori, cor mio, ch'io moro."	"Die my heart, for I die."
Cui rispose il Pastore:	At which the Shepherd replied:
"Ed io, mia vita, moro."	"And I, my life, die."
Così moriro i fortunati amanti,	Thus the happy lovers died
Di morte sì soave e sì gradita,	a death so sweet and pleasant,
Che per anco morir tornaro in vita.	that in order to die again, they returned to life.

The text painting begins in mm. 31–32 when the word "tremanti" is set to a written-out ornament (a trill or gruppo) in all parts. "Tremanti" ("trembling") sets up a mental space focused on an intense and partially involuntary physical reaction to stress that produces repeated oscillating motions. The written-out ornament sets up a mental space focused on the rapid alternation of a "minor chord" with E♭3 in the lowest voice, and a "major chord" with F♯4 in the highest (which creates an



34. The context for Guarini's poem and Wert's setting of it have been discussed by Laura Macy in "Speaking of Sex: Metaphor and Performance in the Italian Madrigal," *Journal of Musicology* 14 (1996): 1–34.

EXAMPLE 2.3 Giaches de Wert, "Tirsi morir volea," mm. 28–39

(continued)

EXAMPLE 2.3 *(continued)*

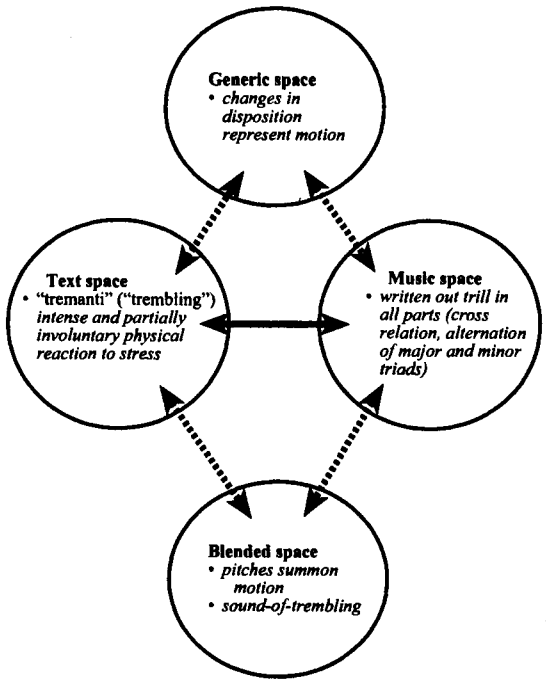


FIGURE 2.5 CIN for mm. 31–32 of Wert's "Tirsi morir volea"

augmented-second cross-relation).[35] Similarities between these spaces suggest correlations between their elements: each chord in the musical space correlates with an end-point of the physical motion summoned by the textual space, and the intensity of the physical reaction correlates with the rapid alternation of major and minor chords and the cross-relation between the outer voices.

It is the correlations between these spaces that set up the CIN shown in figure 2.5. The generic space for the CIN is structured around the idea that changes of disposition represent motion.[36] Physical trembling of the sort summoned by "tremanti" is one instantiation of this notion, and the rapid alternation of musical materials is another. Once again, the emergent structure of the blend can be described in terms of the operations of composition, completion, and elaboration. Composition combines musical pitches with specific features of trembling, so that the pitches summon a sense of physical motion even though the sound-source producing them remains relatively fixed: the singers of Wert's madrigal need not actually tremble when they sing "tremanti." Composition also suggests that trembling has a sound,

35. At the time Wert's madrigal appeared, terms such as "minor chord" and "major chord" were not conventionally used to describe simultaneous sonorities. Writers on music during the period preferred to describe sonorities in terms of their intervallic makeup. In the present context, this more accurate terminology is just a bit unwieldy, and I have consequently used somewhat more familiar and concise modern terms. I trust their anachronistic application here will not prove unduly confusing.

36. This is analogous to the phi phenomenon noted by Gestalt psychologists. See Kurt Koffka, *Principles of Gestalt Psychology* (London: Routledge and Kegan Paul, 1935), 179.

even though most actual trembling is done in relative silence. If we complete the pattern suggested by the basic mapping, we can infer that once the physical action stops the sound will stop. Finally, through elaboration we can imagine that successions of restricted groups of pitch materials could depict intense physical actions more complex than trembling, perhaps even extending to the interaction of physical bodies.

Although the elaboration of a blended space is often left to our imagination, at times it may be explicitly developed. This is indeed what Wert does in the measures immediately following the setting of "tremanti." Here are some of the salient features of the music of mm.33–38:

- Starting with the pickup to m.33, the women's and men's voices engage in a rapid alternation of entrances.
- The beginnings and endings of the entrances are elided, so that the singing is seamless.
- The spacing between entrances is gradually compressed, culminating in the joining of men's and women's voices in mm.37–38; in fact, this is the first time in the madrigal that the two vocal groups sing together.
- The setting is almost entirely homophonic within each group of voices.
- The harmonic material is highly restricted, consisting almost entirely of triadic sonorities built on G, D, and F.
- In m. 38, the music breaks off, and there is a half measure of silence.

The alternation of restricted groups of pitch material, the charged interaction of the vocal groups, the sudden breaking off of the voices in m.38, and the context provided by the blend produced by the text painting of "tremanti"—all summon an image of intense physical activity followed by a sudden suspension of that activity. It is an image that gives sounding representation to the sort of death—sexual orgasm—about which the poem obsesses. This image also offers a way to ground the double entendre exploited by Guarini, built on the paradoxical connection between life at its most intense and death. Both sexual climax and death are marked by sharp, nearly immediate contrasts: orgasm followed by quiescence; the clamor of life followed by the silence of death. Wert's music, building from the common ground shared by sexual climax and death, breathes life into a play of words that, by this point in the sixteenth century, had become a rather common commonplace.[37]

It is important to emphasize that not all combinations of text and music will yield rewarding conceptual blends. For a blend to occur, there not only needs to be some correlation between two domains, but the domains must also have a uniform topography. In some cases—certain strophic songs, for instance—the correlation between text and music is simply too general to generate a compelling blend. In

37. My interpretation of connections between sexual climax and death is somewhat different from that offered by Laura Macy. Noting that early physiological accounts saw both sex and death as an emission of spirit, Macy writes that "this link is surely at the bottom of the metaphoric use of the word death to mean sexual climax" ("Speaking of Sex," 5). While I would not want to deny the importance of this connection, my argument is that commonalities between the larger physiological processes of both orgasm and death could also serve to ground the metaphor and that Wert's music provides a musical analogue for these.

other cases—formulaic songs composed for opera or reflecting the more commercial side of popular music—the correlation between text and music may be so tenuous as to be virtually nonexistent. Also important are the conceptual models that inform the interpretation of the correlation between the input spaces for a blend. A careful listener who is nonetheless unaware of the context of Palestrina's music, for example, will almost certainly realize that something is going on in the passage cited in example 2.1 but may interpret the music as "sad" or "losing energy." If conceptual models associated with the act of descent, or with this particular portion of the Mass, are not activated, the listener may get no farther than this. Similarly, Wert's climactic moment, for a listener who does not understand the text (either for lack of knowledge of Italian or out of innocence of the double entendre), may simply be heard as "exciting." In both cases, the conceptual blends will remain latent: potential but not actualized opportunities for the construction of meaning.

As Wert's madrigal suggests, conceptual blends involving text and music may be relatively extended. Chapter 6 will consider such blends in greater depth, showing how they develop over the course of entire songs, how the same text set to new music can give rise to two very different songs, and how music alone can elaborate a blend first set up by text and music.

Conceptual Blending and Program Music

In theory, conceptual blends may involve mental spaces associated with any domain of thought. Musical domains could thus be correlated not only with domains associated with language but also with physical gesture or color.[38] In the following, I would like to consider the conceptual blends that occur when instrumental music is associated with an extra-musical program. Although such programs are almost always invoked through language, the connection between the musical and linguistic domains is much looser, and the concepts that emerge from the blend are somewhat more variable. The generality of such blends also allows them to cover greater expanses of music—in the example with which I am concerned here, an entire symphony.

Ludwig van Beethoven's Symphony No. 6 in F major, Op. 68 ("Pastorale") is among the most well-known of instrumental works with which extra-musical programs have been associated. In the case of the Sixth Symphony, this association was aided by the descriptive titles Beethoven gave individual movements (such as

38. The correlations I refer to here are between the conceptual domains associated with music and with colors or gestures; this fits with my notion of concepts as not necessarily linguistic. However, I am not thinking of synaesthesia, where stimuli applied to one of the five senses produces responses in one or more of the other senses as well; I view this phenomenon as functionally automatic and thus not involving concepts. Synaesthesia between music and color is common enough to have warranted relatively extensive research, and no end of commentary. See, for instance, Lawrence E. Marks, *The Unity of the Senses: Interrelations among the Modalities* (New York: Academic Press, 1978); Wilson Lyle, "Colour and Music: An Introduction," *Music Review* 43 (1982): 261–64; Michael Hurte, *Musik, Bild, Bewegung: Theorie und Praxis auditiv-visueller Konvergenzen* (Bonn: Verlag für systematische Musikwissenschaft, 1982); and Jonathan W. Bernard, "Messiaen's Synaesthesia: The Correspondence between Color and Sound Structure in His Music," *Music Perception* 4 (1986): 41–68.

"Scene by the Brook"). As Richard Will has pointed out, the programmatic aspects of the Sixth Symphony created difficulties for those who sought to give an account of the work, for the simplistic representation of natural sounds seemed in conflict with the received wisdom that Beethoven's music referred to nothing outside itself.[39]

Symptomatic of this uneasiness with Beethoven's program was Donald Francis Tovey's outright rejection of any link between such natural sounds and the music of the Sixth Symphony. Tovey writes, "In the whole symphony there is not a note of which the musical value would be altered if cuckoos and nightingales, and country folk, and thunder and lightning, and the howling and whistling of the wind, were things that had never been named by any man, either in connection with music or with anything else."[40] With the correlation between the domain of nature and the domain of music sundered, Tovey paves the way to approach the work as "a perfect classical symphony" and to claim for it a place in the pantheon of Beethoven's works.

Nevertheless, Tovey's analysis of the symphony seems to speak of something other than absolute music. Describing an important moment in the slow movement, he writes,

> The deep shadow of this remote key of G flat becomes still deeper as C flat, which, changing enharmonically to B natural, swoops round to our original key B flat. At the outset of this wonderful passage the theme was that of the first subject with the murmur of the brook becoming articulately melodious in the clarinet and the bassoon. At the moment when the melody gathers itself up into a sustained phrase and makes its enharmonic modulation, there comes a phenomenon full of deep meaning. From this point nothing is left of the melody but sustained notes and bird-song trills; the whole of the rest of the return to the main key is harmonic and rhythmic. In this as everywhere else the movement remains true to type, a perfect expression of the happiness in relaxation.[41]

Here we have key areas that swoop, clarinets and bassoons that are articulate, and melodies capable of independent motion, all within a movement that expresses the happiness there is to be found in relaxation.

At first glance, Tovey's prose seems to retain the very correlation between the domains of music and nature that he had earlier rejected, and to develop a conceptual blend based on this correlation. Still present are the murmur of the brook, the bird-song trills of melody, and the general atmosphere of the pastoral, all wedded to Beethoven's music. Closer consideration, however, shows that the correlation of music and nature cannot explain the structural attributes of the imaginative domain summoned by Tovey. Although nature includes living beings, music does not; at best, music comprises sounds that occur within a temporal framework. The independent agency implied by Tovey, evident in the articulate and goal-directed entities he imagines, also seems somewhat out of step with the commonplace view of

39. Richard Will, "Time, Morality, and Humanity in Beethoven's *Pastoral* Symphony," *Journal of the American Musicological Society* 50 (1997): 271–329.

40. Donald Francis Tovey, *Symphonies* (vol. 1 of *Essays in Musical Analysis*) (London: Oxford University Press, 1935), 45.

41. Tovey, *Essays in Musical Analysis*, 1: 51. The reference is to mm. 78–85 of the slow movement.

nature as a domain in which events are guided not so much by individual volition as by larger forces working from without. In short, it is one thing to link elements of nature and musical sounds to create a domain in which the cuckoo sings with the timbre of the clarinet and the sound of a brook is summoned by undulating patterns in the strings. It is rather another to animate musical sounds and to endow them with their own volition.

As it turns out, Tovey's interpretation does not rely on a simple correlation between music and nature. Instead, Tovey activates a much larger network of mental spaces to produce his interpretation. Central to this network is one of the most common of conceptual blends, that of anthropomorphism (which played an important role in the blend that produced A. A. Milne's Eeyore). The basic correlation that underlies this blend can be seen in statements like "The car is being stubborn today —I just can't get her to start." In this mapping, the domain of inanimate objects is structured by the human domain; more specifically, *human being* is mapped onto *car*, and a volitional state proper to humans (*stubbornness*) is mapped onto the mechanical state of the car (*not-starting*).[42] A blend that exploits this mapping might then attribute additional volitional or emotive states to the vehicle ("I think the car wants to stay home," "She's mad because I haven't changed her oil"), or extend into the nonvehicular domain ("I don't think the toaster likes me, it keeps burning the bread"). In its most abstract form, this blend involves two input spaces, as shown in the CIN of figure 2.6. One recruits structure from the human domain, the other from some non-human domain. The correlation of these two spaces gives rise to the blended space of anthropomorphism, whose emergent structure reflects the counterpart correlations of the input spaces. Within this space, non-human entities become endowed with the characteristics and intellects of humans while retaining many of the features that make them distinct from humans. An anthropomorphic car may be stubborn and sullen, but it will also be able to stay outside year round (even though it may not "like" to do so).

The generic space for the CIN connects entities with entities and states with states. According to the logic proper to the network, the events that occur within each source domain have causes that follow from the rules that govern the behavior of entities that populate the domain. *Stubbornness* in the human domain reflects personal idiosyncrasies and may be abetted by external circumstances that render the current situation unsatisfactory. According to conventional wisdom, people are stubborn either because they were born that way or because they are unhappy with the way things are and will not take any action (other than being stubborn) until things change. *Not-starting* in the domain of automobile mechanics is caused by electromechanical conditions that are insufficient to initiate or produce sustained combustion. The car will not start because there is something wrong with the engine. It is important to note that, although the generic space may have a structure that is strongly image-schematic, generic spaces are often rich with detail. Generic spaces

42. Note that to ascribe a state associated with a living entity to a nonliving entity is not the same thing as to endow the latter with life. The statement "The car won't start—I think it died" does not entail a belief in animistic vehicles, but only correlates a particular state associated with living beings (*being dead*, or *being no-longer-alive*) with the mechanical state of the car (*never-to-start-again*).

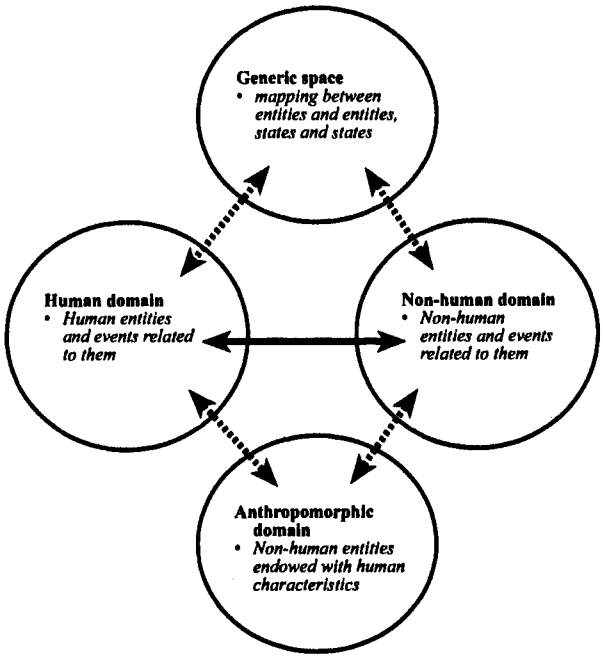

FIGURE 2.6 CIN for anthropomorphic blend

are not necessarily primitive or schematic—they only define the basic topography common to all of the spaces in the blend.

Tovey activates the mental space of anthropomorphism early in his essay when he writes, "The Pastoral Symphony has the enormous strength of some one who knows how to relax."[43] Within the blend that results from correlating the human and musical domains, musical events become actors endowed with their own characteristics and capable of their own acts of volition. Thus the transition that follows the first subject of the opening movement of the symphony "leads in three indolent strides to a second subject which slowly stretches itself out over tonic and dominant as a sort of three-part round."[44] Tovey develops an anthropomorphic perspective on nature more gradually, bringing it to fruition only in his account of the end of the slow movement. "Suddenly for a moment all is silent; we have no ears even for the untiring brook, and through the silence comes the voice of the nightingale, the quaint rhythmic pipe of the quail, and the syllabic yet impersonal signal of the cuckoo."[45] Here elements of nature (brooks and birds) become actors, each endowed with individual characteristics and capable of individual acts of volition. In both cases, the correlation of human and non-human domains gives rise to imaginative conceptual blends: symphonies that know how to relax, musical passages that stride, brooks that do not tire, and cuckoos capable of impersonal signals.

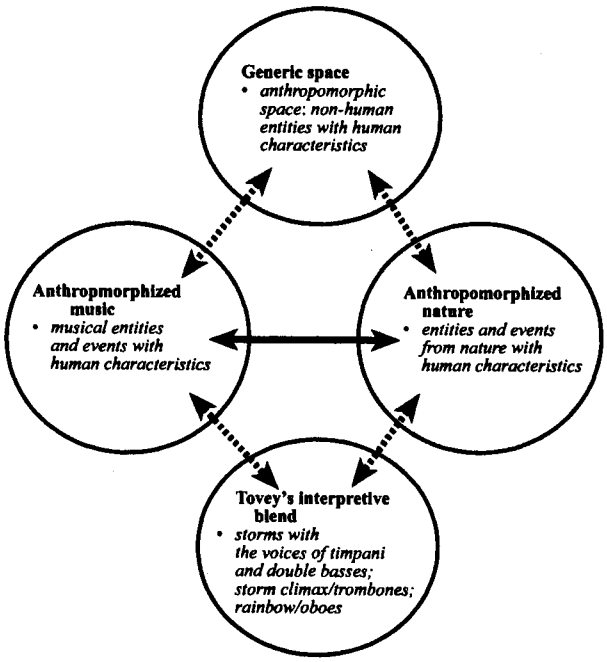

FIGURE 2.7 CIN for Tovey's analysis of the Beethoven Pastoral Symphony

Construing both music and nature in anthropomorphic terms makes it possible for Tovey to connect the two in a further blend, shown in figure 2.7. The generic space for this network is the blended space of figure 2.6. One of the input spaces is that of anthropomorphized nature, which includes natural agents who act within and respond to their native environment ("nature"). The other input space is that of anthropomorphized music, which includes musical agents who act within and respond to their native environment ("music"). In the blend, aspects of the input spaces are combined to create unique entities and relations. Here the murmur of a brook becomes an articulate melody for clarinets and bassoons; here Beethoven's music can be conceived as natural without having been reduced to nature.

The three operations that produce emergent structure in the blended space—composition, completion, and elaboration—are all evident in Tovey's account of the end of the fourth movement: "The storm moves in grand steps to its climax. This is marked by the entry of the trombones. . . . Then the storm dies away, until with the last distant mutterings of the thunder the oboes give a long slow fragment of bright sustained melody on the dominant of F. This has been aptly compared with a rainbow."[46] Composition unites the lives and interests of natural agents and musical agents. In the final twenty measures of the fourth movement, the thunder mutters with the voices of the timpani and double basses, who also prepare the tonality of the closing fifth movement precipitated by the retreat of the storm.

46. Tovey, *Essays in Musical Analysis*, 1: 55.

Completion supplies additional structure. Beethoven's terse title for the fourth movement is "Gewitter, Sturm" ("Thunderstorm, Tempest"), which says nothing of the aftermath of a storm. Nonetheless, we know that rainbows often follow storms, and so the "bright sustained melody" of the oboes can summon the image of a rainbow, a completion suggested but not necessitated by the input spaces.[47] Elaboration develops the blend by pursuing its logic. The storm, as a magnificent entity, moves with grand steps. The climax of its terror and wrath (enacted through musical agents) is marked by the entry of new musical agents (the trombones). As these passions abate, musical agents gradually disappear (a change only implicit in Tovey's prose) until only a bare few remain. Perhaps most striking about this elaboration is that a single natural agent (the storm) appears to be brought fully to life only through a multiplicity of musical agents. Such a genesis, while inexplicable in the natural domain, is fully consonant with the idiosyncrasies of the musical domain. There, individual musical entities (such as movements or entire symphonies) are often understood to emerge from the actions of the subentities (such as themes or tonal areas) that they comprise.

Tovey thus mobilizes a number of mental spaces to provide an account of Beethoven's symphony. The most active spaces are those that contribute to a blend of anthropomorphized natural and musical elements. This blend gives Tovey a way to describe music that seems naturalized but does not reduce to a simple correlation of natural and musical sounds. Less active, but still important, are spaces involved in blends fundamental to this primary network. These include spaces built up from the domain of human entities and events, along with the domains of nature and music. Tovey's description makes only sparing use of these subsidiary blends, since they cannot provide the naturalized account of music that is the goal of his essay. Far in the background is the generic space common to anthropomorphic blends, which defines the core cross-space mapping and logic that underlie the entire network.

Summary

Conceptual blending is a dynamic process of meaning construction that involves small, interconnected conceptual packets called mental spaces, which temporarily recruit structure from conceptual domains in response to local conditions. When blending occurs, a portion of the structure from two correlated input spaces is projected into a third, blended space. As part of this process, the operations of composition, completion, and elaboration produce structure within the blend that is not found within either of the input spaces. This structure only becomes possible through the concepts and relations produced by conceptual blending.

The structure common to the mental spaces within a conceptual integration network is reflected in the generic space. This space defines the core cross-space mapping and is organized according to a basic logic that remains consistent throughout the network. Generic spaces are not necessarily primitive or image-

47. This suggestion is also followed by the animators of Walt Disney's *Fantasia*, who not only supply a rainbow to accompany this moment in Beethoven's symphony but integrate it within the multileveled, quasi-mythical story they set to the music.

schematic—they only define the basic topography common to all of the spaces in the blend.

In a basic blend, four spaces will be active (although not necessarily to the same degree): the generic space, the input spaces, and the blend. It often will be the case, however, that additional spaces will be activated, to a greater or lesser extent, as the construction of meaning proceeds. In certain passages within Tovey's account of Beethoven's Sixth Symphony, as many as six spaces may be active. In addition to the blend, these include mental spaces built up from the domains of music and nature, from the domains of anthropomorphized music and nature, and from the generic domain of anthropomorphism. This multiplicity of spaces explains the complexity of Tovey's account, as well as its interpretive richness. It also serves to explain the seeming contradiction entailed by Tovey's desire to deny the programmatic aspect of Beethoven's symphony while responding to the powerful impressions to which it gives rise.

More generally, evidence from conceptual blending lends credence to the idea that music is an independent conceptual domain. As I have shown in my analyses of text painting and program music, musical concepts combine with concepts from other domains to create blended concepts that suggest striking possibilities for the imagination. More to the point, musical syntax (from the perspective developed in chapter 1) can be seen contributing to the blended concepts associated with Wert's text painting and Beethoven's program music. In the former, Wert's deployment of musical materials sets the stage for an enactment—both by the voices of the singers and by our imaginations—of the sort of death with which Guarini's poem is concerned. As but one example from the latter, Beethoven's conclusion of the fourth movement and preparation for the fifth (the distant mutterings of the timpani notwithstanding) provide a moment of contrast and articulation that clearly supports our imagining one process ending (the storm) and another beginning (the shepherd's song of joyful thanksgiving). And musical spaces can inform our understanding of generic spaces: to hear Wert's musical climax is to get new insight into climax as a general phenomenon, be that climax sexual, cerebral, or even visual; to hear Beethoven's transition is to get a glimpse of how natural events like storms can be thought of not simply as personages but also as processes.

Each of these aspects of conceptualizing music will be taken up in more detail in chapter 6, within the context of the analysis of the nineteenth-century Lied. There it will be possible to see, to a greater extent, how processes of cross-domain mapping and conceptual blending construct and contribute to our understanding of both music and the world as a whole.

CHAPTER THREE

CONCEPTUAL MODELS AND THEORIES

As part of her efforts to understand the everyday knowledge with which people make sense of music, the music theorist Jeanne Bamberger has often asked young children to develop ways to represent familiar melodies or simple rhythmic patterns. One way Bamberger does this is to have a child arrange a specially constructed set of bells, called Montessori bells, so that he or she can play a given tune. Bamberger then asks the child to invent instructions so someone else could play the tune on the bells as they've been arranged.

For those who have even a passing acquaintance with music, an encounter with Montessori bells can be a truly disorienting experience. Developed as part of the materials for the Montessori curriculum, the bells are designed to encourage children's exploration of sound and music. With this in mind, they are carefully constructed to be identical in appearance: the lowest-sounding bell looks just like the highest-sounding one, as do all those in between. Only by striking each bell with a small mallet can the different pitches of the various bells be discovered. Each bell is attached to a wooden stem mounted on a wooden base so that the bells are physically independent of one another. There is, in consequence, no set arrangement of the bells, just as there are no visual cues as to their pitch: how the bells might be arranged, whether in casual play or in the performance of some tune, has to be determined by each person who uses them. As a further challenge (or an additional resource), a complete set of Montessori bells contains duplicates: there are eight bells with white bases, which make up a diatonic scale from C_4 to C_5, and thirteen bells with brown bases, which make up a chromatic scale from C_4 to $C\sharp_5$. Thus for each white-based bell there is one brown-based bell with a matching pitch—but again, just which bells match must be discovered by the user.

In the course of her research, Bamberger discovered that children use one of two general strategies when building a tune with the bells. Children following the first strategy arrange the bells in the order in which the pitches occur in the tune. To build the first phrase of "Happy Birthday," for instance, the bells might be placed one after another to create a bell-path of the sort shown in figure 3.1, with the arrow indicating the order in which the bells are set down. (Note that two G-bells are used, one for each time the pitch G occurs anew in the tune. That is, a separate

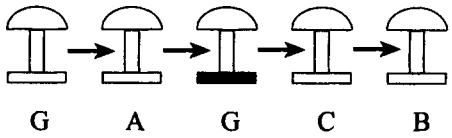

FIGURE 3.1 Bell-path no. 1 for the first phrase of "Happy Birthday" (open bases, white bells; solid bases, brown bells; arrows show direction of play)

bell is not provided to accommodate repeated notes in immediate succession. In this illustration, the second G-bell is taken from the set of brown-based bells.) Playing this much of the tune is a relatively simple matter of retracing the building process and striking each bell in turn (with the first bell getting two hits). The spatial arrangement of the bells, then, is in direct correspondence with the succession of pitches in the first phrase of the tune.

Children following the second strategy start by putting the bells in order, typically from low to high. Once this is done, they figure out the sequence in which to strike the bells in order to play the tune. Figure 3.2 illustrates the results of this strategy for the first phrase of "Happy Birthday." The bells are arranged from low to high (left to right); numbers indicate the order in which the bells should be struck, and arrows indicate the direction of motion. (Note that only one G-bell is required by this strategy; however, the path through the bells is considerably more complex.) As figure 3.2 shows, the placement of the bells no longer corresponds to the succession of pitches that make up the tune. The second strategy does not rely on a spatial analogue for the succession of pitches in the tune, as does the first. Compensation for this loss in immediacy is provided by a gain in flexibility: to play a different tune, the child needs simply to discover what new succession of hits will produce the correct results—the bells themselves do not need to be reordered.

Bamberger calls the representation produced by the first sort of strategy "figural" and that produced by the second "formal."[1] Figural representations highlight the unique "figures" (or groupings of musical materials) that make the tune what it is.

1. Jeanne Bamberger, *The Mind behind the Musical Ear: How Children Develop Musical Intelligence* (Cambridge, Mass.: Harvard University Press, 1991), 24–26; idem, "Cognitive Issues in the Development of Musically Gifted Children," in *Conceptions of Giftedness*, ed. Robert J. Sternberg and Janet E. Davidson (Cambridge: Cambridge University Press, 1986), 398–99. In personal correspondence (20 May 2000), Bamberger notes that formal strategies, as far as she has seen them among both children and adults, only occur with people who have had some training in music or who play an instrument.

Bamberger also observes that "representation" (the term I favor here) tends to imply more fully worked-out cognitive processes than a term like "description." Although I respect this distinction (especially where it applies to the activities of young children who may not really be concerned with "representing" anything), I shall retain "representation" in my discussion, but with the understanding that it applies to a quite general set of cognitive structures. Representation, defined thus, embraces image-schematic constructs, perceptual symbols, concepts, and actions—whatever is necessary to make real-world phenomena available (to re-present them) to the higher-level cognitive processes associated with theories. For further discussion of this approach to representation, see Mark Turner, "Design for a Theory of Meaning," in *The Nature and Ontogenesis of Meaning*, ed. Willis F. Overton and David S. Palermo (Hillsdale, N.J.: Erlbaum Associates, 1994), 91–108; and Antonio R. Damasio, *The Feeling of What Happens: Body and Emotion in the Making of Consciousness* (New York: Harcourt Brace, 1999), 320.

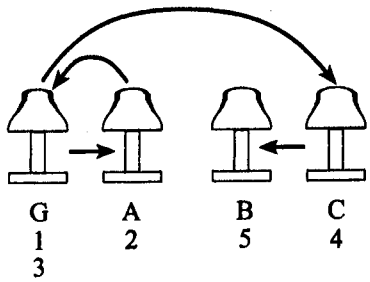

FIGURE 3.2 Bell-path no. 2 for the first phrase of "Happy Birthday"

Formal representations, in contrast, tend to obscure the unique characteristics of the tune but situate musical elements within a more general context applicable to any number of tunes. Bamberger's research suggests that figural representations are among the earliest formed by children. Formal representations develop somewhat later as the child's sense of how to organize and represent materials matures.

Bamberger's primary interest in the distinction between figural and formal representations was with the developmental changes that led to the transformation of the one into the other. Nonetheless, the contrast between these two strategies also points to different ways to construe relationships among musical concepts. That is, figural strategies offer one way to characterize these relationships, and formal strategies another. Perhaps more important, both remain options even after the passing of childhood, as is shown by the transformational networks employed by David Lewin in his analyses of late-nineteenth- and early-twentieth-century music. While Lewin's networks certainly have their abstract side—they owe much to theories of mapping that are employed in formal algebra—they also offer a way to represent unique relationships among musical events: they are figural as well as formal.[2]

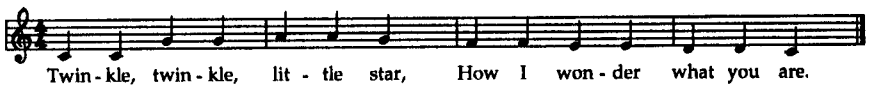
These different ways to think about the essential relationships that obtain within what is putatively the same sonic domain (here, the first phrase of "Happy Birthday") demonstrate the role of two basic cognitive structures—conceptual models and theories—in our understanding of music. *Conceptual models*, which are the more basic structures, are made up of relatively limited correlations of concepts and are specific to a given domain. (We caught glimpses of such models in the discussion of categorization in chapter 1 and saw the role they played in cross-domain mapping in chapter 2.) *Theories*, in contrast, are extended structures that coordinate a number of conceptual models to provide a more comprehensive account of the world.[3] Figural

2. See David Lewin, *Generalized Musical Intervals and Transformations* (New Haven, Conn.: Yale University Press, 1987); and idem, *Musical Form and Transformation: Four Analytic Essays* (New Haven, Conn.: Yale University Press, 1993). Lewin makes explicit reference to Bamberger's work in his analysis of Karlheinz Stockhausen's *Klavierstück III*; see Lewin, *Musical Form and Transformation*, 45–47. I should note that Bamberger's work is by no means limited to early childhood development, and that she, too, takes the position that figural and formal strategies are not restricted to developmental stages in childhood. For instance, in dialogues built into *The Mind behind the Musical Ear*, she attributes figural strategies to one college-age interlocutor and formal strategies to another.

3. As is evident from this initial characterization, "theory," as I define it, embraces cognitive structures far more modest than those with which modern scientific theory is occupied. The connection between such cognitive structures and scientific theory is explored in greater detail in the next section.

strategies, on the one hand, rely on one set of conceptual models and lead to one theory of musical organization. Formal strategies, on the other hand, rely on another set of conceptual models and lead to a somewhat different theory of musical organization.

Both conceptual models and theories are central to our understanding of the world as a whole; however, both often remain implicit. It is only when they are teased out in the course of work such as Bamberger's, or as the result of deliberate reflection on our thought processes, that either conceptual models or theories come to the fore. In this chapter, I explore the structure and function of conceptual models and theories and show the part they play in both informal and formal accounts of musical organization. In the first section I examine the role conceptual models and theories play in the musical representations of one of Bamberger's subjects, an eight-year-old boy named Jeff. Jeff's encounters with music engage him in a struggle to come to terms with basic musical concepts, and they reveal music theory—that is, a theory specific to music—in the making. In the second section, I show how the cognitive structures demonstrated by Jeff's nascent theories of music connect with similar structures proposed by researchers in a wide variety of fields, from artificial intelligence and cognitive science to anthropology and ethnomusicology. This will serve to generalize the construal of conceptual models and theories beyond Jeff's specific situation and lay out some of their additional properties. In the third section, I turn to two of the more influential theories of music within the last three centuries of the Western tradition: the music theory of Jean-Philippe Rameau and that of Heinrich Schenker. My objective is to show how they employ the same basic cognitive structures that can be seen in children's figural and formal strategies for tune building.



DEVELOPING A THEORY OF MUSICAL ORGANIZATION

Learning to Play "Twinkle" on the Bells

Jeanne Bamberger worked with Jeff for about six months in the Children's Learning Lab at MIT, starting in the fall of 1975.[4] She set him the task of building the tune "Hot Cross Buns," first with the sonic resources provided by a simple computer program and later with the Montessori bells. After Jeff achieved some facility with these tasks, Bamberger had Jeff concentrate on the tune "Twinkle, Twinkle, Little Star," using only the Montessori bells. In consequence, at the point we take up Jeff's story he has already learned some things about tunes and the properties of the bells, although "Twinkle," with its comparatively more complex structure, presents new challenges. In what follows, the focus is on the first phrase of "Twinkle" ("Twinkle, twinkle, little star, / How I wonder what you are"; the musical notation is given in ex. 3.1) and on two of the bell-paths Jeff constructed in order to play it.

4. "Jeff" is a pseudonym adopted by Bamberger to preserve the boy's anonymity. An extensive account of Bamberger's work with Jeff is given in chaps. 6–12 of *The Mind behind the Musical Ear.*

EXAMPLE 3.1 The first phrase of "Twinkle, Twinkle, Little Star"

In preparation for Jeff's work with "Twinkle," Bamberger had selected eleven bells from the complete Montessori set and put them out on a table.[5] Included were all of the white-based bells (providing a complete C major scale) and three brown-based bells: the C-, E-, and G-bells. Once Jeff had familiarized himself with the bells, Bamberger proposed that he try building "Twinkle." After beginning with the C-bell, Jeff searched among the available bells until he found one that matched the next pitch of the tune. He placed this bell next to the C-bell, and then played both to re-create the beginning of the tune (that is, the pitches that fit the words "Twinkle, twinkle"). To find the bell for "little," he once again searched among the available bells, and when he found the right one he placed it next in line. He again played what he had assembled of the tune ("Twinkle, twinkle, little") before returning to the remaining bells to find the one corresponding to the next pitch of the melody.[6]

Jeff's preference was to use the white-based bells first. He turned to the brown-based bells only when there was no white-based bell left that would provide the pitch for which he was looking; this first happens with the recurrence of the note G on the word "star." As a way of giving a visual representation of the division between the two subphrases (or "figures") of "Twinkle," Jeff left a space between the first four bells and the second four bells (marking the first four bells as one group and the second four bells as another). This produced the arrangement shown in figure 3.3. The result is a figural representation of the tune, with each successive bell corresponding to a successive pitch of "Twinkle." Performing the tune is simply a matter of beginning at one end of the bell-path and proceeding to the other (but with some bells getting two hits, and others only one).

After Jeff had completed his bell-path, Bamberger asked him to come up with instructions so someone else could play "Twinkle" on the bells as he had set them out. Jeff's initial solution was quite straightforward: he simply drew eight short vertical lines, with each line corresponding to a bell. The corresponding notation looked something like this:

| | | | | | | |

His intent was that the player should start at the beginning and play straight ahead to the end (mimicking, incidentally, his process of setting up the bell-path), some-

5. Bamberger's account of Jeff's first work with "Twinkle" can be found in *The Mind behind the Musical Ear*, 183–92.

6. The strategy of playing through as much of the tune as he had built before searching for the next pitch is one Jeff used throughout the tune-building exercises I discuss here.

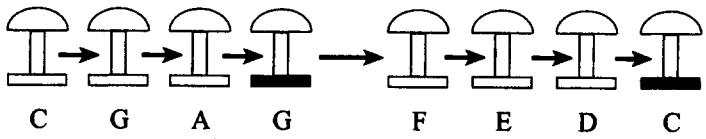


FIGURE 3.3 Jeff's initial bell-path for the first phrase of "Twinkle, Twinkle"

thing made manifest when, at Bamberger's prompting, he put in numbers to show the sequence of actions:

1	2	3	4	5	6	7	8

With a bit of additional prompting, Jeff concluded his notation by adding another set of numbers to show how many times each bell was to be struck:

2	2	2	1	2	2	2	1
|	|	|	|	|	|	|	|
1	2	3	4	5	6	7	8

With this, Jeff's first session with "Twinkle" was complete: he had constructed a bell-path with which he could play the first phrase of the tune, and he had come up with a notation that would allow another child to do the same (once the meaning of the numbers and lines had been explained).[7]

Conceptual Models and Theories in Jeff's First Version of "Twinkle"

Jeff's actions, as he constructs a bell-path for "Twinkle" and then invents a notation for both the path and the actions to be performed on it, are based on a number of suppositions:

- The pitch-events of the tune are embodied by the bells that reproduce them.[8] In this way, each pitch-event (which is invisible and ephemeral) is given visible manifestation by a bell.
- Each of the pitch-events of the tune is unique. It follows that there will be a different bell for each pitch-event; Jeff does *not*, at this point, recognize the pitch equivalence of the two G-bells or of the two C-bells.
- The succession of temporal events that make up the tune can be represented through the spatial disposition of the bells. Since this succession is

7. It is worth noting that Jeff's notation is tied to his bell-path: were the additional space between the fourth and fifth bells eliminated, his notation would almost assuredly lead to a distortion of the temporal spacing of the pitches of "Twinkle."

8. By "pitch-event" I mean a pitched sound framed relative to some temporal context (so that it is an "event"). As will be seen, because building the tune involves arranging the bells in space, the temporal aspect of pitch-events is almost always conflated with spatial location.

conceived of as linear, the bell-path is likewise linear; similarly, the pause between the two subphrases is represented by a greater amount of space between the fourth and fifth bells.

- Playing the tune is a matter of performing actions along a path specially constructed for this tune. These actions are unidirectional—the player starts at one end of the bell-path and proceeds straight through to the other—and mimic the process of building the path. Playing the tune constitutes one large, continuous motion, articulated by the smaller motions of striking each individual bell.

These suppositions, the relationships between them, and the way they help guide Jeff's actions as he sets up his bell-path can be characterized in terms of four sorts of cognitive constructs: concepts, conceptual models, conceptual domains, and theories.

Concepts. Musical concepts, as noted in chapter 1, have the following attributes: they are a product of processes of categorization, they are part of the means through which we guide present and future action, and they are not necessarily linguistic. The concepts basic to Jeff's perspective include (but are not limited to) those associated with pitched sounds, with the individual Montessori bells, with the pitch-events that make up the first phrase of "Twinkle," and with the notion of performing the tune (as distinct from, say, listening to the tune).

Conceptual models. Conceptual models consist of concepts in specified relationships. Three conceptual models play a prominent role in Jeff's figural strategy. The first model correlates pitch-events and objects. Accordingly, the constituent pitch-events of "Twinkle" are construed as objects that endure even after the acoustic signal has faded away. This perspective is reinforced by the physical and visual evidence provided by the bells. In turn, each bell can stand for a pitch-event, even when it has not been struck.[9] The second model translates temporal relationships into spatial relationships. Events separated by equal amounts of time are interpreted as objects separated by equal amounts of space; events separated by unequal amounts of time are interpreted as objects separated by unequal amounts of space. This model informs Jeff's arrangement of the bells on the table, so that there is a greater space between the two bells that mark the end and the beginning of the two consecutive subphrases (the fourth and fifth bells) than between the bells within each subphrase. The third model links physi-

9. While I believe that the conceptual models I describe here accurately reflect the cognitive structures that guide Jeff's actions, they should be generalized only with great caution. Bamberger notes that some children believe that a bell will sound differently if it is moved to another place. Indeed, there is good evidence that Jeff is more concerned with spatial location than with pitch. For discussion of a particularly revealing moment in his development, see Bamberger, *The Mind behind the Musical Ear*, 204–09. To simplify matters I shall continue to focus on pitch-events (since these ultimately inform the "meaning" given to any particular location along the bell-path or action-path), with the understanding that the full description of an "event" requires specification of both its temporal and spatial coordinates.

cal actions with a sequence of sounds. As a result, "Twinkle" acquires a corporeal dimension to go with its acoustic dimension. Each action produces another of the pitch-events of "Twinkle," and, just as the pitches of "Twinkle" form a coherent whole, so does the sequence of physical actions.[10]

Conceptual domains. Each of these conceptual models sets up a conceptual domain. The first model sets up a domain of sound-objects, populated by physical embodiments of ephemeral sonic events. The second model sets up the domain of pitch-space, quite apparent in the arrangement of bells on the table. As Jeff has constructed it, pitch-space consists of temporal and structural relationships between sound-objects. The third model sets up a domain associated with a practiced sequence of actions, what Bamberger calls a "felt path."[11] It should be noted that these conceptual domains are not completely exclusive of one another: in general, conceptual domains will overlap to the extent that the conceptual models on which they are based share concepts and relationships.

Theories. Theories coordinate a number of conceptual models in order to guide inference and reason. In this case, the three conceptual models described above are coordinated by a theory—Jeff's theory—of "Twinkle." According to this theory, a representation of the tune can be constructed by arranging a series of unique sound-producing objects in space in order of their appearance in the tune, producing a unidirectional path that, if traversed with the appropriate actions, will yield a sounding version of the tune. Jeff's notation for "Twinkle" is a symbolic manifestation of this theory: each sound-producing object is represented by a separate line.[12] The uniqueness of these objects is indicated by the series of numbers that is placed beneath these lines; the actions that will yield the tune are indicated by the numbers that are placed above.

There will be more to say about each of these constructs, but first let us see how Jeff's theory of "Twinkle" changes as Bamberger alters one aspect of the task of constructing a representation of the tune.

Jeff's Second Version of "Twinkle"

Jeff continued to work with "Twinkle" for a number of weeks and became quite adept at building the tune according to his first theory. One day, as an outgrowth of a pitch-matching task that she had asked Jeff to do, Bamberger changed the set of

10. In some cases, these physical actions are constitutive of the tune in a way that the arrangement of the bells is not. For instance, the bell-path gives no clues as to how many times each bell should be hit, which, of course, is an integral part of the action-path.

11. Bamberger, *The Mind behind the Musical Ear*, 213.

12. My use of "symbol" with respect to Jeff's notation is not very heavily freighted—the symbols are at best ad hoc, and under different circumstances Jeff might use quite different symbols to accomplish the same notational goals. However, I do want to say that Jeff's notation correlates with his concepts—that is, the marks he puts down stand as symbols for some of the concepts in terms of which he understands "Twinkle."

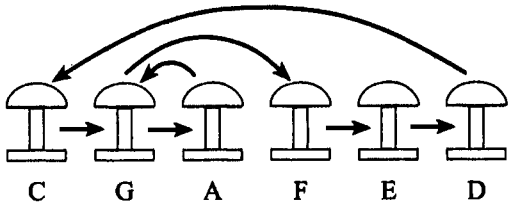

FIGURE 3.4 Jeff's modified bell-path for the first phrase of "Twinkle, Twinkle"

bells Jeff had to work with by removing the brown-based bells.[13] This left Jeff with only one bell for each pitch-type. Jeff built the tune as usual until he came to the place where, in accordance with the strategy based on his first theory, he would find and position the brown-based G-bell. When he could not find the bell, he stopped his work and said, "I need another bell."

Bamberger did not press Jeff further at this point, but a few days later she returned to the task. This time, Jeff decided to look for the needed bell among those he had already arranged in the bell-path. After first trying the C-bell, he moved to the G-bell (second in the bell-path) and discovered that it provided the pitch he was looking for. Jeff eventually was able to build up the entire tune using only the white-based bells, creating the bell-path and action-path shown in figure 3.4. While this arrangement of the bells is more parsimonious—only six bells are needed instead of eight—the action-path through the bells is more complex, requiring both switchbacks and leaps over intervening bells. As a result, the bell-path and action-path are no longer in simple correspondence with one another.

As before, Bamberger asked Jeff to come up with a notation that would enable someone else to play "Twinkle" on the bells as he had arranged them. This time, however, the complexities of the action-path required to play the tune on the new arrangement of bells posed some challenges, and it was only after a number of attempts that Jeff was able to develop the notation shown in figure 3.5. The notation shows two important innovations. First, by means of arrows, Jeff is able to show just how one negotiates the switchbacks and leaps necessary to play "Twinkle." Second, the numbers now refer to only one thing: the number of hits each bell gets. The serial notation Jeff used for his first version of "Twinkle" has been abandoned, since there is no longer a one-to-one mapping of bells to pitches.

Conceptual Models and Theories in Jeff's Second Version of "Twinkle"

While some of the suppositions behind Jeff's construction and notation of the second version of "Twinkle" are the same as those for his first version, some are different. Unchanged are the notions that the pitch-events of the tune can be embod-

13. Bamberger did this in part to see if she could move Jeff from a figural representation of the tune toward a formal representation. For a fuller account of this aspect of Bamberger's work with Jeff, see *The Mind behind the Musical Ear*, chap. 10.

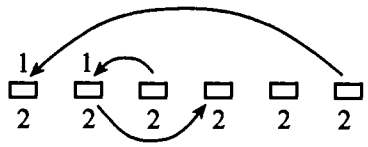

FIGURE 3.5 Jeff's notation for his modified bell-path for the first phrase of "Twinkle, Twinkle"

ied by the bells that reproduce them and that playing the tune is a matter of performing actions along a path in a specially constructed pitch-space. Changed are Jeff's ideas about pitches and about the relationship between temporal events and spatial disposition. In a conceptual shift that ultimately had profound implications for Jeff's understanding of musical organization (as Bamberger's further work with Jeff showed), he now recognizes that pitch-events are not entirely unique: some pitches will be repeated over the course of a tune. A given bell can thus serve as a sound-source for more than one pitch-event. This realization has the consequence of loosening the relationship between when pitches happen in the tune and how representatives of these pitches can be disposed in space. As a result, playing "Twinkle" is no longer a matter of following a unidirectional path through pitch-space. Even though time might still be conceived of as moving uniformly in one direction, the motions needed to play "Twinkle" are no longer unidirectional and serial: the player moves forward and backward, sometimes striking the bells serially, sometimes leaping over one or more bells to find the next pitch of the tune.

The conceptual shift associated with Jeff's changed ideas about pitches, pitch-space, and temporal order is an example of what Douglas Hofstadter calls *conceptual slippage*. As Hofstadter defines it, conceptual slippage is the context-induced dislodging of one concept by a closely related one, within the mental representation of some situation.[14] Here, the context is provided by Bamberger's removal of the brown-based bells from those Jeff had to work with in constructing "Twinkle." What has slipped is Jeff's concept of a pitch-event—specifically, how pitch-events are unique. Jeff still clearly realizes that the G that comes after the first C of "Twinkle" is different from the G that comes after the first A—after all, they occur at different points in the tune. He now knows, however, that both can be played on the same bell. This in turn means that the temporal uniqueness of pitch-events will not necessarily translate into spatial uniqueness: the two distinctly different Gs of the tune can be found in the same place on the bell-path. Jeff's concept of pitch-event as *a specific pitch in "Twinkle"* has been dislodged by a concept of pitch-event as *a general type of sonic event that is manifested at a particular point in the temporal progress of "Twinkle."*

Because all of the conceptual models through which Jeff structures his under-

14. Douglas R. Hofstadter and the Fluid Analogies Research Group, *Fluid Concepts and Creative Analogies: Computer Models of the Fundamental Mechanisms of Thought* (New York: Basic Books, 1995), 198. The idea of conceptual slippage has proven quite important in Hofstadter's work in that it introduced a level of flexibility and fluidity into the computer programs his group developed, features that were absent from earlier artificial intelligence programs.

standing of "Twinkle" incorporate the concept of pitch, the slippage of this concept cascades through the system. The correlation between sounds and objects provided by the first conceptual model is now looser than before, and the domain of sound-objects it sets up is populated with generic, rather than specific, entities. In consequence, the functional distinction Jeff made between brown-based bells and white-based bells (preferring to work with the latter first) is no longer necessary—now there are only bells. The second model, which maps temporal relationships onto spatial relationships, is more profoundly affected. While temporal and spatial events are still connected (Jeff's bell-path still has a beginning and an end), the independence of temporal succession and the spatial arrangement of sound-sources is far more evident. Reflecting this, the domain of pitch-space has been reshaped: once pitches are conceived as generic entities, they start to have more to do with each other than they do with the specific sounds that make up "Twinkle." These alterations in the notion of spatial disposition then influence the third conceptual model. While the physical actions that produce "Twinkle" can still be seen as a coherent whole, it is a whole made of a larger number of disparate parts (including switchbacks and leaps). This creates a *physical* manifestation of the growing separation of the tune from the medium through which it sounds: one can now get lost along the action-path in a way that would have been unlikely with the first bell-path Jeff constructed.

As a result of these changes, Jeff's theory of "Twinkle" is changed as well. According to this modified theory, "Twinkle" can be built using various generic sound-producing objects in space in the approximate order of their occurrence in the tune. A relatively complex action-path is then imposed on this arrangement, which, if properly executed, will yield a sounding version of the tune. Again, Jeff's notation for "Twinkle" is a symbolic manifestation of this theory: there are no longer unique entities that correspond to each of the constituent pitches of the tune, and performing the tune involves a series of complex actions. In terms of the two basic strategies Bamberger observed, Jeff has begun to move from a figural representation to a formal one.

The Function and Structure of Theories

At this point, it will be useful to pause and consider five features of theories revealed by Jeff's two approaches to constructing "Twinkle" on the bells.

First, theories serve as a guide for actions, both mental and physical. Each of Jeff's theories of "Twinkle" allows him to create an arrangement of the bells that will enable him to play the tune. Using these theories, Jeff would be able to find a way to arrange similar objects—glasses filled with varying amounts of water, marimba bars, pots and pans—so that he could play "Twinkle" on them. Should something change in one of these arrangements (for instance, if one of the bells was covertly switched for a bell with a different pitch), Jeff would most likely be able to find the problem and suggest ways of remedying it. In order to avoid confusion later, I want to broaden the characterization of this feature and say that theories serve as a guide to understanding and reasoning. Although this seems a bit grand when applied to Jeff's situation—after all, Jeff is someone who is much more predisposed to action

than to talking about action—it makes clear that the actions with which I am concerned are not of an automatic or unconscious sort but are a manifestation of either implicit or explicit patterns of reasoning.

Second, theories provide answers to conceptual puzzles. When Jeff, using his first theory of "Twinkle," could not find a brown-based bell to complete the tune, his theory told him that he could not continue building the tune, and he stopped. Of course, this is not a very satisfying answer to the puzzle, not the least because it points to the inadequacy of the theory as a guide for further actions. Jeff's second theory of "Twinkle," in which the concept of a pitch-event has slipped toward a more generic perspective, is able to provide a solution by reinterpreting the function of one of the bells already in the bell-path, thereby permitting him to continue building the tune.

Third, theories simplify reality. Jeff does not attempt to make the proportional spacing of the bells replicate the temporal intervals between the pitch-events of the tune—it is enough that there is a somewhat larger space between the bells that end the first subphrase and those that begin the second. Jeff's notation (and, presumably, his theory) also do not specify the tempo at which "Twinkle" should be played, how hard the bells should be struck, whether the player should be seated or standing, and so on.

Fourth, theories are relatively extended cognitive structures. As analyzed here, both of Jeff's theories involve at least three conceptual models, which describe relationships among a number of concepts and which set up conceptual domains. Each conceptual model can operate independently of the others: construing pitches as objects does not necessarily require arranging the objects in any particular way, nor does it necessarily involve physical actions performed on these objects (to which mental rehearsal by musicians bears testament); temporal successions (particularly those that do not involve music) can be represented spatially without involving pitch-objects, and so on. Theories, however, coordinate such models into systems for inference. The systematic quality of theories (in the sense that they involve coordinated—and thus interrelated—conceptual models) is evident in the way the slippage of Jeff's concept of pitch-event cascades through his theory of "Twinkle": it affects each of the conceptual models involved.

Fifth, theories are dynamic. When Jeff's concept of pitch-event changes, his theory of "Twinkle" changes as well. Theories thus respond to changes in circumstances and (as Bamberger's further work with Jeff shows quite clearly) can grow even more extensive as they are developed to deal with a broader range of circumstances.

Although Jeff's efforts to construct and notate bell-paths for playing "Twinkle" give a glimpse into how we structure our understanding of music, the view is limited by the specificity of his situation, which is that of a young boy struggling with basic musical concepts. In order to know what it means to have a theory, and to connect Jeff's functional and implicit theories with the abstract and explicit theories of writers like Rameau and Schenker, we need to consider in greater depth the nature and function of the cognitive structures—conceptual models and theories—basic to our understanding of the world as a whole.

CONCEPTUAL MODELS AND THEORIES

As chapter 1 demonstrated, the last quarter of the twentieth century bore witness to a great deal of research on categorization—research that fundamentally changed our understanding of the process of categorization and its role in human cognition. And as shown by chapter 2, at about the same time, work in metaphor theory and cross-domain mapping blossomed, resulting in similar changes to our understanding of the role played by mapping structure from one domain onto another. It does not appear, however, that we will come to regard this time as one in which work on conceptual models and theories came to fruition. While much interesting work has been done—work to which I shall refer in the following—it has not converged on broad agreement as to what counts as a conceptual model (or even what such structures should be called), nor has it produced any unified view of what constitutes a theory.

Two factors have contributed to this situation. First, the functions we call "the mind" and the organ we call "the brain" are both staggeringly complex—indeed, Gerald Edelman has called the brain the most complicated material object in the known universe.[15] Further, mind and brain are not coextensive in any simple way: mind functions extend at the least to the central nervous system, and much of what the brain does is not directly involved with what we conventionally accept as mind functions.[16] Mind and brain thus admit of any number of structural descriptions, and in consequence there is great diversity in how writers have characterized constructs like conceptual models and theories. The second factor, which is related to the first, is that researchers have tended to focus either on conceptual-model-like structures or on theory-like structures, but rarely on both. The advantage of this strategy is that it limits the amount of cognitive structure that has to be explained. The disadvantage is that it makes it difficult to explain how relatively low-level structures like conceptual models coordinate with relatively high-level structures like theories.

In what follows, I give an account of cognitive structure that begins with concepts and extends through theories. In line with my analysis of the cognitive structure behind Jeff's strategies for building "Twinkle," I distinguish among concepts, conceptual models, conceptual domains, and theories. I should make clear that I assume humans rarely, if ever, make explicit reference to structures of this sort in the process of reasoning about a given situation. Instead, as is evident from Jeff's responses to the challenges presented by building tunes with the Montessori bells, we most typically are completely unaware of things like concepts and conceptual models, no matter how evident they are in our patterns of reasoning. Concepts, conceptual models, conceptual domains, and theories are, by and large, implicit cognitive structures: they can be teased out through experiment or analysis, but they need

15. Gerald M. Edelman, *Bright Air, Brilliant Fire: On the Matter of Mind* (New York: Basic Books, 1992), 17.

16. Things get even more complicated when emotions and feelings are factored into our account of cognition, for there is strong evidence that these are both "of the body" and "of the mind." Antonio Damasio has offered compelling arguments on this point; see in particular Damasio, *Descartes' Error: Emotion, Reason, and the Human Brain* (New York: Avon, 1994); and idem, *The Feeling of What Happens.*

not be explicit to be useful to us in reasoning about the world. I also do not want to suggest that these constructs have unitary representations, either cognitively or physiologically. Indeed, recent work indicates that the lines between entities such as concepts, models, domains, and theories are more often blurry than clear and that there are no simple neurobiological explanations for any of them. My distinctions are thus pragmatic ones, intended to reflect the different sorts of cognitive work done at different levels of structural complexity and the compass of the conceptual structures that result.

In the first subsection that follows, my focus is on conceptual models and their relationships to concepts and conceptual domains. In the second subsection, I turn to theories and explore what recent research in anthropology and developmental psychology can tell us about what it means to have a theory.

Conceptual Models

BASIC FEATURES OF CONCEPTUAL MODELS As I define it here, a conceptual model consists of concepts in specified relationships. To get a better idea what this means, let us return to one of the models used by Jeff in his initial attempts to construct a bell-path for "Twinkle," the model that translates temporal events into spatial events. The concepts required for the model are event and object. Both of these are very broad Type 1 categories: the typical event is something that happens in time; the typical object is something that persists over time. And, as always with this sort of category, there are boundary cases that challenge what is typical: a rainbow is in some respects an event (since it happens only as a result of certain atmospheric conditions), but, in other respects, an object (since it persists—if briefly—over time). In the model, events and objects are related to one another by a cross-domain mapping between pragmatic construals of time and space, which interprets durations (that is, the amount of time between events) as spatial dispositions (that is, the amount of distance between objects).[17] Large units of time are represented by distantly spaced points, small units of time are represented by closely spaced points, and equivalent temporal units get equivalent spacing. This way of interpreting time can be seen in the distribution of marks for minutes on the face of an analog clock: marks for five-minute intervals are relatively far apart, marks for one-minute intervals are relatively close together, and equivalent units get equivalent spacing.[18]

Conceptual models are drawn from two sources. The first, and perhaps most important, is culture, especially as it is represented by the people around us. We learn conceptual models by observing and imitating the actions of others and by abstracting models from the lessons we are taught. Conceptual models are thus part of the shared body of knowledge that constitutes culture. As Naomi Quinn and Dorothy

17. Modern physics, of course, does not retain the clear separation between the categories time and space that is necessary for this mapping.

18. The spatial representation of temporal units on the face of an analog clock reflects in part the mechanism that moves the hands at a steady rate across the clock face. Compare this to the face of a sundial, on which the marks for equal units of time are not spaced equally.

Holland put it, culture is "not a people's customs and artifacts and oral traditions, but what they must know in order to act as they do, make the things they make, and interpret their experience in the distinctive way they do."[19] Conceptual models may also be created through cross-domain mapping. The propositions and structure of a model framed relative to one domain are applied to another domain; if the process is successful (if it allows us to structure effectively our knowledge of some aspect of the target domain), a new conceptual model is born.

Models, once learned or created, are stored in memory and called up to organize our understanding of a given set of circumstances. Each of the models Jeff used in his theory of "Twinkle" was learned or developed before he attempted to build the tune (even if, as in the case of the model that correlates pitch-events with objects, it was learned only when he worked with "Hot Cross Buns") and was recalled from memory when needed for the new task.

Although there has been wide interest in constructs like conceptual models, there has been an almost equally wide variety of construals of mental models of this sort.[20] There is general agreement on two basic features, however. First, conceptual models are of relatively restricted extent—that is, they structure a quite limited portion of our knowledge of the world. Second, conceptual models are abstractions from experience—they do not replicate the outside world in all its detail but model

Needless to say, these constructs are by no means equivalent to each other. However, all involve the basic features I outline for conceptual models.

aspects of it as a guide to understanding. Modifying a distinction drawn by Clifford Geertz, these are models *for* understanding a particular set of circumstances rather than models *of* the circumstances themselves.[21]

Conceptual models are thus a very basic and yet abstract construal of how the world is organized—they are examples of how concepts first become useful through being related to other concepts.[22] Because we cannot think without thinking in terms of relationships of concepts, conceptual models are part of the warp and woof of our knowledge of the world: they represent the way the world *is*. However, this is not to say that conceptual models reflect, in a simple way, an objective and unchanging reality, even if they are crucial to the way we construct *our* reality.

In earlier work, I proposed, following George Lakoff, that models of the sort I am concerned with here were idealized.[23] Idealization is a way to account for instances when there is a poor fit between a conceptual model and actual circumstances. For example, the conceptual model that sets up the notion of a sound-object runs into something of an obstacle when it comes to the human voice, since it is difficult to find the physical object that correlates with vocal sound. Most of the time this difficulty is ignored: confronted with the sounds of the human voice, we continue to think in terms of sound-objects. A conceptual model concerned with sound-objects could thus be regarded as an ideal to which actual circumstances may or may not conform.

I now think it better to regard idealization as belonging to a later stage in conceptualization. As they typically function, conceptual models are immediate and transparent: they represent our working notion of reality. Accounting for why a conceptual model does not fit a given situation belongs to a less immediate level of cognitive structure occupied with reasoning and causal explanation. This is the level of the theory. One job of theories, then, is to explain discrepancies between circumstances and conceptual models, even if this explanation is little more than the recognition that the model works in most, but not all, cases. The distinction reflected in this perspective is one I shall maintain throughout the following: conceptual models are immediate and not consciously evaluative; theories are always evaluative—they provide an interpretation of circumstances and possible courses of action based on this interpretation.

Conceptual models are a response to, not a simple reflection of, the outside world. They deal with only a small portion of that world and represent its structure

21. Geertz draws his distinction between models without reference to cognitive processing, focusing only (but quite importantly) on how models are used. A "model for" is used to guide physical relationships; a "model of" is a symbolic representation of a particular situation. See Clifford Geertz, "Religion as a Cultural System," in *Anthropological Approaches to the Study of Religion*, ed. Michael Banton (New York: Frederick A. Praeger, 1966), 7–8. While I assume that conceptual models have a symbolic representation, I do not assume these symbols are necessarily available for conscious manipulation (that is, they may be what Lawrence Barsalou calls "perceptual symbols," which were mentioned above in chap. 2).

22. In function and structure, conceptual models bear a resemblance to the very simple, image-schematic stories described by Mark Turner in *The Literary Mind* (New York: Oxford University Press, 1996), chaps. 2 and 3. Such stories may involve little more than a record of the action of throwing a ball but nonetheless are essential to our understanding of the world.

23. Lawrence Zbikowski, "Large-Scale Rhythm and Systems of Grouping" (Ph.D. diss., Yale University, 1991), chap. 4.

in ways that have more to do with cognitive efficiency than with accuracy. Nonetheless, changes in the structure of the outside world will at times require changes to a conceptual model. As we saw in the preceding discussion, the absence of the brown-based bells caused Jeff's concept of a pitch-event to slip, resulting in changes to the conceptual models basic to his theory of "Twinkle." On a more local level, biological processes will have a similar, if more incremental, effect on the structure of our conceptual models. For instance, every time we remember something, we strengthen some synaptic connections and weaken others, "re-wiring" our brain on a micro-level and subtly transforming the memory we would seek to recall. Such changes will have an influence, slight but cumulative, on our conceptual models. Conceptual models are thus dynamic at both the global and the local level, although, because of their immediacy, this fluidity is rarely evident.

REPRESENTING CONCEPTUAL MODELS My thinking about conceptual models has been shaped in important ways by research in artificial intelligence from the 1970s and 1980s—in particular, the work of Marvin Minsky and of Roger Schank and Robert Abelson[24]—and I find it useful to characterize conceptual models in terms of simple propositions linked together to create a very basic system of inference. I thus represented the conceptual models in chapter 1 as a collection of interlinked nodes and shall use similar representations in chapters 4 and 5. I should note, however, that I propose these models, and this way of representing them, much in the spirit of that early work in artificial intelligence: as a place to start a description of the processes basic to reason and inference. The models are generalized, and they are presented in a way that connects with a wide body of research. But they are not meant to represent a true, or even empirically verified, picture of what humans have in their heads when they reason about various situations. This is not to say that there is no empirical evidence for conceptual models, only that my purpose in this book is to show how conceptual models are used rather than to make an argument for exactly what they comprise or how they are structured. As I discuss in the concluding chapter, I believe much work has to be done before a detailed picture of the structure and function of conceptual models can be developed.

CONCEPTUAL MODELS AND CONCEPTUAL DOMAINS In the conceptual model for sound-objects, the concept of a sound is linked with the concept of an object through a process of cross-domain mapping. Elements from the invisible and ephemeral domain of sound are correlated with those from the visible and enduring domain of objects, and structure is mapped between the domains, giving rise to sound-objects. The domains involved in this mapping—the domain of sound and the domain of objects—are broad and relatively generic. In comparison, the domain of sound-objects is rather more specific. I shall call the more specific domains set up by conceptual models *conceptual domains*.

The specificity of conceptual domains is manifested in two ways. First, because

24. Minsky, *The Society of Mind*; Roger C. Schank and Robert P. Abelson, *Scripts, Plans, Goals and Understanding: An Inquiry into Human Knowledge Structures* (Hillsdale, N.J.: Erlbaum Associates, 1977).

some of the relationships proper to a conceptual domain may not obtain in the more generic domain (or domains) from which it descends, the scope of the conceptual domain is more limited: for example, not everything that can be said of sound-objects can be said either of sounds or of objects. Second, conceptual domains are typically associated with specific phenomena or experiences. The conceptual domain of sound-objects set up by Jeff's model pertains to his experience with the Montessori bells and with the task of building a bell-path for "Twinkle." This particular domain is instantiated by the various bells used to construct the bell-path for "Twinkle," but it can be expanded to include things whose relationship to sounds or objects is more abstract, such as marks on a page or physical places on a musical instrument.

I regard conceptual domains as distinct from mental spaces; again, this is a departure from my earlier work. As described in chapter 2, mental spaces are complex and transitory sites for meaning construction and for reasoning. Furnishing a mental space requires drawing on a number of coordinated conceptual domains. One way to achieve this coordination is through the recursive application of conceptual models. Through recursion, the structuring principles that give rise to a conceptual model are subsequently applied to the *elements* of a conceptual domain originally created by the same, or another, conceptual model. For example, consider applying a conceptual model for anthropomorphism to the conceptual model for sound-objects. (Anthropomorphism, it will be recalled from the discussion of anthropomorphic blends in the second part of chapter 2, maps the properties of living beings onto objects.) This application maps the properties of living beings onto sound-objects, yielding a mental space populated with animistic pitches. Admittedly, such a space is fairly fantastic—even those with a steadfast belief in the viability of an organicist interpretation of pitch structure usually rely on conceptual blends rather than on the rather curious idea of animistic pitches—but not entirely dissimilar from mental spaces populated by pitches that obey the laws of classical physics.[25]

Another way to achieve the coordination of conceptual domains is by linking conceptual models into a system for reasoning about the world—that is, by creating a theory.

Theories

When I outlined the structure and function of theories in the preceding discussion, I did so with reference to an eight-year-old boy's attempts to arrange some rather unusual bells so as to play the first phrase—and only the first phrase—of "Twinkle, Twinkle, Little Star." But is this really a theory in the way Darwin's theory of natural selection is a theory, or in the way Einstein's special theory of relativity is a theory?

Scientific theories, viewed from a broad perspective, have the features of theories

25. Organicist construals of pitch relationships are discussed in chap. 7. Early in his career, Jean-Philippe Rameau construed pitch relations in terms of Newtonian physics; for a discussion, see Thomas Christensen, *Rameau and Musical Thought in the Enlightenment*, Cambridge Studies in Music Theory and Analysis, 4 (Cambridge: Cambridge University Press, 1993), 7–11.

I outlined above. They serve as a guide for understanding and reasoning, and they provide answers to conceptual puzzles. Thus Darwin's theory sought to explain (among other things) why finches on various islands of the Galápagos group had different-shaped beaks and why similar variations could be observed in other species.[26] Scientific theories also simplify reality. For instance, Darwin's theory did not take into account the effect of inheritance on variation: if natural selection were the only process affecting variation, variation should become less with each successive generation until it finally disappears altogether. However, because there is a recombination of parental traits in offspring, each successive generation has new variations. Finally, scientific theories are extended cognitive structures that are subject to change: Darwinian evolutionary theory was eventually refined to take into account the effect of inheritance, as well as natural selection, on the evolution of species.

Despite these similarities, there are nonetheless significant differences between scientific theories and theories of the sort that Jeff used in his encounters with "Twinkle." Jeff's theories are of quite limited extent, pertaining only to the way bells or similar objects might be arranged to play a particular song, and they have the limited function of guiding his actions within this specific context. Scientific theories, by contrast, attempt to account for as broad a range of phenomena as possible, and they offer predictions that can be proved true or false by any of a number of researchers working independently. These features have contributed to the success of scientific theories as a type, a success demonstrated by the incredible explosion of knowledge in the hard sciences over the past two centuries. It is no wonder that explorations of the structure and function of scientific theories generated an extensive literature in the twentieth century and that scientific theories have become a standard to which all other theories are compared.

The distance, then, between Jeff's theories and scientific theories is considerable, enough so that using "theory" for the former might seem ill advised. Nonetheless, work by anthropologists and others over the past thirty years has provided evidence that scientific theories are but one sort of general theory and that the process of theorizing is both various and omnipresent. More recently, research by developmental psychologists has shown that even very young children make use of theory-like structures to guide their actions. These two lines of research, which I review briefly in the following paragraphs, do not diminish the distance between Jeff's theories and those of modern science, but they do suggest that these two types of theory represent points along a continuum rather than discrete entities.

CULTURAL THEORIES The notion of a cultural theory (as distinct from a scientific theory) came to prominence in the 1960s and reflected a growing aware-

26. One can see the puzzle that challenged Darwin emerging in his earliest writings. After noting, in *The Voyage of the Beagle* (first published in 1839, three years after the *Beagle* returned home), the gradation in the sizes of the finches's beaks, Darwin makes this prescient comment: "Seeing this gradation and diversity of structure in one small, intimately related group of birds, one might really fancy that from an original paucity of birds in this archipelago, one species had been taken and modified for different ends." Charles Darwin, *The Voyage of the Beagle*, with an introduction by Leonard Engel (Garden City, N.Y: Doubleday, 1962), 381 (chap. 17).

ness among anthropologists that Western models for representing knowledge, including those of anthropology, were not always adequate or appropriate for non-Western cultures. Here are three examples of the kind of knowledge that caused anthropologists and those working in related fields to rethink what was meant by a theory.

1. Research by Brent Berlin and his associates on ethnobotanical classification (mentioned in chapter 1 in connection with the way processes of categorization were reconceptualized during the 1970s) demonstrated that the taxonomic systems of indigenous cultures could be every bit as complex as those of Western biologists. Berlin's further work has shown that ethnobotanical classification reflects, in great part, the order that is inherent in nature and that it also achieves a measure of comprehensiveness by classifying unknown species through making reference to known species.[27]
2. For more than a thousand years, long-distance noninstrumental navigation has been practiced in Polynesia and Micronesia. Experienced navigators routinely sail their outrigger canoes up to one hundred fifty miles between islands in an area where less than 0.2 percent of the surface is land. Edwin Hutchins—perhaps uniquely qualified as someone with expertise in navigation, ethnography, and artificial intelligence—has shown that this method of navigation is based on a computational system distinct from (yet comparable to) that of Western navigation.[28]
3. The cure for snakebite among the Rama Indians of Nicaragua is a complicated affair involving ritual, diet, beliefs in the supernatural, and herbal medicines especially prepared by snakebite doctors. For instance, after someone has been bitten, the victim must make sure the snake is killed; if the snake is not killed, the Rama believe the person cannot be cured. While under cure, the patient is placed on a special diet, with foods prepared in a special way; the Rama believe that this is necessary to avoid endangering the lives of other members of his or her household. Although it is difficult to sort out just which aspects of the snakebite cure have medical efficacy and which do not, the cure appears to be reasonably effective, saving the patient over three-fourths of the time.[29]

One way to account for the stability and efficacy of the knowledge represented by each of these sets of cultural practices is to construe it as organized by a theory (a theory of botanical classification, or navigation, or snakebite cure). In that this knowledge is specific to a particular culture or ethnographic context, anthropolo-

gists have designated the corresponding theories cultural theories, folk theories, or ethnotheories.[30]

One thing that distinguishes cultural theories from scientific theories is that scientific theories have an explicit tradition of verification: it has to be possible to replicate experimental results that support the theory, or the theory is cast into question. While cultural theories clearly have efficacy—the classification of a wealth of plant life, navigation between distant islands, and cure from snakebite all actually occur—they are not subjected to the open and constant scrutiny that marks the modern scientific method. Cultural theories, in contrast to scientific theories, organize a relatively stable body of knowledge that changes only gradually—and most often imperceptibly.[31] Cultural theories, as a further manifestation of cultural knowledge, thus both reflect and constitute culture.

As I construe them, cultural theories need not be explicit; indeed, theories are often manifested as patterns of behavior rather than as explicit statements describing how a specific situation should be understood or what actions are appropriate for a given set of circumstances.[32] This is particularly important for music, for theories of music may be both implicit and nonverbal.[33] A glimpse of an implicit and at least partially nonverbal theory of music was provided by Steven Feld's research on the Kaluli of Papua New Guinea, which was touched on in chapter 2. Feld showed that Kaluli terminology centers around waterfall imagery, which yields a number of highly distinctive ways to describe the contour of musical descents. By contrast, there is only a single term in Kaluli to describe musical ascents.[34] This does not mean that the Kaluli conception of musical ascent is undifferentiated—were an

30. Of course, "ethnotheory," as a sort of Third World shadow of "theory," is not a very comfortable concept: "theory" always remains the privileged term. For discussion of the related topic of the relationship between ethnopsychology and psychology, see Catherine Lutz, "Ethnopsychology Compared to What? Explaining Behavior and Consciousness among the Ifaluk," in *Person, Self, and Experience: Exploring Pacific Ethnopsychologies*, ed. Geoffrey M. White and John Kirkpatrick (Berkeley: University of California Press, 1985), 35–79.

For an illuminating discussion that also bears on this matter, framed with respect to folk models (which have the function I here ascribe to theories), see Ladislav Holy and Milan Stuchlik, "The Structure of Folk Models," in *The Structure of Folk Models*, ed. Ladislav Holy and Milan Stuchlik (London: Academic Press, 1981), 1–34.

31. Although historical evidence suggests that changes in the theories (and the corresponding conceptual models) that are constitutive of culture have often been so gradual as to escape notice, the incursion of Western commercial and technological culture into traditional societies during the past two decades has accelerated the rate of change markedly—all of the researchers I cite note the effect of this incursion into the cultural practices they study. Further discussion of this point, framed relative to musical practice, is taken up in chap. 5.

32. My construal of cultural theories as at least potentially implicit differs from that of Roy D'Andrade, who has proposed that cultural theories are always explicit. See D'Andrade, *The Development of Cognitive Anthropology*, 172–73.

33. My thinking here follows that of John Blacking, who proposed that implicit theory embraces both verbal and non-verbal discourse about music. See Blacking, "Music, Culture, and Experience," in *Music, Culture, and Experience: Selected Papers of John Blacking*, ed. Reginald Byron, with a foreword by Bruno Nettl (Chicago: University of Chicago Press, 1995), 228–31.

34. Steven Feld, "Flow Like a Waterfall: The Metaphors of Kaluli Musical Theory," *Yearbook for Traditional Music* 13 (1981): 31–32.

ascending melody played improperly, they would be quick to call attention to the mistake—but that, within the broader cultural context relative to which musical concepts are framed, ascents are not privileged and thus require only the barest of descriptive terms.[35]

In sum, cultural theories have the same general features that Jeff's theories and scientific theories have. They serve as a guide to reasoning and inference, provide answers to conceptual puzzles, and simplify reality. They are extended cognitive structures, and they are subject to change. But cultural theories suggest two extensions to the conception of theory that I have outlined thus far. First, theories should be seen as manifestations of cultural knowledge. Jeff's theories must thus be understood as developed within the context of a larger set of cultural practices, and so should those of modern science. Second, theories can be implicit and to some extent nonverbal. Without a doubt, explicit theories are immeasurably important to the advancement of knowledge, for their precepts are available for public debate, discussion, and modification. Even so, implicit theories make up a great part of our cultural and private knowledge, knowledge that becomes visible only when these theories are subjected to challenge or analysis.

THEORY IN VERY YOUNG CHILDREN The fact that theories are everywhere—in science, in culture, and in our personal construals of the world—suggests that they are basic to human understanding. This perspective has received support from recent research by Alison Gopnik and Andrew Meltzoff, who have shown that children use patterns of reasoning quite similar to those of scientists to organize their understanding of the world. Focusing on experimental evidence gathered from studies with nine- and eighteen-month-old children, Gopnik and Meltzoff have demonstrated that children's understanding of the world replicates the structure and function of scientific theories.[36] For instance, six-month-old infants do not appear to realize that spatial contact is required to move an object: they assume that if the object moved shortly after they performed some action (like kicking their legs), it was this action that caused the object to move. At around eight to ten months, however, infants begin to develop a theory of action on objects—that is, they appreciate that their actions can affect objects only if they are spatially in contact with those objects. As they grow older, children come to realize that this theory does not work in all circumstances: if an object is out of reach and she is given a toy rake, the one-year-old will use the rake to make contact with the object

35. For other work on implicit theories of music, see Simha Arom, *African Polyphony and Polyrhythm: Musical Structure and Methodology*, trans. Martin Thom, Barbara Tuckett, and Raymond Bond (Cambridge: Cambridge University Press, 1991), 139–40; idem, "New Perspectives for the Description of Orally Transmitted Music," *World of Music* 23 (1981): 43; James R. Cowdery, *The Melodic Tradition of Ireland* (Kent, Oh.: Kent State University Press, 1990); and Ruth M. Stone, *Let the Inside Be Sweet: The Interpretation of Music Event among the Kpelle of Liberia* (Bloomington: Indiana University Press, 1982).

36. Alison Gopnik and Andrew N. Meltzoff, *Words, Thoughts, and Theories* (Cambridge, Mass.: MIT Press, 1997). Those who have worked with infants and young children will appreciate the cleverness with which the experiments which produced this data were designed and the rigor with which they were carried out. For a report intended for a more general audience, see Alison Gopnik, Andrew N. Meltzoff, and Patricia K. Kuhl, *The Scientist in the Crib: Minds, Brains, and How Children Learn* (New York: William Morrow, 1999).

(where the six-month-old might simply wave the rake at random), although this contact alone will not make the object come any closer. By eighteen months of age, children refine the theory of action on objects further still, and, now realizing that just touching the object is not enough, an eighteen-month-old will adjust the rake so that it captures the object correctly.[37]

According to Gopnik and Meltzoff's view, infants and young children develop their knowledge much as scientists do. They start with an initial theory for a particular set of circumstances (the relationship between actions and objects). They conduct a variety of experiments (reaching out to grab objects, observing how objects move as a result of their actions). Then they refine and adapt the theory on the basis of the experimental results (when touching the object alone does not produce the desired results, for example, infants and young children will modify the theory to acknowledge that spatial contact must be of a specific sort). Indeed, Gopnik and Meltzoff go even further to argue that it is not so much that there is a scientist in the child as it is that there is a child in the scientist: the cognitive role of theories in earliest childhood is the same as the cognitive role of theories at maturity.

The strong claim that Gopnik and Meltzoff make in *Words, Thoughts, and Theories*—that theory (scientific or developmental) is a means of finding truth and that theorizing is an evolutionary adaptation conducive to the survival of the species—gives occasion for pause, if only because each theory frames "truth" a bit differently.[38] Nonetheless, the weaker version of the claim—that the theories of children resemble those of scientists—is somewhat more promising. Thomas Kuhn, as part of the central conceptual frame for his essay on thought experiments, noted that both children and scientists sometimes hold paradoxical views of phenomena and that both learn when these paradoxes are made evident.[39] According to Kuhn's argument, thought experiments—which introduce no new evidence and would thus seem to offer no opportunity for learning—are one way of making paradoxical views of phenomena evident and thus advancing scientific knowledge. Although only implicit in his discussion, Kuhn appears to consider the thought processes of children to be analogous to those of scientists inasmuch as both experience the same sort of "nonempirical" learning.

While we have much to learn about the cognitive structures that guide the behavior of very young children—it is hardly a pun to say that developmental psychology is still in its infancy—evidence has begun to accumulate in support of the

37. Gopnik and Meltzoff, *Words, Thoughts, and Theories*, chap. 5.

38. Paul L. Harris offers a somewhat different argument against what Gopnik and Meltzoff call the "theory theory" (that is, the theory that children have theories of the world), based on two points: first, that the theories of children and lay adults do not count as true theories; second, that the pursuit of truth is not what guides the scientist's day-to-day activities. As is evident from the preceding, I differ from Harris on the first point; however I am in broad agreement with his second point. See Harris, "Thinking by Children and Scientists: False Analogies and Neglected Similarities," in *Mapping the Mind: Domain Specificity in Cognition and Culture*, ed. Lawrence A. Hirschfield and Susan A. Gelman (Cambridge: Cambridge University Press, 1994), 294–315.

39. Thomas S. Kuhn, "A Function for Thought Experiments," in *The Essential Tension: Selected Studies in Scientific Tradition and Change* (Chicago: University of Chicago Press, 1977), 242–46.

notion that theories are a basic structure of human understanding.[40] Whether the theories of children are of exactly the same sort as those of modern science remains to be seen; however, it does seem that these two sorts of theories have a similar structure and that they are responses to the same impulse to understand the world.

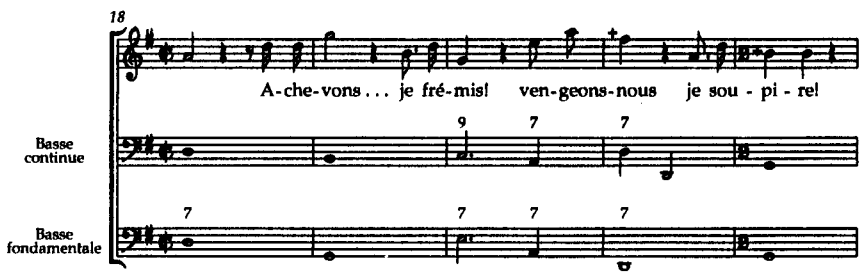
COGNITIVE THEORIES AND MUSIC THEORIES Based on his work building "Twinkle" with the Montessori bells, I do not think that there is a strong case to be made for characterizing Jeff as a scientist. Jeff is not really involved in a wide-ranging search for knowledge, aided by a protocol of experiment and analysis. Jeff is instead doing his best to meet a fairly specific and, for him, relatively challenging task. He is similar to a scientist, however, in that theory is an important cognitive tool, serving to guide his actions and make the elusive world of sound a bit more comprehensible. On the basis of evidence from anthropology and developmental psychology, Jeff is not alone in using theory in this way, for theories are part of the very fabric of human thought. Given this context, the fact that Jeff should have a theory of music, primitive as it may be, is not surprising. Indeed, we should only be surprised if we could find no evidence for the sort of cognitive theories I have described. Even so, if the distance between Jeff's theories and those of modern science is considerable, the same can be said of the distance between his theories and those of music theory as a discipline. In the next section, I shrink this distance just a bit by showing how the same cognitive structure evident in Jeff's theories can be seen in the mature work of two authors who made music theory their life's work: Jean-Philippe Rameau and Heinrich Schenker.

CONCEPTUAL MODELS, THEORIES, AND MUSIC THEORY

During the eighteenth century, Jean-Philippe Rameau (1683–1764) was widely recognized as the foremost opera composer in France. Rameau had intellectual aspirations, as well as musical ones, however, and these he first brought to fruition in his *Traité d'harmonie* of 1722. The *Traité* offered two ideas that changed thinking about musical organization throughout Europe. First, it suggested that the rich but complex lexicon of chordal sonorities used in early-eighteenth-century music could be simplified and rationalized by granting certain arrangements of notes priority (the theory of chord inversion). Second, it proposed that musical organization was governed by privileged relationships between specific harmonic entities (the theory of harmonic progression). In part because of the novelty of these ideas, in part because of Rameau's famously treacherous prose, these theories were subject to a variety of reinterpretations and misunderstandings by those who adopted them, and Rameau himself continued to revise and refine his theories through no fewer

40. For further work on the role of theories in reasoning by children, see Frank C. Keil, *Concepts, Kinds, and Cognitive Development* (Cambridge, Mass.: MIT Press, 1989); and Frank C. Keil, Daniel T. Levin, Bethany A. Richman, and Grant Gutheil, "Mechanism and Explanation in the Development of Biological Thought: The Case of Disease," in *Folkbiology*, ed. Douglas L. Medin and Scott Atran (Cambridge, Mass.: MIT Press, 1999), 285–319.

than five additional treatises and a host of other writings until almost the last years of his life.[41]



Heinrich Schenker (1867–1935) was an Austrian pianist, critic, and music theorist who supported himself primarily through giving private lessons. Schenker's writings include the journal-like series *Tonwille* and *Meisterwerk*, analyses of Beethoven's piano sonatas and Ninth Symphony, and three main treatises: *Harmonielehre* (1906), *Kontrapunkt* (1910–1922), and *Der freie Satz* (1935). Through these publications, Schenker developed two ideas that had a profound influence on Anglo-American music theory during the latter half of the twentieth century. First, he maintained that highly complex musical compositions were the result of elaborations of more basic and abstract structures. Second (and related), he held that musical works consisted of a number of hierarchical levels, proceeding from the most basic and abstract to the most complex and concrete, and that each successive level involved a further elaboration of a preceding level.[42]

The theories of music developed by Rameau and Schenker are complex, highly formalized systems for describing and analyzing music. In what follows, I consider each from the perspective on theories developed in this chapter, using short musical analyses by Rameau and Schenker to provide glimpses into their respective theories. This will allow me to show some of the cognitive substructure of their theories, and it will also reveal some important features of extended theories of music.

Rameau on a Recitative by Lully

As do most of the music treatises of the early eighteenth century, Rameau's contain few if any analyses of actual works of music. An exception is found in his *Nouveau système* of 1726, where he provides an analysis of an entire recitative from Jean-Baptiste Lully's opera *Armide* of 1686, written on a libretto by Philippe Quinault.[43] An excerpt from the analysis is given in example 3.2. The top two staves are as they would have appeared in Lully's score: a vocal line with text, below which is the *basse*

EXAMPLE 3.2 Rameau's analysis (1726) of mm. 18–22 of Armide's recitative from act 2, scene 5 of Lully's *Armide*

41. For a more complete and more elegant account of Rameau's music theory, see Christensen, *Rameau and Musical Thought in the Enlightenment*.

42. The notion of hierarchy employed by Schenker is somewhat complex and is discussed further in chap. 7.

43. Jean-Philippe Rameau, *Nouveau système de musique théorique et pratique* (Paris: Ballard, 1726), 80–90.

continue part, with Arabic-numeral figures to indicate how the harmonization should be completed. Added beneath these is a staff for Rameau's *basse fondamentale*, which encapsulated his analysis of Lully's music.

Rameau's basse fondamentale had its origins in the precept that each chord had one fundamental sound (in modern terms, its root), from which the remaining notes were derived. In his analyses and descriptions of various successions of chords, Rameau would notate each of these fundamental notes on an additional staff, thus giving an account of what he considered to be the basis of any given harmony. The basse fondamentale was more than just a record of chord roots, however: it also allowed Rameau to give an account of musical syntax. The way Rameau accomplished this is more than a little complicated, but the essential points are as follows.[44] To explain why chord Y followed chord X rather than chord Z, Rameau exploited the notion of cadence prevalent in eighteenth-century music theory: chord Y followed chord X because the two were part of a normative cadence formula. As part of this formula, chord X would invariably be a major chord to which was added a minor seventh (in modern terminology, a dominant-seventh chord). Rameau came to regard the dissonance introduced by this seventh as the mechanism that led to cadence: the dissonant notes strike together, and the collision leads to the appearance of the chord that completes the cadence—what Rameau called the *tonique*. The chord that preceded the tonique, with its fundamental bass a fifth above that of the tonique, was called the *dominante-tonique*.[45] Of course, music of even the simplest sort involves more than tonic chords preceded by their dominants, but the basic pattern gave Rameau a place to begin his explanation of musical syntax. This he did by using the basse fondamentale to show the cadential relationships he took to be the motive force in music, even if this meant that the note indicated in the basse fondamentale could be related through only the most circuitous means to the chord that actually appeared in the music.[46]

Returning to the passage from Lully's recitative, there are two places where the note of the basse fondamentale is different from that of the basse continue. In m. 19, Rameau indicates that the fundamental of the chord B-D-G is G, an interpretation wholly in keeping with modern thought about chordal inversion. In m. 20, however, Rameau takes E as the fundamental of the C-E-G chord and implies that a D should be added to the chord; thus the 7 above the E of the basse fondamentale. This interpretation reflects his belief that the chord with A as its fundamental should be preceded by its dominante-tonique, which has E as its fundamental and which should be accompanied by the dissonant seventh; thus the E and D of m. 20. As an additional complication, Rameau added the figure 9 to the basse continue part of the version of Lully's score that appeared in the *Nouveau système*. In this way he was able to accept Lully's bass-note C and accommodate his own added D by

44. My discussion draws on that of Christensen in *Rameau and Musical Thought in the Enlightenment*, 106–23.

45. As mentioned in n. 25, Rameau employs a cross-domain mapping between the physical and musical domains to characterize musical progression. Consequent to this mapping, individual pitches are construed as physical objects that obey the laws of Newtonian physics.

46. For more on the function of the basse fondamentale as an extra-musical commentary on music, see Allan Keiler, "Music as Metalanguage: Rameau's Fundamental Bass," in *Music Theory: Special Topics*, ed. Richmond Browne (New York: Academic Press, 1981), 83–100.

suggesting that the latter should appear as a dissonant ninth above the bass. The fact that the E of the basse fondamentale appears *above* the C of the basse continue is not a problem for Rameau, since the C is explained by his notion of *supposition*—it functions as an ornamental note below the true bass note E.[47] From the perspective of modern music theory, Rameau's interpretation of m. 20 is viewed as completely wrongheaded, whereas his interpretation of m. 19 is viewed as essentially right. It is important to note, however, that *both* interpretations follow from Rameau's theory of musical organization and its account of musical syntax.

Rameau's treatment of Lully's recitative in the *Nouveau système* was not to be his last. In 1753, Jean-Jacques Rousseau offered a competing analysis of Lully's recitative, taking Rameau's discussion as a point of departure.[48] Rousseau's intent was to show that French musicians—even the most celebrated—had no idea of how to set text (in contrast to Italian musicians who, in Rousseau's view, did). Singling out the passage cited in example 3.2, Rousseau writes

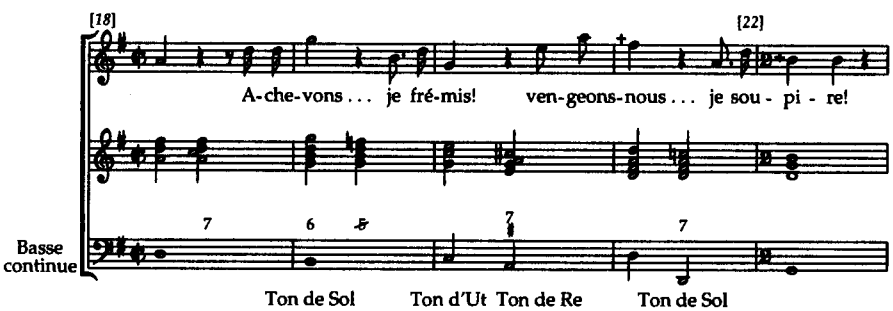
> Certainly here is the most violent moment in the whole scene. It is here that the greatest struggle is taking place in Armide's heart. Who would believe that the Musician has left all this agitation in the same key, without the slightest intellectual transition, without the slightest harmonic distinction, in a manner so insipid, with a melody so little distinguished and so inconceivably clumsy, that instead of the last verse spoken by the Poet,
>
> *Achevons; je frémis. Vengeons-nous; je soupire*
> [End it; I tremble. Avenge myself; I sigh]
>
> the Musician says precisely this:
>
> *Achevons, achevons. Vengeons-nous, vengeons-nous.*
> [End it; end it. Avenge myself; avenge myself.][49]

Rameau responded to Rousseau's polemic with the 1754 *Observations sur notre instinct pour la musique, et sur son principe*, which set out to prove two points: that harmony is the most important aspect of music (prior to both the melody or the text that is sung) and that French music excels in the way it uses harmony.

The idea that harmony was the most important aspect of music was not new for Rameau, for he had argued the point in his 1722 *Traité*. In the *Observations*, however, the argument takes a slightly different form, based on the premise that our understanding of music begins at an instinctual level that reflects a natural principle. This principle exists, Rameau argues, in the harmony that results from the reso-

47. For further discussion, see Christensen, *Rameau and Musical Thought in the Enlightenment*, 120–29; and E. Cynthia Verba, "The Development of Rameau's Thoughts on Modulation and Chromatics," *Journal of the American Musicological Society* 26 (1973): 69–91.

48. Jean-Jacques Rousseau, "Letter on French Music," in *Essay on the Origin of Languages and Writings Related to Music*, trans. and ed. John T. Scott, Collected Writings of Rousseau, 7 (Hanover, N.H.: University Press of New England, 1998), 168–73.



49. Rousseau, "Letter on French Music," 171–72. At this "most violent moment," the princess and sorceress, Armide, is about to take her revenge on the hero Renaud, who, enchanted, sleeps before her. However, confusion freezes Armide's vengeful hand as love casts a spell more powerful than that which grips the sleeping hero. At the point singled out by Rousseau, Armide swings back and forth between a steely determination to kill her foe and a desire to melt into his arms.

nance of every vibrating system, or *corps sonore*, including musical instruments and the human voice.[50] The essential elements of this harmony—the principle it reveals—are the intervals of the octave, twelfth, double octave, and seventeenth, or, in a more compact representation, root, third, and fifth.

According to Rameau, these intervals are generated not only above the root (as overtones) but below the root as well.[51] These "undertones" gave Rameau a way to explain the origins of the minor mode. In the *Observations*, he also used the intervals below the root to explain the affectual qualities of the subdominant in contrast with those of the dominant. The dominant is a product of the overtones; in consequence, it arouses feelings of vigor and joy. The subdominant—literally, the "underdominant"—is a product of the undertones; thus, it gives rise to feelings of weakness, gentleness, tenderness, and sadness.[52]

Having established this perspective on harmony and harmonic function, Rameau argued that Quinault's text was served perfectly by Lully's music, most particularly so in the case of the passage quoted in example 3.2. Rameau's argument, illustrated by the example given in example 3.3, runs as follows: shortly before this point, the music has been in E minor. With the D dominante-tonique of m. 18 (which sets the angry, ascending "Achevons"), the music establishes G major (Ton de Sol in ex. 3.3). At "je frémis," this G is converted into the dominante-tonique of C. This represents a move to the subdominant of G (Ton d'Ut), which is accompanied by a melodic descent. With "vengeons-nous," the dominante-tonique of D is introduced. This represents a move to the dominant of G (Ton de Re), which is accompanied by a melodic ascent. Finally, with "je soupire," D is converted into the dominante-tonique of G. Although this signals a return to G (Ton de Sol), it is also a move to the subdominant of the immediately preceding key of D, and it is accompanied by a final melodic descent. According to Rameau, Lully relies on our

51. The claim is first made in Rameau's *Génération harmonique ou traité de musique théorique et pratique* (Paris: Prault fils, 1737; facs. ed. Monuments of Music and Music Literature in Facsimile. Second Series, Music Literature, 6 [New York: Broude Brothers, 1966]), 4–5.

52. Rameau, *Observations*, xii–xiii.

instinctual responses to these oscillations between the dominant and the subdominant to summon Armide's swings between revenge and love: each move toward the dominant arouses in us feelings appropriate to her revenge; each move toward the subdominant arouses feelings appropriate to the dissolution of her resolve. Rameau's analysis of this passage serves as the capstone to his argument in the *Observations*: the excellence of French music, the appreciation of which had eluded Rousseau, is embodied in the way it exploits our instinct for music in the service of musical expression.

Rameau's revised analysis necessitated some important changes in his basse fondamentale for this passage. In the *Observations*, he reads the second half of each of mm. 18–21 as including a dissonant seventh (which is in inversion in m. 19), reflecting the dominante-tonique chords that establish the keys of G, C, D, and finally G. Perhaps more important, the chord in the first half of m. 20 no longer serves as the dominante-tonique of the chord in the second half of the measure, for this would undercut Rameau's assertion that C major is in effect at the beginning of the measure: the note in the basse fondamentale is now C instead of E, and there is no 7 above it. As Rameau's theory changed, so did his analysis.

Rameau's intent with this analysis, as with the theory of music on which it is based, is to explicate the principles of musical organization and musical syntax. He does this by focusing on harmonies and harmonic relationships, reading out the larger implications of the basse continue—that is, not only the notes that will complete the musical texture but also the musical sense made by the bass line itself—and making them explicit through the basse fondamentale. The project is a large and complex one, and Rameau's analysis of Lully's recitative lets us glimpse only a portion of all that he would try to say about musical organization. Nonetheless, this vignette is enough to show how Rameau's music theory is a theory in the more general sense developed in this chapter, for all of the five features of theories are clearly in evidence:

THEORIES GUIDE UNDERSTANDING AND REASONING Rameau's theory gives an account of harmonic progression—that is, it provides an explanation of why one chord follows another. Given a bit of context connected with a particular chord, we could make a reasoned judgment about what the following chord would most likely be. Through the notion of chordal inversion, his theory also explains relationships between chords that comprise the same pitch classes. In the analysis shown in example 3.3, the harmony in the first half of m. 19 is "the same" as that in m. 22, even though their bass notes are different. Finally, by locating the origin of music in the naturally occurring corps sonore, Rameau's theory offers a way to account for the emotions music evokes in humans. One set of emotions (broadly, the happy ones) is associated with notes generated above the corps sonore; another set (the sad ones) is associated with notes generated below the corps sonore.

THEORIES PROVIDE ANSWERS TO CONCEPTUAL PUZZLES One of the profound puzzles that Rameau sought to solve in the *Observations* is why music moves us. This he did by proposing that the corps sonore was not simply an acoustic phenomenon but a natural one, too: we are moved by music in conformance with

natural laws. A more parochial puzzle concerns successions of bass notes that do not conform to his notions of harmonic progression (such as the C3 to A3 in m. 20 of ex. 3.2, from Rameau's first analysis in the *Nouveau système*). Rameau suggests that the given bass note has, essentially, an ornamental function and the real bass note (indicated in the basse fondamentale) is the one that conforms to the proper progression of harmonies. Of course, the "puzzle" here could be seen as simply a manifestation of the limitations of Rameau's theory—it is one that disappears when the theory changes, as it has by the time of the *Observations*. Nonetheless, the issue raised by this puzzle/non-puzzle points up something important about theories and conceptual puzzles: theories, through the way they describe situations, tend to create puzzles, for which the theory then offers solutions. When the theory changes, these puzzles often disappear, to be replaced by new puzzles specific to the new theory.[53]

THEORIES SIMPLIFY REALITY As a composer of many successful operas, Rameau knew well that music consisted of more than just successions of dominant and tonic chords. Focusing on this succession to the exclusion of others, however, allowed Rameau to give an explanation of why one harmony followed another, and thus to give an explanation of harmonic progression. And Rameau's account of the way humans respond to music greatly simplifies the emotional response to music, reducing it to an essential binarism at a variance with the range of emotion evoked by effective musical works.

THEORIES INVOLVE A NUMBER OF CONCEPTUAL MODELS Rameau's complete theory coordinates a large number of conceptual models, ranging from models for pitch-events and intervallic relationships to models for ornament and expressivity. Three models stand out in both of his analyses of Lully's recitative: the conceptual model associated with the corps sonore, which uses basic acoustic properties to explain relationships among musical events; the conceptual model for musical mechanics, which maps Newtonian physics onto musical events to explain musical syntax; and the conceptual model for chordal inversion, which describes relationships between the notes that make up a harmony in terms of a set of dependencies created by chord generation. Although the notion of the corps sonore was ultimately absorbed into general thinking about the acoustic origins of music, the latter two models had a profound effect on the music theory of succeeding generations: the success of Rameau's theory was such that later theorists either incorporated these models into their own theories or found substitutes for them in alternative conceptions of chordal progression and inversion.

THEORIES ARE DYNAMIC As is evident from the two analyses of Lully's recitative, Rameau's theory of music changes over time: in the 1726 version, the

53. This situation is somewhat more common in the humanistic disciplines than in the hard sciences. In the latter, the puzzles are typically independent of humans—they obtain whether humans are observing the phenomena or not—whereas in the former the puzzles (and the disciplines, for that matter) would not exist without humans.

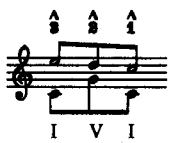
chord at the beginning of m. 20 acts as a dominante-tonique for the chord that follows; in the 1754 version (expanded to account for the drama evoked by the passage), the same chord represents a temporary, but affectually important, harmonic goal. It should be said that when Rameau changed his theories, it was not always for the better: even though these changes allowed him to account for a wider range of phenomena, they often introduced complications that made his theory more unwieldy.

Although Rameau's is a complex and highly elaborate theory, embedded in history and pertaining to a relatively limited musical repertoire, it nonetheless shares significant features with the cognitive theories that are the basic tools of human understanding. To fully comprehend Rameau's theory requires our reclaiming its historical context and bringing our own conceptual models into correspondence with those on which his theory is based. Certain models, such as that for chordal inversion, pose few problems. Others, such as the conceptual model for supposition, have little in common with our own models and require much greater effort to understand. Nonetheless, the distance between his way of understanding and ours, or between either of these and Jeff's, is only a matter of the concepts and conceptual models employed. The basic cognitive structures that make this understanding possible are the same.

Schenker on a Waltz by Schubert

Although Heinrich Schenker adopted some of Rameau's theoretical precepts, his attitude toward them changed over the course of his writings.[54] In his *Harmonielehre* of 1906, Schenker speaks approvingly of Rameau's work, but after World War I, Schenker became highly critical of all things French, Rameau included. His late essay "Rameau or Beethoven?" is a sustained diatribe in which he portrays Rameau as at best ignorant, at worst a malevolent force who contributed to the downfall of music.[55] Rameau was not the only theorist Schenker criticized, however. Even before the war, Schenker had become convinced that German music was being pulled into mediocrity and that music theorists had aided and abetted the process.[56] A central and explicit goal of Schenker's writings on music was to retard or arrest this process by showing the basis for the superiority of a select repertoire of music associated with the heritage of German-speaking countries. Schenker believed that only when the work of composers from Johann Sebastian Bach to Johannes Brahms was once again fully appreciated could humanity be saved from its own excesses.

54. For a fuller account of how Schenker's attitude toward Rameau changed over the course of his writings, see Harald Krebs, "Schenker's Changing View of Rameau: A Comparison of Remarks in *Harmony*, *Counterpoint*, and 'Rameau or Beethoven?,'" *Theoria* 3 (1989): 59–72.



55. Heinrich Schenker, "Rameau or Beethoven? Creeping Paralysis or Spiritual Potency in Music?," in *The Masterwork in Music: A Yearbook*, trans. Ian Bent, ed. William Drabkin, Cambridge Studies in Music Theory and Analysis 5 (Cambridge: Cambridge University Press, 1994–97), 3: 1–9.

56. Heinrich Schenker, *Counterpoint: Book I: Cantus Firmus and Two-Voice Counterpoint*, ed. John Rothgeb, trans. John Rothgeb and Jürgen Thym, New Musical Theories and Fantasies, 2 (New York: Schirmer Books, 1987), xxvii–xxx.

Basic to Schenker's music theory were two ideas: first, that the forces that shape music are independent of humans; second, that these forces determine fundamental aspects of musical syntax.[57] These forces are made manifest in what Schenker called the *Naturklang*, or chord of nature, consisting of the overtones generated from a single fundamental, with priority granted to those closest to the fundamental.[58] Couching his argument in strongly organicist terms, Schenker proposed that these overtones were first witness to the desire of the tone to propagate itself.[59] This desire also gave rise to various *Ursätze*, or fundamental structures, each of which began with either the third, fifth, or octave of the fundamental. As shown in example 3.4, an Ursatz consists of a simple two-part counterpoint. The notes with upward stems make up the *Urlinie* (or fundamental line), which descends stepwise from the *Kopfton* (or head note—here, the third of the fundamental).[60] Below this, in one-to-one counterpoint, is the *Brechung* (or arpeggiation); in example 3.4, this consists of an alternation between the fundamental and fifth of the Naturklang. The Ursatz represents an idealized succession of musical materials, all of which are in clearly specified relationships with each other. It thus provides an account—abstract, minimal, but nonetheless complete—of musical syntax: that is, how musical materials are organized to produce the elements of musical discourse.

As Schenker would have it, the skilled composer, in intuitive response to the powerful urges of the Naturklang, elaborates an Ursatz further and further until, finally, a complete work is born. The possible elaborations of Ursätze are manifold

EXAMPLE 3.4 A Schenkerian Ursatz beginning on the third of the fundamental

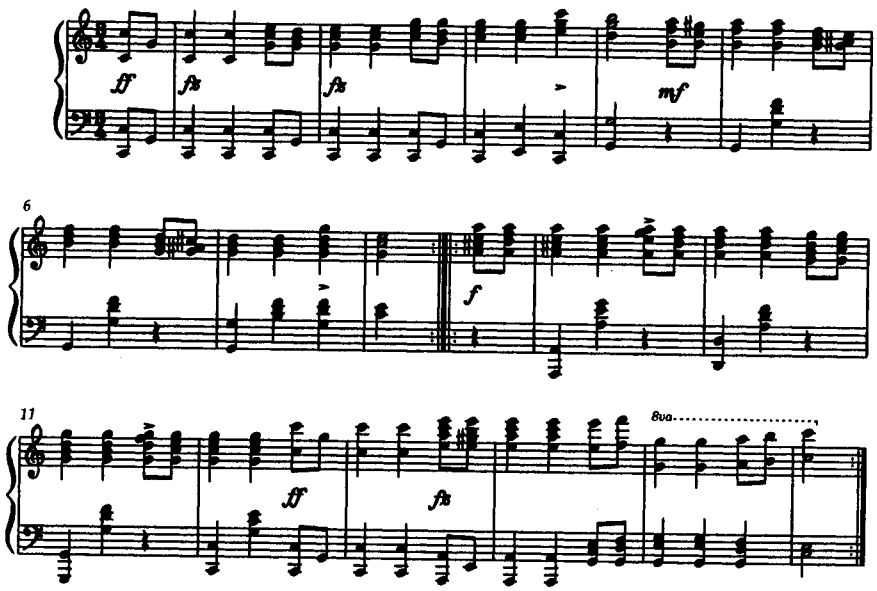
57. These two aspects of Schenker's music theory are discussed in a bit more depth in chap. 7.

58. Although there are obvious affinities between Rameau's corps sonore and Schenker's Naturklang, the latter is more complex in both the overtones proper to the system and their application to musical structure. In general, the idea that there was an acoustical basis to musical organization was a commonplace of nineteenth-century musical thought, and there is little evidence that Schenker's thinking on this matter was directly linked to that of Rameau.

59. "It is self-evident that the urge to produce unending generations of overtones belongs to every tone in equal measure. One might also compare this urge to that of animals, for it appears in fact to be in no way inferior to the procreative urge of a living being." ["Es ist selbstverständlich, daß den Trieb, Generationen von Obertönen ins Unendliche zu zeugen, jeder Ton in gleichem Maße besitzt. Man darf, wenn man will, auch diesen Trieb einem animalischen vergleichen, denn er scheint in der Tat dem Fortpflanzungstrieb eines Lebewesens durchaus nicht nachzustehen."] Heinrich Schenker, *Harmonielehre*, Neue musikalische Theorien und Phantasien, 1 (Stuttgart: J. G. Cotta'sche, 1906), §13, p. 42.

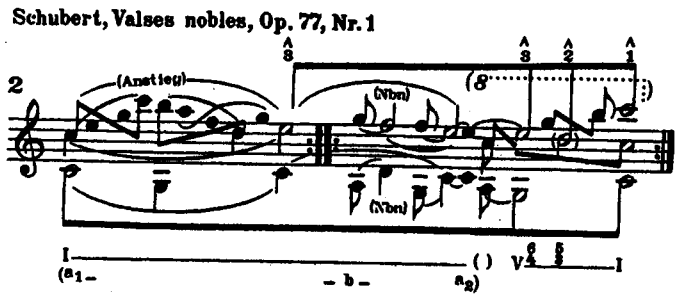
60. Translating Schenker's terminology is a notoriously fraught issue. For a discussion, see Robert Snarrenberg, "Competing Myths: The American Abandonment of Schenker's Organicism," in *Theory, Analysis and Meaning in Music*, ed. Anthony Pople (Cambridge: Cambridge University Press, 1994), 29–56. In the following, I shall rely on Schenker's original terms (followed, at their introduction, by common translations) as presented in Schenker, *Der freie Satz*, Neue musikalische Theorien und Phantasien, 3 (Vienna: Universal-Edition, 1935).

and, for all intents and purposes, are coextensive with the repertoire Schenker sought to explain. Within these possibilities, two main types of elaboration can be distinguished. The first is a manifestation of the desire of individual components of the Ursatz to assert control over longer spans of music. This occurs through the process of *Verwandlung* (transformation or prolongation), realized through a variety of compositional stratagems.[61] The second type of elaboration replicates whole sections of the Ursatz on subsidiary levels of musical structure, thus presenting the Ursatz in a sort of structural diminution. In both cases, the Ursatz is a first level of musical syntax, whose elements are subsequently transformed or reiterated to create more extensive musical utterances. This notion of syntax is different from Rameau's in two important respects. First, rather than describing local, event-to-event relationships, Schenker's theory attempts to account for relationships over the course of an entire work. Second, where harmony was the starting point for Rameau, for Schenker, musical syntax starts with the contrapuntal voice-leading of the Ursatz.



Of course, composers rarely if ever committed the successive elaborations of the Ursatz to paper. According to Schenker, creating a musical composition that both conformed to and properly expanded on an Ursatz was the work of genius. The best a nongenius could do was to come to an appreciation of the finished work by retracing the successive elaborations of the Ursatz through a series of hierarchical levels, which proceed from the background (the most minimal elaboration of the Ursatz) to the foreground (which often resembles a simplified version of the finished work).[62] The result is a striking image of musical structure that shows musical syntax operating on a number of levels and within a number of different time frames within each composition.

To represent the elaborations of an Ursatz and the hierarchical levels that resulted, Schenker developed a unique set of graphical symbols that he used in his analyses. These allowed him to show relationships among structural elements and also made manifest the replication of elements across the various levels of an elaborative hierarchy. As an example, let us turn to Schenker's analysis of the first of Franz Schubert's *Valses nobles*, Op. 77. The score for the work is given in example 3.5; Schenker's graphic analysis appears in example 3.6 (the Ursatz for the analysis is the same as that given in ex. 3.4). Although not all of the features of Schenker's graphic notation need concern us here, a few will be useful for orienting ourselves and for understanding his analysis. Open note heads in the graph (with the exception of the F5 neighbor note after the double bars) represent components of the Ursatz; generally speaking, slurs and beams mark off larger syntactic units. The graph omits the rhythmic figuration, filled-out chords, and much of the registral detail of Schubert's waltz, as well as various subsidiary passing and neighbor notes



61. The transformation (or prolongation) of elements of the Ursatz is more than a little complicated, and Schenker used a number of terms in order to capture the variety of ways it is accomplished. See Schenker, *Der freie Satz*, §45, p. 49.

62. Actual musical analysis most often proceeds in the reverse direction, going from completed musical work, to foreground, to background.

EXAMPLE 3.5 Franz Schubert, *Valse noble*, Op. 77 No. 1, D. 969

EXAMPLE 3.6 Schenker's analysis of Schubert's Op. 77 No. 1

and brief arpeggiations. Nonetheless, it does not take too much imagination to see (and hear) the outlines of the opening of the waltz in the first portion of Schenker's graph.

After the double bars, the connection between Schubert's music and Schenker's graph is somewhat less immediate, and the graph becomes somewhat more complicated. Schenker's basic argument, however, is clear: mm. 9–11 serve as contrasting material that prolongs the Kopfton, and after m. 12, the music returns to a modified version of the opening material that culminates in the completion of the Ursatz. The completion of the Ursatz is accomplished in spite of two complications. First, scale degree 2 is not actually present in the music—Schenker shows this by placing the $\hat{2}$ of the Ursatz in parentheses. Second, the Ursatz is brought to com-

pletion in a higher octave than that established by the Kopfton in m. 8, which runs counter to Schenker's principle of *obligate Lage* (obligatory register).[63]

Schenker's theory, then, offers a view of Schubert's waltz as a sort of abstract discourse structure. The first eight measures (the a_1 section) serve as introduction, providing an *Anstieg* (initial ascent) from C5 through D5 to the Kopfton E5. The next four measures (the b section) offer a contrast, prolonging the Kopfton through a neighbor-note figure (indicated with "Nbn" in ex. 3.6). The final four measures (the a_2 section) return to the opening material, modified in order to complete the Urlinie and bring about the conclusion of the piece. According to Schenker, to the extent that we understand this discourse structure, we understand how the Ursatz is elaborated to create this unique composition. The force of this understanding is such that we "supply" the D6 of the Ursatz at the conclusion of the waltz, even though it is not literally present in the music.

In the hundreds of analyses that accompanied the exposition of his theory, Schenker showed evidence of similar discourse structures in the works of all of the principal composers from Germany and Austria during the eighteenth and nineteenth centuries, and a few others besides. The theory of music that emerges, not unlike the works whose structure it seeks to explicate, is fascinating in its extent and complexity. Nonetheless, it is a theory with all of the features of a cognitive theory outlined in this chapter.

THEORIES GUIDE UNDERSTANDING AND REASONING Schenker's theory provides a broad account of musical syntax by explaining how musical materials relate to one another in conformance with the rules of counterpoint and harmonic progression. His intent is to describe the entirety of musical works. Given this objective, and the organicist imperative relative to which the theory is framed, Schenkerian analysis provides an explanation for the function and meaning of even the smallest part of a musical composition: one can proceed, in an orderly fashion, from the graph of example 3.6 back to the music of example 3.5. From a larger perspective, Schenker's theory gives an account of form, understood as the various roles that different sections of music play within an overall discourse structure. The indication of a return to the opening material of Schubert's waltz in m. 12 (indicated by Schenker's a_2 below the staff) marks not only a reprise of the opening figure but also a return to the syntactic process initiated by the opening of the waltz. Finally, Schenker also offers an aesthetic theory: he believed that the works most worthy of his theoretical accounts were also the most valuable aesthetically.

THEORIES PROVIDE ANSWERS TO CONCEPTUAL PUZZLES One of the modest puzzles presented by Schubert's waltz concerns the attention we should pay to it. It is one of dozens if not hundreds of waltzes Schubert tossed off to gen-

63. The principle of obligate Lage is a reflection of the urge of the notes of the Ursatz to return to their source, which in all cases should involve a descent from the *Kopfton* to the octave above the fundamental (as in ex. 3.4). However, Schenker himself did not seem to regard obligate Lage as obligatory in all cases—he notes the Schubert waltz discussed here as an instance in which the principle is violated. See Schenker, *Der freie Satz*, §268, p. 175.

erate income. Does it bear the mark of his compositional genius, or is it simply another bit of doggerel churned out to fit the needs of the moment? Schenker's analysis decidedly affirms the former: whether it was written in a few minutes or over the course of several days, the waltz conforms to and properly expands on one of the Ursätze basic to music. As with Rameau's account of Lully's recitative, we also see the theory providing answers to puzzles specific to the theory. In the analysis of the Schubert waltz, these are the complications presented by the apparent departures from the Urlinie in the concluding measures.

THEORIES SIMPLIFY REALITY One of the superficial criticisms made of Schenker's theory is that his graphic analyses leave out all of the surface detail that makes a musical work distinctive and rewarding, and that register, dynamics, and rhythmic figuration are often obscured or ignored. Indeed, the graph given in example 3.6 bears this out. This is not a deficiency, however, but simply something that marks Schenker's theory as a theory: one that simplifies reality as do all theories.[64] The process of theorizing, then, is one of selecting data from a given situation and using them to build a more comprehensive understanding of that situation.

THEORIES INVOLVE A NUMBER OF CONCEPTUAL MODELS Schenker's propensity for neologisms, his attempts to vivify the realm of tones through comparisons to human and animal domains, and his adaptations of the theoretical work of earlier theorists give rise to an astounding number of conceptual models. Two in particular give his analysis of the Schubert waltz a distinctive flavor: the conceptual model associated with the Naturklang, which supplies the organicist basis for his account of musical syntax; and a conceptual model of hierarchy (also organicist, and discussed in further detail in chap. 7) that correlates numerous layers of musical syntax as a way of explaining how basic syntactic structures account for the syntax of an entire work.

THEORIES ARE DYNAMIC In as brief a summary as this, it is not possible to show in any compelling way the dynamic aspect of Schenker's theory over time. Indeed, about the best that can be done is to note Schenker's flexibility with regard to obligate Lage, which suggests that his approach to musical structure is not as rigid as he would sometimes have us believe. Nonetheless, there is a wealth of research that shows that Schenker's theory was a dynamic one, changing in response to both the repertoire and problems he engaged.

Many claims have been made for Schenker's theory of music, a theory that, in its ambition and extent, has few competitors in the Western tradition. No one to my knowledge, however, has claimed that it is cut from the same cloth as the music theory of Rameau or that of an eight-year-old boy from the Boston area. Indeed, I would not want to make such a claim, or at least not without considerable qualifi-

64. Ronald Langacker makes a similar point about the analyses produced by theories of language, noting that "there is certainly some truth in the view that analysis and description inevitably distort subject matter since they cannot be their subject matter." Langacker, *Foundations of Cognitive Grammar*, 1: 14.

cation. In the things that matter most to music theorists, Schenker's theory is simply of another order. Nonetheless, in its general features—in the cognitive work that it does, and in the way that it does it—it shares much not only with Rameau's theory of music and with Jeff's theories of "Twinkle" but also with cognitive theories as a whole.

Features of Extended Theories

The theories of Rameau and Schenker, unlike those of Jeff, are sophisticated intellectual constructs that can account for a wide range of complex musical phenomena. Such theories, which I shall call *extended theories* (in order to differentiate them from more ad hoc theories like Jeff's), have three prominent features. First, extended theories usually engage a problem or problems of long standing, like those of musical expression or musical coherence. Ancillary to this, extended theories often reveal —or create—problems through the constructs they apply to music.

Second, extended theories, as the product of traditions of discourse that often stretch across generations, are utterly embedded in culture. This was quite apparent in the nationalism that informed—indeed, fueled—both Rameau's and Schenker's work. Although it might be easy to dismiss such cultural trappings as extraneous to the business of music theory, judging from the writings of Rameau and Schenker, it is hardly so: they see music as thoroughly implicated in the business of history and nation.

Third, theories like those of Rameau and Schenker are invested in developing systematic accounts of musical organization. This systematic quality can take the form of developing an exhaustive account of musical structure. In some measure, this is what Schenker aspired to, as did Allen Forte in his efforts to provide a theory of pitch organization for atonal music.[65] The systematic aspect of a theory, however, may be somewhat more circumscribed, especially when its focus is musical syntax. Here the goal is not so much to explain everything about musical organization but, rather, what is *s* in musical organization. This is closer to the goals of Rameau's theory, and it tempered both the repertoire Schenker chose to deal with and the problems he engaged.

The topic of musical syntax, especially as a manifestation of the systematic quality of extended theories, brings us back to the paradox that theories simultaneously treat and create problems. The very notion of musical syntax—the idea that musical discourse is in some way organized—is in part a creation of theories that seek to explain musical organization. Depending on the models music theory brings to bear on the problem, musical syntax can be seen to be quite different things: a matter of how one harmony leads to another; an account of how basic contrapuntal and harmonic frameworks are elaborated into full-fledged musical works; or a different explanation altogether. As shall be seen in the next chapter, my own approach to musical syntax is different yet, involved as it is with the way musical materials are arranged to take advantage of and to exploit our ability to categorize musical events.

CONCLUSIONS

Theories, as general cognitive constructs manifested in a wide range of human activity, accomplish their work by correlating a number of conceptual models, each of which sets up a conceptual domain. In some cases, these conceptual domains will be quite similar to one another, but in others, the domains may have very little in common. This means that the topography of any theory, reckoned in terms of the conceptual domains it comprises, will not necessarily be uniform. A theory may thus appear to make contradictory claims when in fact it has simply shifted focus from one conceptual domain to a second, and incommensurate, conceptual domain. Thinking about a theory in terms of its constituent conceptual models can thus be a tool for coming to understand it better, especially where these models are novel or lead the theory in surprising directions.

Theories are also part of culture. The culture specific to music theory, it must be admitted, is a quite rarefied one. Nonetheless, the broader influence of culture can be seen here, too, as was demonstrated by the nationalistic claims made by both Rameau and Schenker. These claims are not extraneous to Rameau's and Schenker's theories but are in fact integral to them—manifestations of the broader culture of which these theories are a part and relative to which they are framed. This is not to deny the uneasiness we may feel when reading the strident claims of the music theory of another era but only to say that they are not so very different from the notions about pitch relationships and chordal inversion common within the same cultural milieu.

Finally, theories of music can tell us something about cognitive structure as a whole. Because the focal domain for music theory is a nonlinguistic one, theories of music demonstrate how we have and correlate nonlinguistic concepts. The abstraction of Rameau's and Schenker's theories notwithstanding, theories of music are often action oriented. These actions can be of a quite visible kind, as demonstrated by Jeff's attempts to set up different bell-paths for "Twinkle," but they can also involve actions less apparent to the eye: theories often suggest ways to attend to or respond to music. Given their involvement with nonlinguistic entities and their concern with action, theories of music can be seen to be deeply involved with embodied understanding in ways that few other highly developed cognitive theories are.

While the preceding chapters have sketched how work in cognitive science can be applied to problems of musical understanding—or, put another way, how our accounts of musical understanding can be brought into line with what is currently known about the mind and brain—much work remains to be done to fill out this picture. The chapters that follow make a start by showing how the framework developed thus far can be used to give accounts of musical syntax, cultural knowledge, musical ontology, text-music relations, and the structure of theories. As I noted in the introduction to this volume, I regard every analysis as based on some theory or collection of theories. The theories I highlight in part II, however, are theories about how basic cognitive processes are manifested in and exploited by musical understanding. In consequence, the analyses that follow are of a somewhat different character than "musical analysis" as it is usually practiced, for my intent is

not only to shed light on specific issues of concern to music scholars but also to refine a theory of music cognition. The examples around which I build my argument are not simply case studies, but are also tools that will help us probe further into the issues discussed thus far.[66]

As should be clear, the view of cognitive structure, theory, and analysis that I have presented thus far is of necessity preliminary, and it deals with only a small part of the potential issues raised even when the domain of inquiry is restricted to the conceptual level of cognition. Nonetheless, as the following chapters will make clear, even this partial view offers striking new perspectives on musical understanding and on what it means to theorize about music.

66. This approach to the role examples play in explorations of the structure of thought is similar to that noted by Mark Turner in his discussion of cognition and rhetoric. See in particular Turner, "Figure," in *Figurative Language and Thought*, ed. Albert N. Katz, Cristina Cacciari, Raymond W. Gibbs, Jr., and Mark Turner (New York: Oxford University Press, 1998), 80.

PART II

ANALYSIS AND THEORY

CHAPTER FOUR

CATEGORIZATION, COMPOSITIONAL STRATEGY, AND MUSICAL SYNTAX

Early in his *Theory of Semiotics*, Umberto Eco surveyed the communicative processes and cultural systems that might be included in the field of semiotics, moving through a list worthy of Jorge Luis Borges: zoosemiotics, olfactory signs, tactile communication, codes of taste, paralinguistics, medical semiotics, kinesics and proxemics, formalized languages, written languages, unknown alphabets, secret codes, natural languages, visual communication, systems of objects, plot structure, text theory, cultural codes, aesthetic texts, mass communication, and rhetoric. Midway through this list he considered what he called "musical codes." He began by proposing that the whole of musical science since the Pythagoreans has been an effort to describe musical communication as a rigorously structured system.[1] However, Eco also observed that, in spite of this tradition of structuralism from which musical semiotics can draw, music poses serious difficulties for semiotic theory: "Music presents, on the one hand, the problem of a semiotic system without a semantic level (or a content plane): on the other hand, however, there are musical 'signs' (or syntagms) with an explicit denotative value (trumpet signals in the army) and there are syntagms or entire 'texts' possessing pre-culturalized connotative value ('pastoral' or 'thrilling' music, etc.)."[2]

Eco developed a somewhat fuller account of what he meant when he characterized music as a semiotic system without a semantic level a bit further on, just prior to setting out the combinatorial rules for semiotic codes. The problem was not that musical syntax cannot be interpreted—indeed, Eco argued that any syntactic system can be interpreted on some level—but that the interpretation of music is resolutely indeterminate. There is thus no depth to the semantic levels produced by musical syntax.[3]

1. Umberto Eco, *A Theory of Semiotics*, Advances in Semiotics (Bloomington: Indiana University Press, 1976), 10. The idea that musical communication is a rigorously structured system is, of course, another way to theorize about music. Interest in such an approach has waxed and waned along with musicians' interest in numerology, mathematics, and science as possible models for musical organization.

2. Eco, *A Theory of Semiotics*, 11.

3. Eco, *A Theory of Semiotics*, 88–90. In advancing this point, Eco engages in a dialogue with Louis Hjelmslev's distinction between semiotic and non-semiotic systems; see Louis Hjelmslev, *Prolegomena to*

I find Eco's comments interesting, not for the view of musical semiotics they provide (since the passages to which I have referred are pretty much all he has to say about music in *A Theory of Semiotics*), but for their clear focus on the importance of musical syntax for musical understanding. Musical syntax is where any semiotics of music must begin. In what follows, I build on this idea, using the perspective on musical syntax introduced in chapter 1. There, I proposed thinking of syntax as a connected or orderly system. In the case of music, organized sequences of musical events properly recognized as syntactic are typically created through a set of musical practices shared among a number of musicians. Within most traditions of music making, however, there is also some latitude in how musical materials can be arranged, and the syntax specific to a particular musical work may emerge only over time. This was the case with the Leidensmotiv from Wagner's *Tristan und Isolde*, for the importance of three successive statements of the motive was something that became evident only once we were well into the opera. In situations such as this, certain aspects of the systematic quality associated with musical syntax are determined by the expressive goals of the individual ultimately responsible for arranging the musical materials. My term for the way such expressive goals are realized is "compositional strategy."[4]

Compositional strategy, conceived in these terms, assumes an alliance between syntax and processes of meaning construction: composers arrange musical materials with relatively specific expressive or communicative goals in mind. This approach takes inspiration from recent work in cognitive linguistics, which does away with a hard-and-fast distinction between syntax and semantics and instead construes language as made up of symbolic structures that consist of form-meaning pairs.[5] A similar perspective can be seen in Mark Turner's work on the iconicity of rhetorical figures. Turner argues that, in some cases, the form of a rhetorical figure is matched to the meaning the speaker wishes to convey, connecting the image-schematic structure of the form with the image-schematic structure of the meaning. Thus a rhetorical figure based on repetition, such as anaphora (which involves the repetition of the same word or group of words at the beginning of successive clauses, sentences, or lines), can be used to summon the image of repeated blows, as in an example attributed to Longinus: "By his manner, his looks, his voice, when

---

a Theory of Language, rev. ed., trans. Francis J. Whitfield (Madison: University of Wisconsin Press, 1963), 111–13. Hjelmslev, for his part, leaves open the question of whether music is a semiotic system in the strict sense he develops.

4. It should be clear from the general way I have formulated the notion of "compositional strategy" that these strategies are not the exclusive property of those traditionally recognized as "composers." In certain situations, performers and even listeners may use such strategies to organize musical materials. Throughout this chapter, I shall simplify things by assuming that composers are the architects of compositional strategies, with the understanding that (mutatis mutandis) these strategies can also be implemented by those not conventionally recognized as "composers."

5. Ronald W. Langacker, "Conceptualization, Symbolization, and Grammar," in *The New Psychology of Language: Cognitive and Functional Approaches to Language Structure*, ed. Michael Tomasello (Mahwah, N.J.: Erlbaum Associates, 1998), 2. Langacker's notion of a symbol is spelled out in greater detail in his *Theoretical Prerequisites* (vol. 1 of *Foundations of Cognitive Grammar*) (Stanford, Calif.: Stanford University Press, 1987), 11–12, 56–58.

he strikes you with insult, when he strikes you like an enemy, when he strikes you with his knuckles, when he strikes you like a slave." The efficacy of such a connection is straightforward enough—as Turner notes, "Involving members of the audience in the image schema of the iconic form automatically involves them in the basic structure of the meaning, thus moving them part way toward accepting the whole."[6] In what follows, I show how compositional strategies in music make use of similar connections between expressive goals and the forms expressions take. Music being music, the meaning that is conveyed is not as direct as that which concerned Longinus, nor as quotidian as that which concerns cognitive linguists. Nonetheless, I argue for a direct connection between compositional strategy and musical syntax: the organization of musical elements into systematic structures is part and parcel of meaning construction in music.[7]

The particular focus of what follows is on the part processes of categorization play in compositional strategies. As discussed in chapter 1, categories of musical events have immediate salience for listeners and are thus important guides to any understanding of how musical materials are organized. Building on the perspective developed in chapter 3, we can say that they are basic to any theory of music. Inasmuch as composers try to shape their music to conform to the capacities of listeners (trying, in Schoenberg's terms, to create musical coherence so that the work can be comprehensible), processes of categorization will also play an important part in compositional strategies. Musical categories are thus a place where the concerns of listeners and the concerns of composers meet.

In the first section of this chapter, I explore the role categories of musical events play in the compositional strategies basic to a musical game attributed to Wolfgang Amadeus Mozart. The game in question is one of a genre, which seems to represent the very antithesis of compositional strategy, since such games produce finished—or nearly finished—musical works simply through tosses of the dice. Embedded within their structure, however, is a set of rather traditional strategies for writing two-part

6. Mark Turner, "Figure," in *Figurative Language and Thought*, ed. Albert N. Katz, Cristina Cacciari, Raymond W. Gibbs, Jr., and Mark Turner (New York: Oxford University Press, 1998), 50–51. Turner's discussion of the iconicity of rhetorical form appears on pp. 49–51. The quotation attributed to Longinus is from Aristotle, *On the Sublime*, trans. W. Hamilton Fyfe, Loeb Classical Library, 199 (Cambridge, Mass.: Harvard University Press, 1995), §20, p. 190. Both a poetic and musical use of anaphora can be found in Bob Dylan's "Knockin' on Heaven's Door," which first appeared in his 1973 album *Pat Garrett and Billy the Kid*. The chorus of the song—consisting of reiterations of the line "Knock, knock, knockin' on heaven's door"—makes use of a repeated note in the melody, as well as a repeated word. Both repetitions correlate with the meaning of the text. Note as well that the meaning is at least potentially figurative, rather than literal, since nowhere in the song is it assumed that heaven actually has a physical door on which one can knock.

7. As I have characterized it here, compositional strategy bears a strong resemblance to the tactical logistics of rhetoric, and it might thus be seen as another instance of the use of ideas drawn from rhetoric to conceptualize musical design (something discussed in greater detail in the first part of chap. 7). As will become apparent, I construe the idea of compositional strategy as rather more general than its rhetorical counterpart, and more involved with issues of immediate importance to musical expression (such as how the temporal succession of musical materials should be arranged). This construal of compositional strategy seems largely consonant with the approach Edward Cone took in his article "On Derivation: Syntax and Rhetoric," *Music Analysis* 6 (1987): 237–55, which was discussed in chap. 1.

musical forms, realized through the manipulation of categories of musical events. During the eighteenth century, these same strategies were applied, on a much larger scale, to sonata form, guiding the way harmonic and thematic materials were laid out. They could also be applied to melodic material alone, however. In the second section of this chapter, I show how this was accomplished through an analysis of the syntax of the principal motive from the first movement of Mozart's "Dissonance" Quartet (K. 465). Taking the different versions of the motive as members of a Type 1 category, the pattern of typicality described by these members as they appear over the course of the movement shows strong similarities to the basic strategies for sonata form. The syntax for these motive forms nonetheless occupies a different layer than the syntax that guides the formal organization of the movement as a whole.

As with the grouping of statements of Wagner's Leidensmotiv, the syntax of the principal motive from the first movement of the "Dissonance" Quartet emerges over the course of the movement. Both the emergence of musical syntax and the independence of syntactic levels is further demonstrated by the first movement of Ludwig van Beethoven's String Quartet, Op. 18 No. 6, which is taken up in the third section of the chapter. Although there is little variation of the principal motivic material for the movement, Beethoven is nonetheless able to imbue two versions of the motive with distinctly different syntactic functions. The categories of motive forms that comprise these versions then become elements at a higher level of syntax. The nesting of syntactic functions can also be seen, in a slightly more complicated way, in the first movement of Beethoven's String Quartet, Op. 18 No. 1, which is discussed in the fourth section of the chapter. There, different versions of the main motive are distinguished by melodic structure and by compositional strategy, and the categories for each become syntactic elements within the movement as a whole. In a concluding section I review the perspective on musical syntax developed over the course of the chapter and give a bit further consideration to how syntax contributes to the construction of meaning in music.

MUSICAL GAMES AND COMPOSITIONAL STRATEGY

A Musical Game Attributed to Mozart

Europe in the latter half of the eighteenth century saw the blossoming of a number of musical games that allowed any person, "without the least knowledge of Musick," to compose minuets, marches, waltzes, and contredanses simply by tossing dice or spinning a top.[8] As if by magic, a series of throws or spins produced a workable piece of music that was different every time the game was played.

The game described here—the *Musikalisches Würfelspiel*—allowed its players to

8. One example is Pierre Hoegi's *A Tabular System Whereby the Art of Composing Minuets Is Made So Easy That Any Person, without the Least Knowledge of Musick, May Compose Ten Thousand, All Different, and in the Most Pleasing and Correct Manner* (London: Welcker, 1770). For further information about such games and comprehensive lists of them, see Leonard G. Ratner, "*Ars combinatoria*: Chance and Choice in Eighteenth-Century Music," in *Studies in Eighteenth-Century Music: A Tribute to Karl Geringer on His Seventieth Birthday*, ed. H. C. Robbins Landon (New York: Da Capo Press, 1979), 343–63; Stephen A. Hedges, "Dice Music in the Eighteenth Century," *Music and Letters* 59 (1978): 180–87; and Sebastian Klotz,

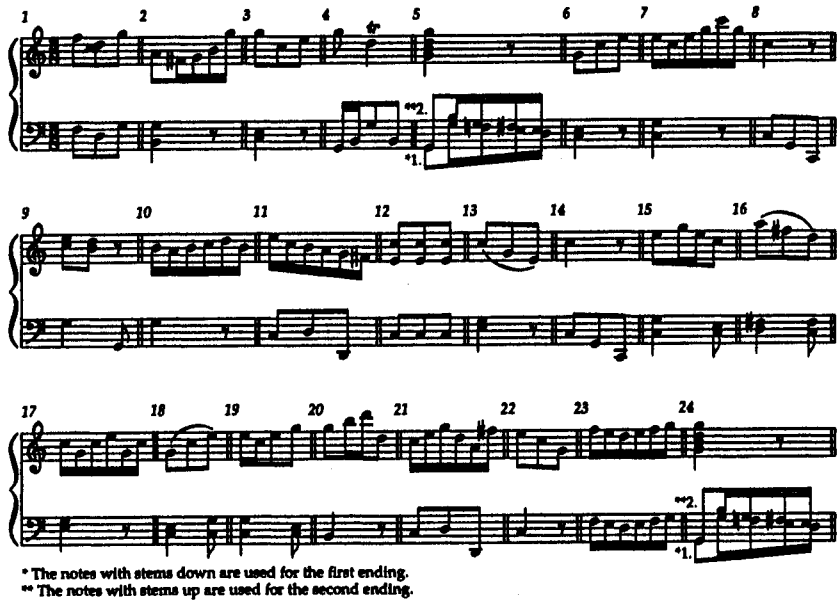
write a sixteen-measure waltz. It is one of several such games attributed to Mozart and is catalogued as K. Anh. C 30.01, but the ascription is hardly secure.[9] Mozart's authorship, in any event, is not my central concern. Instead, I want to focus on the compositional strategies that can be teased out of this particular game.

The game requires the use of a set of dice, and of two tables—a number table (the one used for the first eight-measure period of the waltz is shown in fig. 4.1)

"Ars combinatoria oder 'Musik ohne Kopfzerbrechen': Kalküle des Musikalischen von Kircher bis Kirnberger," *Musiktheorie* 14 (1999): 231–45.

9. See Wolfgang Amadeus Mozart, *Musikalisches Würfelspiel: Eine Anleitung "Walzer oder Schleifer mit zwei Würfeln zu componieren ohne Musikalisch zu seyn, noch von der Composition etwas zu verstehen,"* ed. Karl Heinz Taubert (Mainz: B. Schott's Söhne, 1956). On the matter of the authenticity of the attribution of this particular game to Mozart, see Paul Löwenstein, "Mozart-Kuriosa," *Zeitschrift für Musikwissenschaft* 12 (1930): 342–46; Otto Erich Deutsch, "Mit Würfeln komponieren," *Zeitschrift für Musikwissenschaft* 12 (1930): 595; Herbert Gerigk, "Würfelmusik," *Zeitschrift für Musikwissenschaft* 16 (1934): 359–63; Ludwig Ritter von Köchel, *Chronologisch-thematisches Verzeichnis sämtlicher Tonwerke Wolfgang Amadé Mozarts*, 8th ed., ed. Franz Giegling, Alexander Weinmann, and Gerd Sievers (Wiesbaden: Breitkopf and Härtel, 1983), 581, 910; and Hedges, "Dice Music in the Eighteenth Century," 183.

It is known from sketch studies (unrelated to the particular game under consideration) that Mozart had an interest in musical diversions of this sort; see Köchel, *Chronologisch-Thematisches Verzeichnis*, 581. And a musical dice game survives that is perhaps more reliably attributed to Mozart; it appears, in his hand, on the verso of a manuscript that contains a fragment—also in Mozart's hand—of the G minor String Quintet K. 516. See Hideo Noguchi, "Mozart—Musical Game in C Major, K. 516f," *Mitteilungen der Internationalen Stiftung Mozarteum* 38 (1990): 89–101. K. 516f is significantly different from the game to be discussed below, however, and the disparities that distinguish the two could be seen as arguing against the authenticity of the latter one. The game from K. Anh C 30.01 that produces the waltz, and that I will consider, was published under Mozart's name soon after the composer's death by Johann Julius Hummel (Amsterdam and Berlin, 1793). This is hardly a guarantee of Mozart's authorship, since his name could readily have been used simply to boost the sales of a work by another (and unknown) author.



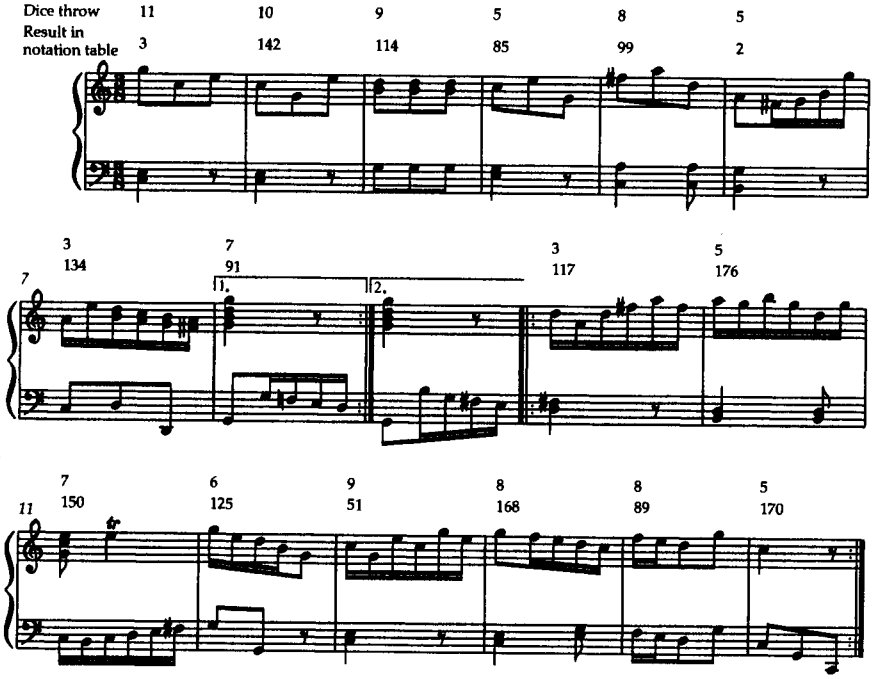


FIGURE 4.2 Portion of the notation table for the *Musikalisches Würfelspiel*

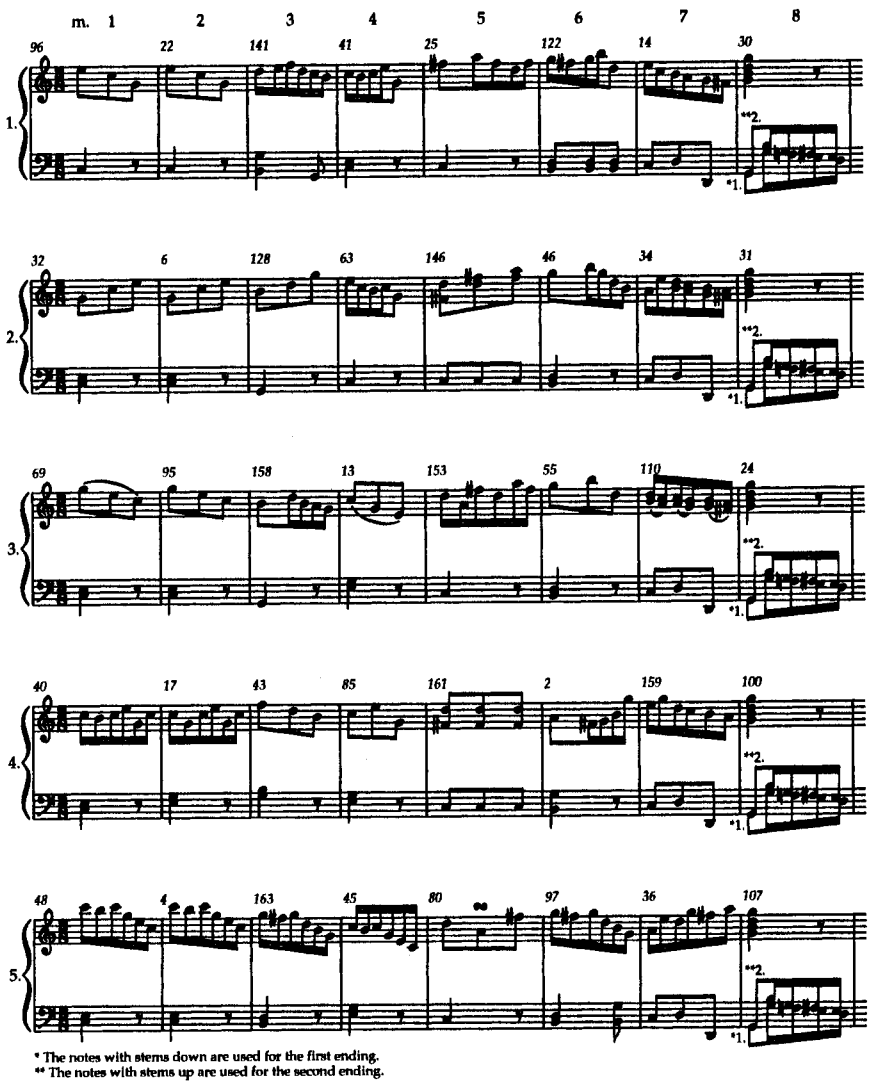
and a notation table (a portion of which is shown in fig. 4.2). For the first measure of music, the player throws the dice and uses the result to find a number in the first column of the table. Thus, the throw 11 gives the result 3 in the first column. The player then turns to the notation table, finds the music designated with a 3 there, and uses it for the first measure of the waltz. For the second measure of music, the player throws the dice again and uses the result to find a number in the second column of the number table. The throw 10 gives the result 142 in the second column; the music that corresponds to 142 on the notation table is then used for the second measure of the waltz. A complete waltz produced by the game is shown in example 4.1. Although the dance is hardly distinctive, it is nonetheless completely serviceable, equal to if not exceeding the quality of the *Tafelmusik* produced by knowledgeable amateurs of the period.

Of course, the point of such games was not the production of works of music, but diversion. There were a number of ways the game could be played: a group of players might sit in a circle and take turns throwing the dice, so that each successive measure was determined by a different player; players might each create their own waltzes, which could then be compared with one another; the entire piece might be written down and then performed; or players might take turns performing the piece as it progressed. In any event, the game offered an amusing and pleasant way to spend a portion of an evening, with the added benefit that music produced by what appeared to be total chance was orderly and coherent, no matter what the skill of the player.

In truth, chance played little part in the success of the music produced by such games. Instead, what was required of the compilers of games such as this one were

EXAMPLE 4.1 Waltz produced by the *Musikalisches Würfelspiel*

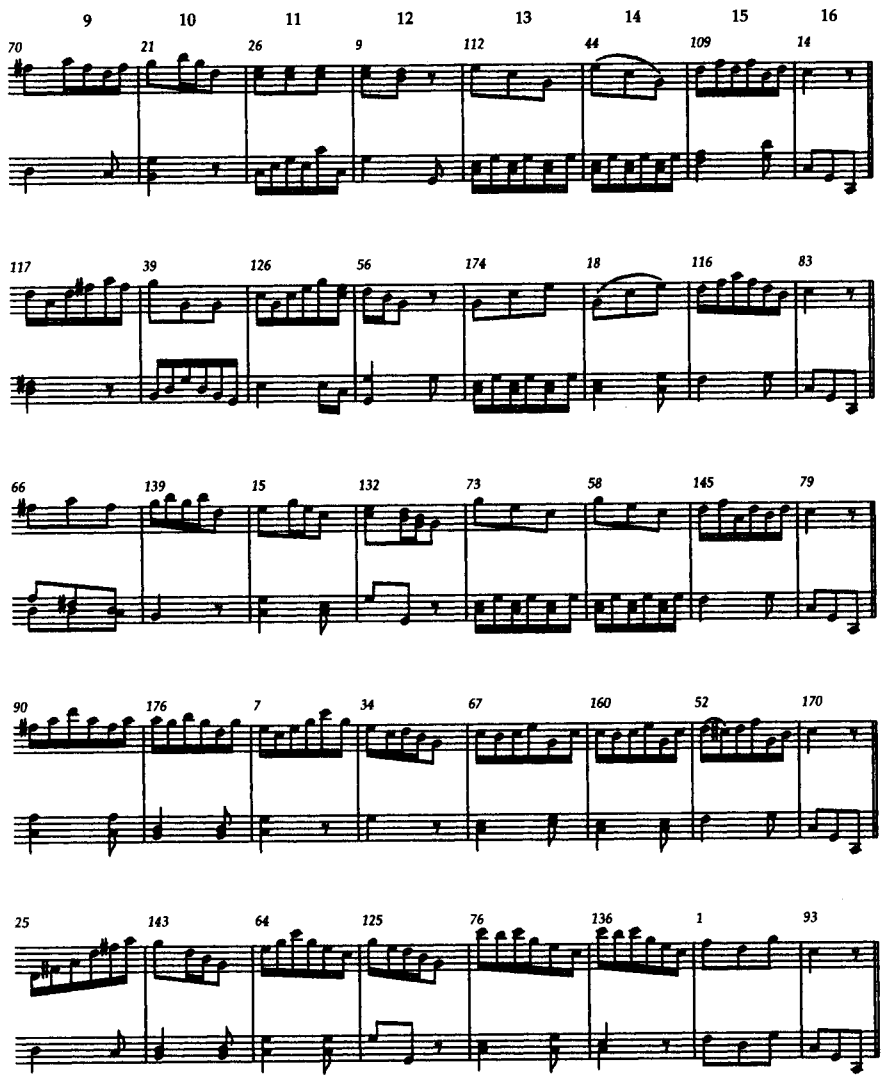


a little knowledge about how to put the game together and an understanding of the formal design of waltzes, contredanses, and the like. One first needs to construct a number table.[10] A table for a sixteen-measure waltz using two dice, for instance, starts with an 11 by 16 grid (for the eleven possible throws of the dice and sixteen measures of the piece; the table shown in fig. 4.1 provides only one-half of this grid). The numbers 1 through 176 are then randomly distributed on the 176 squares of the grid to complete the table. To construct a notation table, it is necessary to write eleven variations on a sixteen-measure waltz, preferably arranging these on a single sheet with the first variation at the top and the eleventh at the bottom. The various numbers of the number table are then mapped onto the individual measures of the eleven variations. For instance, the number table used in our *Musikalisches Würfelspiel* would map the number 96 (found at the intersection of the first row and first column) onto the first measure of the first variation, the number 22 onto the second measure of the first variation, and so on for all 176 measures of the eleven variations. An example of how this might look, derived by working backward from the number and notation tables, can be seen in example 4.2.[11] Once each measure

10. Another approach would be for a number table to be adopted from a previous publication. In fact, the number table for our waltz game is exactly the same as that for the the one published in the Weimar *Journal des Luxus und der Moden* of February 1787. See Karl Heinz Taubert (ed.) *Das Menuett: Musikalisches Wurfelspiel, Paris 1786* (Zurich: Musikhaus Pan, 1988).

11. There is no way to know whether the eleven variations shown in ex. 4.2 are actually the source variations for the game attributed to Mozart: the number found in the first square of the number table

EXAMPLE 4.2 Eleven variations with numbers derived from the number table for the *Musikalisches Würfelspiel*



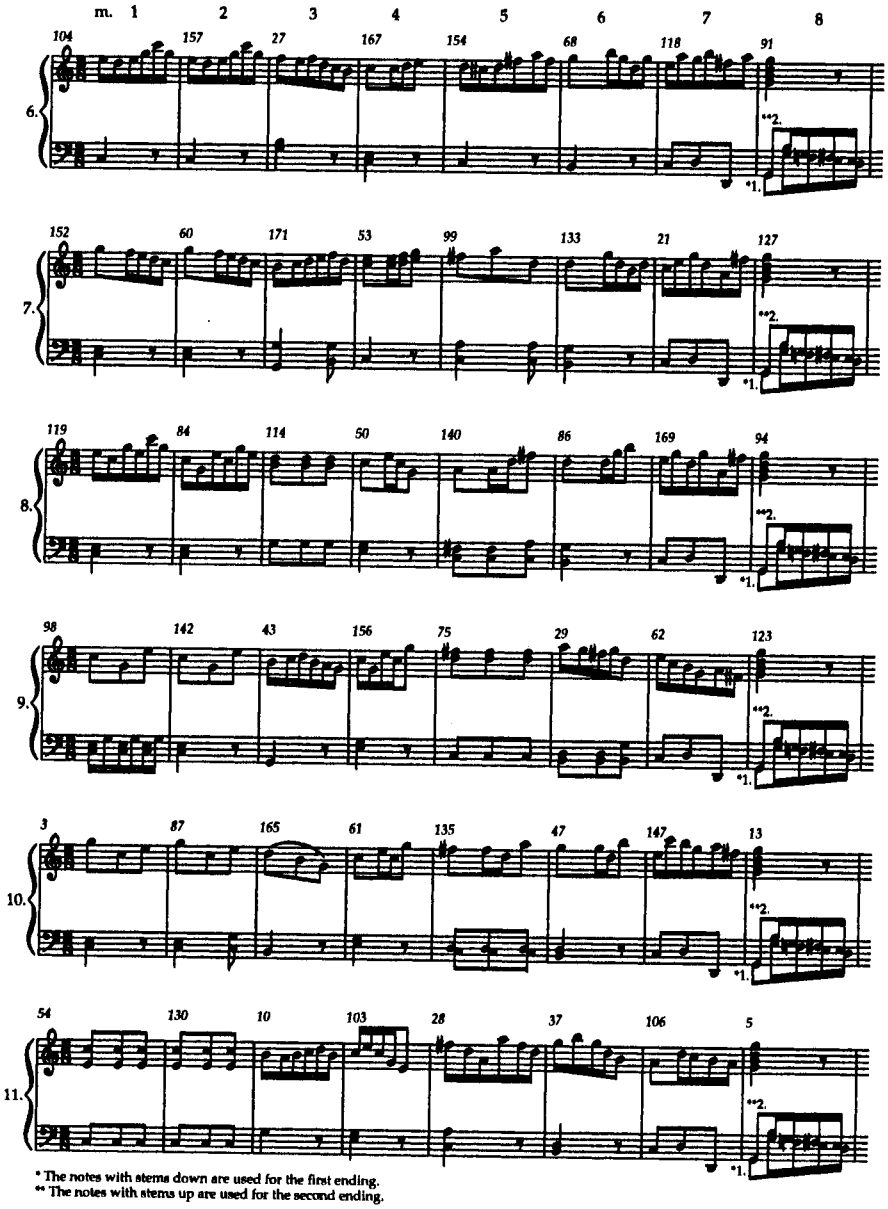
* The notes with stems down are used for the first ending.
** The notes with stems up are used for the second ending.

---

could, in theory, be mapped onto any of the variants of m. 1, and the game would still function properly. However, my focus in the following is not on establishing the original form of each of the eleven variations but on the way the material of each measure is varied. The principal function of ex. 4.2, which puts each measure into its proper column, is to aid discussion of this aspect of the musical game.

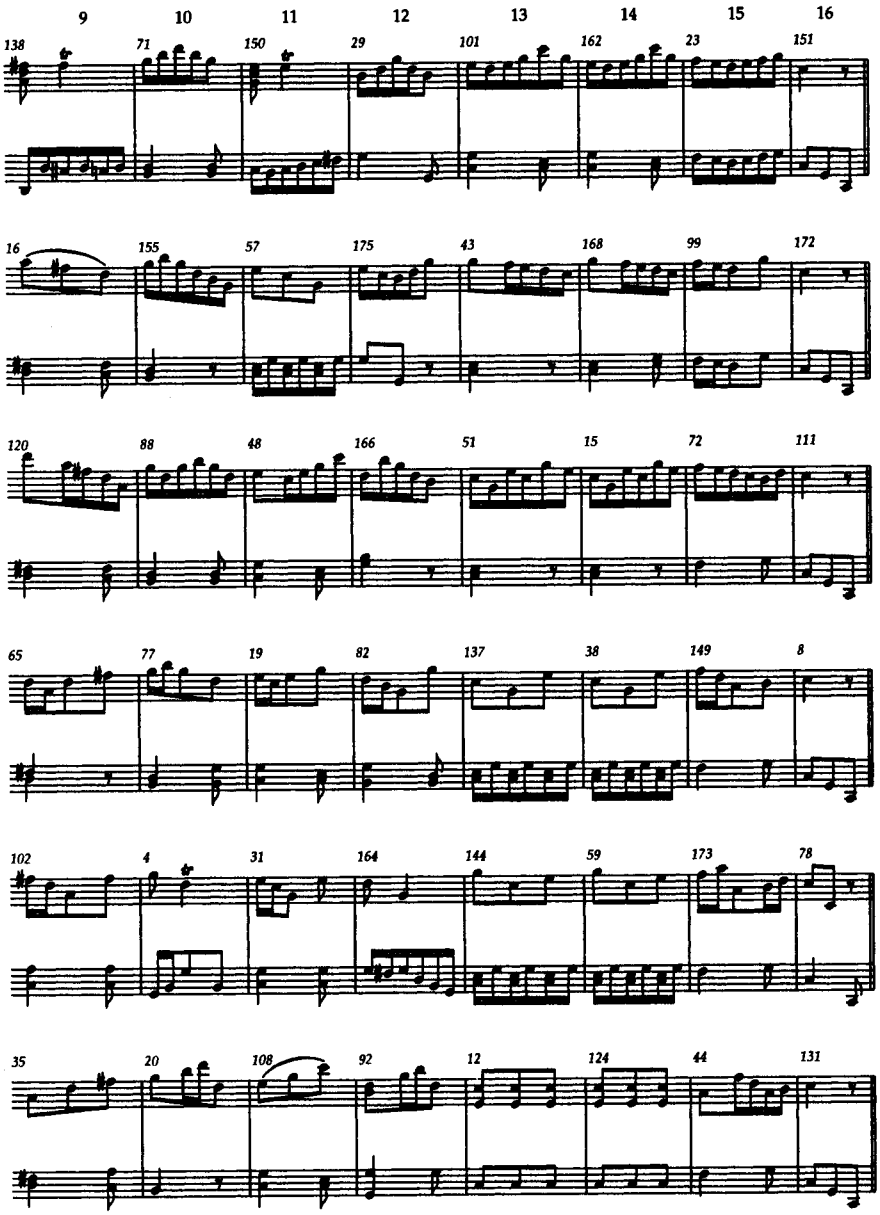
Readers who would like to try their luck at composing a piece with the *Musikalisches Würfelspiel* can use ex. 4.2 (supplying their own dice). The number corresponding to each variation can be read as the result of the throw of the dice; the columns denote the measures of the dance, as in the original number table. Of course, playing the game with the number table and the notation table collapsed together (as in ex. 4.2) takes most of the mystery and pretty much all of the fun out of the game. What remains is the somewhat thin pleasure of finding out what combinations of measures chance will dictate.

EXAMPLE 4.2 *(continued)*



(continued)

has been assigned a number, all of the measures are rewritten, in ascending numerical order, to create the notation table.



The permutational combination required by the game—each of the variants of m. 1 had to make sense with each of the variants of m. 2; each of the variants of m. 2 had to make sense with each of the variants of m. 3; and so on—placed significant constraints on what could be varied and what sort of music was produced by the game. In general, all of the variants of a given measure had to have the same har-

** The notes with stems up are used for the second ending.

EXAMPLE 4.2 *(continued)*

mony, and they typically had the same bass note. The melody for each measure was restricted to generic figures—arpeggios, an occasional scalar run, or sometimes a single note—that could easily be concatenated with other such figures. In truth, the compiler of the game wrote not so much variations on a waltz as variations on the harmonic plan for a waltz, using melodic fragments that served the minimal contrapuntal plan of the whole.[12] Rhythmic figuration offered the chief means of deriving the variants of a given measure, although changes to the beginning melodic note, overall melodic contour, or number of nonharmonic tones were also used to render each variant unique. The result of a game constructed according to this plan was a set of variations that was, for all practical purposes, inexhaustible: there are theoretically 11^{16}—that is, 45,949,729,863,572,161—different waltzes that could be written from the materials provided in example 4.2. The waltzes would not be great music, but their formulaic melodies and predictable harmonic plan were perfectly in keeping with dance forms of the late eighteenth century.

The success of the compositions produced by such games is often attributed to the rationalization of musical materials effected during the eighteenth century, which allowed specific compositional functions to be attributed to musical materials.[13] Although such rationalization is quite evident in the work of music theorists like Joseph Riepel and Heinrich Christoph Koch,[14] and while it is supported by the interchangeability of the components of example 4.2, it is not the only thing that makes the waltz of example 4.1 believable as music. What is also at work is a compositional strategy that shapes the whole of the waltz. The strategy is evident in the overall harmonic plan for the dance, an outline of which is given in figure 4.3. The waltz is divided into four-measure sections; the first section (mm. 1–4) establishes the tonic, the second (mm. 5–8) modulates to the dominant, and then the two sections repeat. The third section (mm. 9–12) remains in the dominant, the fourth section (mm. 13–16) returns to the tonic, and these, too, are repeated. Every one of the waltzes generated by the game will have this basic harmonic syntax. However, a succession of harmonies alone does not create convincing music—Rameau's harmonic theory notwithstanding, every succession of dominant to tonic does not make for a cadence. What is crucially important for the compositional strategy embodied by the *Musikalisches Würfelspiel* is the way the material for each measure is varied. For instance, note that only one version of m. 8 appears in example 4.2

12. Mostly, the counterpoint above the bass is relatively free (within the strictures of style). In a few cases, however—mm. 9–10, for example, where the dominant in $\frac{4}{2}$ position leads to a tonic $\frac{5}{3}$, and at the cadences that conclude each period—the melodic possibilities are constrained by the overall counterpoint in the outer voices.

13. Ratner, "*Ars combinatoria*," 344–45.

14. See Joseph Riepel's *Anfangsgründe zur musicalischen Setzkunst* (1752–68), included in his *Sämtliche Schriften zur Musiktheorie*, Wiener musikwissenschaftliche Beiträge (Vienna: Böhlau, 1996); and Heinrich Christoph Koch, *Versuch einer Anleitung zur Composition* (Leipzig: Adam Friedrich Böhme; Rudolstadt: gedruckt mit Schriften der Löwischen Erben, und Schirach, 1782 [vol. 1]; Leipzig: Adam Friedrich Böhme, 1787–93 [vols. 2–3]; repr. Hildesheim: Georg Olms, 1969), esp. vol. 2. For a translation of portions of the latter, see Heinrich Christoph Koch, *Introductory Essay on Composition: The Mechanical Rules of Melody*, Sections 3 and 4, trans. Nancy Kovaleff Baker, Music Theory Translation Series (New Haven, Conn.: Yale University Press, 1983). The work of both Riepel and Koch is discussed more extensively in the first half of chap. 7 in this volume.

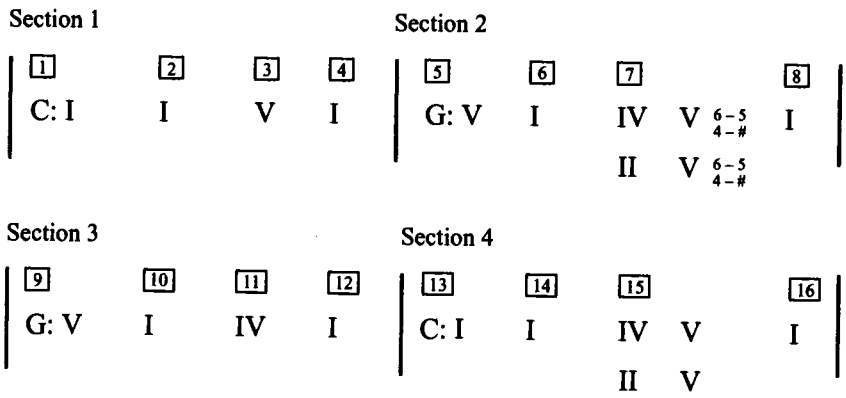

FIGURE 4.3 Basic harmonic plan for the *Musikalisches Würfelspiel*

and, save for the ending of the tenth variation, only one version of m. 16.[15] By contrast, none of the versions of m. 1 are identical. Shaping each of the trillions of waltzes that might be generated by the game is a template that regulates the degree and kind of variation that can occur within the sixteen-measure framework of the dance.

A Template for Compositional Strategy

We can discover the plan of the template if we approach each column of measures in example 4.2 as a Type 1 category of the sort discussed in chapter 1. Each measure-category can be defined in terms of attributes (such as harmony, rhythmic figuration, beginning melodic note, and so on), to which each of the members of the category (that is, the different variants included in the category) supplies values. Each measure-category also has a distinctive profile of typicality, determined by the range of values its members assign to the various attributes and the weight given any particular set of values. For example, the members of measure-category 16 assign two different values for the attribute *rhythmic figure*, but assign one of these ten out of eleven times (as shown in fig. 4.4). With respect to the attribute *rhythmic figure*, we can say that the profile of typicality for measure-category 16 is clearly defined. By comparison, the members of measure-category 15 assign seven different values for the attribute *rhythmic figure*; one value is assigned five times, the other six are assigned once each. The profile of typicality for rhythmic figuration is thus somewhat less clearly defined for measure-category 15.

Two patterns can be glimpsed from figure 4.4. The first concerns which attribute-values change from measure-category to measure-category and which stay the same—for instance, there is no rhythmic figure in common between measure-categories 15 and 16. The second pattern concerns changes in the profile of typi-

15. The lack of variation in mm. 8 and 16 means that only $(11^{14}) \times 2$—merely 759,499,667,166,482—different waltzes can be written using this particular game.

FIGURE 4.4 Values assigned the attribute *rhythmic figure* in measure-categories 15 and 16

cality between measure-categories—as can be seen, there is a relatively sharp contrast between the profiles of measure-categories 15 and 16. These patterns, taken together, create the template that shapes each of the waltzes generated by the game. A somewhat more complete perspective is provided by looking at the values assigned to just two attributes—*harmony* and *rhythmic figure*—in the first section of the waltz, as illustrated by figure 4.5. As can be seen, there is little change in the values that members of measure-category 1 and measure-category 2 assign to these attributes: one new rhythmic figure is introduced and one is dropped, but otherwise the categories are (at least with respect to these two attributes) identical. While measure-category 3 retains most of the rhythmic figures of measure-category 2, the values assigned the harmony are completely different and markedly more various. Finally, measure-category 4 has significant changes in the values assigned both attributes: two new rhythmic figures come to prominence, and the attribute-values for harmony change once more.

	I	I⁶	V	V⁶	V⁷	V⁶₅

m. 3			5	2	3	1	3	4	1		1		2		
m. 4	4	7					2	1						4	4

FIGURE 4.5 Attribute-values for *harmony* and *rhythmic* figure in measure-categories 1 through 4 (*left side*: the values assigned to the attribute *harmony* by the members of measure-categories 1 through 4 and the number of members within each measure-category that assign that value; *right side*: the values assigned to the attribute *rhythmic figure* and the number of members within each measure-category that assign that value)

There are also changes to the profile of typicality for the measure-categories in this section. While the profile for measure-categories 1 and 2 is identical—a typical variant will have a root-position tonic harmony and use either the first or second rhythmic figure—it is less clearly defined for measure-category 3. Although the number and range of rhythmic figures do not change dramatically, there are now four possible values for the attribute harmony, and only a bit of additional weight is put on one of these attribute-values (the root-position dominant is assigned by five of the eleven members of the category). Things come back into focus with measure-category 4—the most typical variant is a first-inversion harmony using either of the last two rhythmic figures—but the profile of typicality is still not quite as clearly defined as it was in the first two measure-categories.

The syntax of this section (reckoned in terms of harmony and rhythmic figure) is one in which new materials are gradually introduced and displace previous material. At the same time, measure-categories with a fairly clear profile of typicality give way to ones that have a less clearly defined profile (a trend reversed somewhat by measure-category 4). Similar syntactic patterns structure the remaining three sections of the waltz. The most important features of the syntactic template for the waltzes produced by the game, taken as a whole, are as follows:[16]

> New attribute-values—especially for rhythmic figure—are introduced throughout the first three sections. At the beginning of section 4, this process is temporarily halted and, coincident with the return C major in m. 13, rhythmic figures are for the first time brought back.
>
> Cadences (such as those that occur in measure-categories 7–8 and 15–16) are marked by a distinctive treatment of attribute-values: values that occur in

16. In developing this characterization of the changes in attribute-values and typicality that can be found in the measure-categories collected in ex. 4.2, I considered the attributes of contour, number of non-chord tones, bass motion, and starting pitch of the melody, as well as harmony and rhythmic figure. I found, however, that focusing on the latter two attributes provides the clearest picture of typicality within—and across—the measure-categories. In consequence, my account of the syntactic template tends to emphasize these attributes.

no other measure-category occur here, and the number of different attribute-values within each measure-category is sharply attenuated. In particular, the measure-categories that correspond with harmonic arrivals (that is, 8 and 16) have the most clearly defined profile of typicality of any of the sixteen.

The syntax of sections 1 and 2 involves complementary processes: section 1 begins with measure-categories that have clearly defined profiles of typicality; the profiles of the measure-categories at the end of the section are less clearly defined. Section 2 begins with measure-categories that have less clearly defined profiles of typicality; at the end of this section, the profiles of the measure-categories are clearly defined.

The syntax of sections 3 and 4 involves contrasting processes: section 3 has the broadest range of attribute-values of any of the sections (there are, for instance, over two times as many different rhythmic figures in section 3 as there are in section 1) and the most poorly defined profiles of typicality. By comparison, the range of attribute-values is much more limited in section 4, and the clarity of typicality is perhaps second only to section 1.

The compositional strategy embodied in this syntactic template is one that would be familiar to aspiring composers of the eighteenth century, for it is in complete accord with the compositional strategies for sixteen-measure dance forms proposed in treatises of the period. Theorists like Riepel and Koch taught that the tonic should be plainly stated in the first section (the measure-categories with tonic harmony in this section have the most clearly defined profile of typicality); there should be clear cadences at the end of the second and fourth sections (in the musical game, this is accomplished by the distinctive treatment accorded the end of sections 2 and 4); and the third section should be planned so that it does not become independent from the whole—in Koch's words, "it must be formed so that it loses its completeness and is bound more closely with the following fourth melodic section"[17]—something achieved in the template by the large amount of variation among the members of measure-categories 9 through 12.

At a more abstract level, the compositional strategy incorporated in the template is, of course, similar to late-eighteenth-century conceptions of what is now conventionally called sonata form.[18] These conceptions divided sonata form into two main

17. Koch, *Introductory Essay on Composition*, 100. Koch's discussion of sixteen-measure dance forms is on pp. 78–117.

18. The classic study of eighteenth-century conceptions of sonata form is Leonard Ratner's "Harmonic Aspects of Classic Form," *Journal of the American Musicological Society* 2 (1949): 159–68. The viability of eighteenth-century conceptions of sonata form, and their relevance for recent literature on the topic of form, have been given a thorough discussion recently in Mark Evan Bonds, *Wordless Rhetoric: Musical Form and the Metaphor of Oration*, Studies in the History of Music, 4 (Cambridge, Mass.: Harvard University Press, 1991). A thoughtful critique of Bonds's work can be found in Peter Hoyt, "Review of Mark Evan Bonds, *Wordless Rhetoric*," *Journal of Music Theory* 38 (1994): 123–43.

It should be noted that recent scholarship has argued for a substantially more complicated view of sonata form than that presented by either Ratner or Bonds. For an insightful discussion, see Scott Burnham, "The Second Nature of Sonata Form," in *Music Theory and Natural Order from the Renaissance to the Early Twentieth Century*, ed. Suzannah Clark and Alexander Rehding (Cambridge: Cambridge University Press, 2001), 111–41.

parts, whose functions were determined by harmonic syntax: the *Exposition* (which set out the tonic and, in major keys, closed on the dominant); and the *Development* and *Recapitulation* (which closed on the tonic).[19] The Exposition presented the principal materials of the movement, much as sections 1 and 2 of the musical game present tonic and dominant; the Development departed from these materials, as does section 3 of the game; and the Recapitulation returned to the material of the Exposition, just as there is a reprise of previously used material in section 4 of the game.

Given these similarities, we can see that the conception of compositional strategy behind the template provides a link between modest sixteen-measure dance forms and sonata form: both rely on the same syntax for organizing musical materials.[20] This points out something rather important about the teaching of composition in the eighteenth century: the highly detailed accounts of dance forms by Koch and others did indeed set out the means by which modest utilitarian works could be generated, but they also schooled students in compositional strategies that could be applied to larger works. These larger works, then, were not simply generated by repeated applications of the compositional techniques described for minuets and the like, but by the reinterpretation of these techniques as strategies for composition that could be applied to categories of musical events. When these categories were realized over longer spans of time, extended works (such as those by Mozart and Beethoven discussed in the following sections) were born.

Typicality Effects and Musical Syntax

What emerges from this analysis of the *Musikalisches Würfelspiel* is the significance of typicality effects for compositional strategy. Important structural points in the syntactic template—the establishment of tonic in the opening measures, the cadence on the dominant at the end of the second section, and the cadence on the tonic at the end of the fourth section—were all marked by measure-categories with clearly defined profiles of typicality. Indeed, a functional distinction between tonic and dominant can be made simply on the basis of the amount of variation present among the members of the measure-categories associated with each. Taking the template as a whole, there is less variation in (and thus a clearer profile of typicality for) measure-categories associated with the tonic (that is, measure-categories 1–2, 4, 13–14, and 16); there is comparatively more variation in (and consequently a less clear profile of typicality for) measure-categories associated with the dominant (that is, measure categories 3, 6, 8, 10, 12, and 15).[21]

19. In the following, I capitalize "Exposition," "Development," and "Recapitulation" when they refer to components of sonata form, reserving the uncapitalized versions of the terms for the compositional techniques through which musical materials are laid out, developed, and reprised. There is, of course, a certain measure of anachronism in applying these terms to eighteenth-century works, especially when sonata form is conceived as a two-part structure; nonetheless, the terms do single out compositional strategies recognized, if not so named, by eighteenth-century theorists.

20. The absence of an explicit link between the discussion of the appropriate compositional strategy for dance forms and that for sonata form has been noted by Bonds; see *Wordless Rhetoric*, 26–27.

21. I interpret the C major harmony of measure-category 11 as the subdominant of G major; note the F♮3 in the bass of the sixth variation.

What also emerged was the possibility of describing the syntactic structure for a two-part form purely in terms of a general set of compositional strategies realized through the manipulation of categories of musical events. There is no doubt that, in the case of the waltz created by the game, harmonic syntax is of central importance; nor is there any doubt that those who have described form with an emphasis on harmonic syntax do it with the assumption that this syntax also embodies compositional strategies applied to other aspects of music. Nonetheless, the account I have provided shows how certain compositional strategies—viewed as a generalized set of processes on musical materials—operate independently of the strategies associated with harmonic syntax.

With these thoughts in mind, let us turn to some actual musical compositions—as opposed to recreational games—that make use of some of the compositional strategies seen in the *Musikalisches Würfelspiel*, as well as more novel strategies that are appropriate for extended and adventuresome instrumental works.

MOZART, STRING QUARTET IN C MAJOR (K. 465), FIRST MOVEMENT. ALLEGRO

The Allegro of Mozart's String Quartet in C major (K. 465) was one of Arnold Schoenberg's favorites for illustrating motivic development of the sort discussed in chapter 1 of this volume. He found the work appropriate for these purposes in part because of the prominence of the motive among the various musical materials and in part because it is easy to find traces of the motive even after it has left the scene (thus supporting the organic conception of musical composition of which Schoenberg was so fond).[22] Because my concern here is not with developing an account of the way a musical whole is derived from a single theme, but with the motive as an element in an unfolding musical discourse, my account approaches the syntax of the principal melodic motive as independent from syntactic levels occupied with harmony and stylistic formulae, and independent from musical signs or syntagms of the sort noted by Eco. I shall, however, consider how these are correlated with the syntax of the principal motive toward the end of my analysis.

Mozart completed the quartet in C major during January of 1785, and in September of that year it was published by Artaria in Vienna as one of a set of six quartets dedicated to Joseph Haydn.[23] The first movement of K. 465 begins with an Adagio (mm. 1–22) remarkable for its harmonic peregrinations and rather odd pitch juxtapositions, which together earned the work its nickname as the "Dissonance" Quartet. The ensuing Allegro, by contrast, has hardly anything dissonant

22. For a discussion of Schoenberg's analyses of this movement, see the Commentary by Patricia Carpenter and Severine Neff in their translation of Schoenberg's *The Musical Idea and the Logic, Technique, and Art of Its Presentation* (New York: Columbia University Press, 1995), 53. Schoenberg first developed his idea of "developing variation"—which he later, and famously, applied to the music of Brahms—in an analysis of this movement made in 1917; see Arnold Schoenberg, *Coherence, Counterpoint, Instrumentation, Instruction in Form*, ed. Severine Neff, trans. Severine Neff and Charlotte M. Cross (Lincoln: University of Nebraska Press, 1994), 41.

23. For a fuller account of the quartet and its companions, see John Irving, *Mozart: The "Haydn" Quartets*, Cambridge Music Handbooks (Cambridge: Cambridge University Press, 1998).

about it. The Allegro is cast in sonata form, and the principal melodic motive appears prominently in five places: the opening and end of the Exposition (mm. 23–51 and 91–106, respectively); the Development section (mm. 107–54); and the opening and end of the Recapitulation, extending into the Coda (mm. 155–70 and 211–46). My discussion concentrates on the first three of these, with briefer comments on the beginning of the Recapitulation and the Coda.

Measures 23–51 of the Allegro

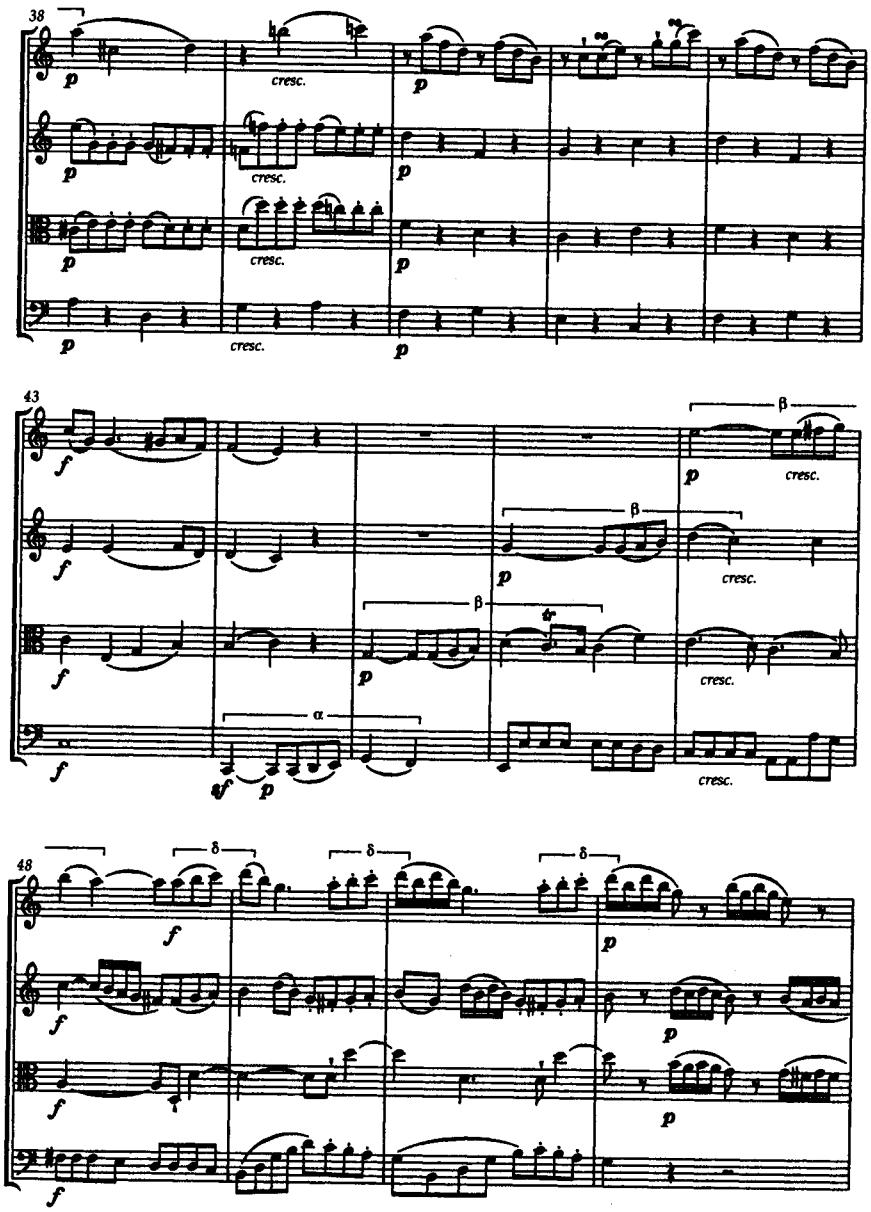
Example 4.3 gives the first twenty-nine measures of the Allegro. The principal motive of the movement is presented in the first violin in mm. 23–24, and then again in mm. 25–26 (symbolized with α in ex. 4.3). Using an analytical perspective that will inform each of the remaining analyses, I shall approach the various forms of this motive as a cognitive category, structured around a conceptual model. I shall leave open the question of the status of these conceptual models—that is, whether they are empirically verifiable constructs or simply convenient analytical tools—and proceed on the general understanding developed in chapter 1 and briefly reviewed at the beginning of this chapter: categories are basic structures in terms of which we understand the world, they are organized around conceptual models, and they represent a common ground where the concerns of listeners and composers meet.

The model for the category consists of three correlated conceptual elements, characterized as the things necessary for a melodic fragment to count as an instance of the motive:

- a rhythmic pattern that spans two measures of common time: 
- a rather specific diatonic contour, consisting of four elements (each is shown in ex. 4.4); in order of succession, they are

  (i) a sustained first note
  (ii) an ascending stepwise motion through a third
  (iii) an upward skip of a third
  (iv) a downward step

- an implied harmonic change from the first to the second measure of the motive

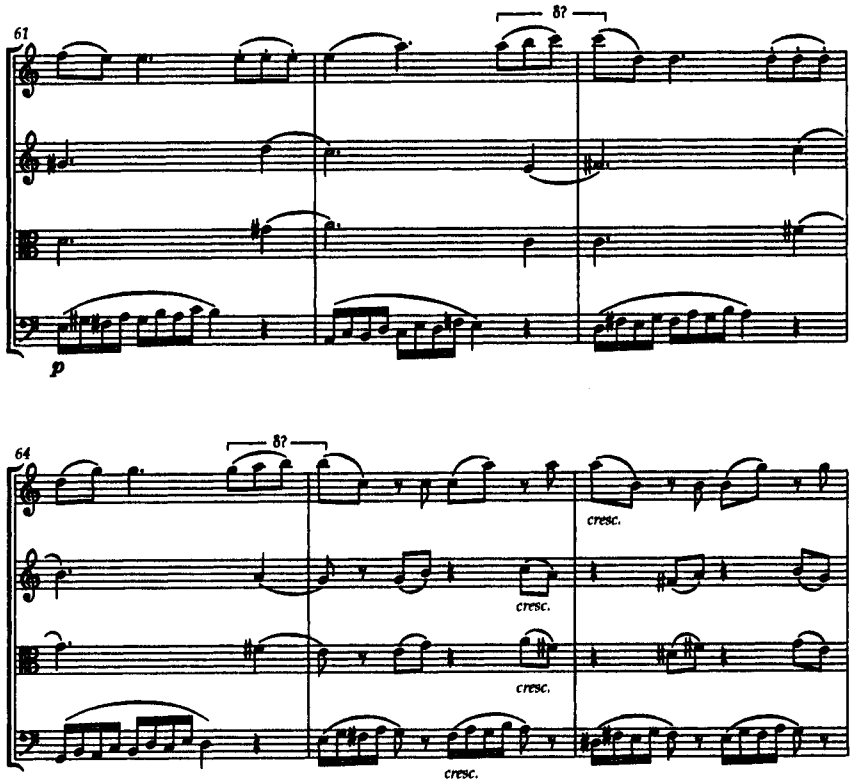


The contour of the motive gives rise to two distinctive intervals: the fifth spanned by ii and iii; and the fourth between i and the last note of iv. Although the implied change in harmony is masked in mm. 23–24 (owing to the viola's pedal point), in most other cases it is quite apparent.

After mm. 23–26, there are three further instances of the motive that correspond to this model: two in mm. 31–34 (with the motive accompanied by the second violin), and one in the cello in mm. 44–45 (with the cello's concluding half note taking the place of the quarter-note and quarter-rest of the original). Somewhat less-typical forms appear in the first violin in mm. 27–28 and in the ascending cascade of mm. 45–48 (β in ex. 4.3). In each case, the very end of the motive has been

EXAMPLE 4.3 W. A. Mozart, String Quartet K. 465, first movement, mm. 23–51

EXAMPLE 4.3 *(continued)*



EXAMPLE 4.4 Schoenberg's analysis of the main motive from W. A. Mozart, String Quartet K. 465, first movement

modified: in mm. 45–48, the most significant change is to the end of the rhythmic figure; in mm. 27–28, both the end of the rhythmic figure and contour pattern have been changed. One additional version of the motive, heard in the first violin in mm. 35–36 (γ in ex. 4.3), is still less typical, retaining most of the rhythmic pattern of the original, but only element ii of the contour.

One other bit of musical material (shown with δ in ex. 4.3) seems to demand affiliation with the motivic category. As but a subcomponent of the motive—the ascending gesture that ends on a strong beat—it is hardly typical of the category. Indeed, hearing the fragment as a member of the category requires that it appear in close proximity to more typical members of the category. When a similar gesture occurs in mm. 62–63 and 64–65 in the midst of the first subsidiary theme (as shown in ex. 4.5), it is decidedly subservient to the alternation of ascending and

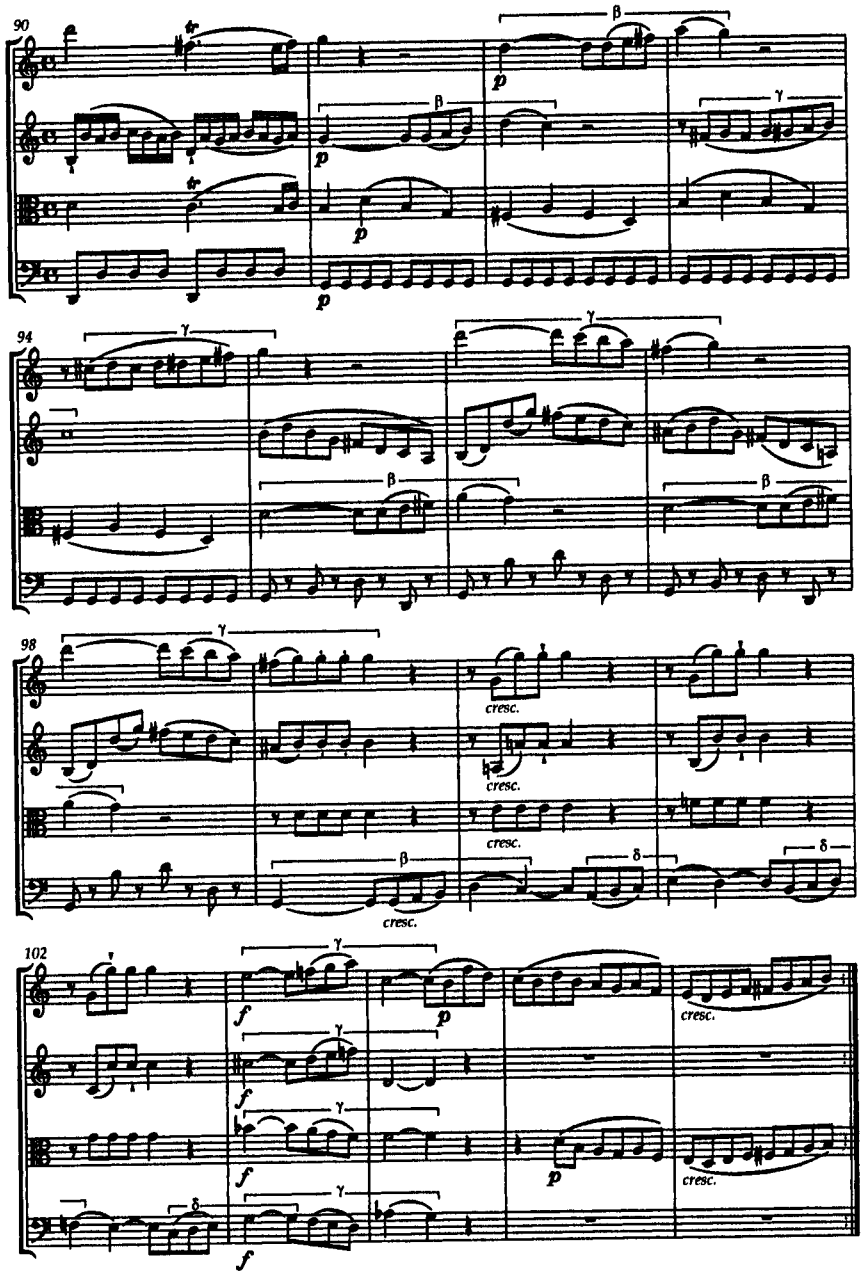
EXAMPLE 4.5 W. A. Mozart, String Quartet K. 465, first movement, mm. 61–66

descending skips that dominates the musical scene, having lost its connection to the principal motive. The change in the way we hear this fragment—in mm. 48–51, as belonging to the category that includes the principal motive; in mm. 62–65, as a rather generic bit of filler—is an example of the phenomenon of conceptual slippage noted in chapter 3, but one applicable to purely musical concepts. The context that induces this slippage is the absence of the principal motive and the presence of new material associated with the first subsidiary theme.

The melodic syntax for these opening measures, then, involves setting out the most typical members of the category first—indeed, these provide the basis for the conceptual model for the category.[24] Less typical members of the category follow (in mm. 27–28 and 35–36), and, in mm. 37–43, the motive temporarily disappears altogether (save for the δ fragments). It then reappears in its most typical form in m. 44, immediately followed by three slightly less typical versions. After this, there are further δ fragments that lead to the generic cadential material that prepares for the entrance of the first subsidiary theme in m. 56.

Taken as a whole, the motive forms presented in mm. 23–51 are a relatively normative Type 1 category. What is striking, however, is the dynamic shape of the category as it is presented over the course of time. Although typical members dominate the musical texture in the first half of the section, they momentarily disappear from the texture in the second half, to be brought back at an important moment preceding the transition to the first subsidiary theme. The importance of the principal motive for the melodic syntax of mm. 23–51, then, is less a function of its constant presence and more a function of its memorability and cognitive utility. These make possible a musical syntax of both exposition and development: exposition as the motive is first established in its most typical form; and development as less-typical variants are then introduced.

Measures 90–106 of the Allegro



After its gradual departure in mm. 44–51, the motive disappears completely for forty measures, during which time two subsidiary themes are presented in the dominant. When the motive does return, it is at a moment of opportunity, following a final emphatic cadence of the sort that usually signals the conclusion of a section or that prepares the way for additional thematic material. By bringing back the main motive at this point, Mozart ties together the beginning and end of the Exposition. The bonds are relatively loose ones, however, for it is a variant of the main motive rather than the original that is introduced, and the compositional strategy applied to the statements that follow is closer to development than it is to exposition.

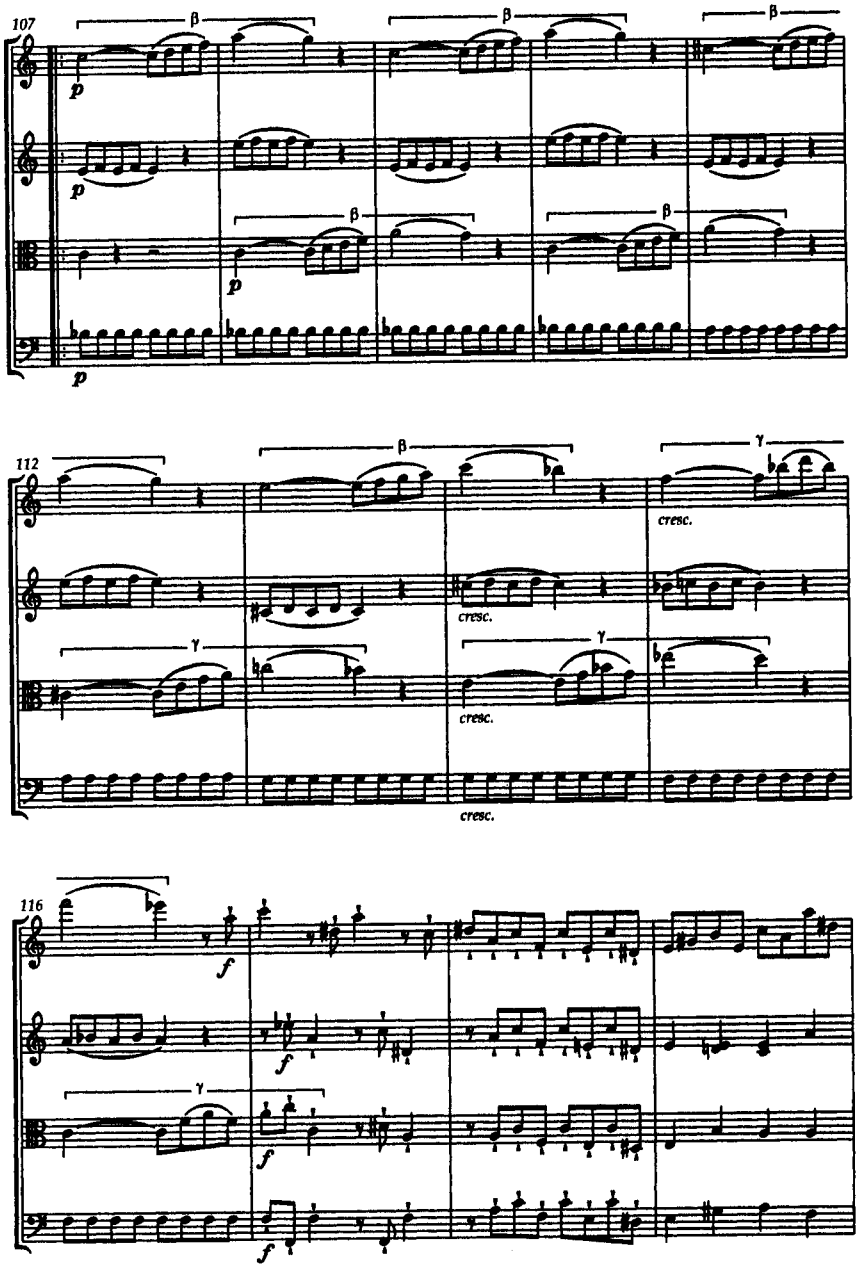
As shown in example 4.6, the motive enters in the second violin in m. 91, just as the first violin achieves its cadential G5.[25] The first violin responds by taking up

24. As noted in chap. 1, it is also possible for the conceptual model for a category of motive forms to emerge over time, although the longer the process is delayed, the more the conceptual model comes into conflict with the global model for a musical theme.

25. The sustained note at the beginning of the motive allows Mozart to introduce it under the cover of cadence, something he exploits at various developmental moments throughout the movement.

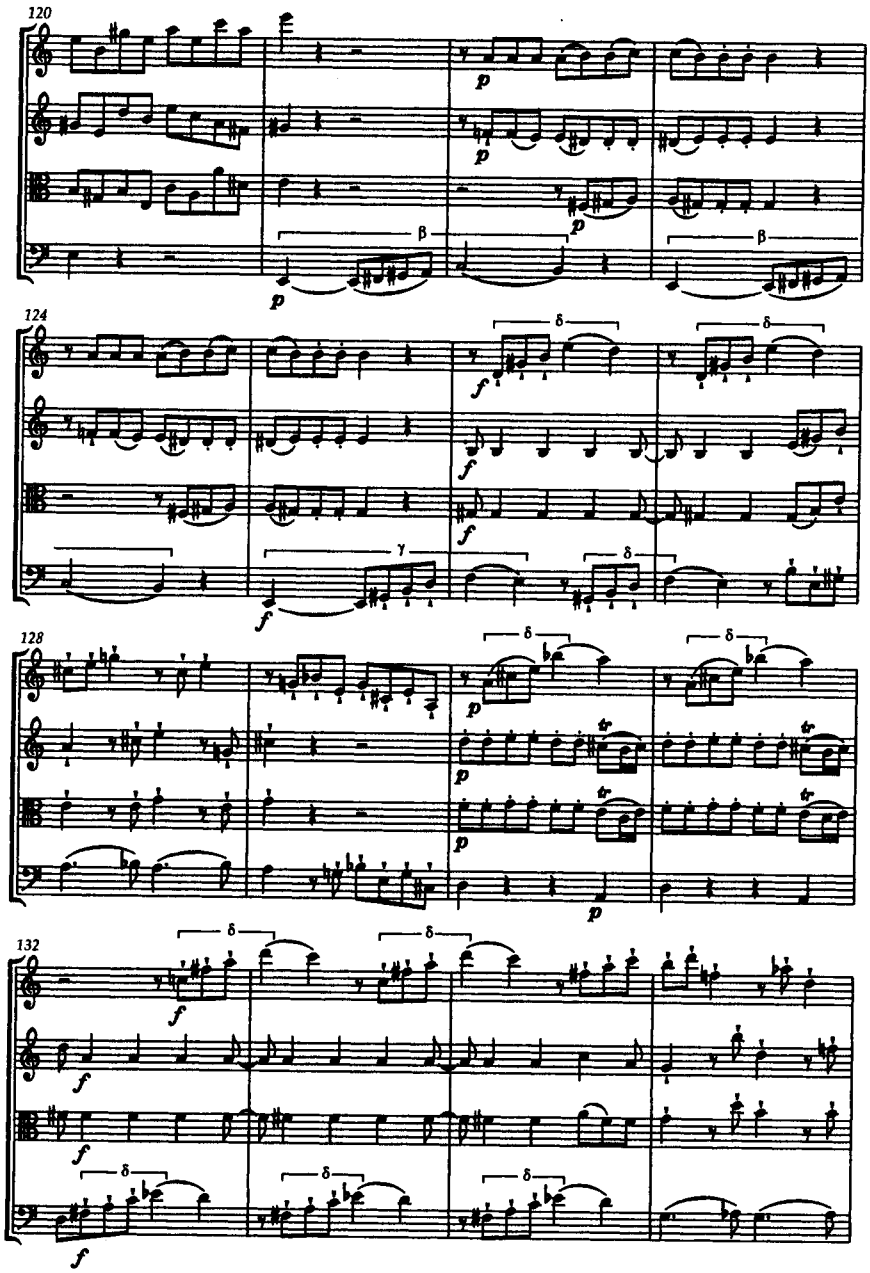
EXAMPLE 4.6 W. A. Mozart, String Quartet K. 465, first movement, mm. 90–106

the motive as well, beginning a short game of motivic tag in which some form of the motive enters in each of the succeeding measures. Here, the initial motive forms are of the β variety, highly similar to the original form but with a slightly modified ending. Although harmonic change is still evident, the constant overlap of motives limits the harmonic possibilities to the tonic and dominant of G major. The sense of harmonic progress that accompanied the original statement of the motive is markedly attenuated: contributing factors are the constant alternation between tonic and dominant, the cello's pedal point in mm. 91–95, and the halving of harmonic rhythm that follows in m. 96.



This reprise of the motive bears witness to new, and somewhat more extensively varied, members of the motivic category. In mm. 93–94 and 94–95, the second and first violins present embellished versions of the motive forms they have just stated (indicated with a γ in ex. 4.6); were it not for the temporal proximity of these to the preceding motive forms, it might be difficult to make a case for their derivation from the original. More obvious is the inverted form of the motive that appears in the first violin in mm. 96–99, and which is then used in the simultaneous presentation of motive forms in all four instruments in mm. 103–104. Finally, the δ fragment that provided a measure of unity at the opening of the exposition reappears in mm. 100–103 to serve as a link between the motive forms that precede and follow it.

Given the absence of the original form of the motive in these measures, a case could be made for modifying the conceptual model for the category so that variants of the sort shown with a β in example 4.6 would be regarded as typical (indeed, such a move would be the first step along a slippery slope of motivic development of the sort that Wagner leads us down with his transformations of the Leidensmotiv). Nonetheless, retaining the sense that we have moved away from what is typical of the category is important for what happens next. If the repeat sign of m. 106 is observed and the Exposition reprised, the typicality of the original version of the motive will be reaffirmed: we will have moved from the edges of the category (as represented by mm. 91–106) back to the center. If we instead proceed from m. 106 into the Development, we will move yet farther toward the fringes of the category.



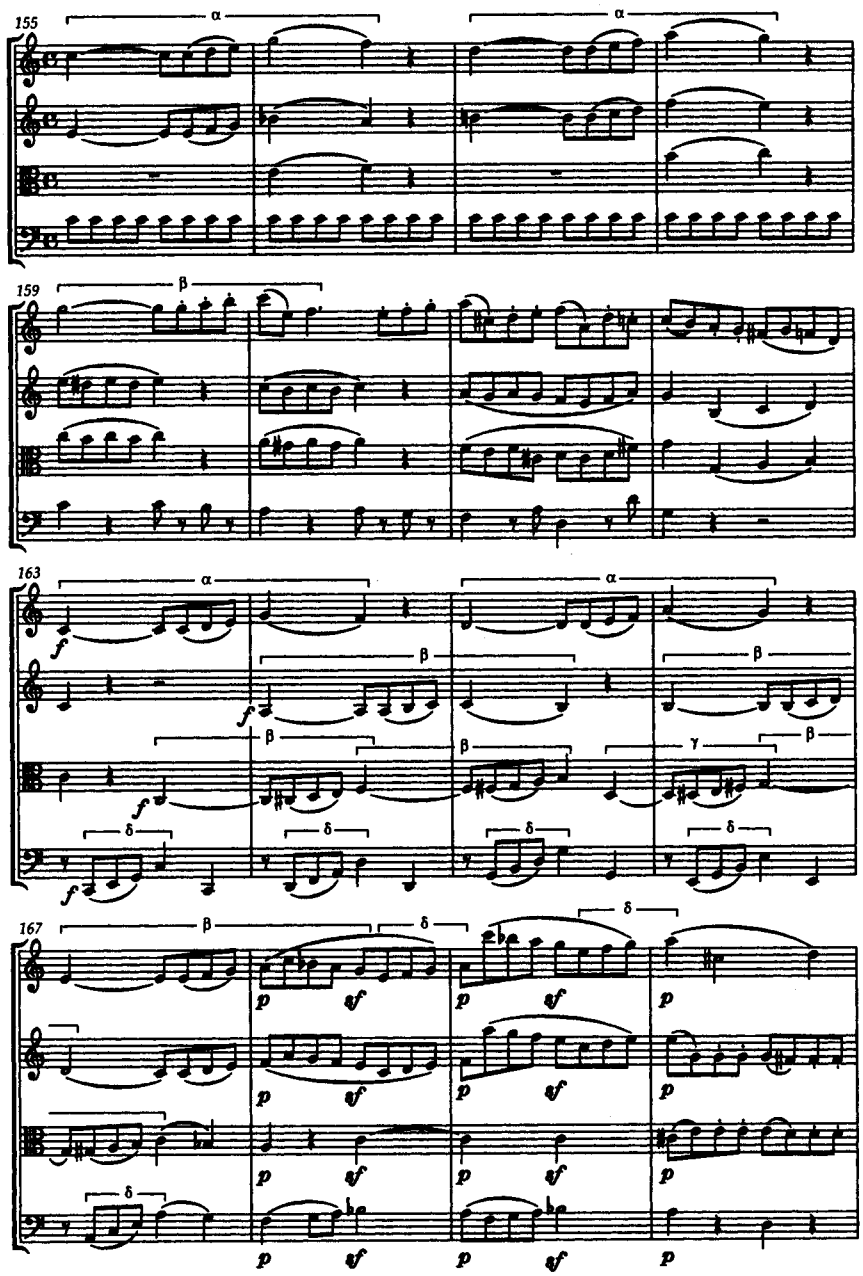
Measures 107–35 of the Allegro

As shown in example 4.7, Mozart begins the Development with a slightly modified version of the original motive, but with changes now made to the middle of the motive rather than to the end: he starts the ascending-third figure a step higher than the sustained note, instead of repeating the sustained note at the beginning of the figure. As a result, the motive, as a whole, now spans a fifth and implies no change of harmony. The chromatic alteration in the first violin at m. 111 moves the motive a bit further away from its typical form, but it is the version in the viola at mm. 112–13 that accelerates the process of transformation. In this version (indicated with a γ in ex. 4.7), the ascending-third figure is replaced with an arpeggio, which becomes a feature of the following motive forms. At m. 117, the arpeggio figure takes over, and the subsequent dissolution of the motive leads to a momentary cadence on the dominant of A minor in m. 121.

EXAMPLE 4.7 W. A. Mozart, String Quartet K. 465, first movement, mm. 107–35

EXAMPLE 4.7 *(continued)*

At m. 121, the cello returns to the form of the motive used at the beginning of the Development (but now within the context of A minor). After two statements, the rising arpeggio figure once again replaces the ascending third within the motive, after which point it displaces the main motive or its variants altogether (as indicated by the preponderance of δ symbols after m. 125 in ex. 4.7). In m. 147 (which is not given in ex. 4.7), the form of the motive used at mm. 107 and 121 makes a final appearance (beginning with the cello's G2, but pointing toward C minor). Given the events that followed the previous two appearances of this form of the motive, this third appearance seems to suggest yet another episode of development. Nonetheless, in m. 151, the motive yields to an ascending cascade of arpeggio-figures (all outlining a G dominant-seventh), which brings the Development to a close.

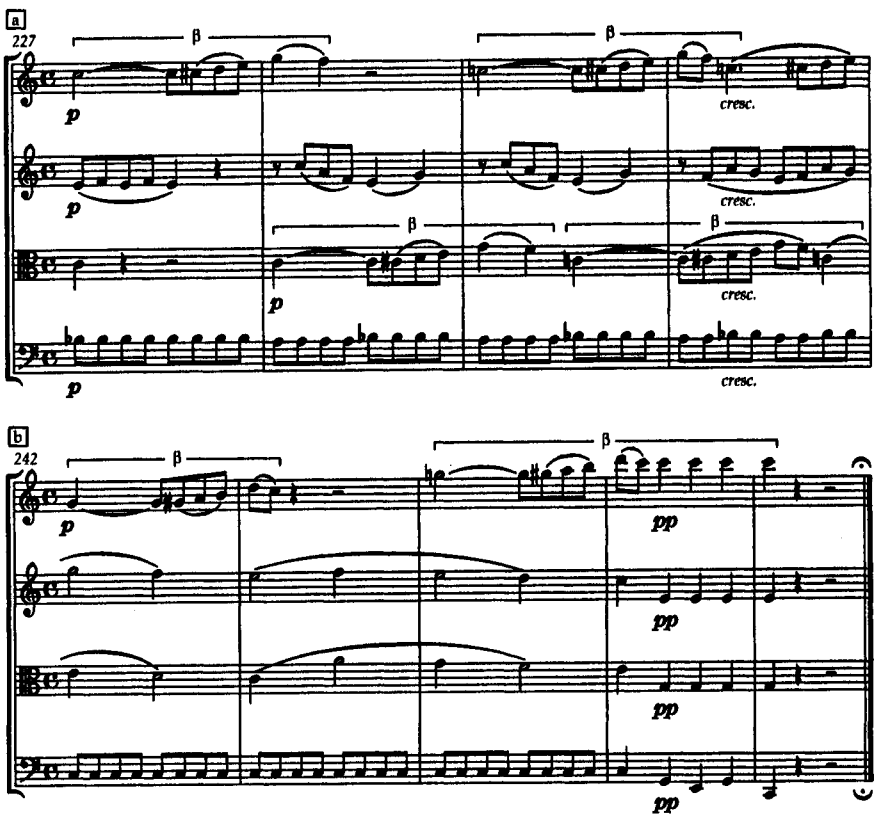


As was the case in the Exposition, in the Development more typical forms of the motive are followed by less typical forms. What is distinctive is the repetition of this pattern in close order (which occurs three times within the forty-odd measures of the Development), and the emergence of the ascending δ figure as the means for Mozart to advance his musical argument. While the slightly varied form of the motive that marks the beginning of each pattern has prominence as a point of reference for this musical argument (and thus represents what is "typical" of thematic material), it lacks the sense of balanced harmonic progression summoned by the original form of the motive. Given the variation of the motive that takes place over the course of mm. 107–35, however, just what *is* typical of the original motive is something of an open question by the time we arrive at the dominant-seventh of mm. 151–55.

Measures 155–60 and 211–46 of the Allegro

The question of motivic identity posed by the Development is answered by the understated but nonetheless confident return of the original motive in mm. 155–58, shown in example 4.8. Although the accompaniment is somewhat different than that used in mm. 23–26, the motive itself is unchanged from its original form: this is the motive at its most typical. Mozart is not content to leave it at that, however. The accompaniment for the second statement of the paired motives, in mm. 163–66, is not only fuller, but it brings back the overlapped motive forms used at the end of the Exposition and at the beginning of the Development. These slightly varied forms of the original (indicated with β in ex. 4.8) recall the developmental cast of the earlier passages, as do the ascending δ figures in the cello. Mozart nonetheless quickly turns away from any further dissolution of the main motive and instead moves with dispatch toward the first subsidiary theme, which commences at m. 176.

The end of the Recapitulation restates the end of the Exposition almost exactly: mm. 91–106 are transposed into C major for mm. 211–26. From this point, the music proceeds either back to the beginning of the Development (if the repeat is taken) or forward to the Coda (which occupies mm. 227–46). As shown in example 4.9a, the latter grows out of the opening of the Development but uses yet another modification of the original motive. This version owes much to that used in mm. 211–13 (the transposed quotation of mm. 91–93), but applies a chromatic



EXAMPLE 4.8 W. A. Mozart, String Quartet K. 465, first movement, mm. 155–70

inflection to the note at the beginning of the ascending-third figure. A further variant then concludes the movement, which is shown in example 4.9b: the end of the motive, shortened from the original half-note–quarter-note figure to the successive quarters of mm. 227–29, is shortened yet again to two successive eighth-notes. Although a similar figure occurs in mm. 229–30, *that* variant refers back to mm. 27–28, for the successive eighths lead immediately to additional material (in the case of mm. 229–30, a repetition of the ascending-third figure). In mm. 242–45, the eighths simply represent a compression of the original motive, and it is with this abbreviated form of the motive that the movement ends.

Although the concluding section recalls the opening of the Development, Mozart allows the prospect of further divergence from the main motive to linger for only a moment before banishing it with a vigorous and triumphant cadence in C major in mm. 234–35. Nonetheless, it cannot be said that the movement ends with an unequivocally typical form of the motive: if the original form of the

EXAMPLE 4.9 W. A. Mozart, String Quartet K. 465, first movement: (a) mm. 227–30; (b) mm. 242–46

motive represents the stable center of the cognitive category of motive forms, the conclusion does not return us to that center. Two factors inform the ending; both are related to global models, which provide a context for the conceptual model that defines what is typical of this motivic category. First, the ending is harmonically quite stable: the final version of the motive introduced in mm. 242–45 reinforces this stability by outlining scale degrees $\hat{5}$ and $\hat{1}$ and by placing the arrival on $\hat{1}$ as close as practicable to the first beat of the metric cycle while retaining the appogiatura figure characteristic of the motive. Second, the most typical version of the motive, in accordance with the global model for music themes relative to which it is framed, represents musical material to be acted upon—it is a theme in the sense of a topic for discourse. At this point in the movement, however, discourse must be concluded: what is required is not a highly typical version of the main motive but a reminiscence of the motive suited to the purposes of ending.

Compositional Strategy, Categorization, and the Allegro

Although I chose not to emphasize it in the preceding discussion, the overall compositional strategy that shapes the Allegro (as opposed to its principal motive alone) has, not surprisingly, a high degree of conformance both with models for sonata form proposed by music theorists during the late eighteenth century and with the syntactic template for the musical game discussed above. The first main section of the work (mm. 23–106, which I have called the Exposition) moves from tonic to dominant, with themes or thematic groups for each key area. The second main section (mm. 107–204) begins by moving through a number of different key areas (the Development) and then turns to music that emphatically confirms the tonic (the Recapitulation). The syntax of this form is articulated by important cadential arrivals (such as the arrival on the tonic in m. 44 or the arrival on the dominant in m. 91), and although melodic themes are important for projecting a key and rendering a particular key area distinctive, they are not the driving force behind this portion of the musical discourse.

Running parallel to this formal syntax, but independent from it, are the compositional strategies that shape the category comprising the various versions of the principal melodic motive of the Allegro. While the most typical members of this category are associated with tonic (and, in their typicality, serve to emphasize the importance of tonic within the formal syntax), members with a high degree of conformance to the conceptual model for the category are also used to initiate presentations of the motive at points not associated with the tonic (such as the end of the Exposition or beginning of the Development). Each of these presentations of the motive (whether on or off the tonic) leads to an increasing number of less typical members of the category, a process that ends either with the introduction of a more typical form (as in m. 44 or m. 155), or with a move toward new thematic material (as happens following m. 49). Through the accumulating evidence of these processes we come to understand the motive as a basis for Mozart's musical discourse—

something to be introduced, varied, and ultimately reprised. A similar understanding does not develop in connection with the subsidiary themes first introduced in the dominant during the Exposition; instead, these are melodic materials with the highly localized syntactic function typically attributed to such themes by eighteenth-century theorists.

Understanding the principal motive as the basis for Mozart's musical discourse, however, is not the same thing as regarding it as the generator of discourse throughout the movement. As I pointed out in connection with example 4.5, snippets of material reminiscent of some other aspect of the motive can be found elsewhere in the movement.[26] Nonetheless, without the context provided by more typical members of the motivic category, we tend not to hear such fragments as related to the principal motive and thus do not hear them contributing to the discourse of which the motive is a part.

It is important to emphasize that the syntax associated with the principal motive of the Allegro is not entirely unique to this movement. As Robert Gjerdingen has shown, composers of the late eighteenth century relied on a variety of stylistic formulae for both the substance and shape of their melodic and harmonic material, and these formulae inform the compositional strategies applied to the motive.[27] However, the way this particular motivic category unfolds—how many typical members of the category are presented before variation ensues, the relative typicality of subsequent members, and the amount of time before more typical members return—is something specific to the Allegro.

The principal motive of the Allegro should also be understood as an instance of the sort of musical topics to which eighteenth-century composers regularly made recourse (and to which Eco referred in his acknowledgement of musical "signs"). Mozart's motive is a good example of the "singing style" as characterized by Leonard Ratner, and the lyrical presuppositions of this topic do much to shape just what components of the motive are called on for the purposes of variation.[28] Nonetheless, I think Mozart's motive is also more than simply a musical topic, for in its status as a remarkable musical category—remarkable in the variety of members the category comprises, and remarkable in the way the manipulation of these members contributes to Mozart's overall musical argument—it transcends topicality to become an essential element within the musical discourse peculiar to the Allegro of the C major quartet.

26. A thorough analysis that makes an argument for the omnipresence of the principal motive can be found in Bonds, *Wordless Rhetoric*, 102–10.

27. See in particular Robert O. Gjerdingen, *A Classic Turn of Phrase: Music and the Psychology of Convention*, Studies in the Criticism and Theory of Music (Philadelphia: University of Pennsylvania Press, 1988); idem, "Revisiting Meyer's 'Grammatical Simplicity and Relational Richness,'" in *Cognitive Bases of Musical Communication*, ed. Mari Riess Jones and Susan Holleran (Washington, D.C.: American Psychological Association, 1992), 225–43; and idem, "Courtly Behaviors," *Music Perception* 13 (1996): 365–82.

28. For examples and discussion of musical topics, see Leonard G. Ratner, *Classic Music: Expression, Form, and Style* (New York: Schirmer Books, 1980), 9–29. For a discussion of musical topics of this sort within the specific context of musical semiotics, see Victor Kofi Agawu, *Playing with Signs: A Semiotic Interpretation of Classical Music* (Princeton, N.J.: Princeton University Press, 1991), 17–34.

BEETHOVEN, STRING QUARTET IN B♭ MAJOR, OP. 18 NO. 6. FIRST MOVEMENT

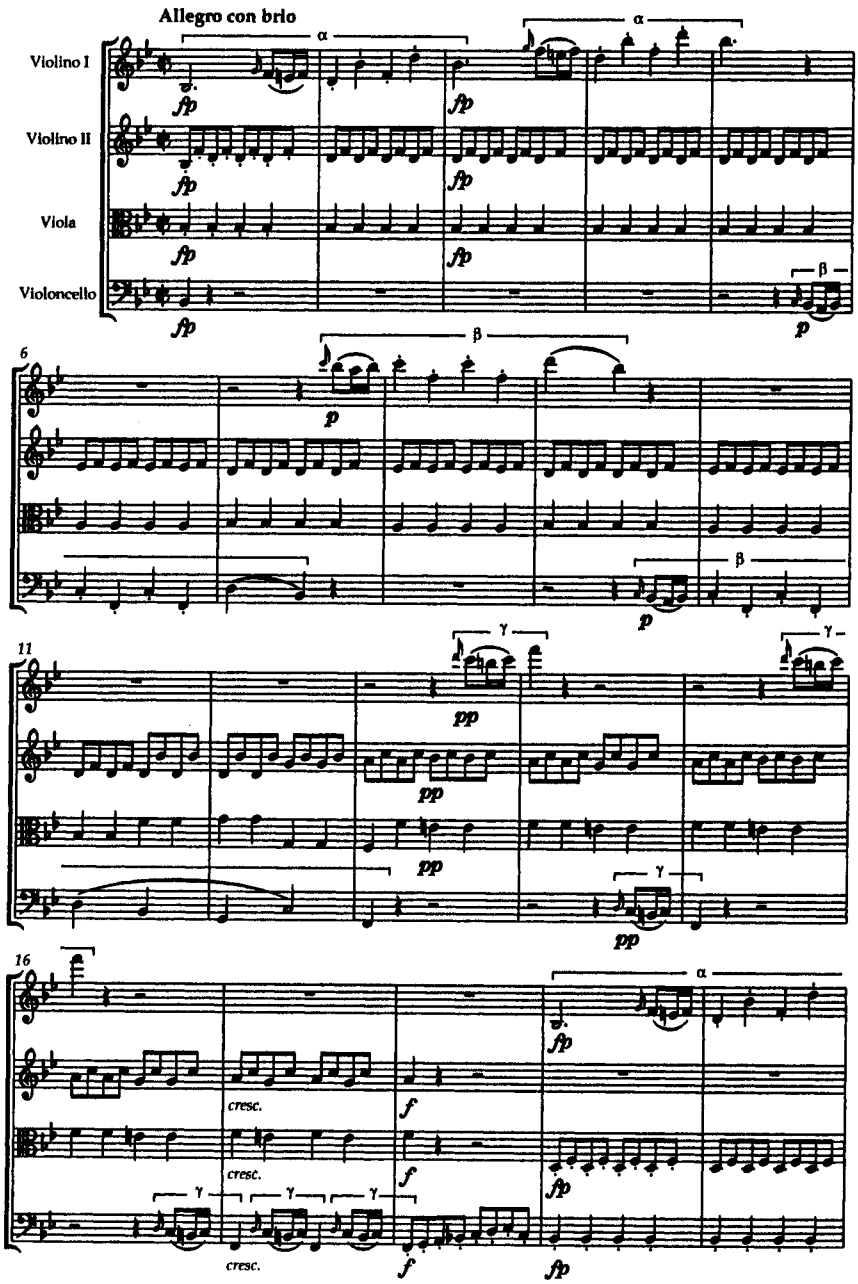
Joseph Kerman devoted the first quarter of his classic study of the Beethoven string quartets to the Op. 18 set (which date from 1798 to 1800), rightly believing that these early works held important keys to understanding how Beethoven transformed what had been a relatively modest genre into the ne plus ultra of chamber music.[29] But Kerman had little patience with the first movement of the sixth quartet, for he found scant evidence of the sort of motivic development that would become the hallmark of Beethoven's mature style.[30] In truth, the opening motive of the work undergoes hardly any transformation over the course of the movement: its syntax is not easily explained in terms of relative degrees of typicality among category members. What is involved instead is a category that includes two distinctly different forms of the motive, forms distinguished not only by the materials from which they are fashioned but also by the way they are used. The different uses of these two forms suggests a higher level of syntax that includes both, and this in turn gives a glimpse into the process by means of which musical topics, of the sort discussed by Ratner and alluded to by Eco, are formed.

Ratner, for his part, characterized this movement as "pure buffa, a dancing cartoon."[31] As can be seen in example 4.10, the two forms of the principal motive contribute much to the effect, providing a musical Tweedledum and Tweedledee to the listener's Alice.[32] The first of these (α in ex. 4.10) sketches a rapid ascent through a broken arpeggio on the tonic and, aided in the first case by a slightly overemphatic *fortepiano*, sets out the first beats of mm. 3 and 5 as points of arrival. The second form of the motive (β in ex. 4.10), suave and somewhat understated, introduces the dominant and is metrically more open. In mm. 7 and 9, it ends on the second main beat of the measure; in its third appearance, it ends on the first beat of the measure, but only after its ending is extended by mm. 12–13. The overall harmonic contour of the β form is also relatively flat: in mm. 5–7, for instance, it begins and ends on B♭2, while m. 6 is preoccupied with a simple alternation of the fifth and root of the dominant chord.

29. With this characterization I mean to take nothing away from the accomplishments in this genre by Haydn or Mozart, but only to suggest that it is with Beethoven that the quartet eventually becomes a site for the active contestation of musical values and that this represents a new possibility for chamber music. See, for instance, Daniel K. L. Chua, *The "Galitzin" Quartets of Beethoven: Opp. 127, 132, 130* (Princeton, N.J.: Princeton University Press, 1995). The issue for musicologists, then, is the extent to which the early quartets prepare the way for this transformation of the genre.

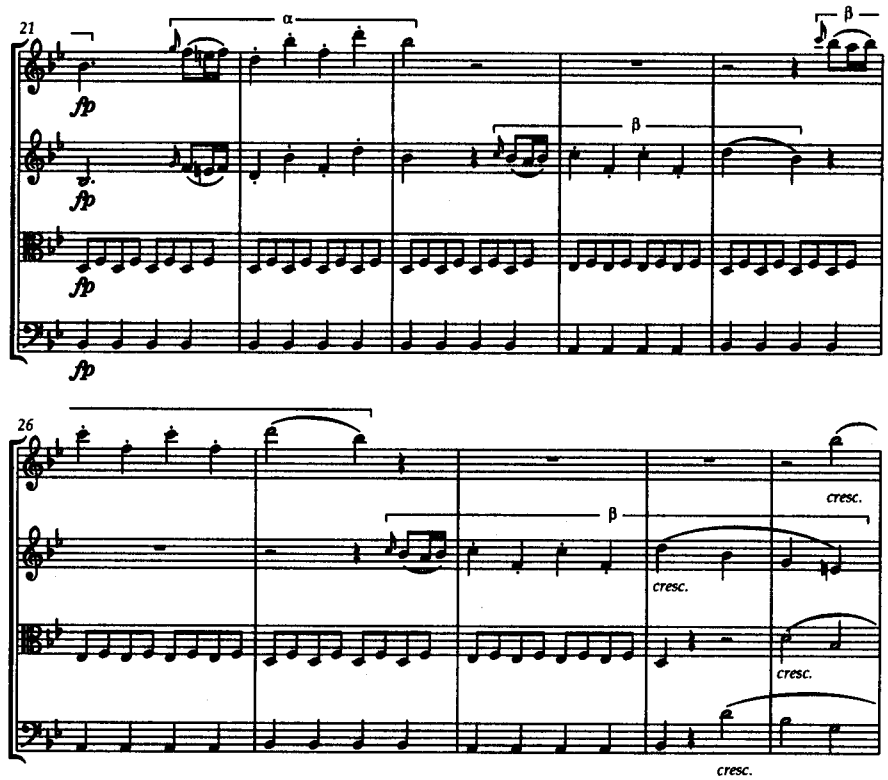
30. Joseph Kerman, *The Beethoven Quartets* (New York: W. W. Norton, 1966), 71–74.

31. Leonard G. Ratner, *The Beethoven String Quartets: Compositional Strategies and Rhetoric* (Stanford, Calif.: Stanford Bookstore, 1995), 89.



32. In *Through the Looking Glass*, Alice quotes a nursery rhyme about Tweedledum and Tweedledee, and, after hearing this, the two brothers reply:

"I know what you're thinking about," said Tweedledum; "but it isn't so, nohow."



"Contrariwise," continued Tweedledee, "if it was so, it might be; and if it were so, it would be; but as it isn't, it ain't. That's logic."

Lewis Carroll, *The Annotated Alice: Alice's Adventures in Wonderland and Through the Looking Glass*, introduction and notes by Martin Gardner, illustrated by John Tenniel (New York: W. W. Norton, 2000), 181. In a note to this passage, Gardner observes that the nursery rhyme may descend from a bit of doggerel by John Byrom (an eighteenth-century hymn writer and teacher of shorthand), which recounted the rivalry between George Frideric Handel and Giovanni Battista Bononcini.

EXAMPLE 4.10 Ludwig van Beethoven, String Quartet, Op. 18 No. 6, first movement, mm. 1–30

EXAMPLE 4.10 *(continued)*

Commenting on the deliberate and somewhat stagy entrances of α and β is a fragmentary form of the motive (γ in ex. 4.10). This consists of only a turn and a leap (first ascending, then descending); its entrances reverse the expansion of the distance between strong metric accents occasioned by the extension of mm. 12–13, shrinking it first to one-measure and then (in mm. 17–18) half-measure intervals. This process of acceleration culminates in an arrival on the dominant in m. 18, embellished with a run in the cello that returns the music to the tonic and to the α form of the motive.

To better understand the distinctive features of and relationships between these three forms of the motive, as well as their progress through the movement, let us consider conceptual models for each; diagrams for the models are given in figure 4.6. The conceptual model for the category of α forms consists of five correlated conceptual elements, characterized as the things necessary for a melodic fragment to count as an instance of this version of the motive:

- the rhythmic pattern ¢ 𝅗𝅥 𝅗𝅥 𝅗𝅥 𝅗𝅥 | 𝅗𝅥 𝅗𝅥 𝅗𝅥 𝅗𝅥 | 𝅗𝅥.
- the motive begins with a turn figure (here, around $\hat{5}$)
- the continuation of the motive involves a broken arpeggio with ascending contour (here beginning on $\hat{3}$ and ascending through a sixth to $\hat{1}$)

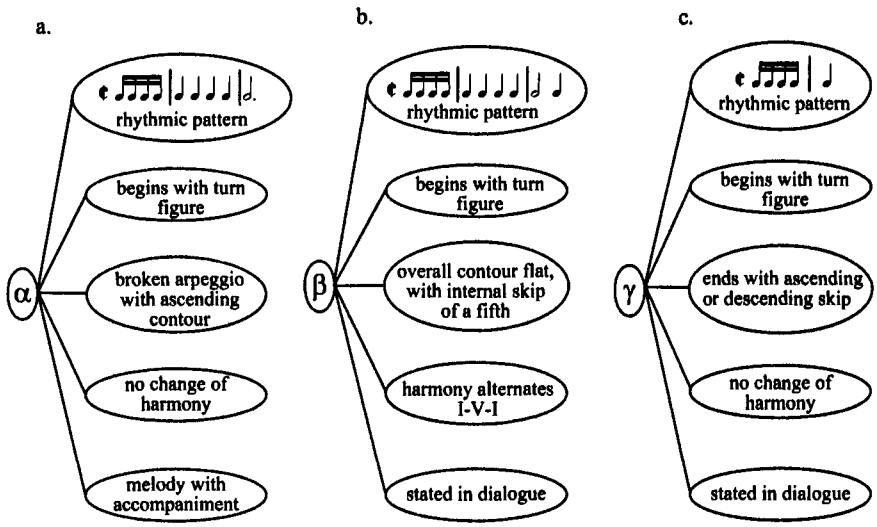


FIGURE 4.6 Conceptual models for the three forms of the principal motive from Beethoven, String Quartet, Op. 18 No. 6, first movement, mm. 1–30: (a) the α form; (b) the β form; (c) the γ form

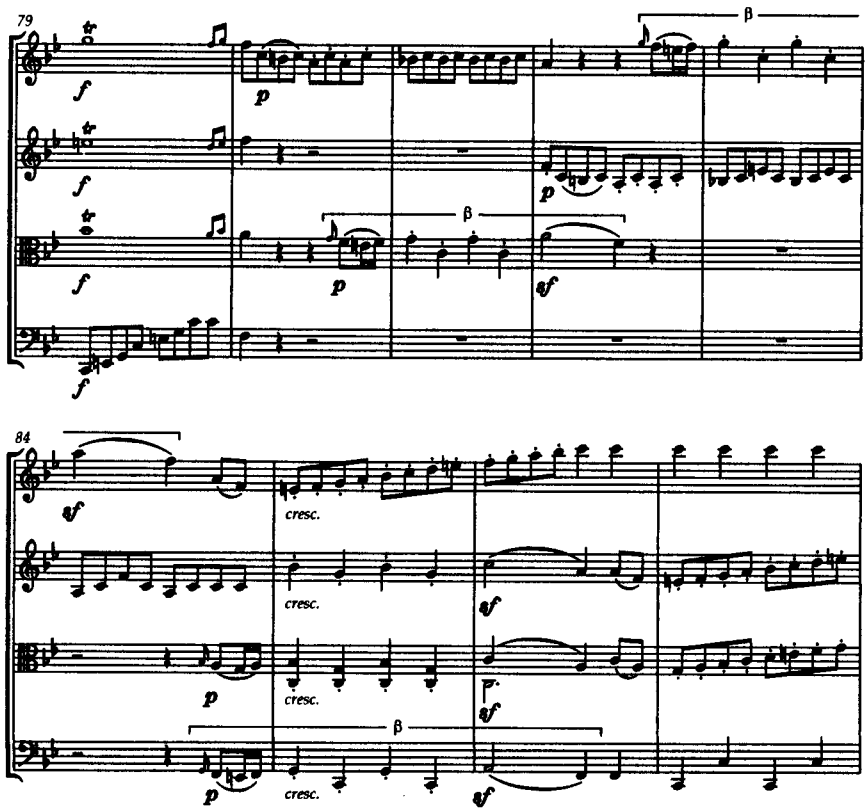
- there is no change of harmony implied by the motive
- the motive is presented as a melody supported by accompaniment in the remaining strings[33]

Each of these elements could, of course, be broken down into smaller parts. This is particularly true of the rhythmic pattern, which is extended by the β form of the motive and truncated by the γ form. As indicated by figure 4.6b, the conceptual model for the β form retains most of the first two components but alters the last three. The γ form continues this process, retaining only the turn figure that is the motive's most characteristic feature.

Slightly varied restatements of the α and β forms of the motive in mm. 19–29—the texture thickened somewhat, and with the two violins taking part in the dialogue proper to the β form of the motive—lead to a long pedal on the dominant of F major preparatory to the statement of the second theme, which commences in m. 45. What is remarkable, from the perspective on musical syntax I have developed thus far, is the nearly complete lack of typicality effects among these materials. While it would be quite possible to include them all in a single category for the motive, framed relative to a conceptual model that combines the essential elements of those included in figure 4.6, there does not seem to be a compelling argument for regarding either the α and β form as more typical of the category. A better case could be made for conceiving of the γ form as a less typical member of the category (if only on account of its fragmentary nature), but it is a bit hard to say just



33. There are, of course, other ways the motive could be characterized. For instance, the rhythmic figure I identify does not include the very first note of the piece. My chief reason for seizing upon this figure is for comparison with other forms of the motive. Should one wish to include the first note, the remaining forms of the motive would represent even more radical departures from the standard established by the α form.

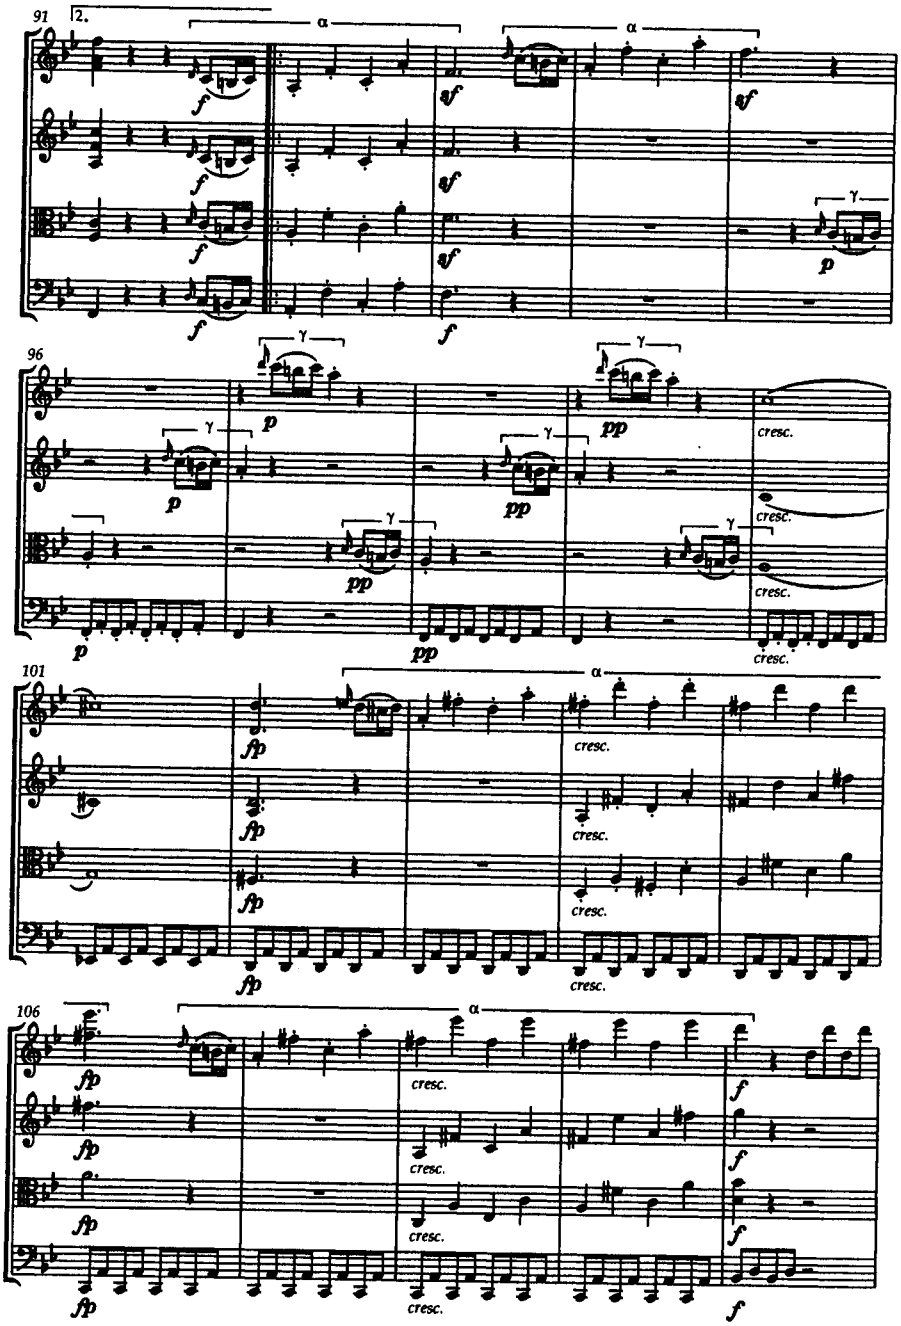
what it is less typical of. It could be derived from either the α or the β form, and without further variants it remains somewhat difficult to settle the question.

Subsequent to a cadence on F major in m. 80 that wraps up the exposition of the second theme, the β form of the motive reappears, as shown in example 4.11. Although it has been transposed to F, and its third statement in the cello is accompanied by parallel tenths in the viola and by a reprise of the passagework from the bridge in the first violin, it is otherwise exactly the same as when it appeared in the context of the first theme group. This restatement has two consequences. First, it confirms the character of the β form of the motive that was established in the opening measures—that is, it reinforces the conceptual model outlined in figure 4.6b. Second, it draws out a function of β implicit in the initial exposition of motive forms, which was to close off musical discourse. Where the α form of the motive sets out the conditions for musical discourse—establishing a two-measure hypermeter and opening the melodic range to cover more than two octaves—the β motive, with its pedestrian alternation of tonic-dominant-tonic and restricted range, provided closure. Following m. 80, the motive has a similar function, but now it serves to close off the discourse of the entire Exposition.

The syntactic functions of the α and β forms of the motive are due in part to

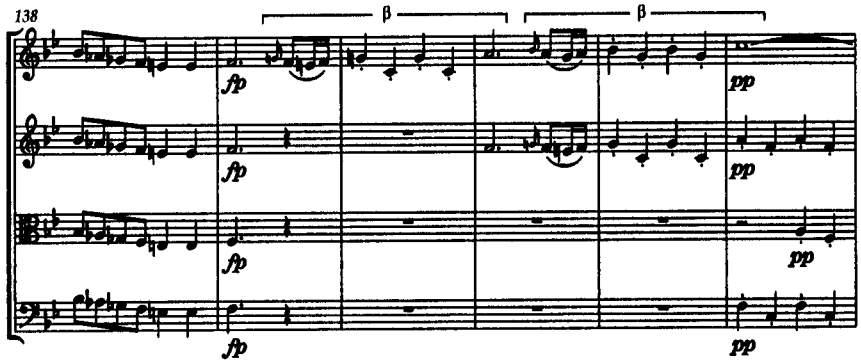
EXAMPLE 4.11 Ludwig van Beethoven, String Quartet, Op. 18 No. 6, first movement, mm. 79–87

their resemblance to similar figures in other compositions: α has all the features of a prototypical opening gesture within eighteenth-century style, and β has much in common with prototypical closing gestures. It should be emphasized, however, that how such motives are used is also important. As Janet Levy has pointed out, Joseph Haydn, at least on occasion, used closing gestures as his opening material.[34] The use of a closing gesture in this way is in part comic—it creates a piece that seems to end before it has begun—but it also makes possible some marvelously ambiguous seams: one is not sure whether a particular passage is a beginning or an ending. The possibility of this ambiguity testifies to the importance of the way musical materials are used within a particular composition, as distinct from how similar materials are used in other compositions. For a gesture to signify "opening," it has to be *used* in openings; for a gesture to signify "closing," it has to be *used* for closings.



The α form of the motive's function as an opening gesture is confirmed when it initiates the Development, which begins with a tutti statement of the motive, immediately echoed by a solo statement in the first violin (as shown in ex. 4.12). These slightly less than typical versions of the motive (which has heretofore always appeared as melody with accompaniment) are followed immediately by the γ form, which tosses a repetition of the head of the α form just heard back and forth between the upper strings. In mm. 103–110, two further variants of the α form appear, which extend the motive both metrically (to four measures) and intervallically (to a compass of an eleventh, and then a twelfth). These expansions lead to G minor, which initiates a rapid cycle of keys explored through the medium of the thematic material that first served as a bridge between B♭ and F back in mm. 33–43.

In m. 139, there is a weak cadence on F, followed immediately by a reappearance of the β form of the motive (shown in ex. 4.13). Stated, as it is, in F major, it recalls the end of the Exposition; however, this particular version does not conform completely to the conceptual model diagrammed in figure 4.6b. The rhythmic profile has been changed and is now the same as that of the α form; the dialogue presentation typical of β forms is absent, replaced here by one unaccompanied and one accompanied statement. Nonetheless, although close to thirty measures of the Development remain, this entry of the β form of the motive signals the end of the harmonic exploration initiated by the variant α forms in mm. 103–10: F major having been regained, the remainder of the Development simply serves to postpone the inevitable return to the opening material. Just as it has each time before, the β form of the motive confirms a closing of harmonic structure.



With the return to B♭ in m. 175, there is an exact reprise of the first eighteen measures of the movement, after which the γ form of the motive is presented in a series of close-order repetitions that initiate the bridge to the second theme. At the conclusion of the movement, the β form returns once more, as it did in mm. 80–86, only this time confirming a final close on B♭.

34. Janet Levy, "Gesture, Form, and Syntax in Haydn's Music," in *Haydn Studies: Proceedings of the International Haydn Conference, Washington, D.C., 1975*, ed. Jens Peter Larsen, Howard Serwer, and James Webster (New York: W. W. Norton, 1981), 355–62.

EXAMPLE 4.12 Ludwig van Beethoven, String Quartet, Op. 18 No. 6, first movement, mm. 91–110

EXAMPLE 4.13 Ludwig van Beethoven, String Quartet, Op. 18 No. 6, first movement, mm. 138–43

As Kerman noted, there is little development of the principal motive in the first movement of Beethoven's Quartet, Op. 18 No. 6. This is not to say that the motive is uninvolved in the syntax of the movement, however, only that the musical discourse is not, in any significant way, about this motive. Thus the α form of the motive signals an opening for musical discourse, but it is not discourse about α. Even when the α form makes an attempt to grab center stage at the beginning of the Development, the effort ends up being little more than comedic bluster: knowing only how to begin, it cannot quite figure out how to continue, and after two attempts (in mm. 102–10), it gives up. Similarly, the β form of the motive closes off discourse, but it is not always a discourse in which β has been involved (as in its appearances at the end of the Exposition and Recapitulation, and in the Development). Thus the two motive forms, by virtue of the way they are used, contribute to a larger syntax concerned not with them but with the progress of the movement as a whole.

Despite their similarities, I believe these two motive forms are distinct enough in their features to be regarded as separate, though related, categories (something illustrated by the conceptual models of fig. 4.6). The syntactic function that accrues to each over the course of the movement—with the α form used only for openings, and the β form used only for closings—gives further support to this distinction. Nonetheless, I regard distinguishing the motive forms on the basis of syntactic function to belong to a later and more theoretical stage of understanding. Accordingly, categorizing the motives is relatively immediate, while understanding the way they function within the work emerges only over time.

As I have noted, these two forms of the motive bear resemblance to stylized musical gestures that signal openings and closings. However, I would argue that, at least on the abstract level concerning processes that pertain to musical categories, their function within the movement does not derive from these gestures. To be blunt, I do not believe knowledge of such stylized figures is necessary to understand Beethoven's musical argument. That it would enrich this understanding I have no doubt, but this is not the same as asserting such knowledge as a precondition for making sense of the discourse of the movement. Instead, the function of the α and

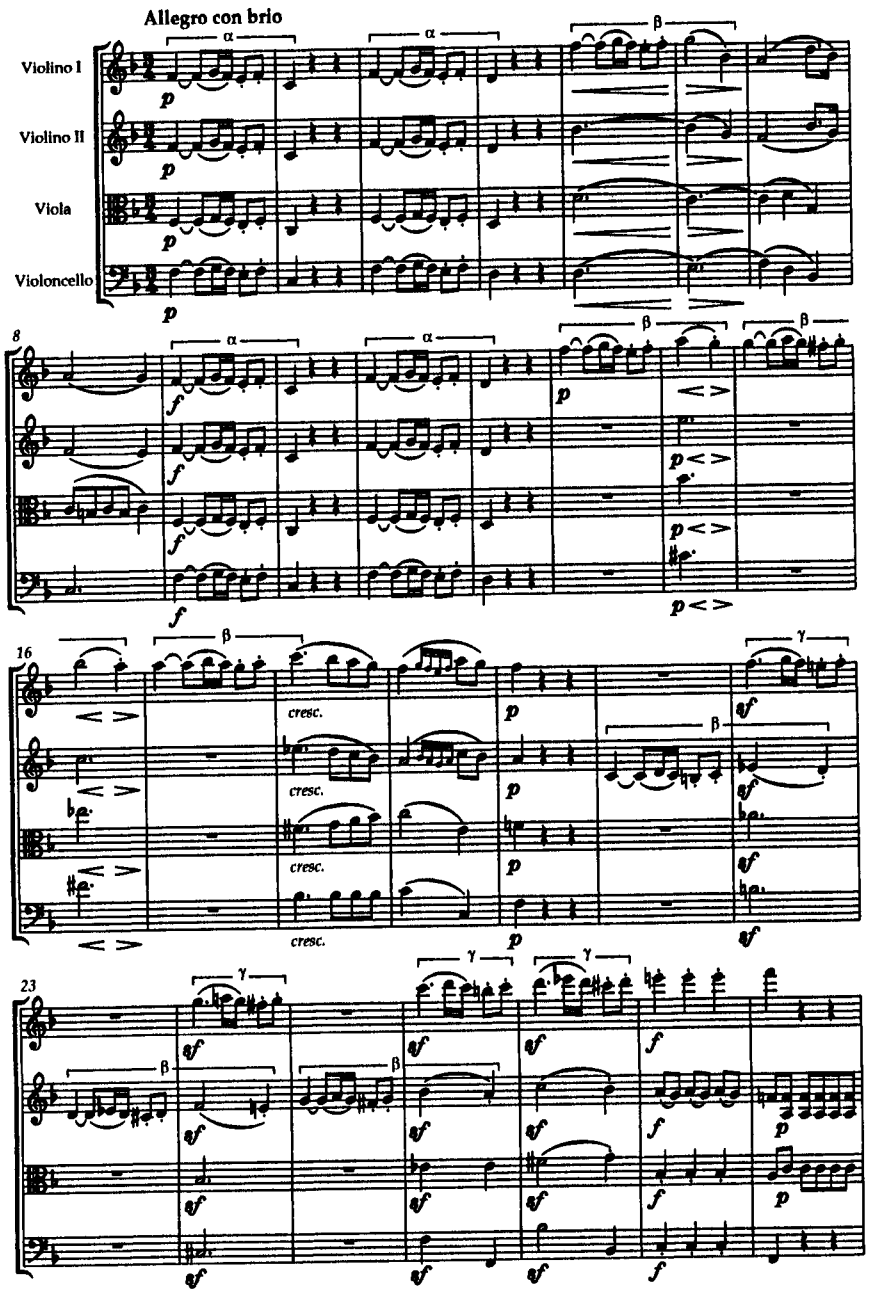
β forms of the motive is an emergent property consequent to the way they are constituted (as contrasting yet similar motivic structures) and the way they are used within this movement.

The notion that Beethoven's use of these motives bestows particular functions on them further suggests how musical topics come to signify the things they do. Granted, the musical material for any topic needs to meet certain prerequisites of harmony and counterpoint and conform to general expectations about affect. But beyond this, one must acknowledge the significance of the way composers have used particular musical gestures—that is, their prevalence within a certain historical and cultural milieu—in establishing the things these gestures come to signify. Put another way, signification is not an inherent property of musical materials but derives from how they are deployed in particular works of music—that is, from the syntactic function with which they are invested.

BEETHOVEN, STRING QUARTET IN F MAJOR, OP. 18 NO. 1, FIRST MOVEMENT

Where the discourse of the first movement of Beethoven's B♭ major quartet tends not to be about its opening motive, the discourse of the first movement of the F major quartet has difficulty being about anything else: as A. B. Marx famously observed, the opening motive occurs no fewer than 131 times within the 427 measures of the movement.[35] Within this multiplicity, two categories of motive forms can be distinguished, differentiated both by their constituent features and by the compositional strategy that is applied to them. The distinction between these two categories becomes especially plain in the Development, when a new and highly dynamic variant of the motive appears that combines features of both. The importance of this variant for developing Beethoven's musical argument is affirmed in the Coda, which revisits all three forms of the motive.

The compositional strategy associated with these various motive forms is relatively complicated, and it was not completely successful in Beethoven's first attempt at the movement, a version described in great detail in a thorough study by Janet Levy.[36] In what follows, I discuss how this strategy is manifested in the Exposition, Development, and Coda of the second (and final) version of the F major quartet, and then turn to Beethoven's first version to explore how it was brought to its final form.



The Exposition

In a manner similar to the first movement of the B♭ major quartet, the F major quartet opens with a principal motive that takes two distinctly different forms. The first (α in ex. 4.14) is assertive, direct, and ends on the first beat of the measure. The second (β in ex. 4.14) is voiced in a lighter manner, is harmonically fluid, and ends

36. Janet M. Levy, *Beethoven's Compositional Choices: The Two Versions of Opus 18, no. 1, First Movement*, Studies in the Criticism and Theory of Music (Philadelphia: University of Pennsylvania Press, 1982).

EXAMPLE 4.14 Ludwig van Beethoven, String Quartet, Op. 18 No. 1, first movement, mm. 1–29

on the third beat of the measure. Joining these is a fragmentary form (γ in ex. 4.14) whose character is less distinctive, and which plays a much more subsidiary role in the Exposition. This fragment consists of little more than the stylized turn figure common to all forms of the motive (and which was almost certainly the basis for Marx's impressive tally). It is this feature of commonality that, as Ratner has noted, allows the motive to fit seamlessly into a variety of different contexts.[37]

As with the preceding analyses, we can characterize the distinctive features of and relationships between various motive forms by considering conceptual models for each; diagrams for the models are given in figure 4.7. The conceptual model for the category of α forms consists of five correlated conceptual elements, characterized as the things necessary for a melodic fragment to count as an instance of this version of the motive:

- the rhythmic pattern
- the first part of the motive outlines a stylized turn figure
- the motive ends with a small downward skip
- the motive is stated tutti
- the motive has a relatively static harmonic context

Save for the change in dynamics from the first to the second pair of statements—*piano* replaced by *forte*—all four of the statements of this form of the motive in the opening measures conform to this model. Put another way, the members of the category presented in mm. 1–4 and 9–12 assign a relatively restricted range of values to the attributes picked out by the conceptual model.

Where the members of the α motivic category are all quite similar to one another, the members of the β category are rather more diverse. In mm. 13–18, the

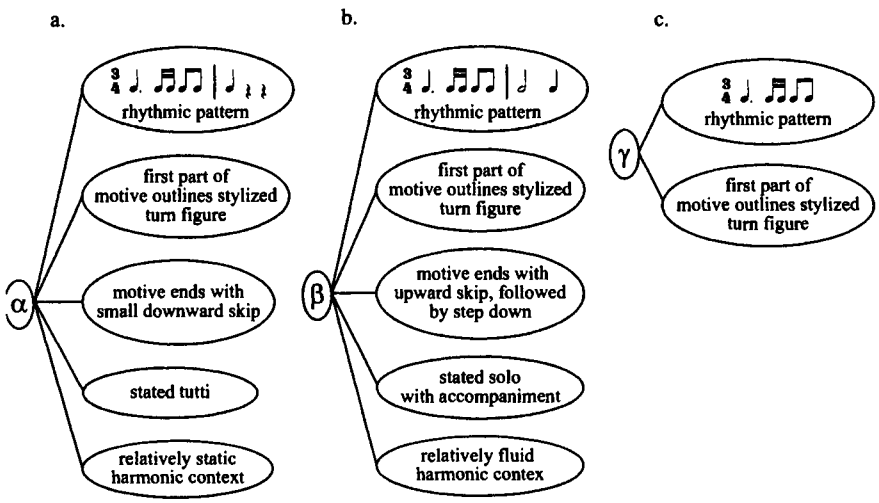

FIGURE 4.7 Conceptual models for the three forms of the principal motive from Beethoven, String Quartet, Op. 18 No. 1, first movement, mm. 1–29: (a) the α form; (b) the β form; (c) the γ form

37. Ratner, *The Beethoven String Quartets*, 12–13.

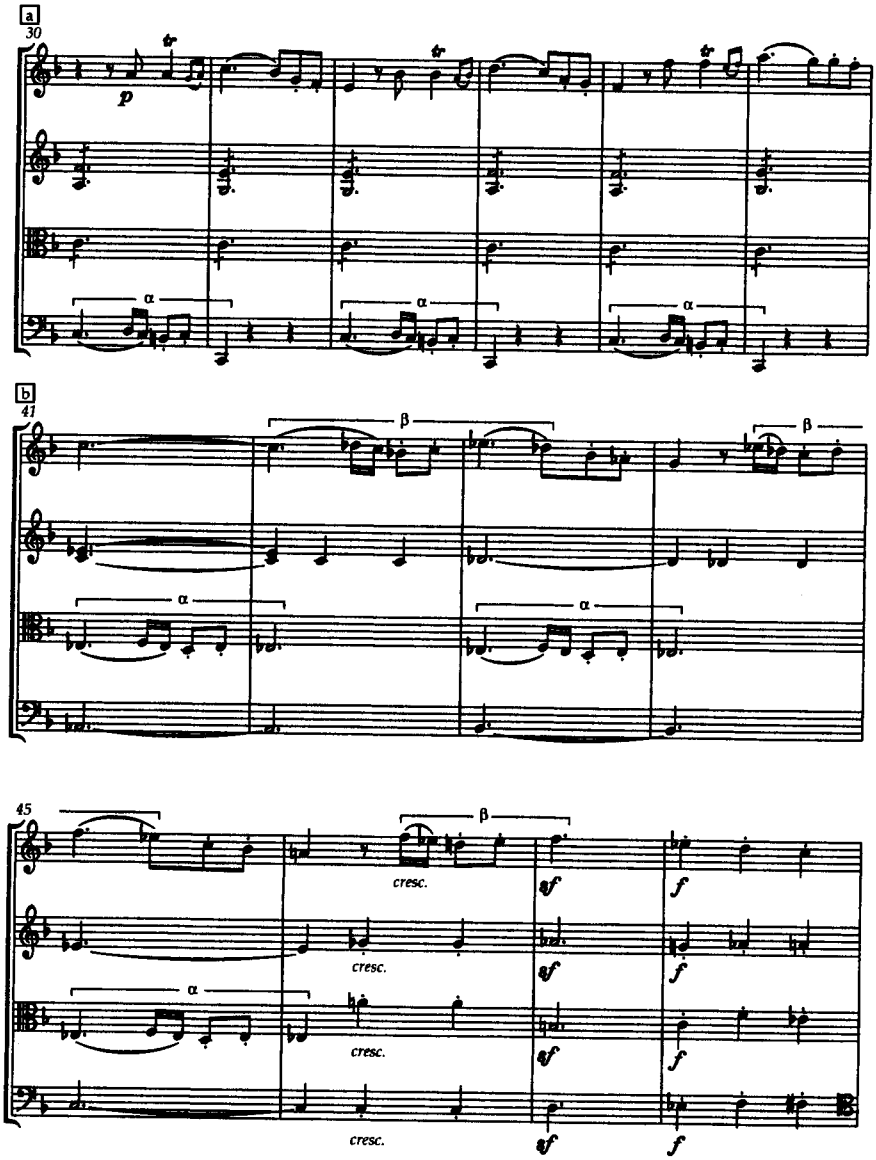
first measure of each statement of the motive is unaccompanied, an appogiatura over a fully-diminished seventh chord is introduced (in mm. 14 and 16), and the end of the last statement (in mm. 17–18) has a slightly modified rhythmic profile.[38] Versions of the motive that appear in mm. 21–26 are similar to those of mm. 13–18, but include echoes provided by the γ fragment as part of their accompaniment. The category of β motives is, as a consequence, much more diverse: category members represent a relatively wide range of attribute-values.

In the remainder of the Exposition, not only are these two categories of motives maintained but also Beethoven continues to treat them as he did in laying out the first key area. The α motives (for the most part) continue to stay close to the conceptual model around which their motivic category is structured, and the β motives (for the most part) continue to diverge in various ways from the conceptual model around which their motivic category is structured. The Exposition thus reinforces both the structure of the two categories and the compositional strategies through which they were first presented.

After the opening thematic group, the α form of the motive is prominent in four places, putting in appearances twice in the transition to C major: once in the middle of the second thematic group, and preparatory to the cadences that conclude the exposition. In each case, one of two relatively minor variants is used.

The first variant, which initiates the transition that begins in m. 30 (as shown in ex. 4.15a), differs from the model in that it is stated solo against accompaniment and in alternation with a competing figure in the first violin and then concludes with a skip down an octave. From a harmonic perspective, this variant is more static than the original α form in that it prolongs but a single pitch-class (here, C) through the combination of the turn figure and an octave skip; Ratner has noted that, in this form, the motive evokes the sound of a musette.[39]

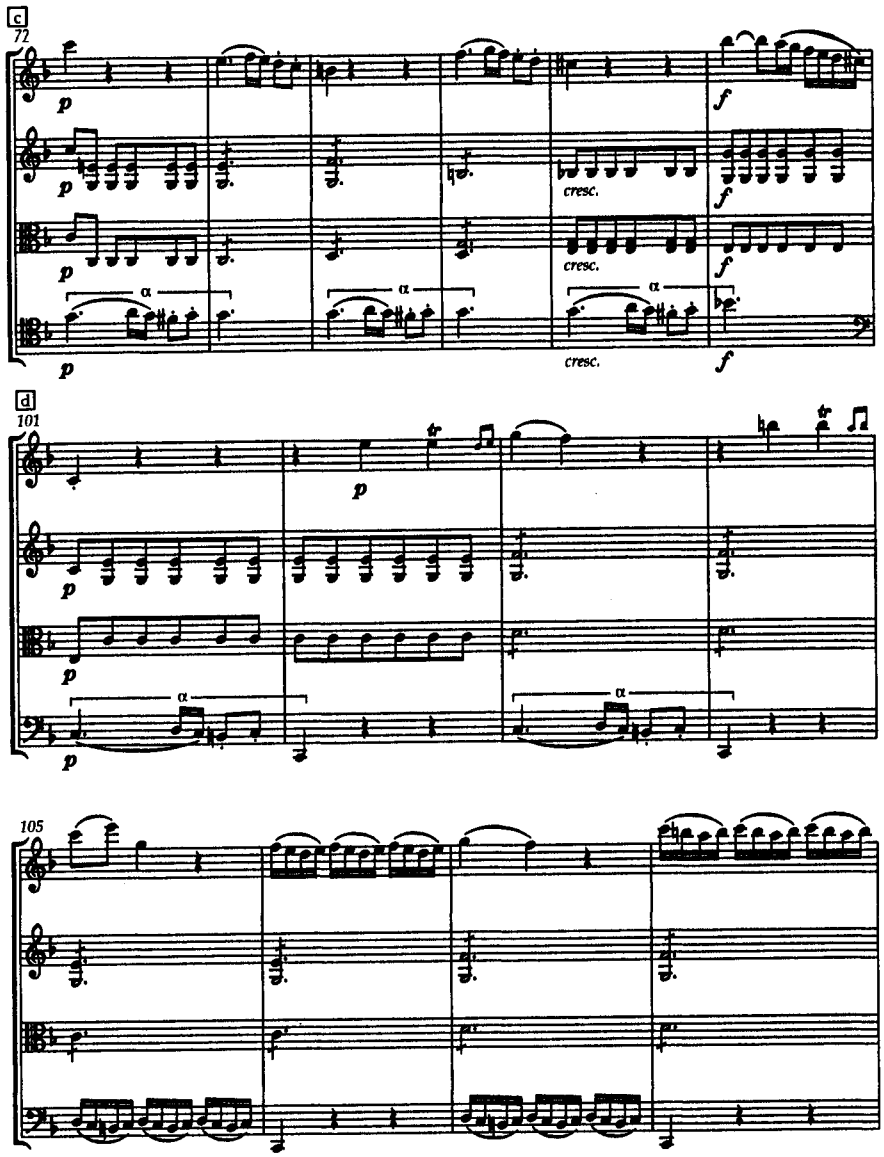
The second variant of the α form of the motive, introduced by the viola in mm. 41–42, is similar to the first, but it concludes with a repeated note instead of an octave skip (as shown in ex. 4.15b): rather than a single pitch-class, now only a single pitch (E♭3) is prolonged. Appearing against the α form is a β form (in the first violin), whose features are discussed below.



This same variant of α is used by the cello in mm. 72–77 in the midst of the second theme group (see ex. 4.15c).[40] An interesting complication here is that the figure with which this appearance of the variant competes (stated in the first violin) can easily be heard as a further variant of the α form of the motive: admittedly, only the rhythmic profile and the beginning of the turn figure are retained (and, unlike other α variants, this one is sequenced upward), but placed against the second α variant the similarities are striking.

38. In the first version of the quartet, the initial statement of the β form of the motive (in mm. 5–6) was also unaccompanied. The difference in texture, however, is less striking than the clarification of harmonic context provided by the accompaniment Beethoven added, which helped emphasize the contrast between the α and β forms.

39. Ratner, *The Beethoven String Quartets*, 14.



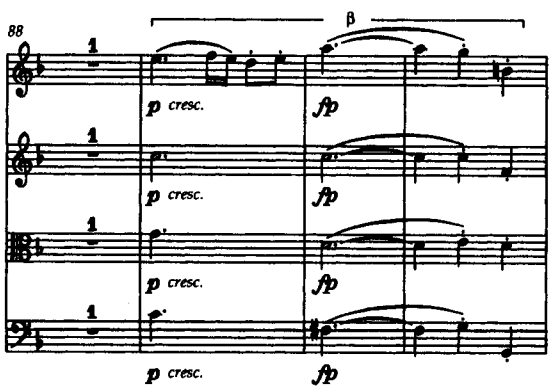
40. Note that the cello appears here an octave lower than in most published scores. This reading of the passage reflects that of the new *Beethoven Werke*.

EXAMPLE 4.15 Ludwig van Beethoven, String Quartet, Op. 18 No. 1, first movement, variants of the principal motive: (a) mm. 30–35; (b) mm. 41–48; (c) mm. 72–77; (d) mm. 101–8

(continued)

EXAMPLE 4.15 *(continued)*

Heard as a variant of the α form of the motive, it offers the first real challenge to the standard of typicality for the motivic category.



The first variant of α returns in the cello in mm. 101–104 (shown in ex. 4.15d) against a figure in the first violin that can be related to the β form of the motive; this passage is discussed in a bit more detail below.

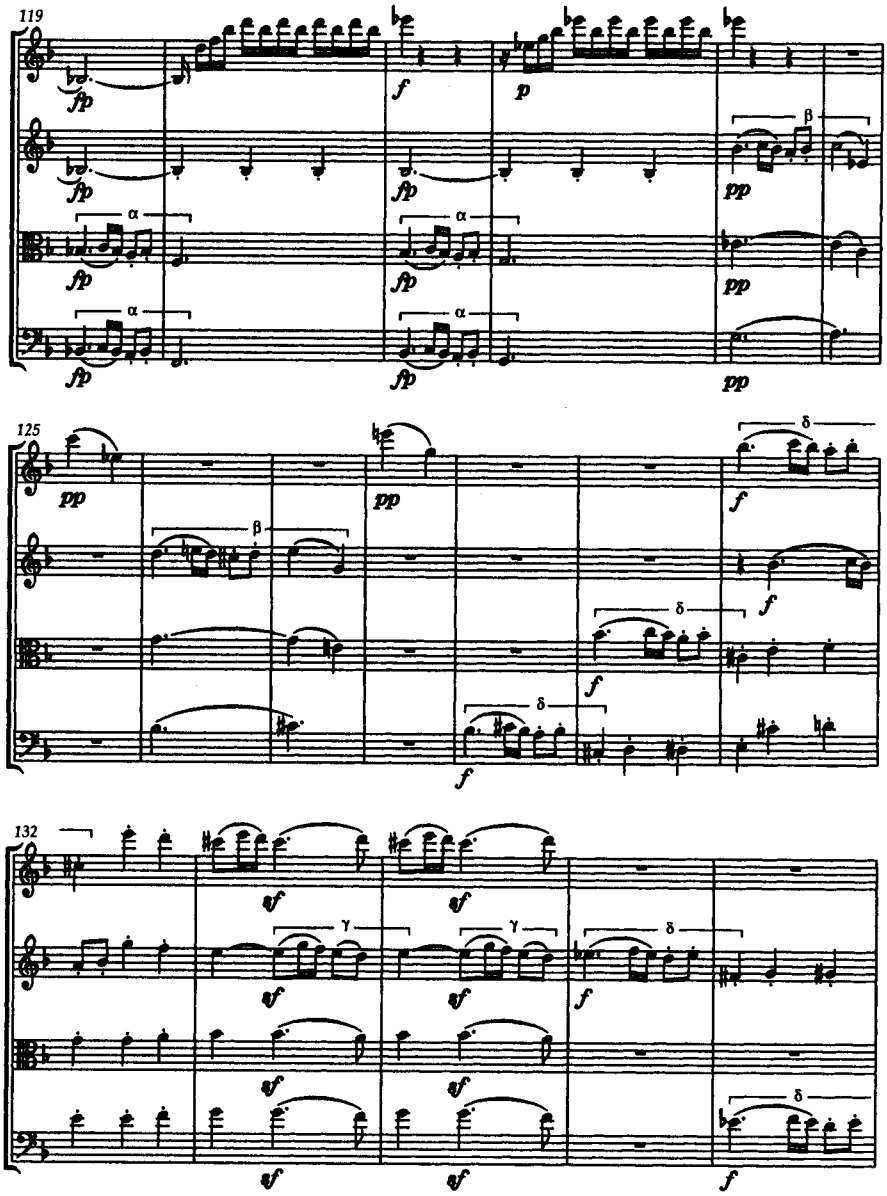
In contrast to the ubiquity of the α form of the motive, the β form makes only two appearances after m. 30. The first, already mentioned above, is in m. 42 (see ex. 4.15b). Here the motive appears with an altered rhythmic profile (lacking its first note and using the variant ending first introduced in m. 18), and, in its role as counterstatement to the modified α form in the viola, with less independence than before. The third entrance of the variant (in m. 46) departs further still, with its ending a durational augmentation of that used in the preceding measures. A similar augmentation of the tail of the β form is heard in mm. 89–91 (as shown in ex. 4.16) after a general pause that interrupts the material from the second thematic group. Save for this augmentation, this variant of the β form of the motive is quite close to the very first version of β, heard in mm. 5–6.

The variant heard in mm. 89–91 is the last explicit reference to the β form of the motive before the conclusion of the Exposition. Nonetheless, the appogiatura figure that came to be a feature of β beginning in m. 14 figures quite prominently in the counterstatement to the final appearance of the α form in mm. 101–104 (shown in ex. 4.15d). When this counterstatement is embellished with a repeated turn figure in m. 106 (answering the embellishment of the α variant in m. 105), the connection becomes somewhat more plausible: the counterstatement could be heard as a further variant of the β form of the motive. This interpretation is supported by two things: first, there is the close relationship between the α and β forms of the motive throughout the Exposition (exemplified by their juxtaposition in mm. 41–48). Second, the turn figure typical of all forms of the motive is replicated, in compressed form, by the combination of the trill and termination on the third beat of m. 102 and the appogiatura of m. 103 (and further varied in mm. 104–105).

The possibility of extending the category of β motives to include the counterstatement of mm. 102–105, together with the connection between the category of α motives and various counterstatements (in mm. 41–48, 72–77, and 101–108), suggests a way our concept of the β form of the motive might slip further still. If we return to the transition that begins in m. 30 (ex. 4.15a), we note a similarity between

EXAMPLE 4.16 Ludwig van Beethoven, String Quartet, Op. 18 No. 1, first movement, mm. 88–91

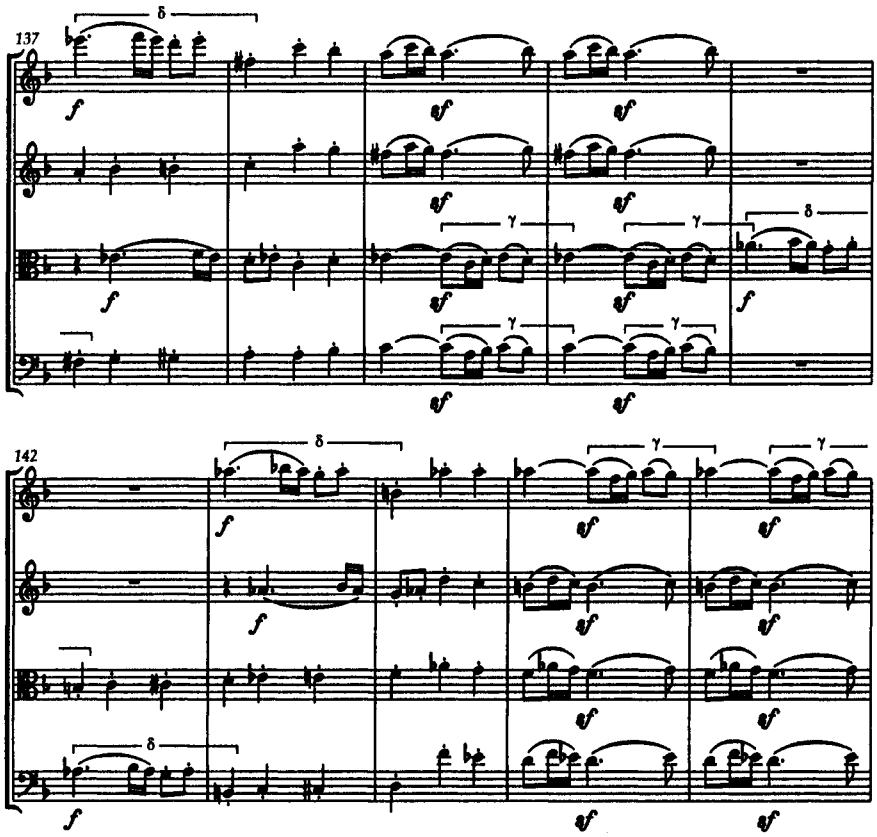
the accompanimental figure in the first violin and the β variant from mm. 17–18: the rhythmic pattern and contour of mm. 31, 33, and 35 is the same as that of m. 18. Our return to these measures becomes literal rather than imaginary if the Exposition is repeated: hearing mm. 30–35 after the several pairings of the α form of the motive with counterstatements and the extensions of the β form that occur during the first pass through the Exposition could provide enough pressure to cause significant slippage within our concept of the β form. This, in turn, might lead us to embrace the accompanimental figure of mm. 30–35 within that form when we encounter it for the second time.



Perhaps more remarkable than the conceptual fluidity of the β form of the motive is the resistance of the α motive to change: despite numerous juxtapositions with rival materials, it remains constant. Indeed, these two categories of motive forms can be further distinguished by the compositional strategies associated with each. Over the course of the Exposition, α forms are subjected to relatively little variation, and most members of the category are close to the conceptual model outlined in figure 4.7a. In contrast, β forms are varied almost from the outset. While the conceptual model for the category of β forms still makes sense—it captures the salient features of members of the category as presented in the opening measures and serves to distinguish them from members of the category of α motives—the range of values that members assign to the attributes picked out by the conceptual model is much broader, and a given variant is rarely repeated. The difference between the compositional strategies applied to each category of motive forms lends a distinctive character to them: α as stable in the face of various challenges; β as an agent of change and transition. Although qualities such as these are part of the elemental materials of sonata form, as they are manifested in the first movement of the F major quartet they also pose a kind of problem. The sort of fluidity with which the β form of the motive is associated operates principally in contrast to the stability of the α form. By itself, it is not quite sufficient to create the dynamic energy—the sparks of real transformation—that the Development section will require. For this sort of drama, a new form of the motive is required, but one that draws on the musical materials and syntax developed over the course of the Exposition.

The Development

After a brief A major flourish, the Development revisits α and β, recalling the opening of the Exposition (as shown in ex. 4.17; the example does not include the A major flourish). While each motive departs slightly from its respective conceptual model—the α motive includes light accompaniment in the upper strings, and the β motive acquires an echo—for the most part the conceptual model for each category is reaffirmed. Beethoven then introduces a new form of the motive that reconfigures the properties of α and β and transforms the possibilities for musical discourse.



The new motive form (shown with a δ in ex. 4.17) is launched in m. 129 through a series of imitative entrances. Although motive forms have appeared at one-measure intervals before, here they differ only in the octave in which they are stated. This manner of presentation makes reference to a topic to which Beethoven often made recourse in the Development sections of his instrumental works: the

EXAMPLE 4.17 Ludwig van Beethoven, String Quartet, Op. 18 No. 1, first movement, mm. 119–46

(continued)

EXAMPLE 4.17 *(continued)*

learned style that includes fugue and canon.[41] This new motive form resembles a member of the category of α motives. It is new in its isolation, harmonic stasis, and clear assertion of the downbeat of each measure as a point of initiation (rather than a point of articulation within a larger gesture, as it is in the second measure of a typical member of the β category of motives). However, the dissonant interval formed by the downward leap consequent to the turn figure (a diminished seventh—B♭3 to C♯3 in mm. 129–30) demands continuation beyond the downbeat, a fluidity reminiscent of the β form of the motive.[42] This amalgam of features and the way they dominate the measures that follow suggest that δ constitutes a new category of

41. For a discussion of the learned style, see Ratner, *Classic Music*, 23–24.

42. Given both the emphasis of the large downward leap and the fact that the leap is dissonant, the δ form of the motive is more ambiguous at the hypermetric level than either the α or β forms: where the previous forms of the motive can be heard in terms of pairs of strong and weak measures, such a grouping in the case of the δ motive is much more arbitrary. This is not to say that determining which measure of the α and β forms of the motive is strong or weak at any given point is a simple matter, however. Janet Levy and Roger Sessions, for instance, give interpretations of the accentuation of mm. 1–2 that are the exact opposite of one another. See Levy, *Beethoven's Compositional Choices*, p. 10, n. 28; and Roger Sessions, *The Musical Experience of Composer, Performer, Listener* (Princeton, N.J.: Princeton University Press, 1950), 13–14.

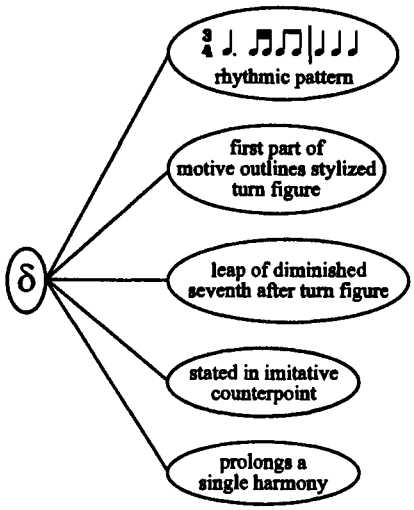


FIGURE 4.8 Conceptual model for the δ form of the principal motive from Beethoven, String Quartet, Op. 18 No. 1, first movement, mm. 129–44

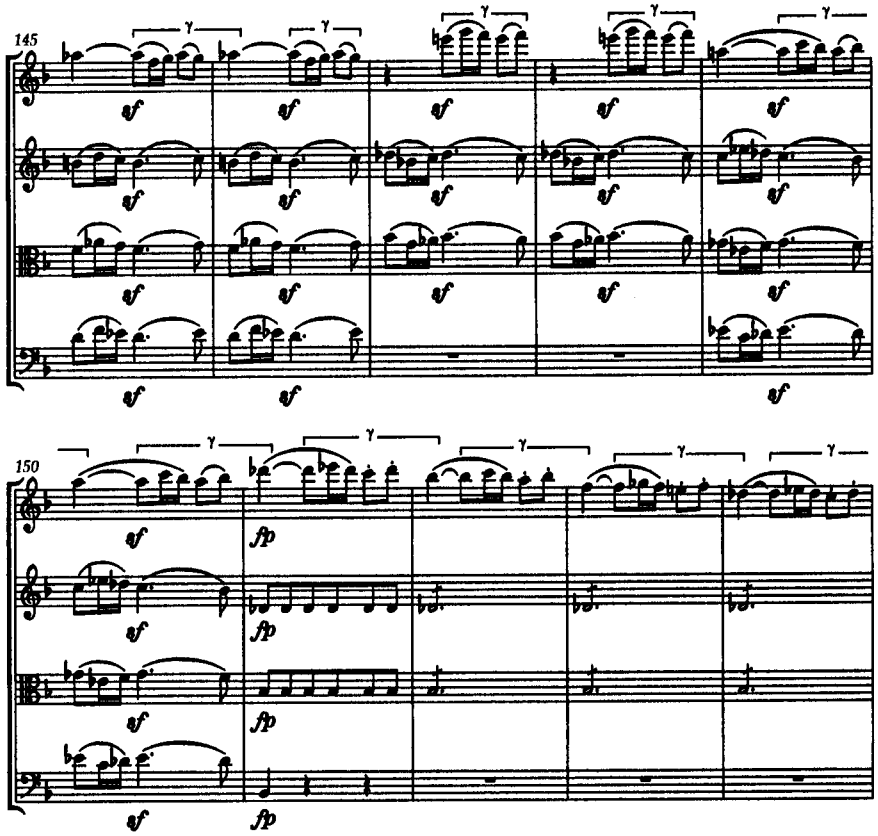


motive forms. The conceptual model for this category (diagrammed in fig. 4.8) consists of five correlated conceptual elements, characterized as the things necessary for a melodic fragment to count as an instance of this version of the motive. While this model has much in common with those diagrammed in figure 4.7, it also demonstrates enough differences to warrant its being used to distinguish the δ form from any of the other forms of the motive important in the movement.

Beethoven follows mm. 129–34 with two similar sections, the first beginning in m. 135, the second in m. 141. Each section begins with a slightly different pattern of entrances among the instruments, and each section prolongs a single fully diminished seventh chord: C♯^{o7} (mm. 129–34), F♯^{o7} (mm. 135–40), and B^{o7} (mm. 141–46).[43] Each section also includes a variant of the γ fragment, based on the turn common to all forms of the motive but with a *sforzando* on the second beat: it first appears in the second violin in mm. 133–34, and subsequently in the viola and cello (mm. 139–40) and first violin (mm. 145–46). In truth, the variant of γ is difficult to hear, for within these imitative sections it must compete with the ♩♬♩· figure that comes to dominate the first half of each measure in which the fragment appears. Nonetheless, as can be seen in example 4.18, the fragment is gradually transformed,

43. This is in fact the same sequence of fully diminished seventh chords initiated in mm. 14–16; however, that sequence led not to a B^{o7} chord but to a B♭ pedal preparatory to the first full cadence on F in mm. 19–20.

In his analysis of mm. 129ff., Ratner interprets each fully diminished seventh chord as a leading-tone harmony with a normal resolution; see Ratner, *The Beethoven String Quartets*, 15. Indeed, on the very last eighth-note of mm. 128 and 129 there is a D minor chord, as there is a G minor chord in mm. 139 and 140, a C minor chord in mm. 145 and 146, and F and B♭ minor chords in mm. 147–50. However, I hear these harmonies as simply embellishing the fully diminished seventh chords that dominate these measures. This hearing is not without its theoretical problems—it suggests the kind of dissonant prolongation that has vexed a number of music theorists over the past two decades—but it has the advantage of capturing the intensity and uncompromising nature of this passage.

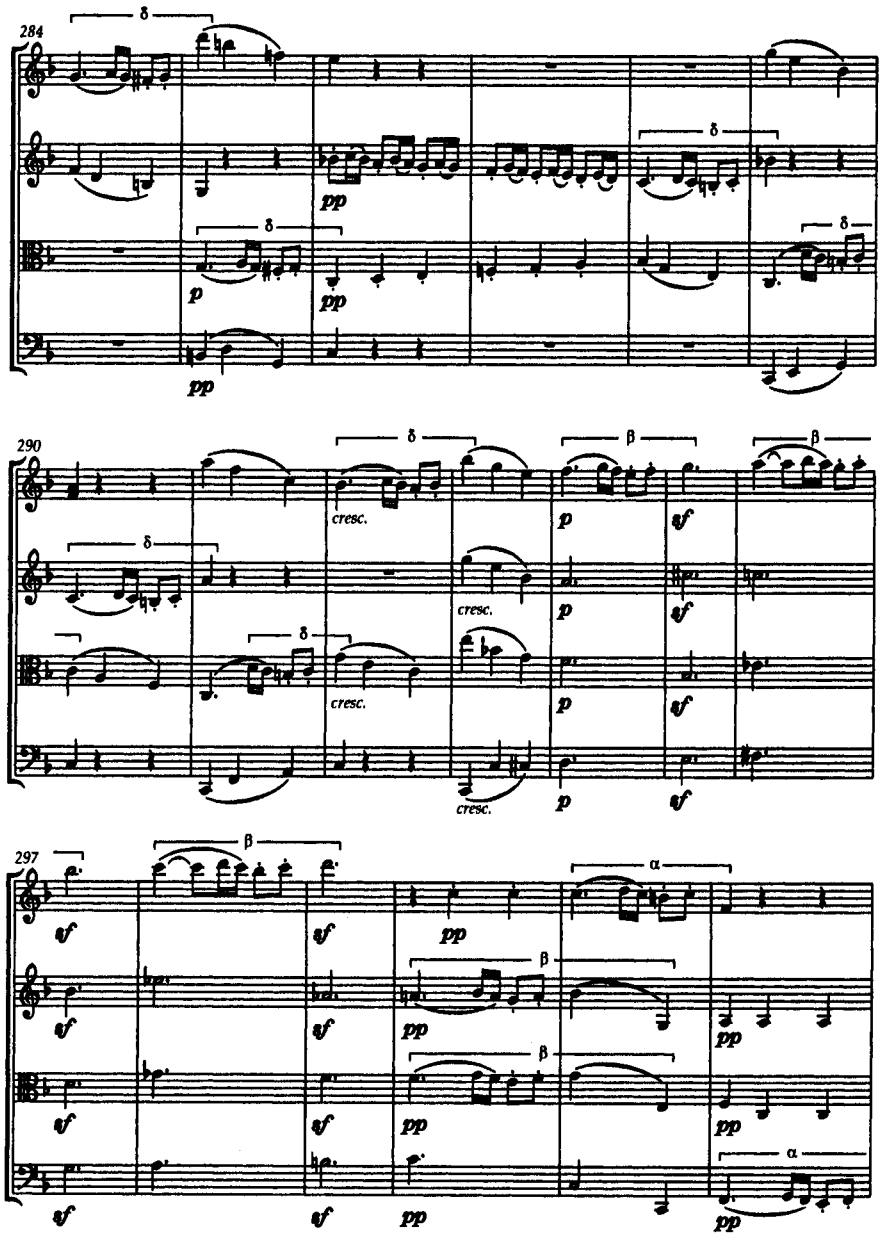
EXAMPLE 4.18 Ludwig van Beethoven, String Quartet, Op. 18 No. 1, first movement, mm. 145–54

over the course of mm. 147–51, into the γ fragment as it originally appeared. So transformed, it leads in a cascading sequence to the arrival on the dominant of F major in m. 167. In one sense, however, this is not the γ fragment as it was first heard in mm. 22–27, for that fragment was one-half of a two-measure motive. By contrast, the fragment of m. 151 and following is heard as the extension, in one voice, of the imitative entrances initiated in m. 129.

With its abrupt introduction of the learned style, combination of features from both the α and β forms of the motive, and prolongation of dissonant harmonies, the δ form of the principal motive provides elements of contrast and continuity with the preceding music. And compared with the various changes visited upon α and β in the course of the Exposition, the repetitions of mm. 129–46—both on the level of the individual motives that make up the imitative passages and on the level of the separate sections that prolong three different fully diminished seventh chords—make for an island of stability within the changing fortunes of the principal motive. Nonetheless, this moment of stability provides its own disruptions, and not only because it is based around a sequence of fully diminished seventh chords. The balance that had existed between the α and β forms of the motive—one associated

with a syntax of stability, the other with a syntax of fluidity, and each necessary for the other—has now disappeared: what is left after δ has done its work is only the chattering of the γ form of the motive. This, and passagework scales over a dominant pedal, is all that remains until the α form of the motive reasserts itself at the beginning of the Recapitulation.

Recapitulation and Coda



The appearance of motive forms in the Recapitulation, which begins with a literal return to the opening of the movement in m. 179, follows the same general outline as that of the Exposition. Missing, however, are almost all of the members of the β category of motives. After the initial response to the α motives (mm. 183–86, an exact repetition of mm. 5–8), β disappears, along with other vestiges of the opening twenty-odd measures, including the sequence of fully diminished seventh chords from mm. 14–16 that had their extension in mm. 129–46. Beethoven replaces mm. 9–29 with a brief episode that veers off toward G♭ major, which in its latter half makes reference to the transition that began in m. 30, and which also absorbs the function of the statement and counterstatement of motive forms in mm. 41–48.[44] The consequence of these changes is that the α form of the motive goes virtually unchallenged in the Recapitulation, for both the β form and the syntax of fluidity with which it was associated are absent. What we are left with is a clear impression of the stability—even obstinateness—of the α form of the principal motive.[45]

Beethoven does offer a final challenge to this stability in the Coda, which begins in m. 274. After a pair of short ascending passages in staccato quarter notes (mm. 274–81) that recall the quarter notes that followed δ in the Development and a brief descending figure built from the paired sixteenth-note portion of the stylized turn figure (mm. 282–83), the main motive reenters in the first violin in m. 284 (see ex. 4.19). With the viola's entrance at the octave below in m. 285, and continuation with the same sort of staccato quarter-notes that began the Coda, the reference is clear: Beethoven means to summon the δ form of the motive, although without its *fortissimo* entrances or dissonant harmonies. On the one hand, the subsequent entries (beginning in m. 288) hint at the possibility of further development as the motive is tossed back and forth between different voices; on the other hand, they all serve to prolong the dominant. The possibility of development becomes a bit more real with the move to the submediant, in m. 294, and the reprise of a variant of the β form of the motive. While the rhythmic figure is different from a typical member of the β category, the syntactic references are clear: the motive is sequenced upward (as it was in mm. 13–18, 21–26, and 123–27), and its harmonic

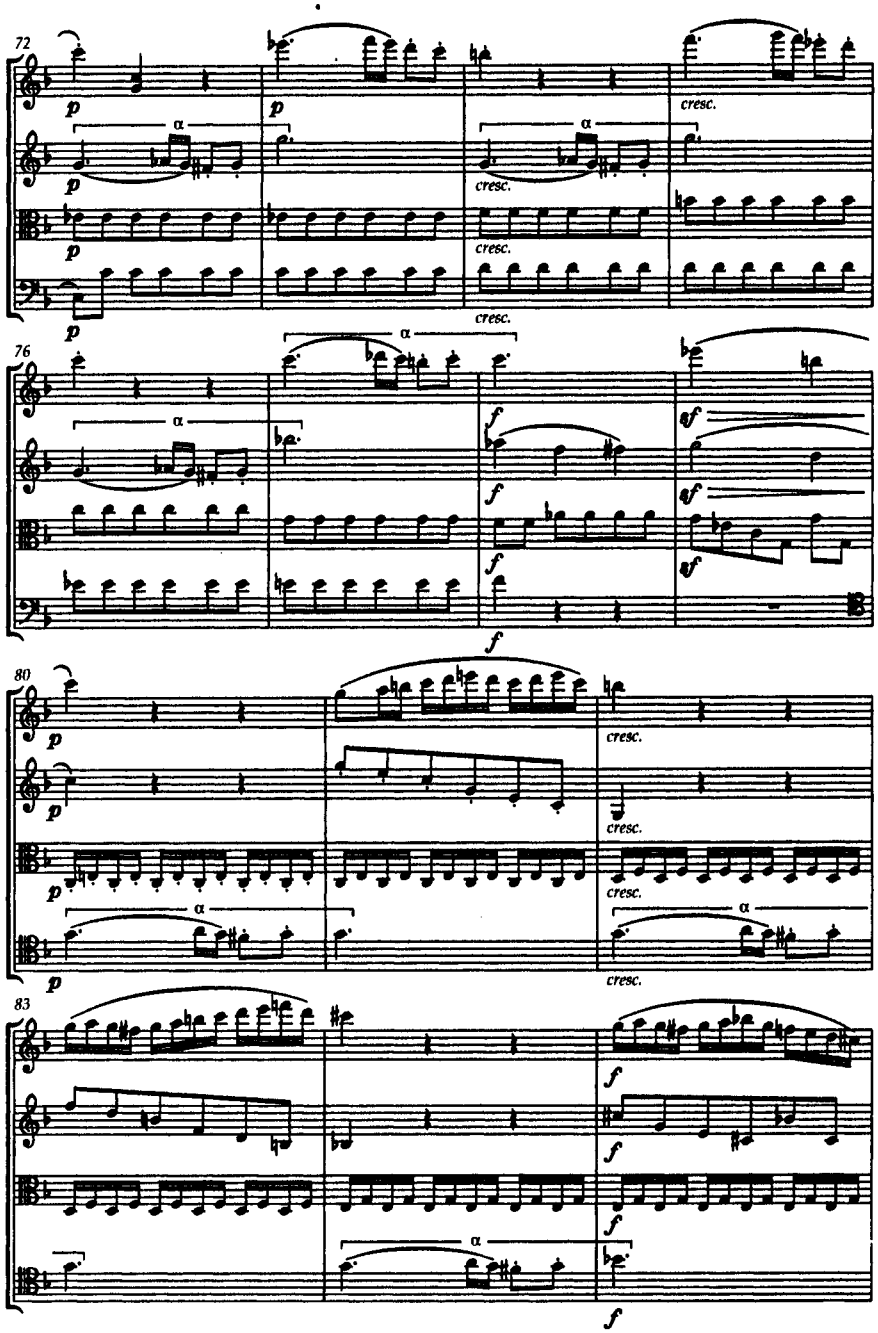
44. Levy notes that these changes tend to draw together various features of the original transition; see Levy, *Beethoven's Compositional Choices*, 79–83.

45. The impression of the solidity of the α form of the motive is given further support by Beethoven's decision to eliminate the repeat of the second section of the movement (that is, the Development and Recapitulation), one of the significant changes he made between the first and second versions of the quartet.

EXAMPLE 4.19 Ludwig van Beethoven, String Quartet, Op. 18 No. 1, first movement, mm. 284–302

context is thoroughly fluid, including four fully diminished seventh chords (in mm. 295, 296, 298, and 299) and a cadential dominant (in mm. 300–301). Against the resolution of the $\frac{6}{4}$ over this dominant, the α form of the motive finally enters (in the first violin in m. 301), and for the first and only time in the movement, its concluding downward leap outlines a falling $\hat{5}$–$\hat{1}$, signaling an end to the peregrinations suggested in the preceding measures.

After this closing gesture, there is one more bit of dialogue between α and β (not shown in ex. 4.19). The cello, beginning and ending on F2, repeats the variant of α that ends with a repeated note (in mm. 302–303 and 304–305, a variant first heard in mm. 41–42). It is answered by a variant of β reminiscent of that just heard in mm. 294–299 (played in thirds in the first and second violins in mm. 306–307 and 308–309). True to form, these β variants pull away from F major by introducing its $\flat\hat{6}$ (D♭), but they are answered by a cadential gesture that returns the movement, for once and for all, to F major.



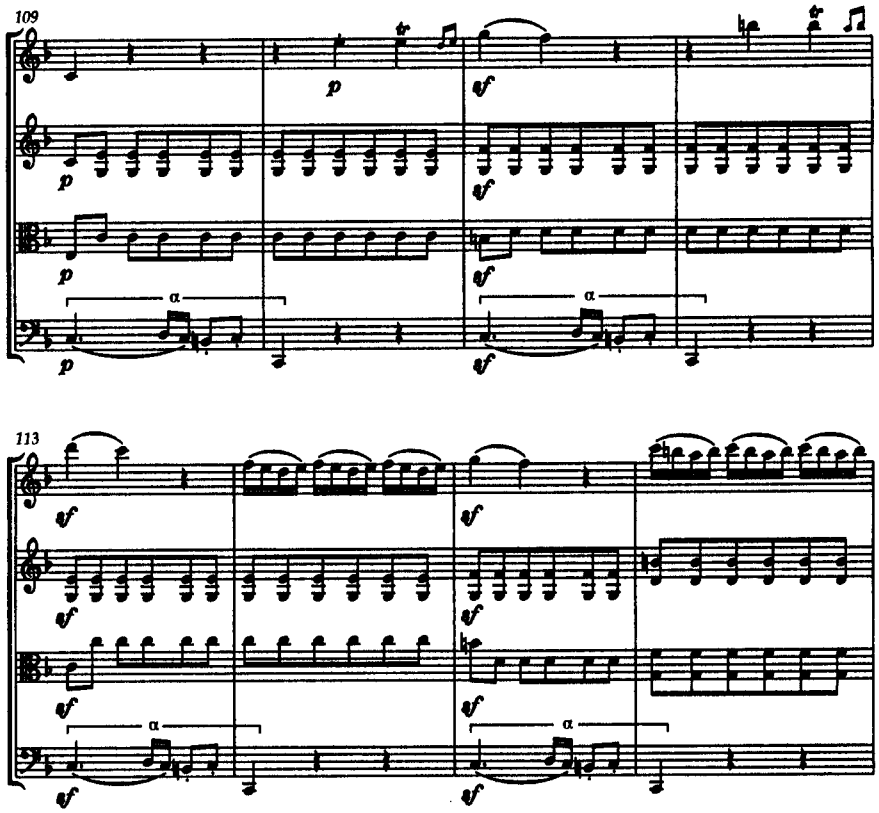
With regard to the principal motive of Beethoven's F major quartet, the Coda has a summational function that is twofold. First, the Coda revisits each of the three categories of motive forms that appeared over the course of the movement, doing so in reverse order of their initial appearance. Second, the Coda revisits the syntax with which each of these categories was associated. The Coda begins (much as did that of the first movement of Mozart's "Dissonance" Quartet) with a reference to the Development; the subsequent allusions to δ suggest a challenge to the integrity of the principal motive (through fragmentation) but also take place within a context of overall stability (with the bulk of the entrances linked to the dominant of F). The β motives that follow these δ forms exemplify the syntax with which β is most often associated: although the broad range of features exhibited by members of the category of β motives is not in evidence, the harmonic fluidity typical of the category is well represented by the fully diminished seventh chords prominent in the passage. And the final α motive, with its summoning of cadence, is the very embodiment of general, processive stability, yielded by the compositional strategies most often used for the category of which it is a member.

Changes between the First and Second Versions of the F Major Quartet

Janet Levy observed that one of the principal differences between the first and second versions of the F major quartet is the greater concision of the second version.[46] Beethoven accomplished this in a number of ways, which together resulted in the elimination of a significant number of statements of the α form of the principal motive. Basic elements of the plan Beethoven followed in his revisions are evident in the changes made to the episode involving the α motive initiated in the midst of the second key area. The passage as originally written is given in example 4.20. In the fourteen measures spanned by the episode, there are seven clear statements of the α motive. In the second version of the movement, this episode was cut back to

46. See Levy, *Beethoven's Compositional Choices*, 2–4.

EXAMPLE 4.20 Ludwig van Beethoven, String Quartet, Op. 18 No. 1 (first version), first movement, mm. 72–85

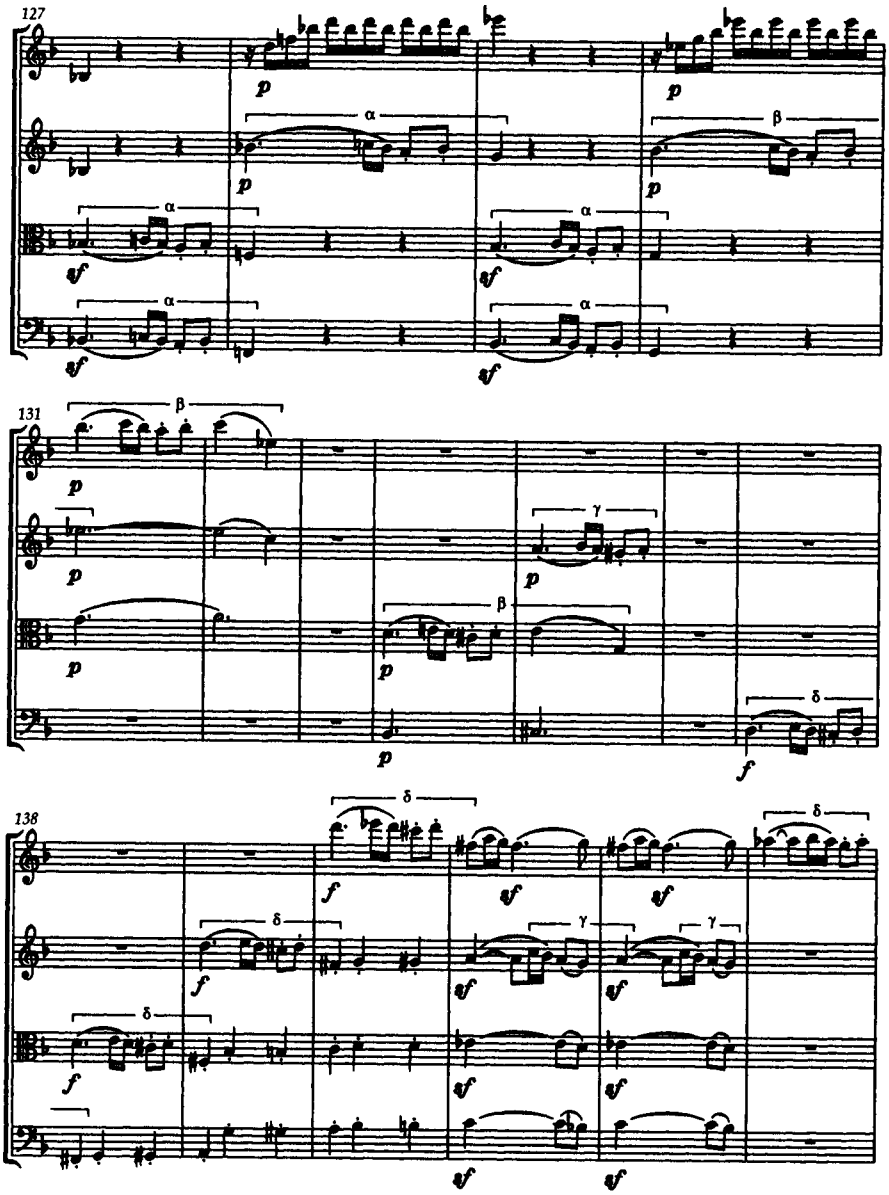


six measures (which are given in ex. 4.15c), with only three statements of the α form of the motive. But perhaps more important than simply reducing the appearances of the α motive, Beethoven appears to have rethought how it fits into the overall musical fabric, as a closer inspection of his first attempt at this episode reveals.

The original version of the passage divides into two parts, the first in C minor (mm. 72–79), the second in C major (mm. 80–86). In both parts, there are three main statements of the α motive: in the C minor section these are in the second violin, and each ends with a large ascending leap; in the C major section the statements are given in the cello and end with a repeated note. (The latter form of the α motive is heard in a prior episode, given in ex. 4.15b, which is substantially the same in both versions of the movement.) Each of the second violin's statements is answered by a counterstatement in the first violin. The counterstatements in mm. 73 and 75 begin with a turn figure and share their rhythmic profile with the α form of the motive. On the other hand, the counterstatement of m. 77 answers with the same variant of the α motive that will be heard momentarily in the cello. The cello's three statements of this α variant are not given similar counterstatements but are answered instead by passagework in the first violin, which ultimately leads out of the episode.

When revising this passage, Beethoven cut the C minor section, salvaging the first violin's counterstatements of mm. 73 and 75. These he placed an octave lower, but still in the first violin (see ex. 4.15c). He omitted the counterstatement of m. 77, changing the first violin's music so that it starts with what appears to be another counterstatement, but which then dissolves into passagework that leads out of the episode. The effect of these alterations is not just concision but a view of the α motive that is changed in three ways. First, by dropping the three statements of the motive made by the second violin in the C minor section, Beethoven eliminated a further variant—namely, one that ends with a large leap—from the category of α forms. Second, the counterstatements made by the first violin, now closer in register to the cello's statements of the motive, make a direct if limited challenge to the structure of the α motivic category. Third, changing the last counterstatement so that it leads out of the episode (rather than echoing the cello's third statement of the α motive, as the original version of m. 77 would) lets the challenge stand, albeit only for a moment or two. Thus, in the revised version of the passage Beethoven has not only achieved great concision, but he has also accomplished two strategic goals: he has tightened the boundaries of the α motivic category, and he has intimated how these boundaries might be challenged.

A similar elimination of outright statements of the α motive and modification of the structure of motivic categories occurs with the final statement of the motive at the end of the Exposition. In the first version of the passage, shown in example 4.21, the "musette" variant of the α motive (in mm. 109 and 111) is answered by a counterstatement with a trill and appogiatura (in mm. 110 and 112). When the phrase is repeated (in mm. 113–16), the counterstatement is embellished by repeated turn figures, but the α motive is not. In Beethoven's revisions, both the counterstatement and the "musette" variant are embellished when the phrase is repeated (mm. 105–108 of ex. 4.15d). Although this removes two explicit state-



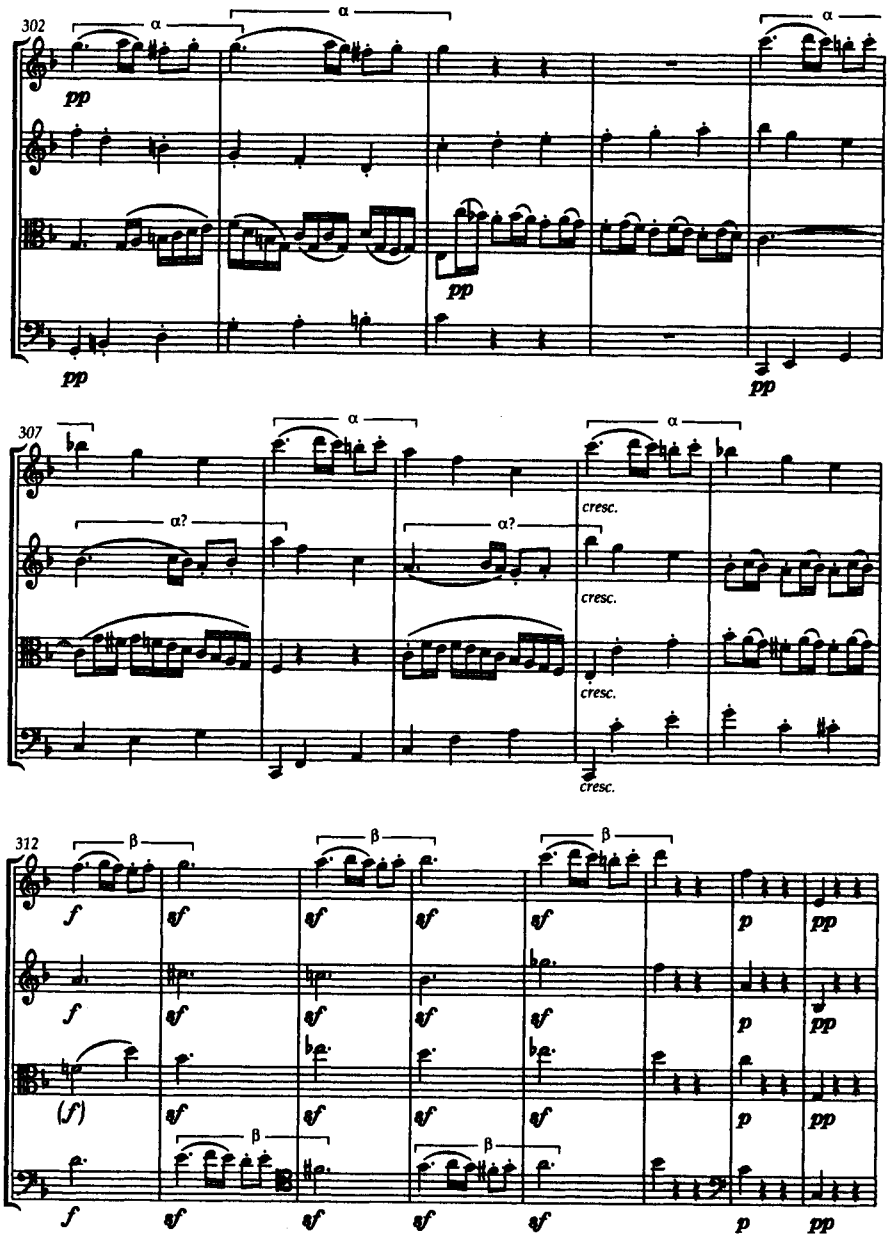
EXAMPLE 4.21 Ludwig van Beethoven, String Quartet, Op. 18 No. 1 (first version), first movement, mm. 109–16

ments of the α motive (and, consequently, could be seen to weaken the structure of that category), the change makes it possible to hear the first violin's counter-statements as further variants of the β motivic category (a possibility raised in the earlier discussion of ex. 4.15d).

A further result of Beethoven's decision to reduce the number of appearances of α in the revised version of the movement was a clearer distinction and more even balance between the α and β forms of the motive. In the Development of the first version of the movement, for instance, the two forms of the principal motive blend into one another. As shown in example 4.22, the entrances of the α form subsequent to the A major flourish that opens the Development are first answered by an α form of the motive and then by a variant of β (mm. 127–32). Appearing above the extended tail of this answering β is another β (a quite typical member of the category), which leads, after a pause, to yet one more entrance of β (itself answered by a γ fragment, as it was in m. 21 and following). Thus an episode beginning with the α form of the motive ends with the β form of the motive, blurring the distinction between the two. In Beethoven's revised version (ex. 4.17),

EXAMPLE 4.22 Ludwig van Beethoven, String Quartet, Op. 18 No. 1 (first version), first movement, mm. 127–43

the two forms are successive but do not overlap: α and β stand out more clearly as separate entities.



Beethoven's revisions to the Development also resulted in a sharper distinction between the δ form of the motive and the α and β forms, especially where the syntax of the motivic categories is concerned. In the original version, the answering statements by the second violin (first α in m. 128 of ex. 4.22, then β in m. 130) both enter at the octave above the viola. They thus anticipate the imitative entrances of δ in mm. 137 and following. When these answers are removed in the second version (cf. ex. 4.17, m. 119 and following), the entrances of δ seem fresher—the introduction of the learned style seems more of an innovation. The entry of δ in the first version of the movement, moreover, leads to a consonant harmony (the dominant of G minor), and the downward leap at this point is a minor sixth (ex. 4.22, mm. 137–38). In the revised version, δ leads to a dissonant harmony (ex. 4.17, mm. 129–30), and the downward leap is a diminished seventh. In sum, in the original version of the Development δ seems to grow out of a generalized idea of the principal motive (α and β blurring together); after Beethoven's revisions, the introduction of δ is more striking, and it contrasts sharply with the statements of α and β that precede it.

Revisions to the Coda offer a final bit of evidence that the changes Beethoven made were with the intent of more clearly differentiating between different versions of his principal motive. The original version of the Coda, starting at the point that references to the principal motive become explicit, is given in example 4.23. In the first half of this excerpt, Beethoven relies heavily on the α form of the motive, providing statements of it that begin variously on G and C in the first violin, and B♭ and A in the second violin. Because the latter have an ascending skip after the turn figure, they could also be heard as a variant of the β form of the motive, but the quality of the α form of the motive still pervades. In m. 312, with the shift away from the dominant to the submediant, the β form of the motive enters in earnest, with a clear reference to the successive entries between β and γ over the fully diminished seventh chords found in the Exposition. This series of β motives leads ultimately to a conventional, if deliberately underplayed, cadence.

In the second version of the Coda (ex. 4.19), the α motive is withheld, and the first references are to the δ form. As noted in the discussion of example 4.19, the syntax of the passage owes much to the fluidity associated with the process of developing musical materials and extends to the β motive that enters in m. 294. When the α form of the motive finally returns in m. 301, it is coincident with a perfect authentic cadence and signals a definitive end to the possibility of further development raised by the entrances of the δ motive.

The changes Beethoven made to the first movement of the F major quartet, then, had two important results. First, they created a more balanced relationship between the α and β forms of the motive in the Exposition. Second, the distinctions between the three main categories of motive forms are more sharply drawn. These changes make the syntax associated with each category somewhat more apparent—that is, we can more easily hear the role of each motive form in the discourse of the movement as a whole.

EXAMPLE 4.23 Ludwig van Beethoven, String Quartet, Op. 18 No. 1 (first version), first movement, mm. 302–19

Compositional Strategy and Multiple Levels of Musical Syntax

As A. B. Marx noted, the principal motive of the first movement of Beethoven's F major string quartet is a nearly constant presence, never far from the listener's ear. The function of this dense network of motives, however, is not so much to lend the movement coherence—after all, Beethoven actually reduced the number of times the α form of the motive appeared when he revised the movement—but to set up a musical discourse separate from but coordinated with the harmonic and thematic syntax of sonata form. This discourse involves not simply a syntax specific to the principal form of the motive (as in the case of the first movement of the "Dissonance" Quartet), but higher levels of syntax of the sort seen in the sixth quartet from the Op. 18 set.

Beethoven's compositional strategy depends on clear distinctions between different forms of the motive. These distinctions are made not only on the basis of audible features of the motive (of the sort captured in the conceptual models of fig. 4.7) but also on the compositional strategies that lend a distinctive character to each category of motive forms: α as stable in the face of various challenges and β as an agent of change and transition. By the end of the Exposition, a delicate balance has been established between the two, a balance not in evidence in the first version of the quartet, where the category of α motive-forms dominated.

This balance is maintained through the first part of the Development, but it is disrupted by the introduction of the δ form of the motive and the topic of the learned style (ex. 4.17, m. 129). It is only with the Recapitulation that the focus comes back to the α form of the motive, where it stays (with little or no competition from β) until the Coda. The disruption created by δ and the recuperation facilitated by α suggest a function for the topic of the learned style within Beethoven's compositional practice: the fugato on the δ form of the motive creates the impression of "development" by temporarily suspending the normative syntax for the projection of tonal areas associated with α and β, a syntax restored only with the reprise of α at the beginning of the Recapitulation. This function of α is in evidence again at the end of the movement when, after hints at further development and harmonic fluidity in the Coda, α returns as the melodic voice of the final cadence in F major.

The distinctions among these three forms of the principal motive—distinctions that make possible a musical discourse that is focused on the changing fortunes of the motive over the course of the movement, and that were made more apparent in Beethoven's revisions to the movement—suggest that motivic analysis could be refined by attending to how motives are used, rather than to how successfully they can be traced back to some Ur-type. Such a refinement makes possible an appreciation of multiple levels of syntax—levels that interact with the overall harmonic and thematic syntax of the musical work, and which collectively engage more and less immediate levels of cognitive processing. Ultimately, an appreciation of this refinement leads to a better understanding of how compositional strategies shape our conceptions of musical organization.

CONCLUSIONS

For Umberto Eco, one of the mysteries of semiotics was that music could have a fairly well developed syntax and yet no apparent semantic depth. Music meant something, but outside of conventionalized signs like those associated with military or pastoral music, it was quite difficult to say what this was. In this chapter, I have not tried to address this problem head on; indeed, describing the origins and scope of musical meaning is an endeavor far more ambitious than what I undertake here. I have, however, tried to argue that musical syntax and semantics are better viewed as points along a continuum than as discrete domains. More directly, composers (as well as others who bring music to life) make use of strategies that disrupt and redefine musical syntax as part of a process of meaning construction.

My path into these compositional strategies has been through categorization, on the assumption that categories of musical events represent a common ground where the concerns of composers and listeners meet. The viability of this assumption was demonstrated by the structure of the waltzes produced by the musical dice game. Where formal structure needed to be clearly defined (for instance, at the end of each half of the waltz), the range of category members within each measure-category was quite narrow, and what was typical of the relevant measure-category was quite apparent. Where formal structure could be more open (for example, at the beginning of the second half of the waltz), the range of category members was quite wide and typicality harder to determine. Typicality could thus be used to define formal syntax, a syntax that not incidentally coordinated with—and thus confirmed—harmonic syntax.

A somewhat different example of a compositional strategy organized around typicality was seen in the category for the principal motive of the first movement of Mozart's "Dissonance" Quartet. At important moments in the movement—at the beginning and close of the Exposition and Recapitulation, and in the Coda—either thoroughly or highly typical forms of the motive made their appearance. These were followed by less typical members of the motivic category, leading either to a reprise of a typical form or to new musical material. This basic process—a syntax of typicality yielding to atypicality—was repeated three times in the course of the Development, ending only with the appearance of a thoroughly typical form that signaled the start of the Recapitulation. While the compositional strategies that shaped the different versions of the principal motive ran parallel to the formal syntax of the movement, they were nonetheless independent. The motive thus emerged as a topic for musical discourse, whose progress could be followed along with the other strands of musical discourse comprised by the movement.

By contrast, the principal motive of the first movement of the B♭ major quartet from Beethoven's Op. 18 never functioned as a topic for musical discourse. Although the motive forms fell into two distinct categories, individual members never strayed far from their respective conceptual models. In consequence, the immediate level of syntax for the categories of motive forms was not particularly interesting, since members were almost always quite typical of their category. However, over the course of the Exposition each category acquired distinct functions: one (α)

signaled the opening of musical discourse; the other (β) signaled the close of discourse. This emergent syntax was then exploited in the Development and more generally served to show how musical topics of the sort described by Ratner could come into being.

It was in Beethoven's F major quartet from Op. 18 that we saw both of these levels of syntax come together. As with the B♭ major quartet, Beethoven introduced two categories of motive forms (α and β) in the Exposition, with a third (γ) playing a decidedly subsidiary role. A compositional strategy focused on typicality was applied to both categories, but where the range of variation for α was relatively narrow, for β it was quite wide. Contextual pressures on β even suggested that the concept of what counted as a member of the category could slip to include a number of rather remote variants, a kind of slippage that never seemed to threaten α. By the end of the Exposition, and even into the beginning of the Development, α and β appeared to maintain a delicate balance, the former stable in the face of various challenges, the latter an agent of change and transition. Beethoven then introduced a new form of the motive (δ) to disrupt this balance, creating a species of development of high drama: α and β were swept from the stage, vanquished by a volatile combination of properties drawn from each. Balance within the movement as a whole (but not between α and β) was restored with the return of α at the start of the Recapitulation. Even the developmental urges of the Coda could not threaten this equilibrium. The compositional strategies applied to the principal motive, then, operate on both a local level (within a given category) and global level (among groups of categories). Again, these syntactic levels are independent of but coordinated with those for the overall harmonic and thematic structure of the movement—the syntactic strands associated with the principal motive are multiple, but they do not exhaust the syntax of the whole.

In sum, these analyses suggest that the construction of meaning in music can be achieved through the way composers choose to deploy the elements of musical syntax. Of course, compositional strategy is not the only source of meaning construction in music—I have also pointed out the contributions of musical topics and cross-domain mapping to musical semantics—but it is one to which our knowledge of categorization can be profitably applied. As the meeting place for the concerns of composers and listeners, categories of musical events are important to both compositional strategy and musical syntax, for they represent a means through which uniquely musical meaning can be created.

CHAPTER FIVE

CULTURAL KNOWLEDGE AND MUSICAL ONTOLOGY

As part of a search for an interpretive theory of culture and consequent to a critique of early work in cognitive anthropology, Clifford Geertz momentarily and somewhat famously turned his thoughts to music as an example of culture. Taking a Beethoven string quartet as his case in point, he suggested that no one would identify the quartet with its score, with the skills and knowledge needed to play it, with the understanding of it possessed by its performers or audience, with a particular performance of it, or with some mysterious entity transcending material existence. There was one perspective, however, that Geertz thought would meet with general agreement: "That a Beethoven quartet is a temporally developed tonal structure, a coherent sequence of modeled sound—in a word, music—and not anybody's knowledge of or belief about anything, including how to play it, is a proposition to which most people are, upon reflection, likely to assent."[1]

By this example, Geertz intended to put to rest, for once and for all, the notion that culture exists as some sort of program inside people's heads. Nonetheless, if music is not knowledge or belief, then what is it? Geertz's definition of music as "a coherent sequence of modeled sound" is simply too broad, for it would have to include strings of Morse code, speech in an unknown tongue, and the cries of various animals. Indeed, from the perspective of this definition, there is, in principle, nothing to distinguish music from noise or noise from music.[2] "Music" is a category constructed by humans, not a substance or set of relations floating free in the world.

1. Clifford Geertz, "Thick Description: Toward an Interpretive Theory of Culture," in *The Interpretation of Cultures: Selected Essays* (New York: Basic Books, 1973), 11–12.

2. Much can and has been said regarding the relationship between music and noise. Three sources from the last ninety years represent the range of issues engaged by the topic: Luigi Russolo, *The Art of Noises* (1916), trans. Barclay Brown (New York: Pendragon Press, 1986); Jacques Attali, *Noise: The Political Economy of Music*, trans. Brian Massumi, with a foreword by Fredric Jameson and an afterword by Susan McClary, Theory and History of Literature, 16 (Minneapolis: University of Minnesota Press, 1985); and the improvised performances by Derek Bailey, Pat Metheny, Gregg Bendian, and Paul Wertico on *The Sign of 4* (Knitting Factory Works, [CD] KFW 197, 1997).

I indicate the media of the recordings I cite with the following abbreviations: CD = compact disk; LP = 33 RPM record; 78 = 78 RPM record.

As such, the notion of music is dependent upon and constrained by human knowledge, which presumably resides with individual humans. Having said this, it must also be said that the continued existence of a Beethoven string quartet does not depend on the personal knowledge of any one individual. Music is indeed a cultural fact, and culture is largely public and interpersonal.

Cultural knowledge, as represented by Geertz's example, is thus a bit of a paradox. On the one hand, it is not something that is determined by any one individual: culture is, as Geertz maintained, public. On the other hand, individuals need such knowledge if they are going to participate in culture, and it is through the participation of individual humans that culture—and cultural knowledge—is maintained.

The problem, as framed by Geertz's example of a Beethoven quartet, is more specifically one of musical ontology—that is, the ontological status of a work of music. In the West, it is common to regard pieces of music as having an objective status, speaking of a "work of music" as one might of a painting or sculpture. This habit of thought persists in spite of the transience of musical phenomena: unlike a painting or sculpture, a "musical work" has no enduring material existence. The enigma of "works" that are of profound cultural importance and yet are totally ephemeral has led to a number of attempts by philosophers and others to account for the objective status of the work of music and, by extension, music itself; thus the problem of musical ontology.[3] A contrasting perspective has developed among ethnomusicologists who, working chiefly with non-Western music, have noted the fluidity of musical practice and a concomitant absence of any ascription of permanence to the products of musical activity. These observations render doubtful any universal solution to the problem of the ontology of the musical work, or even "music," since many cultures do not show linguistic or practical evidence of equivalent concepts.[4] And yet, musical practice within these cultures, while fluid, is certainly not

3. Thoughtful discussions of the problem of musical ontology can be found in Lydia Goehr, *The Imaginary Museum of Musical Works: An Essay in the Philosophy of Music* (Oxford: Clarendon Press, 1992); Philip V. Bohlman, "Ontologies of Music," in *Rethinking Music*, ed. Nicholas Cook and Mark Everist (Oxford: Oxford University Press, 1999), 17–34; and Nicholas Cook, "At the Borders of Musical Identity: Schenker, Corelli and the Graces," *Music Analysis* 18 (1999): 179–233. See also the essays collected in Michael Talbot, ed., *The Musical Work: Reality or Invention?* (Liverpool: University of Liverpool, 2000).

4. Examples of cultures the languages of which lack a word equivalent to "music" or concepts equivalent to that of a "musical work" include the Hausa of Nigeria, the Macuma Shuar of Ecuador, and the Mapuche of Argentina; Charles Keil reports such a lack in over twenty languages of the African continent and gives detailed discussion of the methodological problems involved in studying such cultures. See David W. Ames and Anthony V. King, *Glossary of Hausa Music and Its Social Contexts* (Evanston, Ill.: Northwestern University Press, 1971), ix; William Belzner, "Music, Modernization, and Westernization among the Macuma Shuar," in *Cultural Transformations and Ethnicity in Modern Ecuador*, ed. Norman E. Whitten, Jr. (Urbana: University of Illinois Press, 1981), 735–36; Carol E. Robertson-DeCarbo, "*Tayil* as Category and Communication among the Argentine Mapuche: A Methodological Suggestion," *Yearbook of the International Folk Music Council* 8 (1976): 39; and Charles Keil, *Tiv Song* (Chicago: University of Chicago Press, 1979), 27–52.

I should make clear that what I find dubious is a universal solution to the problem of the ontology of a musical work. I do not think it is impossible, however, to speak about "music" in the case of a culture that does not show linguistic or practical evidence of such a concept, as long as one does not attempt to colonize that culture by insisting that its members, when they try to make sense of their own experiences and cultural practices, make use of the term.

unregulated. In general, the habit of objectifying aspects of musical practice is omnipresent; in consequence, the problem of musical ontology, while most properly one that arises only among those who believe in an objective status for the work of music, also has applications to situations where no such object is posited.

In this chapter, I propose that solutions to the problems of cultural knowledge in general, and of musical ontology in particular, can be found in what we now know about processes of categorization. In brief, knowing that Beethoven's quartet is music—or that anything else is music, for that matter—means knowing how to categorize sequences of sound-events in accordance with conceptual models shared with other members of a culture. More specifically, each "work of music"—or whatever other unit of cultural currency we choose to focus on—constitutes a Type 1 category of the sort discussed in chapter 2.[5] On the one hand, the transparency and immediacy of the conceptual models that guide the process of categorization explain why we describe works of music in the same language we use for objects: we speak of "the Beethoven quartet" just as we speak of "the red cup," even though the former (as sounding music) is a phenomenon completely unlike the latter.[6] On the other hand, because membership in Type 1 categories is by degree, a certain amount of fluidity is possible, varying in degree with the cultural context relative to which the conceptual model for the category is framed. We might include a wide variety of performances in the category for the Beethoven quartet—some more, some less competent, even some in an arrangement for four-hand piano—but we could well draw the line at a version for pitched percussion and automobile horns.

In what follows, I explore the idea that musical works can be thought of as Type 1 categories and that such categories are a manifestation of cultural knowledge. I approach this issue by taking a close look at two popular songs from the early twentieth century: "I Got Rhythm" and "Bye Bye Blackbird." Songs like this challenge our ideas about what constitutes a "work of music": while they are almost always associated with a score (as is a Beethoven quartet), they are also part of a performance tradition that involves some level of improvisation (introducing the fluidity typical of many non-Western performance traditions).

"I Got Rhythm" provides a good example of this situation, for there were multiple competing versions of the song almost from the moment it appeared on Broadway late in 1930. In the first section below, I consider a number of recordings

5. Of course, a work of music could be regarded as a Type 2 category were necessary and sufficient conditions for category membership specified. This is how I would interpret Nelson Goodman's proposal that the score is the absolute determinant of musical identity. Goodman writes, "If we allow the least deviation [from the score], all assurance of work-preservation and score-preservation is lost; for by a series of one-note errors of omission, addition, and modification, we can go all the way from Beethoven's Fifth Symphony to *Three Blind Mice*. Thus while a score may leave unspecified many features of a performance, and allow for considerable variation in others within prescribed limits, full compliance with the specifications given is categorically required." Nelson Goodman, *Languages of Art: An Approach to a Theory of Symbols*, 2nd ed. (Indianapolis: Hackett Publishing, 1976), 186–87.

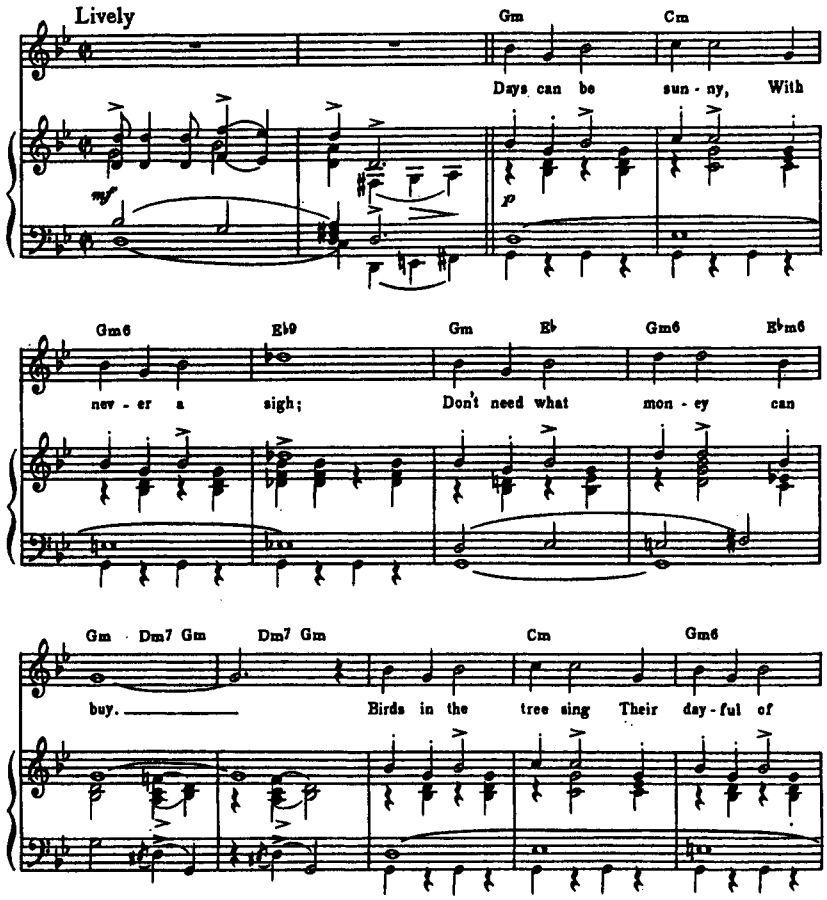
6. There are, of course, aesthetic perspectives that support this habit (such as that associated with the "work-concept," as described by Lydia Goehr in *The Imaginary Museum of Musical Works*, 89–119) and technological innovations that give it credence (like music notation and sound recording), but these are not preconditions for the notion of a musical object.

of the song made during the 1930s and 1940s, explore how the model for the song changed and how it stayed the same, and show that both the fluidity and the stability of this model are straightforward consequences of our use of categorization to organize our understanding of music.

"Bye Bye Blackbird" presents a somewhat different problem, which takes us deeper into the relationship between categorization and cultural knowledge. Written as a popular song during the 1920s and quite successful when it first appeared, it never really entered the standard repertoire until a recording by Miles Davis in 1956 transformed the song into a jazz tune.[7] Because there was no tradition of gradual change, it was possible for radically different models for the song to coexist and come into conflict. In the second section below, I consider this sort of conflict in light of what Mikhail Bakhtin called double-voiced discourse and what Henry Louis Gates Jr. calls Signifyin(g). I attempt to show that a fuller account of how we categorize musical works requires that we go outside of the relatively parochial concerns of musical performance and consider the context in which musical performance takes place.

In the third section, I offer some concluding thoughts on cultural knowledge, musical ontology, and the cognitive processes through which we structure our understanding of the world. I end the chapter with some reflections about how the perspective on musical ontology I offer here can change the way we view music theory.

CATEGORIZATION, MUSICAL ONTOLOGY, AND CULTURAL KNOWLEDGE



A Multiplicity of "Rhythm"s, 1930–1946

"I Got Rhythm" was written by George and Ira Gershwin for their musical *Girl Crazy*, which opened on Broadway on 14 October 1930. The song, intended to be a show stopper, appeared near the end of the first act, and its refrain was repeated a number of times: to accompany a tap dance chorus after the final vocal refrain; as an encore for Ethel Merman, whose success with the song became legendary; as part of the mostly instrumental entr'acte before the second act; and, sung by the whole company, as the show's concluding number.

The song itself, the score for which is given in example 5.1, comprises an introduction, verse, and refrain. The melody of the verse begins with an eight-measure phrase in G minor (featuring a prominent $\flat\hat{5}$ at its midpoint), which is given a var-

7. I borrow the distinction between a song and a tune from Richard Crawford, who writes, "in the jazz tradition, we usually speak of tunes, not songs. A jazz tune is defined first and foremost by its structure: by the pattern of repetition and contrast in its melodic phrases and the harmonic framework underlying them. Second, it is defined by its ethos: by the mood it projects and the tempo at which it is played. Only third does its melody come into play, for in the jazz tradition the melody is often little more than an entrée into the performance; after being heard, it is usually discarded for free melodic invention by the performers." Richard Crawford, "George Gershwin's 'I Got Rhythm' (1930)," in *The American Musical Landscape* (Berkeley: University of California Press, 1993), 221, 225.

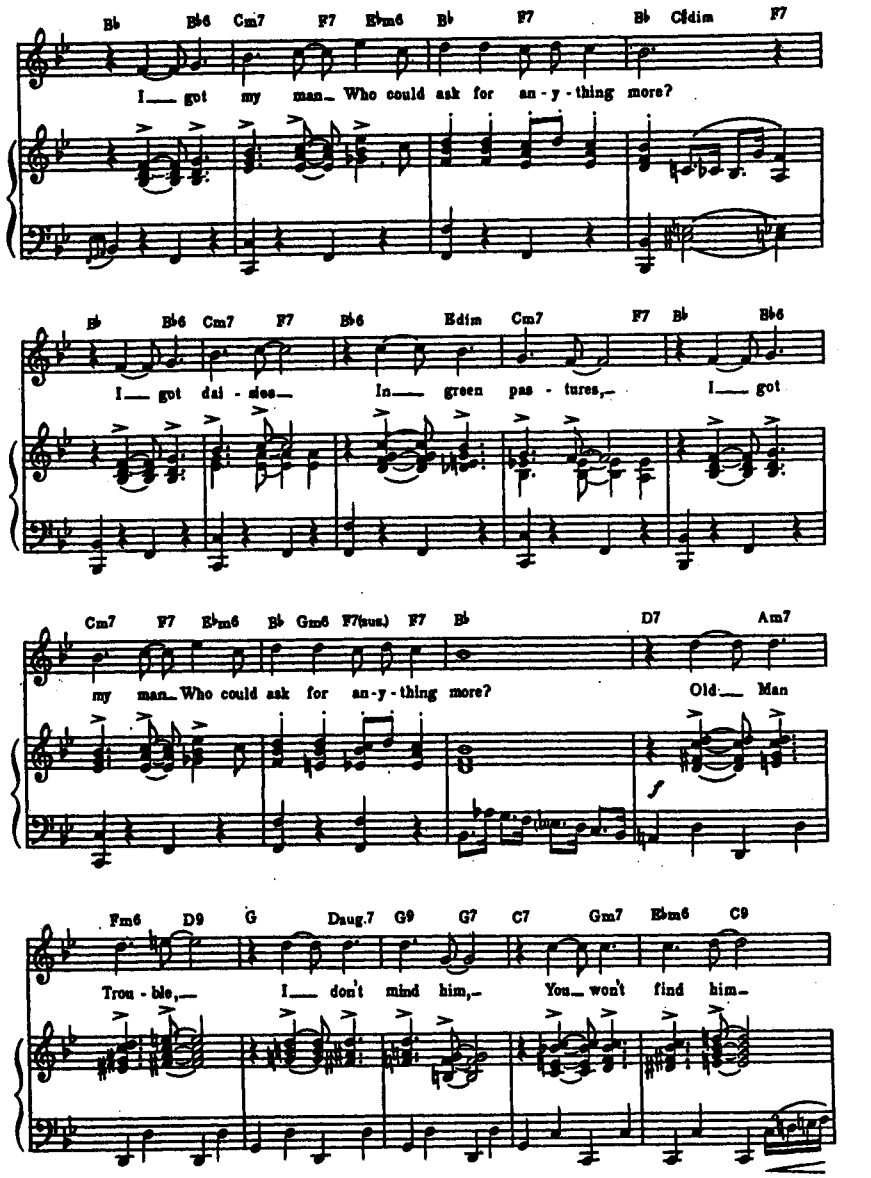
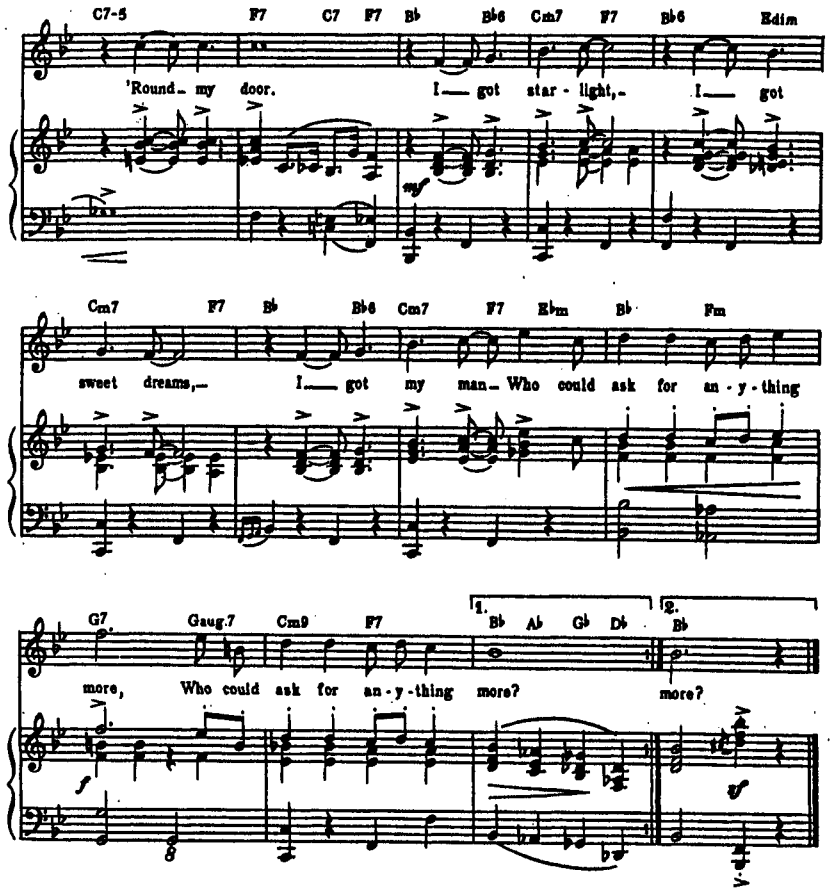
(continued)

ied repetition. This is followed by a four-measure phrase, which is also repeated (again, with variations), after which a two-measure transition leads to the refrain. The refrain is in the AABA form typical of popular songs of this period, but it includes an ascent to F5 near the end of the last A section. This climactic rise requires a two-measure tag to bring the melody back to B♭4 and yields a 34-measure AABA' form.



"I Got Rhythm" was only rarely recorded as it appeared in the original show. Although it contributed significantly to her professional career, Ethel Merman did not record it until 1947. Many amateurs and semi-professional musicians must have performed the song from the sheet music, which did reproduce the music as it

EXAMPLE 5.1 *(continued)*



appeared in *Girl Crazy*. This was not the case, however, with professional musicians. Even in the earliest recordings (made within a few weeks of the show's opening), the verse loses its introductory (and narrative) function and is used instead as an interlude between repetitions of the refrain. For example, the recording made on 23 October 1930 by Red Nichols and His Five Pennies (a group drawn from the pit orchestra for *Girl Crazy*) begins with an instrumental version of the original refrain,

EXAMPLE 5.1 *(continued)*

(continued)

EXAMPLE 5.1 *(continued)*

followed by the refrain with vocal.[8] Only after this does the music for the verse enter, but without vocals. The recording concludes with two more statements of the refrain, also without vocals. A very similar arrangement was used by Fred Rich and a studio band in their recording of 29 October 1930. The overall form of their rendition consists of three refrains (the second with vocal), followed by an instrumental verse, followed by one complete and one partial statement of the refrain (the latter using only the B and A' sections to conclude the performance).[9]

In the two years following the opening of the show, almost all of the recordings that appeared made use of vocals, although none of which I am aware used the words for the verse.[10] With the instrumental version recorded by Don Redman and

9. Fred Rich and His Orchestra, "I Got Rhythm," in *1930—You're Driving Me Crazy: Portrait of a Year in Music* (Phontastic, [CD] PHONT CD 7618, 1992).

10. A fairly comprehensive list of recordings of "I Got Rhythm" from 1930 to 1942, based on Brian Rust's *The American Dance Band Discography 1917–1942* (New Rochelle, N.Y.: Arlington House, 1975), is included in Crawford's "George Gershwin's 'I Got Rhythm,'" 222–25.

His Orchestra on 30 June 1932, however, we encounter a new approach to the song.[11] In this arrangement, the verse was eliminated completely, as was the role of the vocalist. The result is something very much like the version of "I Got Rhythm" that can be found in jazz fake books, such as shown in example 5.2.[12] After 1932, the number of recordings that include vocals drops off precipitously, and "I Got Rhythm" became a tune used by dance bands for instrumental improvisation—a jazz "standard"—as may be observed in recordings by Red Norvo and His Swing Sextette in 1936 or Chick Webb and His Little Chicks in 1937.[13] Seen from the perspective of these recordings, George Gershwin's own performance of "I Got Rhythm" as a set of variations for piano and orchestra is somewhat anomalous, for there is little if any sense of improvisation, nor is this music intended for dancing.[14]

From 1932 to 1942, recorded performances are remarkably consistent in their approach to "I Got Rhythm": all use the same thirty-four-measure form, all make

EXAMPLE 5.2 Jazz fake book version of George and Ira Gershwin's "I Got Rhythm." "I Got Rhythm," words and music by George Gershwin and Ira Gershwin, © 1930 WB Music Corp. (Renewed). All rights reserved. Used by permission. Warner Bros. Publications U.S. Inc., Miami, FL 33014.

11. Don Redman and His Orchestra, "I Got Rhythm," in *Don Redman and His Orchestra, 1931–1933* (Classics, [CD] 543, 1990).

12. Jazz "fake books" typically contain hundreds of songs. Generally, as is true of the piece in ex. 5.2, each is given as a melody, along with chord symbols that outline a basic harmonization and some minimal instructions for performance; the words for the songs may or may not be included. These materials allow players familiar with jazz performance practice to give an acceptable rendering of a song even if they have never played it before—that is, they can "fake" their way through a performance.

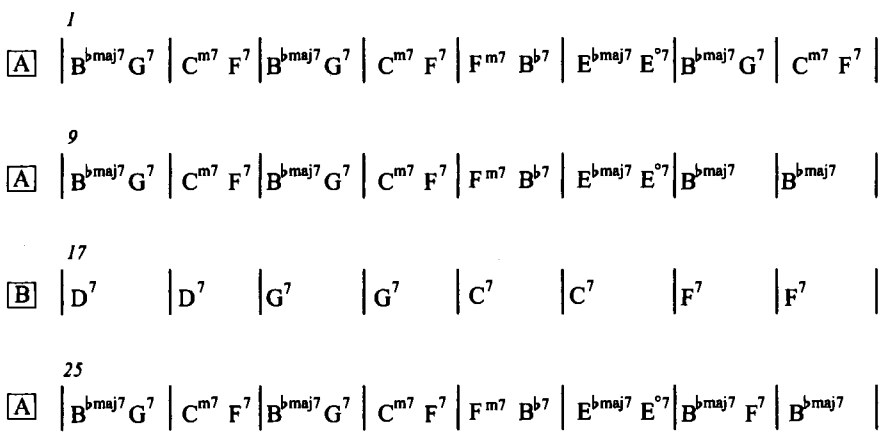
13. Red Norvo and His Swing Sextette, "I Got Rhythm," in *Red Norvo* (Time-Life Records, [LP] STL-J14, 1980), originally recorded 16 March 1936; Chick Webb and His Little Chicks, "I Got Rhythm," in *Spinnin' the Webb: Chick Webb and His Orchestra* (GRP Records, [CD] 513678L, 1994), originally recorded 21 September 1937.

14. George Gershwin, "I Got Rhythm," in *Gershwin Performs Gershwin: Rare Recordings 1931–1935* (Musical Heritage Society, [CD] 512923A, 1991), originally recorded 19 February 1934.

some reference to the original melody, and all preserve the affect and tempo of the original. However, an arrangement recorded by the Jimmy Dorsey Orchestra on 28 November 1942 signaled yet another approach to "I Got Rhythm," for after employing the customary thirty-four-measure format for the head, the band switched to a thirty-two-measure format for the solos.[15] In truth, this was not the first time the musical materials of "I Got Rhythm" had been associated with a thirty-two-measure form. Early on, the song had been used as the basis for a number of other compositions.[16] These derived tunes typically retain the harmonic framework, overall form, and affect of the original song but substitute a new melody and give the whole a new title. In the case of "I Got Rhythm," derived tunes allowed jazz players to keep what was useful from the song—its fast tempo, lively affect, and straightforward harmonic structure—yet escape the limitations of its simple, predominantly pentatonic melody. The earliest recorded tune derived from "I Got Rhythm," Sidney Bechet and the New Orleans Feetwarmers' "Shag" (recorded 15 September 1932), did retain the thirty-four-measure form of "I Got Rhythm," with its two-measure tag at the end of the final A section.[17] However, Fletcher Henderson's "Yeah Man," which appeared the following year, did away with the two-measure tag, yielding a thirty-two-measure form in which all of the A sections were of equal length.[18] There were two advantages to this change. First, the excision of the two-measure tag made the connection between "Yeah Man" and "I Got Rhythm" more obscure: "Yeah Man" could sound a bit more like a brand new tune. Second, jazz practice of this period was beginning to embrace longer solos. The 34-measure form of "I Got Rhythm," it will be recalled, ends with a two-measure tag added to its final A section. A musician who wanted to take two "choruses" in succession would consequently find the regular flow of eight-measure phrases in the background harmonic structure interrupted in midstream with the appearance of the ten-measure A' section. When a musician took two "choruses" on the 32-measure form, however, the succession of eight-measure phrases was constant: the improvisation could stretch seamlessly across the two refrains, allowing the player to build longer melodic lines and to shape the dynamic structure of the solo over larger spans of music. Although after "Yeah Man" the tunes derived from "I Got Rhythm" were invariably based on the thirty-two-

15. Jimmy Dorsey and His Orchestra, "I Got Rhythm," in *Jimmy Dorsey and His Orchestra*, Vol. 2: *1942–44* (Hindsight Records, [LP] HSR-153, 1980). For performances with an emphasis on improvisation that are guided only by a relatively informal arrangement, the practice among jazz performers is to state the tune at the beginning and end of the performance. In these cases, the tune functions as the "head." The head is typically followed by solos over the harmonic framework of the tune, which are, in turn, followed by a concluding statement of the tune.

16. Richard Crawford calls such derived tunes "contrafacts," borrowing the term from one of several medieval practices to which it is linked. The specific practice invoked is one in which new texts are grafted on to preexistent music, which was itself freely adapted. See Crawford, "George Gershwin's 'I Got Rhythm,'" 225, 228–29.



17. Sidney Bechet and the New Orleans Feetwarmers, "Shag," in *Sidney Bechet* (Time-Life Records, [LP] STL-J09, 1980).

18. Fletcher Henderson and His Orchestra, "Yeah Man," in *Fletcher Henderson, Developing an American Orchestra, 1923–1937* (Smithsonian Collection, [LP] R 006, 1977), originally recorded 18 August 1933.

measure form, it was only around 1942 that this form was brought to "I Got Rhythm" itself.

At first, the thirty-two-measure form was used only for solos—the head retained its thirty-four-measure form, complete with the two-measure tag (as in the Jimmy Dorsey arrangement). By the mid-1940s, however, even the tag for the head had fallen away. When Charlie Parker recorded "I Got Rhythm" with a group of all-star performers on 22 April 1946, the thirty-two-measure form was used for the head, as well as for the twenty-three choruses that followed.[19] The transformation of "I Got Rhythm" into a platform for improvisation is even more evident in a recording made two years earlier by Lester Young and the Kansas City Six. In this performance, not only is the thirty-two-measure harmonic pattern used throughout, but also the melody of the song is never stated.[20] In this form—that is, as a thirty-two-measure, AABA harmonic structure—"I Got Rhythm" came to be one of the basic elements of the jazz player's musical vocabulary: the "Rhythm changes" shown in example 5.3.[21]

EXAMPLE 5.3 Scheme for "Rhythm changes" (based on the harmonic structure of the thirty-two-measure form of "I Got Rhythm"). "I Got Rhythm," words and music by George Gershwin and Ira Gershwin, © 1930 WB Music Corp. (Renewed). All rights reserved. Used by permission. Warner Bros. Publications U.S. Inc., Miami, FL 33014.

19. Charlie Parker and others, "I Got Rhythm," in *Bird: The Complete Charlie Parker on Verve* (Verve/Polygram Classics, [CD] 837 142-2, 1988).

20. Lester Young with the Kansas City Six, "I Got Rhythm," in *The Tenor Sax: Lester Young, Chu Berry and Ben Webster: The Commodore Years* (Atlantic, [LP] SD 2-307, 1973), originally recorded 28 March 1944. That the performance by Young's group resulted from an arrangement employed for successive performances rather than happenstance is suggested by an alternate take of the same tune recorded the same day (included on this album), which uses precisely the same arrangement.

21. The term "changes" refers to a conceptual structure that consists of a succession of harmonies correlated with a metric and hypermetric framework. Knowing this structure—knowing where and when the harmonies change—is essential for creating convincing improvisations.

On the importance of "Rhythm changes" as a basic harmonic prototype, see Paul F. Berliner, *Thinking in Jazz: The Infinite Art of Improvisation*, Chicago Studies in Ethnomusicology (Chicago: University of Chicago Press, 1994), 76-78.

From the evidence provided by recordings, then, what counted as "I Got Rhythm" changed from 1930 to 1946 as the song was transformed from a Broadway or popular song, to a jazz standard, to a platform for improvisation. This précis is not quite accurate, however, for even as new conceptions of the song emerged, older ones remained in circulation. Benny Goodman, for instance, continued to use the thirty-four-measure form of the refrain even after others had adopted the thirty-two-measure form;[22] productions of the musical (including the 1943 movie *Girl Crazy*, starring Mickey Rooney and Judy Garland) continued to use the entire song after most other performances had omitted the verse.[23] From almost the moment of its introduction, there were multiple "Rhythm"s in circulation, and what belonged under the rubric "I Got Rhythm" depended on where you stood in the stream of American popular culture.

Categorizing "I Got Rhythm"

Collected in table 5.1 are all of the versions of "I Got Rhythm" discussed thus far. How might someone go about categorizing these various versions were they encountered in the course of daily life rather than as a pre-selected list? That is, assuming one were not so fortunate as to have each performance identified as "a performance [or recording, or rendering] of 'I Got Rhythm,'" what would be the basis for including any or all of these in the category *performances of "I Got Rhythm"*? As shown in chapter 1, categories like this are organized around a conceptual model that sets up an idealized representation of what counts as a typical member of the category.[24]

As a place to begin, let us consider a conceptual model focused on the attributes of the song as it first appeared in *Girl Crazy* (leaving aside the variants created as the song was reprised over the course of the musical). The model (which I shall call the "pop-music" model, for reasons that will become clear below) is diagrammed in figure 5.1 and consists of five correlated conceptual elements, characterized as the things necessary for an adequate performance of the song. Two aspects of this model should be clarified. First, although the verses of popular songs were often omitted in performance, I take the fact that composers still bothered to write verses and that the verse was included, in some form or another, in early recordings as evidence of its importance to the identity of the song. Second, my distinction between variation and improvisation is based on the extent rather than the presence of musical materials not specified by the score: if these materials are relatively limited, I would tend to regard them as a product of variation; if they are extensive, I would tend to regard them as a product of improvisation. Where to draw the line involves another set of conceptual models for performance practice; nonetheless, the distinction is relatively clear in early recordings.

22. Benny Goodman Sextet, "I Got Rhythm," in *Benny Goodman* (CBS Records, [LP] P5 15536 CP, 1981), originally recorded 18 September 1945.

23. Although the plot line for the movie is completely different from that of the musical, the musical numbers are the same.

24. By "categories like this" I mean not categories involving musical works specifically, but the categories we use in daily life generally.

TABLE 5.1. Select Performances of "I Got Rhythm"

Performers	*Date of Recording*
Red Nichols and His Five Pennies	23 October 1930
Fred Rich and His Orchestra	29 October 1930
Don Redman and His Orchestra	30 June 1932
George Gershwin	19 February 1934
Red Norvo and His Swing Sextette	16 March 1936
Chick Webb and His Little Chicks	21 September 1937
Jimmy Dorsey and His Orchestra	28 November 1942
Lester Young with the Kansas City Six	28 March 1944
The Benny Goodman Sextet	8 September 1945
Charlie Parker and others	22 April 1946

Applying this model to the performances listed in table 5.1 yields the typicality effects characteristic of Type 1 categories. Most typical would be the performances by Red Nichols's and Fred Rich's groups; performances from the original production of the musical (which are not included in the list of recordings) would of course also be reckoned as highly typical.[25] By contrast, the performance led by Gershwin, which drops the verse and lyrics, would not conform as well with the model. Even less typical would be the performances led by Redman, Norvo, Webb, and Goodman, for all these add a substantial emphasis on improvisation. Finally, on the fringes of the category would be the performances led by Dorsey, Young, and Parker, for these not only omit the verse and lyrics but also use a thirty-two-measure form of the refrain as a platform for extended improvisations.

As we see in this example, conceiving of various renditions of a song as a Type 1 category organized around a conceptual model offers a way to explain the peculiar ontological status of musical works. Our sense that there is only one thing that should be called "I Got Rhythm" is supported by the idealization basic to the model and to the model's role as the conceptual anchor for the category. At the same time, our ability to accept as members of the category things that do not fully correspond to this model shows how the model functions as a guide to understanding the structure of the category as a whole. Although Charlie Parker's "I Got Rhythm" is not like Ethel Merman's "I Got Rhythm," it shares enough attributes with the latter that we will not want to exclude it from the category outright. Further, the model can provide a basis for describing why we would grant Parker's performance a liminal rather than a central status within the category—we might say something along the lines of "He uses too much of that crazy improvisation, so he really isn't playing 'I Got Rhythm.'"

25. There was no recording of the original production of *Girl Crazy*. However, there was a painstaking recreation of the 1930 production undertaken by Elektra Nonesuch in 1990, and Lorna Luft's performance there (in the part of Kate Fothergill originated by Merman) agrees in most respects with the version of "I Got Rhythm" recorded by Merman in 1947. See George Gershwin and Ira Gershwin, *Girl Crazy* (Elektra Nonesuch, [CD] 79250-2, 1990), recorded 26–28 February 1990.

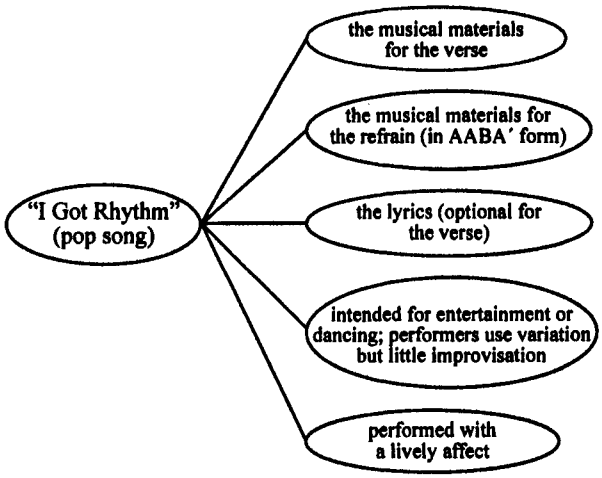


FIGURE 5.1 Pop-music model for the category *performances of "I Got Rhythm"*

Useful as this approach to musical ontology is, it demands at least a bit of further elaboration: we need to find a way to describe how the conceptual model for a musical work changes over time. After all, while Parker's 1946 performance might have been regarded as unusual by some, it is clear from the musical practice of his contemporaries that it was far from exceptional. Here Richard Crawford's account of three different approaches taken to "I Got Rhythm" during the years 1930–1942 provides a helpful guide.[26] The first approach, in which "I Got Rhythm" was treated as a popular song, is similar to that assumed by the pop-music model diagrammed in figure 5.1. The second approach described by Crawford is one in which "I Got Rhythm" is treated as a jazz standard. A conceptual model that fits this approach is diagrammed in figure 5.2 and consists of five things necessary for an adequate performance.[27] Adopting this model would, of course, change what counted as a typical version of the tune. Now the performances led by Redman, Norvo, Webb, and Goodman would be central to the category, and the performances led by Dorsey, Young, and Parker only a bit less typical. Far more atypical would be the performance led by Gershwin, with its relative lack of emphasis on improvisation, and the performances by Red Nichols's and Fred Rich's groups, with their inclusion of the verse.

The third approach to "I Got Rhythm" noted by Crawford was as a musical structure that served as the basis for various derived tunes. I would like to generalize this somewhat to accommodate the slightly expanded time frame represented by the recordings collected in table 5.1. After 1942, "I Got Rhythm" served not only as the basis for derived tunes but also as a framework for improvised performance—

26. Crawford, "George Gershwin's 'I Got Rhythm,'" 218.

27. Explicit mention of the melody in this conceptual model is intended as a hedge against confusing "I Got Rhythm" with any of the tunes derived from it.

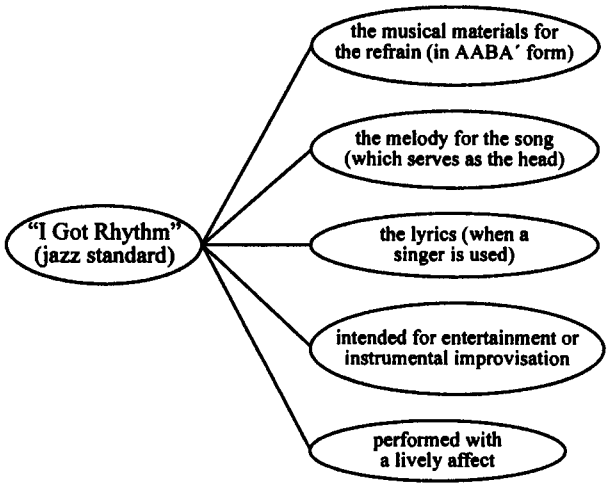

FIGURE 5.2 Jazz-standard model for the category *performances of "I Got Rhythm"*

a framework embodied in the "Rhythm changes" of example 5.3. This leads us to a third model for "I Got Rhythm," which is diagrammed in figure 5.3. This "improv" model, conceived as a skeletal vehicle for improvisation and composition, consists of four things necessary for an adequate performance. Once again, what would count as a typical version of the tune changes. From the perspective provided by the improv model, the performances led by Young and Parker would be most typical, with that led by Dorsey following close behind. The performances led by Redman, Norvo, Webb, and Goodman, with their allegiance to the original form and melody of Gershwin's song, would now be regarded as less typical, and the performances led by Gershwin, Nichols, and Rich would have to be considered as thoroughly atypical.

Let us now return to the matter of how the conceptual model for a musical work changes over time. If we take these three models as an historical sequence—the pop-music model followed by the jazz-standard model, which is followed by the improv model—we can see that each successive conceptual structure retains some of the elements of the previous structure and either modifies or drops others.

- The jazz-standard model retains from the pop-music model the elements concerning affect and the materials of the refrain. It changes those relating to function and lyrics, and it adds an element specifying the presence of the melody. (The latter is implicit in the "materials of the refrain" inherited from the pop-music model, but it is made explicit here).
- The improv model retains from its jazz-standard counterpart the element concerning affect. It changes the components of the model associated with the refrain, melody, and function, and it drops any requirement for the lyrics.

As is evident from table 5.1, these are not the only models possible, nor should my descriptions of the model be taken as comprehensive or final. One could easily

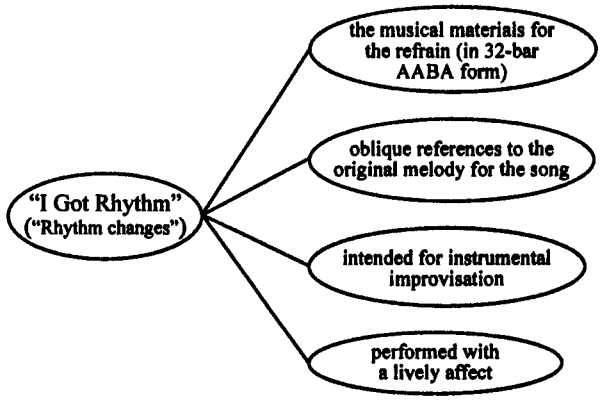

FIGURE 5.3 Improv model for the category *performances of "I Got Rhythm"*

imagine idiosyncratic or transitional models that blend features of those outlined here. Thus a model based on the performance led by George Gershwin, for instance, would borrow some features from the pop-music model and some from the jazz-standard model; a model based on the arrangement played by the Jimmy Dorsey band would incorporate some aspects from the jazz-standard model and some from the improv model. And were such models taken as the basis for our determinations as to what belonged in the category *performances of "I Got Rhythm,"* there would of course be changes in what counted as a typical or atypical member of the category.

When people share the conceptual model for a song (realizing that all such sharing is approximate), they will tend to make similar judgments about what counts as a typical or an atypical rendering of the song (or whether a succession of sounds should even be counted as an instance of the song). As I proposed in chapter 3, sharing knowledge in this way is one of the bases of culture. This becomes especially clear when we consider other roles played by the model for a musical work: as a set of cognitive resources for performance, as a basis for negotiations on how musical practice should proceed, and as a focus for how musical practice can be regulated.

Conceptual Models and Performance

Up to this point, we have considered music that is part of a tradition of performance at least partially regulated by the score. But what of performance traditions in which scores play no part—that is, music that is part of an aural tradition? Where scores (or similar artifacts) are absent, performers must rely on a store of knowledge about music and music making, knowledge often gathered through a long and painstaking process that starts in earliest childhood and continues for many years.

Constantin Brailoiu was perhaps the first to suggest that musical performance within aural traditions relies on stored cognitive constructs. As a way of explaining the source of the divergent performances folk musicians gave of the "same" song, Brailoiu proposed that such performances were ephemeral incarnations of an ideal

archetype stored in the mind of the musician.[28] In his work on African music, Simha Arom adopted Brailoiu's idea, but he called the archetype a "model."[29] James Cowdery, whose research has focused on Irish music, proposed a similar cognitive basis for performance practice, but one derived from the tradition of inquiry centered on the tune family.[30] Cowdery called the construct a "tune model" and conceived of it as a generating pattern in the mind of the performer or musical community.[31] Finally, James Porter has developed detailed descriptions of a succession of conceptual performance models for the changing versions of the song "My Son David" sung by the Scottish singer Jeannie Robertson between 1953 and 1960.[32] For Porter, the conceptual performance model represented a holistic, self-contained concept of a particular song in the mind of the singer.[33] This model enabled the singer to give successive but nonidentical performances of the "same" song on a number of occasions, but the model was nonetheless subject to change over time—that is, the "same" song gradually became a different song as the conceptual performance model changed.

The idea behind all of these approaches is that performers who work within aural traditions base their performance of a given tune on a cognitive construct that is stored in memory and that represents essential features of that tune. In their basic features, such constructs are essentially the same as the conceptual models I described in chapter 3. I have used these same models in this chapter to explain how individuals determine whether a particular performance is of a specific tune and how typical that performance is. The difference that distinguishes my models from those of Brailoiu, Arom, Cowdery, and Porter is that the sort of constructs they pro-

28. The relevant texts in translation and the original are as follows: "Lacking an unchallengeable [musical] text, we must admit that we never collect more than variants and that latent in the singers' minds lives an ideal archetype of which they offer us ephemeral incarnations." ["A défaut de tout texte irrécusable, force nous est d'admettre que nous ne recueillons jamais que des variantes et que, dans l'esprit des chanteurs, vit, d'une vie latente, un archétype idéal, dont ils nous offrent des incarnations éphémères."] Constantin Brailoiu, "Le Folklore musicale," in *Musica aeterna: La Vie et la production musicales de tous les temps et de tous les peuples, en tenant compte particulièrement de la Suisse, de la Belgique, de la France et de la musique de nos jours*, ed. Gottfried Schmid (Zurich: M. S. Metz, 1949), 2: 319.

29. Simha Arom, *African Polyphony and Polyrhythm: Musical Structure and Methodology*, trans. Martin Thom, Barbara Tuckett, and Raymond Bond (Cambridge: Cambridge University Press, 1991), 148.

30. The idea of a tune family was first proposed by Samuel P. Bayard in his classic essay "Prolegomena to a Study of the Principal Melodic Families of British-American Folk Song," *Journal of American Folklore* 63 (1950): 1–44.

31. James R. Cowdery, *The Melodic Tradition of Ireland* (Kent, Oh.: Kent State University Press, 1990), 33.

32. James Porter, "Jeannie Robertson's *My Son David*: A Conceptual Performance Model," *Journal of American Folklore* 89 (1976): 7–26; and idem, "Context, Epistemics, and Value: A Conceptual Performance Model Reconsidered," in *Selected Reports in Ethnomusicology: Issues in the Conceptualization of Music*, 7, ed. James Porter and Ali Jihad Racy (Los Angeles: University of California, Department of Ethnomusicology, 1988), 69–97. Porter's thoughtful appraisal of what might be involved in a conceptual performance model goes well beyond the primitive models I sketch here and should be taken into account in any further application of theories of categorization to ethnographic research.

It should be noted that while Arom, Cowdery, and Porter all use the term "model" for their hypothetical cognitive constructs, they do so without reference to any of the cognitive science research on models or related constructs.

33. Porter, "Context, Epistemics, and Value," 71.

pose are used not for categorizing musical performances, as I attempt to do, but for producing them. In truth, we have already seen conceptual models used in this way, for Jeff's conceptual models for "Twinkle" not only helped him organize the Montessori bells in particular patterns but also guided his actions when he performed the song. In the present context, however, the network of knowledge with which we are concerned is far more extensive than that with which Jeff was engaged. The skills required for an adequate performance of a tune like "I Got Rhythm" (relative to the performance tradition described above) are extensive: a trumpet player, for instance, must know where to find the notes for the tune on her instrument, how to produce these notes in the right order, how to shape this production to create a convincing version of the tune, how to coordinate her playing with that of other members of an ensemble, and so on.[34] For performers, then, there will be a number of conceptual models related to the various challenges of creating musical sound, as well as the conceptual model for a particular piece.

The complexity of this network of knowledge emphasizes once again the importance of the global models relative to which local models are framed. With regard to the conceptual model for a musical work, the global model speeds the process of learning the conceptual model for a new tune and also provides a framework for discourse among musicians. For instance, among performers the jazz-standard model for "I Got Rhythm" (which was diagrammed in fig. 5.2) is framed relative to a global model for jazz practice, which includes the five elements diagrammed in figure 5.4. A comparison of figure 5.4 with figure 5.2 shows that each generic element in the former has its more specific correspondent in the latter. Confronted for the first time with a tune like "I Got Rhythm," a musician who has internalized the global model will already have a start on assembling a local conceptual model to use as a guide in performing the tune. The global model also serves as a frame for discourse (both verbal and musical) about local models. That is, approaching "I Got Rhythm" as a song that belongs to the performance practice of jazz means that features such as its harmonic structure, melody, and character are what are relevant, rather than whether there is a definitive score on which to base performance.

Conceptual models, then, are used not only to structure our understanding of

34. Of necessity, this network of knowledge will include embodied knowledge: what it feels like to make musical sounds and to coordinate this activity with other physical activities. Richard Powers touches on the importance of such knowledge in his novel *Galatea 2.2*, which centers on a hypothetical experiment to replicate aspects of human intelligence on a vast and spreading neural network, implemented via parallel processing on a massive supercomputer. At one point, the implementation, named Helen, asks "How do you sing?" The narrator responds by singing a fragment of a song he learned as a child: "Bounce me high, bounce me low, bounce me up to Jericho." To his amazement, the implementation not only absorbs this song but can later be heard singing it, over and over, like a child trying out her voice. Yet "sing" is not quite the right word, for Powers's narrator realizes that there is something missing: "Helen did not sing the way real little girls sang. Technically, she almost passed. Her synthesized voice skittered off speech's earth into tentative, tonal Kitty Hawk. Her tune sounded remarkably limber, given the scope of that mechanical tour de force. But she did not sing for the right reasons. Little girls sang to keep time for kickball or jump ropes. . . . Helen didn't have a clue what keeping time meant, never having twirled a jump rope, let alone seen one." Richard Powers, *Galatea 2.2* (New York: Farrar Straus Giroux, 1995), 205.

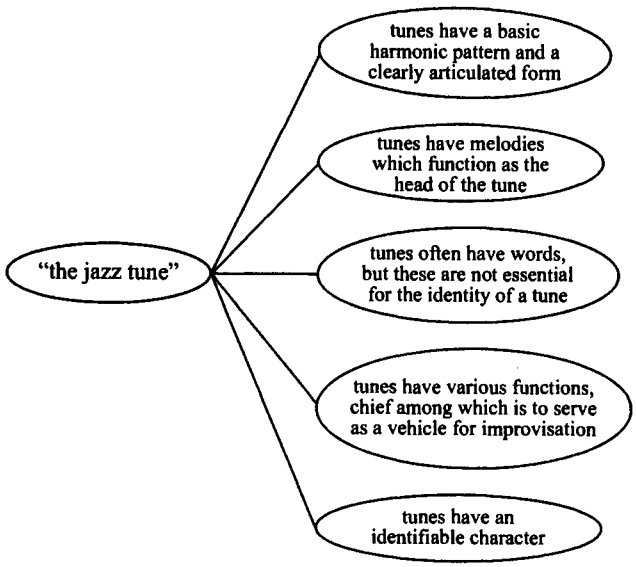

FIGURE 5.4 Partial representation of the global model of jazz practice

what we hear but also to create the things we hear. In both cases, the model is part of a network of knowledge that, through being shared by the members of a musical community and realized in sound, constitutes musical culture.

Negotiating Conceptual Models

Musical practice is not a steady state, as may be seen in the different versions of "I Got Rhythm" collected in table 5.1. Over time, conceptual models will be modified in response to changes in cultural priorities. Rarely are such modifications the result of creative fiat by one individual (although one such case is discussed below, in connection with "Bye Bye Blackbird"). More commonly, they are the product of a gradual series of negotiations within a musical community.

The basic outlines of the process of negotiating the structure of conceptual models can be illustrated by considering two highly simplified situations. Each involves a musician who initiates the process of negotiation by suggesting changes to the constituent elements of a given conceptual model. In the first case, the negotiations occur within a group of musicians occupied with performing the same work; in the second case, the negotiations occur between the musician and an audience of non-performers.

The first situation can be conceived of as taking place in a rehearsal or a performance of the version of "I Got Rhythm" associated with the jazz-standard model. Instead of playing the usual harmonic progression for the refrain, the pianist, without comment, introduces a completely new series of harmonies for the A section and truncates the overall form to thirty-two measures. The other musicians may accept this change (by adjusting their performance to the new harmonies), reject it

(by resolutely hewing to the structure of the original model), or suggest further modifications (by offering their own interpretation of the harmonic progression). This process could also play out with the aid of language (the changed harmonic progression could be announced in advance) or symbols (a chord chart for the changed refrain could be supplied to the other musicians), or through various combinations of musical performance, language, and symbols by any or all participants.

The second situation can be conceived of as taking place during a performance of "I Got Rhythm" by a solo pianist, playing for an audience of nonperformers. Again, instead of the usual harmonic progression for the refrain, the pianist introduces a new series of harmonies and truncates the overall form to thirty-two measures. The audience may respond by accepting the change (through applause or a similar activity), rejecting it (by shouting catcalls or throwing bottles), or suggesting further modifications (by shouting "More!" or "Too much!"). (Of course, it is quite probable that an audience would not even notice changes of this sort, but for the sake of the argument, I shall assume that it did.)

In each of these imaginary situations, some elements of the conceptual model for the tune are changed and some are retained. The conceptual models thus form a framework for negotiation—that is, negotiation is conducted in terms of the conceptual model for the tune. Series of such negotiations then lead to the more substantive changes in conceptual models of the sort suggested by my account of how such models might be linked in a historical succession. Of course, the imaginary situations I have described are highly simplified: as the works of Ruth Finnegan, Paul Berliner, and Ingrid Monson have demonstrated, actual negotiations among musicians are much more complex than those outlined here.[35] Musical discourse is rich and creative, and it includes comedy and irony, as well as meaningful exchanges about the business at hand. Nonetheless, what makes this communication possible is the knowledge shared among musicians, knowledge that is organized by conceptual models.

Limits on Negotiation

The mutability of conceptual models under the social and cultural pressures of negotiation has the potential to destabilize cultural knowledge by transforming it until it becomes alien and unfamiliar. Under certain circumstances, the interconnectedness and dispersion characteristic of cultural knowledge can counteract destabilization, a process noted by Mantle Hood.[36] Under other circumstances, however, the challenge to stability may be significant. In the case of musical practice, such challenges might come from a number of sources: from the innovations of influen-

35. Ruth Finnegan, "The Relation between Composition and Performance: Three Alternative Modes," in *The Oral and the Literate in Music*, ed. tial individuals, from contact with other cultures, from a sudden increase in the complexity of musical practice, or from changes in technology. Faced with this sort of challenge, a musical community may develop strategies to eliminate or control the instability of the conceptual models upon which the practice of that community is based.

One common strategy is to represent key structural elements of a local conceptual model through artifacts such as scores or recordings. Although the score illustrations used for "I Got Rhythm" carry the aura of authority, they actually follow from the conceptual models for the song: a score is an artifactual manifestation of the elements of the conceptual model deemed most relevant to the musical practice of which the model is a part, created as a means of stabilizing the model. The score for the original version of "I Got Rhythm" (ex. 5.1) can thus be seen as a reflection of the conceptual model for pop songs (fig. 5.1). Such songs invariably had a verse, even if it was only rarely performed. Since the songs were often performed by musicians with only limited score-reading abilities, chord symbols (which often do not match the chords indicated by the music notation) are almost always included, and they serve to indicate the minimal materials necessary to accompany the voice. The jazz fake book rendering of "I Got Rhythm" (ex. 5.2) does away with the verse and any specifics about how the accompaniment is to be realized; it reflects the essential features of the jazz-standard model (fig. 5.2). And the "Rhythm changes" of example 5.3 preserve only the bare essentials, cryptic to anyone not schooled in jazz but more than enough to serve musicians as a starting point for improvisation, provided they are familiar with the concepts and relations embodied in the improv model (fig. 5.3). Thus, both in its production and interpretation, musical notation reflects (rather than generates) the local and global conceptual models that constitute musical practice.[37]

The idea that musical notation could serve as a way to control (rather than simply enable) musical practice is not a new one, having been proposed by Charles Seeger over fifty years ago.[38] With respect to Western practice, the limits on negotiation that follow from this reliance on musical notation operate on two levels. First, any given instance of musical notation, as an embodiment of "the work of music," limits negotiation to those aspects of music deemed "nonessential" to the work (such as the specifics of dynamics, timbre, and tempo): these are the things left relatively ambiguous by the score.[39] Second, the *terms* for negotiation become artifactual: any aspect of musical practice that would vie for determining the identity of a musical work must be such that it can be expressed artifactually. Arguments over

37. Leo Treitler has made similar points about the role of notation in medieval music. See Treitler, "Transmission and the Study of Music History," in *Report of the Twelfth Congress, Berkeley 1977*, ed. Daniel Heartz and Bonnie Wade (Kassel: Bärenreiter-Verlag; Philadelphia: The American Musicological Society, 1981), 202–11; and idem, "History and the Ontology of the Musical Work," *Journal of Aesthetics and Art Criticism* 51 (1993): 483–97.

38. Charles Seeger, "Oral Tradition in Music," in *Funk and Wagnalls Standard Dictionary of Folklore, Mythology, and Legend*, ed. Maria Leach and Jerome Fried (New York: Funk and Wagnalls, 1950), 2: 825–29.

39. Nelson Goodman observes that where the score attempts to capture what I have called the "nonessential" aspects of music it ceases to be, in his terms, notational. See Goodman, *Languages of Art*, 183–86.

musical identity (such as those that play out in discussions about the *Urtext* for a score) are arguments about the status and interpretation of artifacts, and any competing account of musical identity must be expressed in artifactual terms.

It bears mention that the authority of notation is not monolithic: most musicians accept notation as something to be interpreted and consider the way it is to be used to create a musical performance a matter for negotiation. And even where notation has been introduced with the explicit intent of eliminating variation within musical practice, it may be circumvented. As Ruth Davis has shown, the modified Western notation applied to Tunisian art music beginning in the 1930s for the purpose of standardizing its melodic tradition has been turned into a creative tool for reinterpreting and redefining that tradition.[40] Notation has thus slowed, but not eliminated, the fluidity of Tunisian musical practice.

Categorization, Musical Ontology, and Cultural Knowledge

By the late 1940s, as we have seen, there were multiple versions of George and Ira Gershwin's "I Got Rhythm" in circulation. There was the show stopper and popular tune from the Broadway musical, the "hot" jazz tune played by any number of dance bands, and the relatively abstract platform for improvisation used as the basis for any number of derived tunes by jazz composers and for extended improvisations by smaller ensembles. Confronted with this multiplicity of "I Got Rhythm"s, how might a listener discriminate between them? Based on what we now know about processes of categorization, we can say that our listener would almost certainly recognize that, while all these versions belonged in the category *performances of "I Got Rhythm,"* not all would represent the category equally well. Depending on the conceptual model around which the category was organized, some versions would be regarded as quite typical of the category, others as less typical, and still others in danger of being excluded from the category altogether. Following Richard Crawford's description of three different approaches to "I Got Rhythm," I proposed three models—the pop-music model, the jazz-standard model, and the improv model—which would yield different interpretations of typicality when applied to a range of performances of the tune. The knowledge represented by such models, when combined with knowledge about musical technique and framed by global conceptual models applicable to an entire repertoire, can also serve as the basis for musical performance within aural traditions. Because they are retained by individual members of a musical community, who may wittingly or unwittingly change the model as they use it, conceptual models are subject to change over time. When such changes are brought to the attention of other members of the musical community, a series of negotiations about what constitutes the model may ensue. At times, changes to conceptual models may be perceived as a threat to the integrity of a musical community, and the community may then seek either to halt or to retard change by placing limits on what can be negotiated.

40. Ruth Davis, "The Effects of Notation on Performance Practice in Tunisian Art Music," *The World of Music* 34 (1992): 111.

Given the various conceptual models we have considered and the ways these models are interpreted and correlated with other types of knowledge, it is clear that the network of knowledge within which any musical work (or similar construct) is embedded is a complex one. And yet we have thus far restricted ourselves to an almost purely musical world. Matters only stand to become more complicated when we contemplate how this world might connect with the cultural context within which musical practice is itself embedded. In the next section, we encounter some of these complications and gain a sense of the richer understanding of musical practice to which they lead, as we explore some of the different ways "Bye Bye Blackbird" was conceived during the middle of the twentieth century.

"BYE BYE BLACKBIRD," SIGNIFYIN(G), AND CULTURAL KNOWLEDGE

On 5 June 1956, Miles Davis, John Coltrane, Red Garland, Paul Chambers, and Philly Joe Jones went into Columbia's 30th Street Studio in New York and recorded three tunes: "Tadd's Delight," "Dear Old Stockholm," and "Bye Bye Blackbird."[41] Although the recording session took place at a time when Davis was actively shaping the sound and repertoire of his quintet, the choice of "Bye Bye Blackbird" was nonetheless somewhat odd. Unlike the other two tunes, "Bye Bye Blackbird" had never been a part of the jazz repertoire, but was simply an upbeat popular song usually played as a foxtrot. Recorded by Davis as a ballad, it acquired a melancholy and an irresistible groove that were thoroughly exceptional.

The choice was made odder still by the racial overtones associated with the tune. First published in 1926, "Bye Bye Blackbird" played a role in the racially charged election campaign for the mayoralty of Chicago in 1927. Big Bill Thompson, a Republican who had successfully cultivated the African American vote to become mayor of Chicago in 1915, returned in 1927 to challenge Democratic mayor William E. Dever. As part of their strategy to fight off this challenge, the Democrats appealed to racial prejudice, voiced specifically through "Bye Bye Blackbird." The ploy ultimately backfired, for it galvanized African American support for Thompson:

> When some of the Dever supporters sent calliopes through the streets piping the strains of "Bye Bye Blackbird," and spreading a circular which displayed a trainload of Negroes headed from Georgia with Thompson as pilot of the train, and the caption: "This train will start for Chicago, April 6, if Thompson is elected," the obvious answer of the colored leaders was: "Elect Big Bill or it's going to be bye-bye blackbirds in Chicago."[42]

41. These three tunes, together with "'Round Midnight," "Ah-leu-cha," and "All of You," were released on Miles Davis, *'Round about Midnight* (Columbia, [CD] CK 40610, 1987), originally recorded 27 October 1955 and 5 June and 10 October 1956. There are extensive transcriptions and a discussion of this recording of "Bye Bye Blackbird" in Berliner, *Thinking in Jazz*; see esp. pp. 678–88.

42. Harold F. Gosnell, *Negro Politicians: The Rise of Negro Politics in Chicago*, with an introduction by James Q. Wilson (Chicago: University of Chicago Press, 1966; originally publ. in 1935, with an introduction by Robert Park, Social Science Studies, 35), 54–55. There is a discussion of a similar cartoon from around the same time that invokes the phrase "Bye Bye Blackbird" in Lloyd Wendt and Herman Kogan, *Big Bill of Chicago* (Indianapolis: Bobbs-Merrill, 1953), 256.

In a similar vein, Jack Chambers reports that during the 1930s, the few African Americans who participated in activities dominated by whites, like the semi-professional National Football League, had the song sung to them by the all-white spectators.[43]

What seems to be reflected in Davis's adoption of the tune is the sort of double-voiced discourse first described by Mikhail Bakhtin: on one level of discourse, Davis's "Bye Bye Blackbird" is an aging pop song, with racial overtones that turn against its performers; on another level, it is a deeply felt rewriting—"felt" both in terms of melancholy and groove—that makes a mockery of the simplistic messages of the song, not least by rising above them. This process of repetition (in the sense of returning to an earlier "text") and revision is associated with a kind of intertextuality Henry Louis Gates Jr. called "Signifyin(g)," which he argued is fundamental and specific to African American rhetorical practice.[44] While Gates's primary focus was on literature, he extended his argument to other domains, music among them, and his arguments have proved compelling to musicologists. Adopting one of Gates's examples, Ingrid Monson was able to show in some detail how John Coltrane's 1960 recording of Richard Rodgers and Oscar Hammerstein's "My Favorite Things" (written in 1959) accomplishes this sort of Signifyin(g). Coltrane's interpretation completely revises the song: the focus is changed from the verse to the interludes, Rodgers and Hammerstein's waltz is transformed into a polyrhythmic extravaganza, and what was an upbeat tune becomes a brooding one.[45]

There is, however, a problem with claiming, in any simple way, that Davis is Signifyin(g) on "Bye Bye Blackbird," and that problem is profiled vividly by a recording of the tune in 1955 by Peggy Lee. In her performance, Lee adopts an exceptionally slow tempo—slower than Davis's—and completely vanquishes the upbeat sentiments of the original song.[46] Lee, too, seems to have engaged in double-voiced discourse, but would we want to say that she is Signifyin(g)? Indeed, this sort of performance practice is so common in jazz—within and without the African American community—that Signifyin(g), present everywhere, would seem to signify nothing.[47]

Two sets of issues, then, are raised by Davis's recording of "Bye Bye Blackbird." First, what is the nature of the double-voiced discourse of Signifyin(g)? Is it in any way distinct from double-voiced discourse as a whole? Second, what part does the reinterpretation of musical works—or, from the perspective developed in the pre-

43. Jack Chambers, *Milestones I: The Music and Times of Miles Davis to 1960* (Toronto: University of Toronto Press, 1983), 237.

44. Henry Louis Gates, Jr., *The Signifying Monkey: A Theory of African-American Literary Criticism* (New York: Oxford University Press, 1988), chap. 2. The parenthetical *g* in "Signifyin(g)" is meant to signal African American pronunciation, as well as to distinguish it from the more general process of "signification"; for discussion, see *The Signifying Monkey*, 46.

45. Monson, *Saying Something*, 106–21.

46. Peggy Lee, "Bye Bye Blackbird," in *Songs from* Pete Kelly's Blues (Decca, [LP] DL 8166, 1955), recorded 6 May 1955.

47. The practice of revisiting the work of other composers and musicians was also common in the music of the previous century: we thus have Beethoven Signifyin(g) on Diabelli in his Op. 120 variations and Brahms Signifyin(g) on Paganini in his Op. 35 variations.

ceding section, revisions to the conceptual model for a musical work—play in Signifyin(g)? In what follows, I begin by developing an approach to double-voiced discourse in terms of a cultural theory of information exchange proposed by the linguist Eve Sweetser. I proceed then to explore some of the conceptual models for "Bye Bye Blackbird" in circulation during the period 1926–1955, and, finally, I return to Davis's interpretation of the tune.

Double-Voiced Discourse and a Cultural Theory of Information Exchange

Mikhail Bakhtin developed his notion of double-voiced discourse with reference to the novels of Dostoevsky, going so far as to claim that this rhetorical mode was essential to Dostoevsky's style.[48] Double-voiced discourse is actually the third of three types of discourse distinguished by Bakhtin. The first type is "direct discourse," which is essentially the unmediated disquisition of the author. The second type Bakhtin called "objectified" or "represented discourse"; its most common form is the direct speech of characters. In "double-voiced discourse" (the third type), the author takes the direct discourse of someone else and infuses it with the author's own intentions and consciousness while still retaining the original speaker's intentions. Thus two discourses and two consciousnesses are present at the same moment.[49]

With this taxonomy in place, Bakhtin further distinguished three types of double-voiced discourse. In the first, the discourse of the author and that of the other person essentially cooperate—the author inflects, but does not substantially change, the discourse of the other person. The second type of double-voiced discourse is associated with parody and irony (this is essentially the sort of discourse Monson deals with in her analysis of Coltrane's "My Favorite Things"). Here the discourse of the author is opposed to that of the other person; as Bakhtin puts it, "the second [that is, authorial] voice, once having made its home in the other's discourse, clashes hostilely with its primordial host and forces him to serve directly opposing aims. Discourse becomes an arena of battle between the two voices."[50] In the third type of double-voiced discourse, the other person's discourse remains outside the purview of the author's, which nonetheless becomes influenced by that of the other person. The result is often a hidden polemic: the author's discourse represents a reaction to the discourse of the other person, but the latter can be heard only by implication—it is never directly represented.

Each of these three types of discourse—and, most important, the three types of double-voiced discourse—can be analyzed with reference to a cultural theory of

48. Mikhail Mikhailovich Bakhtin, *Problems of Dostoevsky's Poetics*, ed. and trans. Caryl Emerson, with an introduction by Wayne C. Booth, Theory and History of Literature, 8 (Minneapolis: University of Minnesota Press, 1984), chap. 5.

49. The premise of double-voiced discourse is that the two domains of discourse remain separate and identifiable; it is thus different from the process of conceptual blending discussed previously in chap. 2 (in that blending is concerned with how elements from two distinct domains come together in a third domain), but it may be seen as a related phenomenon.

50. Bakhtin, *Problems of Dostoevsky's Poetics*, 193. I shall follow Bakhtin's practice and speak of the first voice in double-voiced discourse as that of the "other" and the second voice as that of the author.

information exchange developed by Eve Sweetser. Sweetser used the theory to explain the results of an experiment by Linda Coleman and Paul Kay that was designed to show that the English word "lie" (in the sense of "to prevaricate") functioned like a Type 1 category. That is, rather than following a clear-cut definition, some statements were regarded as typical lies, others as atypical. Coleman and Kay hypothesized that a statement is judged to be a more-or-less good example of a lie on the basis of three conditions. First, the actual statement must be false (a condition that is commonly taken as necessary and sufficient when "lie" is construed as a Type 2 category). Second, the speaker must believe the statement to be false. Third, in uttering the statement, the speaker must intend to deceive the listener.[51] To test this hypothesis, Coleman and Kay constructed eight stories that satisfied all, only some, or none of these conditions. They then asked sixty-seven subjects to determine whether, in the case of each story, a lie had been told. In support of their hypothesis, the results indicated that "lie" functioned as a Type 1 category: judgments of what constitutes a "lie" were not made comprehensively, but, rather, could be made by degree.

Although they were able to prove their hypothesis, Coleman and Kay were not able to explain satisfactorily what it was about the word "lie," or about the conditions surrounding its proper use, that made it function as a Type 1, rather than as a Type 2, category. Sweetser, for her part, proposed that judgments about lies were made relative to a cultural theory of information exchange.[52] The theory, as formulated by Sweetser, consists of three relatively straightforward propositions, which can be stated as rules:

1. *Try to help (do not harm).* This rule is combined with the belief that knowledge is helpful and that misinformation is harmful (which leads to the next rule).
2. *Give knowledge (do not misinform).* Sweetser argues that what counts as knowledge, in everyday terms, is what we believe. All things being equal, we assume that what we believe matches some state of affairs or possible state of affairs: we take what we believe to be true, to count as knowledge. Using this understanding of knowledge together with (1) and (2), we arrive at the final rule.
3. *Say what you believe (do not say what you do not believe).* If what we believe counts as knowledge, and if we wish to be helpful, we must give knowledge.

This chain of entailments represents a cultural theory of information exchange that allows us to reach the somewhat surprising conclusion that if a speaker (S) utters a

52. Eve E. Sweetser, "The Definition of *Lie*: An Examination of the Folk Models Underlying a Semantic Prototype," in *Cultural Models in Language and Thought*, ed. Dorothy Holland and Naomi Quinn (Cambridge: Cambridge University Press, 1987), 43–66. Sweetser's "models" have the same function as the theories described in chap. 3; I have simplified some aspects of her account in the interests of concision.

proposition (P), then that proposition is true. The causal chain can be represented schematically:

a. *S said P.* [as part of an information exchange; from rules (1) and (2)]
b. *S believes P.* [(a) combined with rule (3)]
c. *Therefore, P is true.* [(b) combined with the understanding that we believe what is true and do not believe what is false]

This is, without a doubt, a greatly simplified perspective. What is important is that the model of information exchange set out by the theory works quite a bit of the time, and when it does not work, the theory provides a way to interpret where things went wrong.

To illustrate, let us consider two situations. In the first, I claim that I saw a friend of mine walking down the street. On closer inspection, it turns out to be someone who just looked like my friend. According to the simplest definition, my claim is a lie—a statement that is not true. However, since my behavior as a whole fits with the cultural theory of information exchange (my intent was to provide helpful information), my claim will most likely not be judged a lie. In the second situation, I see someone walking down the street whom I mistake for my friend. Remembering that I owe my friend money and being a cheap sort, I claim that the person I see is not my friend. According to the simplest definition, this is not a lie, since my claim is true: the person walking down the street is not, in fact, my friend. Nonetheless, since I deliberately said what I thought to be misinformation, I have violated the theory of information exchange and my claim might well be judged a lie.

Of course, this straightforward theory of information exchange does not operate in isolation but is interpreted through other cultural theories to explain types of discourse that seem to contravene the theory. Jokes, tall tales, and fiction all may have limited truth-value, but their "lies" are permitted as part of a cultural theory that interprets certain types of exceptional behavior as entertainment. Social lies are based on the recognition that not all forms of knowledge are helpful: rarely when someone remarks "How are you?" do they really want to know how we are. The cultural theory of information exchange is thus filtered through a theory that says maintaining social order through polite behavior is more important than saying what you believe to be true.[53]

Applying Sweetser's example of a cultural theory of information exchange to Bakhtin's first two types of discourse is relatively straightforward. All things being equal, we assume that direct discourse—the voice of the author—involves the truth; we similarly give the benefit of the doubt to the objectified discourse of the author's characters.[54] With double-voiced discourse, however, the application of the

53. For a related view of how information exchanges contribute to and constitute social order, see Michael B. Bakan's account of how various Balinese musicians reported the results of a gamelan competition in *Music of Death and New Creation: Experiences in the World of Balinese Gamelan Beleganjur*, Chicago Studies in Ethnomusicology (Chicago: University of Chicago Press, 1999), chap. 5.

54. The genre of fiction, which is the focus of Bakhtin's analysis, requires an intriguing nesting of theories about information exchange. On the level of everyday life, fiction is generally recognized as nonfactual (except by the delusional). Within a given work of fiction, however, we usually apply the theory of information exchange outlined by Sweetser: we assume that characters say what is true in the con-

theory is a bit more complicated. With the first type of double-voiced discourse—where the discourse of the author and the other person essentially cooperate—the idea that both voices speak the truth is easily accommodated. What results is a sort of heterophony of discourse: two voices saying the same thing in different ways. With the second and third types—parody and hidden polemic—the contradictions and tensions between the two voices suggest that one of the voices must be violating the principles of the cultural theory of information exchange. The traditional resolution of the problem, implicit in Bakhtin's analysis of discourse as a whole, is that in double-voiced discourse, the voice of the author is to be privileged: it is the voice of authority.[55] This resolution requires modification of Sweetser's cultural theory of information exchange by the addition of one further proposition:

4. *The voice of authority is always helpful.*

On the one hand, it is difficult to ascribe this interpretation to Bakhtin without a crushing sense of irony, given his personal history. But on the other hand, it is certainly the case that, in his analyses of double-voiced discourse, the "first" (nonauthorial) voice is the one he most often distrusts.

Given this analysis, equating Gates's notion of Signifyin(g) with Bakhtin's double-voiced discourse brings us to two conclusions. First, the voices of black rhetoric become voices of authority: they are the helpful voices that speak the truth. Second, Signifyin(g) is by no means unique to the African American community—indeed, Dostoevsky and countless other "authors" are also Signifyin(g). But these conclusions are hardly satisfying, for they trivialize the points Gates wishes to make about African American literature and culture and miss the ways language can be used against oppressors.

The solution to these problems lies in two important adjustments to the cultural model of information exchange adumbrated here. First, a distinction must be made between "author" and "authority." For the African American community, the first voice in double-voiced discourse was almost always the voice of "authority." Since experience had shown that the voice of authority was almost always unhelpful, it was a voice to be distrusted. Rather than trusting one of the voices of a double-voiced discourse, it was important actively to distrust one of those voices; by default, the nonauthoritative voice of the author was to be regarded as the helpful one. Second, it did not particularly matter if the statements of the author were true or not. Indeed, as Gates points out, one of the common African American terms for Signifyin(g) is "lies."[56] What mattered more was whether the author, in some way, adhered to the first principle of information exchange: to be helpful. And it is clear that, to an oppressed people, speech that co-opts, mocks, or indirectly challenges the voice of authority, whether the statements made in the course of that speech are

---

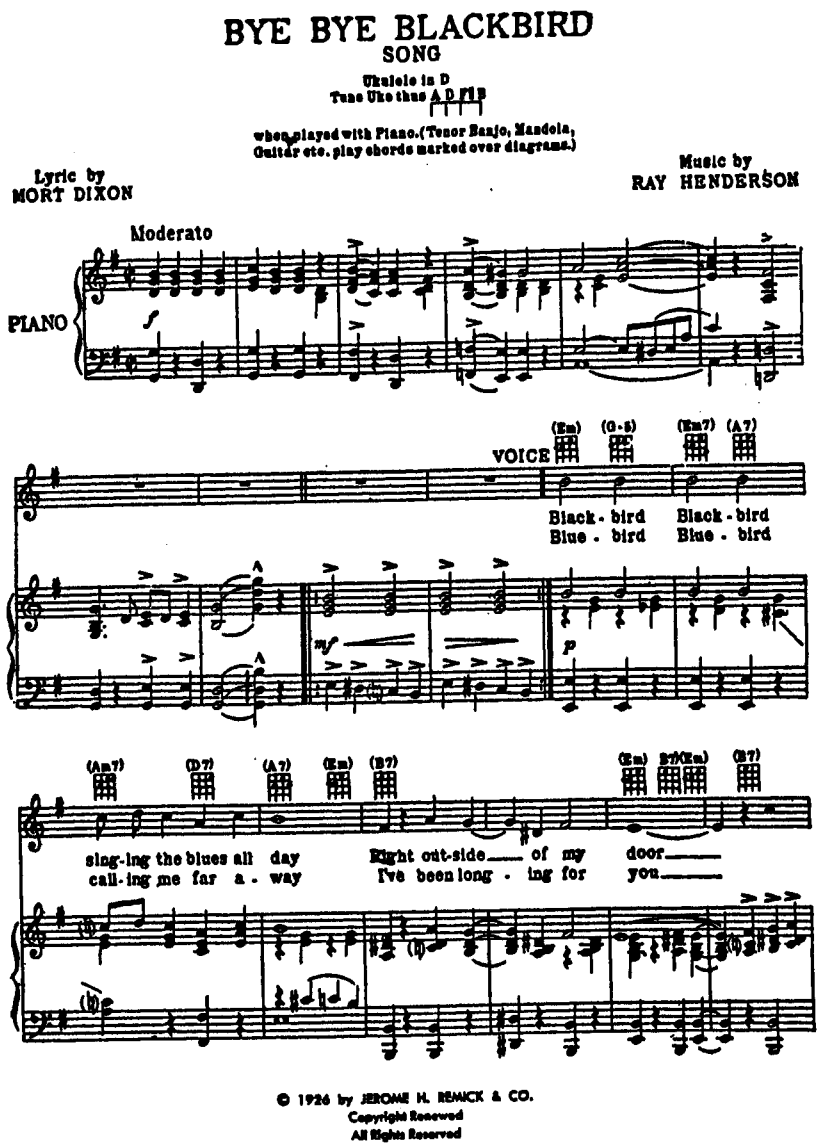
text of the story. When a character says something that is not true within the context of the story (even though it may be true in the everyday world), we then have to fall back on this theory or its elaborations to make sense of the utterance.

55. The pun is not surprising, since "authority" and "author" share the same Latin root (*auctor*).

56. Gates, *The Signifying Monkey*, 56, 71.

true or not, is singularly helpful. With these adjustments, distinctions between double-voiced speech and Signifyin(g) become clear: Signifyin(g) relies on a modified theory of information exchange that assumes that the first voice in double-voiced discourse is the voice of an extracultural authority and that this authority is not to be believed. Under these circumstances, double-voiced discourse is, as Bakhtin characterized it, "an arena of battle between the two voices." However, it is an arena in which the author is at a distinct disadvantage and must rely on whatever combination of truths, half-truths, and lies is necessary to win the day.

My intent with this analysis is to show how Bakhtin's notion of double-voiced discourse functions relative to a highly simplified, yet quite serviceable, rendering of a cultural theory of information exchange and how the double-voiced discourse of Signifyin(g) relies on a modified version of this theory. In applying this perspective on discourse to music, I restrict my discussion to the level of the conceptual model for a work. Musical discourse, understood in this way, is thus concerned with the realization and projection of the conceptual model for a work. In terms of the cultural theory of information exchange (extended to music), our assumption is that the performer intends to project this model and that it is valid for the piece. My decision to impose this restriction is based on practical reasons. It will keep discussion focused on the main topics of this chapter, it will greatly simplify the analyses, and it requires no strong analogy between linguistic and musical discourse. There is, however, no reason that, mutatis mutandis, this treatment could not be extended to more finely grained levels of musical discourse.

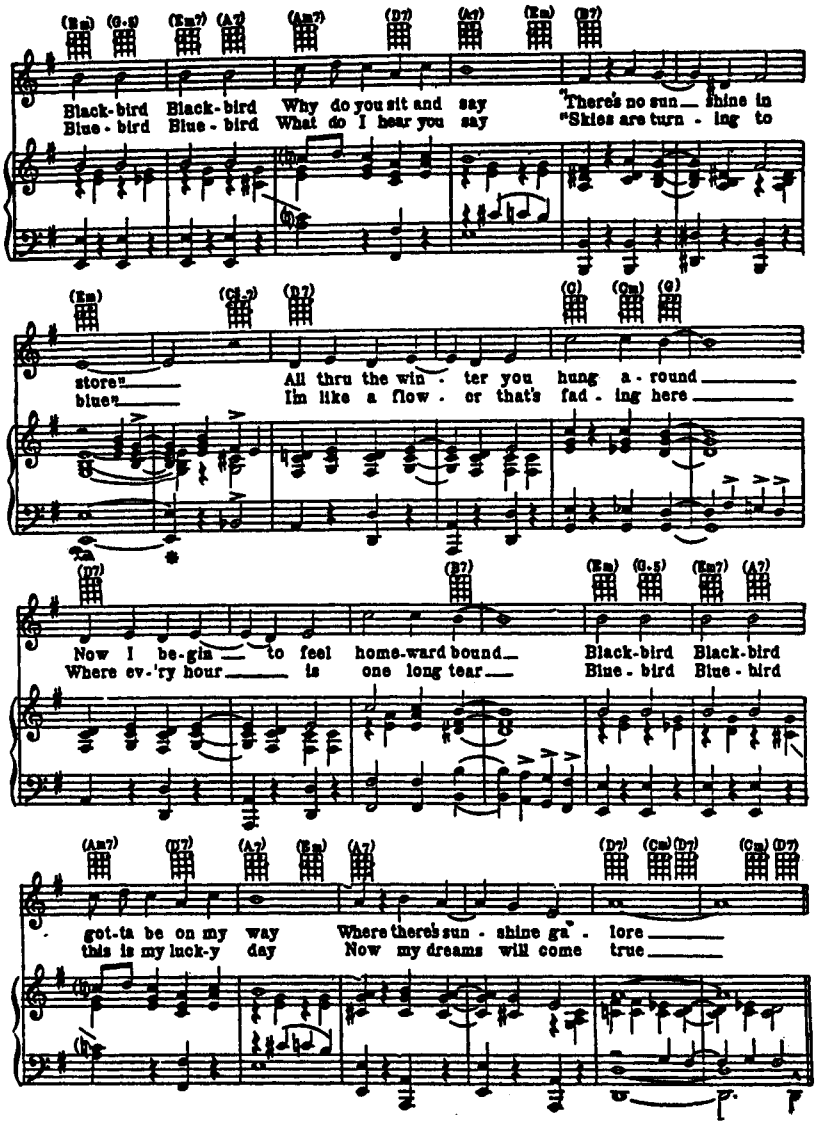


Conceptualizing "Bye Bye Blackbird," 1926–1955

"Bye Bye Blackbird" was written in 1926 by the song-writing team of Mort Dixon and Ray Henderson. The score, given in example 5.4, reveals a song typical of the thousands written during the days of Tin Pan Alley. It consists of an eight-measure introduction (taken from the concluding phrase of the refrain); a two-measure vamp to allow the vocalist to get ready; a thirty-two-measure verse in AABA' form; and a thirty-two-measure refrain in AA'BA" form (where A' presents the material of the A section a diatonic step higher, and A" changes the original A section at midphrase so that it ends on the tonic).[57]

The general topic of the song centers around a narrator in alien or unhappy surroundings, symbolized in the first verse by the trope of winter, the blackbird's doleful pronouncements, and the use of minor mode. The narrator rejects these conditions and looks to where "there's sunshine galore," a promise held out by the refrain: a waiting loved one, a familiar bed, and a light burning in the window, all intro-

57. At least two other scores for "Bye Bye Blackbird" have been in circulation. Both of these are in F major, and both shorten the verse to a sixteen-measure form by omitting the internal AB sections. One score, with the copyright renewed and assigned to the Remick Music Corporation, has a short, four-measure introduction; the sixteen-measure verse; and the refrain. The other, copyrighted in 1948 by the Remick Music Corporation, was printed by Francis, Day and Hunter, London. It gives the refrain first, followed by the introduction and verse. I have found no recordings of performances based on either of these scores.

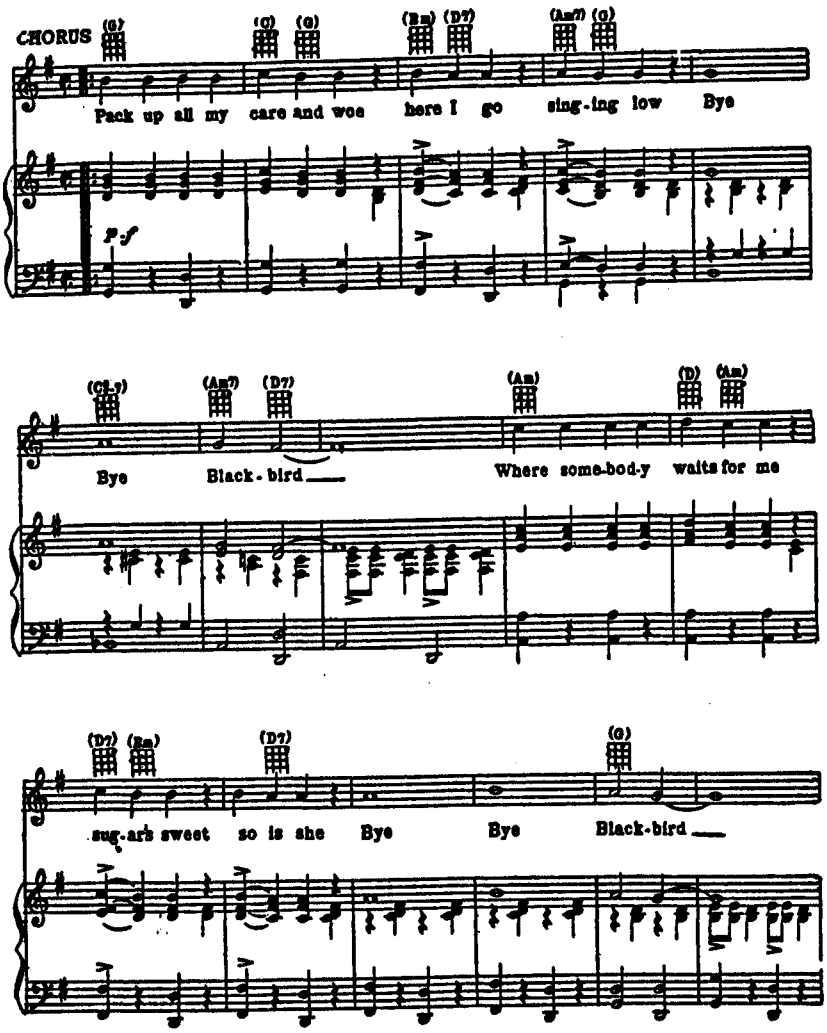


EXAMPLE 5.4 Ray Henderson and Mort Dixon's "Bye Bye Blackbird," © Fred Ahlert Music Group

duced against the backdrop of a sprightly G major. The second verse (which replaces the blackbird with a bluebird) reflects the hope offered by the refrain, conditioned nonetheless by the return to minor mode and references to longing, fading like a flower, and hours that are like "one long tear."

Recordings of the period indicate typical treatments of the song. In their version of 22 April 1926, for example, Bennie Krueger's Orchestra begins with a short introduction (which bears no resemblance to the published one) and proceeds to an

EXAMPLE 5.4 *(continued)*



(continued)

instrumental version of the refrain, verse, and refrain.[58] (As with the early recordings of "I Got Rhythm," the Krueger arrangement uses the verse as an interlude between the refrains.) This is followed by a sung refrain and one final instrumental refrain. The tempo of the recording (♩ = 116–120) is a bit faster than the "Moderato" indicated by the score, but it is perfectly suitable for a foxtrot.[59] Gene Austin's

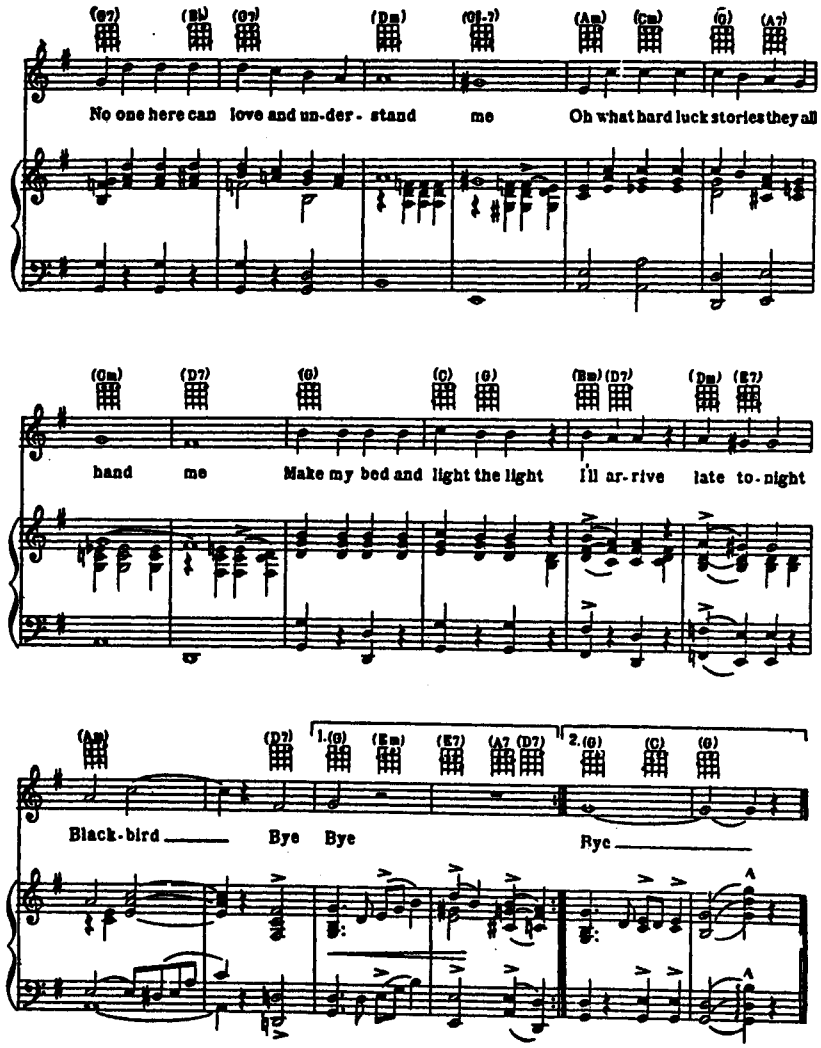
59. The song is in fact identified as a foxtrot on the label of the record, which also includes the rubric "for dancing."



EXAMPLE 5.4 *(continued)*

recording, made a week later, follows the score rather more closely.[60] Although he adds his own introduction and piano accompaniment and varies the melody in the third phrase of the verse, his performance otherwise conforms to the score given in example 5.4, even adhering to a somewhat slower tempo than did Krueger's group (♩ = 96–100). By most standards, "Bye Bye Blackbird" was a hit: it was recorded at least fourteen times between March and June of 1926, and Austin's recording was no. 1 on the *Billboard* charts of 4 September of that year.

60. Gene Austin, "Bye Bye Blackbird" (Victor, [78] no. 20044-B, 1926), originally recorded 29 April.

EXAMPLE 5.4 *(continued)*

The various performances of "Bye Bye Blackbird" recorded in 1926 could be collected into a category organized around a conceptual model quite similar to that used for early versions of "I Got Rhythm." The model, which is diagrammed in figure 5.5, consists of five correlated conceptual elements, characterized as the things necessary for an adequate performance of the song. However, where the pop-music model for "I Got Rhythm" continued to have some currency in the years just after the first appearance of the song (in part because of its association with the musical), the model for "Bye Bye Blackbird" appears to have gone dormant for a

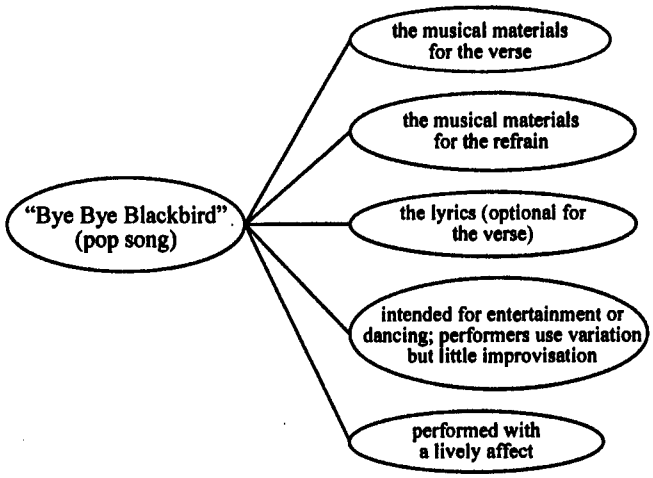


FIGURE 5.5 Model for the category *performances of "Bye Bye Blackbird"*

time: there are few signs of the song having been recorded after 1926 and throughout the 1930s.[61]

New recordings of "Bye Bye Blackbird" did begin to appear in the 1940s. There are a number of indications, however, that by then the conceptual model for the song had changed. The "novelty" recording by Freddie "Schnickelfritz" Fisher and His Orchestra (made on 22 February 1941), with its rapid succession of unlikely instruments (including solo whistling and baritone saxophone) and its "shave-and-a-haircut" ending, is just short of an all-out joke.[62] In a 1941 German propaganda recording by Charlie and His Orchestra, the words of the song are altered to celebrate early Axis victories in the Second World War and to taunt the British ("Bye Bye Blackbird" becomes "Bye Bye Empire").[63] And in a tribute to the songs of 1926 recorded on 27 May 1942 by the piano duo of Marlene Fingerle and Arthur Schutt, "Bye Bye Blackbird" is the final song in a medley that includes "I Know That You Know" and "Baby Face."[64] In each of these recordings, only the refrain of the song is used, and the tempo varies from the moderate swing of Charlie and His Orchestra (♩ = 84) to the Fisher Orchestra's foxtrot (♩ = 120–126). While there are some signs the song has entered the repertoire of "standards"—its verse has

61. Recording, of course, is not the only measure of popular interest in a song: sales of records, piano rolls, and sheet music; programming of the song in live performances; and the playing of recordings on radio broadcasts and in juke boxes would also provide an indication of continued interest in the song. Unfortunately, no information on these indicators is presently available for "Bye Bye Blackbird."

62. Freddie "Schnickelfritz" Fisher and His Orchestra, "Bye Bye Blackbird" (Decca, [78] no. 25357/3788, 1941).

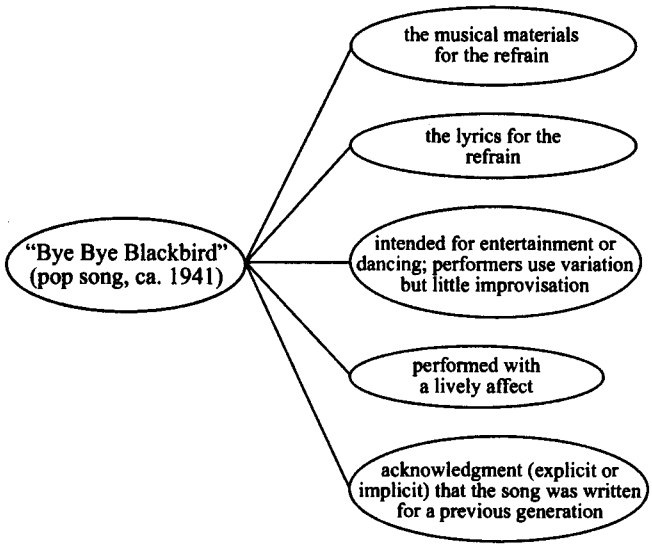

FIGURE 5.6 Model for the category *performances of "Bye Bye Blackbird," ca. 1941*

fallen away, and it is readily available for parody—it is also clearly marked as an "old" song. The conceptual model for the category *performances of "Bye Bye Blackbird," ca. 1941*, then, would consist of five correlated conceptual elements (which are diagrammed in fig. 5.6).[65]

As a consequence of a growing interest in the 1920s as an era, this model was, if anything, reinforced during the post–World War II period. Following the phenomenal success of *The Jolson Story* in the fall of 1946, Warner Brothers films contracted in 1947 for the filming of a similar story with (and about) Eddie Cantor. Although Warner Brothers ultimately dropped the project, Cantor and Sidney Skolsky (producer of *The Jolson Story*) eventually filmed *The Eddie Cantor Story* independently, and it was released in 1953.[66] As part of the soundtrack for the movie, Cantor recorded "Bye Bye Blackbird" in something approximating the style of the 1920s, although using only the refrain of the song.[67] A similar approach can be heard in

65. I do not mean to suggest, with the idea that "Bye Bye Blackbird" was "written for a previous generation," that the fifteen years between 1926 and 1941 actually fill the span of a human generation. However, I do think this period is long enough to mark a significant change in popular tastes, which is what this portion of the conceptual model aims to capture.

66. Herbert G. Goldman, *Banjo Eyes: Eddie Cantor and the Birth of Modern Stardom* (New York: Oxford University Press, 1997), 283–84.

67. Eddie Cantor, "Bye Bye Blackbird," in *Songs by Eddie Cantor from* The Eddie Cantor Story (Capitol, [LP] L-46, 1954). There is no evidence that Cantor recorded "Bye Bye Blackbird" during the 1920s or 1930s, although he might well have performed it in live shows; in fact, Goldman characterizes it as one of the standards of Cantor's repertory from the 1920s. By most accounts, *The Eddie Cantor Story* was a flop; its failure is generally attributed to the inadequacies of Keefe Brasselle (who played the role of Cantor) and to a script that was little more than a remake of *The Jolson Story*. Of the soundtrack, however, Goldman writes: "The musical arrangements were first rate, and the vocals better than might be

Johnny Maddox's recording of the song on piano (accompanied by a rhythm section), released in 1955, which interprets it in a quasi-ragtime style as part of a collection of 1920s songs intended to accompany tap dancing.[68]

During this same period the general fascination with the character and music of the 1920s was given a specific focus when there was a resurgence of interest in early jazz, variously called "New Orleans" or "Dixieland" jazz.[69] Partly, this came about because of a strike by musicians against the recording industry from 1942 to 1944, which led record companies to reissue older recordings. Around the same time, there emerged an audience who felt the swing era had passed but who were not attracted to be-bop, the new jazz style that emerged during the Second World War. In 1950, the actor Jack Webb (now chiefly remembered for his role as Sergeant Friday on the *Dragnet* radio and television series) developed a radio series around a jazz musician in 1920s Kansas City, reflecting contemporary interest in the "roaring 20s" and Webb's own enthusiasm for early jazz.[70] The radio series was eventually developed into the movie *Pete Kelly's Blues*, which Webb directed and in which he also starred. In the movie, Pete Kelly is a bandleader threatened by a gangster who is attempting to extract protection money from musicians. Kelly initially tries to resist but eventually capitulates. As part of his agreement with the gangster, Kelly's band has to take on the gangster's girlfriend, Rose Hopkins (played by Peggy Lee), as a singer. Rose is an alcoholic but can still render a moving ballad. A tragic character, Rose is eventually reduced to the mentality of a five-year-old by alcoholism and by a beating from the gangster.

As part of the promotion of *Pete Kelly's Blues* as a "jazz" movie, Lee, together with Ella Fitzgerald (who played a blues singer working in a roadhouse), recorded an album of songs associated with the movie on 10 May 1955. Although "Bye Bye Blackbird" appears in the movie, neither Lee nor Fitzgerald sings it. Instead, it is rendered by a drunken chorus of band members returning from a late-night party. On the album, Lee retains Rose's persona from the movie and sings the song (consisting only of the refrain) as a slow ballad (♩ = 72–76), with slight allusions to Billie Holiday's distinctive style of inflection.[71] The arrangement makes use of complicated harmonies typical of the treatment of ballads in 1940s and 1950s jazz and

---

expected, considering that Cantor had suffered a major heart attack less than three months earlier and that his voice had lost its former brilliance after World War II." Goldman, *Banjo Eyes*, 284.

68. Johnny Maddox, "Bye Bye Blackbird," in *Tap Dance Rhythms* (Dot, [LP] DLP 3008, 1955).

In the following I refer to this style of jazz as "traditional" jazz, retaining the quotation marks to highlight the function of the term as a rubric rather than a judgment about the place of this music within any historical account of jazz styles. See also Bernard Gendron, "'Moldy Figs' and Modernists: Jazz at War (1942–1946)," in *Jazz among the Discourses*, ed. Krin Gabbard (Durham, N.C.: Duke University Press, 1995), 31–56.

70. Charles Emge, "Meet 'Jazzman' Jack Webb: Swing Era Helped Make Him Music-Conscious," *Downbeat* 22 (10 August 1955): 8.

71. The character of Rose seems to have had a profound personal effect on Lee. In her autobiography, she speaks of Rose in the third person, speculates on whether a visit from James Dean was intended for her or for Rose, and writes of "moving out of Rose's trailer [on the set]" once the film was completed. See Peggy Lee, *Miss Peggy Lee: An Autobiography* (New York: Donald I. Fine, 1989), 165–67.

adds words for the second pass through the refrain that signal a new perspective on the song:

A while ago when I was young, I heard a song and heard it sung
[male chorus sings as distant echo] Bye bye blackbird
I don't know why it makes me sad, a happy song should make me glad
[male chorus] Bye bye blackbird

Singing in her persona as a dissolute, tragic chanteuse, Lee evokes a melancholy that, up to this point, had not been associated with "Bye Bye Blackbird."

Pete Kelly's Blues was, at best, a mixed success critically, and Lee's treatment of "Bye Bye Blackbird" might well have been forgotten (especially since she did not sing the song in the movie). Fate, however, intervened: the singer and pianist Bobby Short heard and liked Lee's recording and decided to approach "Bye Bye Blackbird" in a similar fashion, finding reflective sadness in the refrain rather than joyful anticipation.[72] In his recording of 15 September 1955, Short also adopts a slow ballad tempo (♩ = 84) and fashions his accompaniment out of rich, progressive harmonies. To provide an introduction, he starts with the B section of the refrain, the one section that retains the sense of alienation generated by the original verse: "No one here can love and understand me . . ." The effect is to cast a shadow over the remaining lyrics of the refrain, emphasizing what is negative in them—the narrator's care and woe, distant loved one, and need to travel late into the night—rather than the pleasant things that wait at home. Short also adds his own lyrics for the second pass through the refrain (with words adapted from the song "I'm a Little Blackbird Looking for a Bluebird"):[73]

I've been all over the east and the west, in search of clover to feather my nest,
Bye bye blackbird
I have a daydream the same as you do, why would a daydream have to be hoo-doo?
Bye bye blackbird
No one here can love and understand me,
Oh, what hard luck stories they all hand me. (etc.)[74]

With these two recordings by Lee and Short, "Bye Bye Blackbird" was transformed from an upbeat popular song in a fast tempo, designed for dancing—a "hop" tune, as Short has called it[75]—into a melancholy jazz ballad in a slow tempo, designed for listening. The motivation for this change was not, strictly speaking, musical, for most of the music in *Pete Kelly's Blues* kept to a "traditional" or Dixieland style.[76] Instead, the change was initially motivated (that is, in Peggy Lee's

72. Personal communication from Bobby Short, 8 March 2000.

73. "I'm a Little Blackbird Looking for a Bluebird" was written by Clarke Grant, Arthur Johnston, George W. Meyer, and Roy Turk. It was recorded by both Louis Armstrong and Sydney Bechet in the mid-1920s.

74. Bobby Short, "Bye Bye Blackbird," in *Bobby Short* (Atlantic, [LP] 1230, 1956), recorded 15 September 1955. As will be noted, Short's revised lyrics return to Dixon's original refrain at midpoint (with, "No one here can love and understand me").

75. Personal communication from Bobby Short, 8 March 2000.

76. The soundtrack for the movie (with priceless narrations by Jack Webb) consisted exclusively of

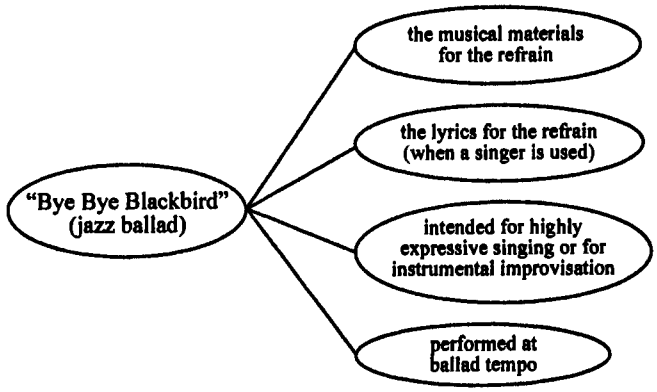

FIGURE 5.7 Jazz ballad model for the category *performances of "Bye Bye Blackbird"*

recording) by a romanticized notion of the female jazz singer, itself derived from any number of nineteenth-century fantasies about performers.[77]

The new conceptual model for "Bye Bye Blackbird" suggested by Lee's and Short's recordings, and diagrammed in figure 5.7, consists of four elements necessary for an adequate performance. Gone is the sense of history that had freighted approaches to the song since the early 1940s; it is replaced by a sense of immediacy generated by the necessarily reflective nature of the performances.

It may be useful at this point to consider differences in the way conceptions of "I Got Rhythm" and "Bye Bye Blackbird" changed over roughly the same period in time. Because "I Got Rhythm" was an enduring part of the popular music and jazz repertoire, its conceptual model changed only gradually, through a process of slow but relatively constant negotiation. In contrast, no such process is in evidence for "Bye Bye Blackbird." After its first blossoming, the tune, and its conceptual model, faded from popular consciousness. When it was recalled during the early 1940s, it was as part of a larger process of revisiting, through music, an earlier era: "Bye Bye Blackbird" was simply emblematic of "a popular tune from the 1920s." When Peggy Lee introduced her version, the change to the conceptual model was sudden and dramatic, by fiat of her character in the movie.

"traditional" arrangements. See "Pete Kelly and His Big Seven" (Matty Matlock and others), *Pete Kelly's Blues* (BMG Special Products, [CD] DRC12081, 1998), originally recorded 7, 9, 11 June 1955.

77. For a recent, and stimulating, discussion of some of these fantasies, see Susan Bernstein, *Virtuosity of the Nineteenth Century: Performing Music and Language in Heine, Liszt, and Baudelaire* (Stanford, Calif.: Stanford University Press, 1998), chap. 3.

My characterization of the persona developed by Lee in connection with *Pete Kelly's Blues* should not obscure the powerful presence of African American women who sang the blues and jazz, or the very real trials to which these women were subjected. (For a discussion of the role of these women in shaping the blues in particular, see Susan McClary, *Conventional Wisdom: The Content of Musical Form* [Berkeley: University of California Press, 2000], 42–49.) I do believe, however, that Lee, as a white entertainer in the United States of the 1950s, was able to choose this persona (much as she chose to emulate Billie Holiday's voice in the course of her performance of "Bye Bye Blackbird") and that part of the framework for this choice was a romanticized notion of the suffering performer.

Thus by the end of 1955 there were two conceptual models for "Bye Bye Blackbird" in circulation. The first conceptualized the tune as a somewhat dated but nonetheless upbeat pop song; the second conceptualized the tune as a slow, melancholy ballad. There may have also been still circulating a third, and more sinister model, derived from the first, that interpreted the song in racial terms—a signal for African Americans to be on guard, that they were not wanted here. It was into the context provided by these models that Miles Davis introduced his version of "Bye Bye Blackbird."

Davis's "Bye Bye Blackbird," Double-Voiced Discourse in Music, and Signifyin(g)

The recording that Davis made with Garland, Chambers, Jones, and Coltrane was strictly instrumental, at a tempo slower than the "hop" version of the tune (♩ = 120), but notably faster than the tempos adopted by Lee and Short. After a brief introduction by Garland, Chambers, and Jones that establishes a loose, almost loping, groove, Davis enters playing the refrain. From his first notes, Davis announces the song as a jazz ballad, using a languid approach to the melody and muted trumpet to create an understated, slightly distant reflection on the song. After the head, Davis takes two choruses, followed by two choruses from Coltrane that occasionally hint at a double-time feel. Garland takes a chorus and a half, and, at the bridge of Garland's second chorus, Davis reenters with the melody and guides the performance to a conclusion.

Davis's principal contributions are to infuse "Bye Bye Blackbird" with an irresistible groove and to establish it as a venue for instrumental commentary and expansion. Although these contributions are by no means insignificant—Davis's recording virtually established "Bye Bye Blackbird" as a jazz standard, something it had never been before—one can also hear the influence of Lee's and Short's recordings in his version. There is, obviously, the slower tempo and hint of melancholy adopted from the jazz-ballad model (although the groove Davis sets up tends to move the tune back toward the pop-music model). There is also, however, the same sense of immediacy that marked Lee's and Short's performances: "Bye Bye Blackbird" is not, in Davis's hands, about nostalgia.[78] Davis has modified the conceptual model for the tune used by Lee and Short, but he has also retained enough of it that we can still recognize its main elements.

The immediate relationship between the jazz-ballad model for "Bye Bye Blackbird" and the model Davis set out in his recording suggests that double-voiced discourse can be accomplished in music when one conceptual model for a musical work is understood to make reference to another conceptual model for the same

78. The element of nostalgia has continued to cling to "Bye Bye Blackbird" as a popular tune (as distinct from a jazz standard) and has been exploited in a number of films. In Jonathan Demme's *Melvin and Howard* (1980), "Bye Bye Blackbird" is the one song Howard Hughes is able to recall when Melvin Dummar presses him—on pain of being thrown out of Dummar's truck—to sing something, and it becomes a deeply felt recollection of Hughes's childhood. In Nora Ephron's *Sleepless in Seattle* (1993), "Bye Bye Blackbird" is cast as the song the boy's deceased mother used to sing to him when he couldn't sleep.

work. If we know Peggy Lee's recording of "Bye Bye Blackbird," hear Miles Davis's, and understand the latter as making reference to the former, musical double-discourse takes place.[79] Musical double-discourse thus requires, minimally, a listener who knows at least two conceptual models for a given work. Connections between the models may be drawn out by the performer, but they may be more oblique and constructed mostly by the listener. Each of the three types of double-voiced discourse described by Bakhtin can be created: an inflection of the first conceptual model by the second (which is what Davis does); a parody of the first conceptual model by the second (which is what Monson describes Coltrane as doing); or tacit reference to the first model by the second (which is one way to conceive how derived tunes operate).

But what of Signifyin(g)? Signifyin(g) would require that the first conceptual model be recognized as the "authoritative" one and that its authority is not to be believed: that is, it is not a valid model for the work. Validity is then granted by default to the conceptual model used by the performer. A consequence is that the validity of this model depends on the rejection of the model associated with authority; it is not granted independently. Under these circumstances, a case can be made that, in his recording of "My Favorite Things," Coltrane is Signifyin(g) on Rodgers and Hammerstein's song: the validity of the Broadway-show-tune model for this song has been rejected, and it is Coltrane's model of the tune that is accorded validity. It is much less clear, however, whether Davis is Signifyin(g) on "Bye Bye Blackbird." It is difficult to ascribe authority of a sort that one should be skeptical of to either Lee's or Short's recordings, and it is unclear whether Davis was aware of, or cared about, the pop-music model for the tune (with or without its overlay of racism). This does not mean that a listener might not hear the recording by Davis as Signifyin(g) on "Bye Bye Blackbird," only that the relationship of Davis's rendition of the song to the concept of Signifyin(g) is much more equivocal.

Under what circumstances might we hear Davis as Signifyin(g) on "Bye Bye Blackbird"? First, Davis could, in the course of a performance (recorded or otherwise), make an obvious reference to one of the earlier models for the tune, perhaps by playing a fragment of the verse or by evoking another nostalgic tune from the 1920s. The other model for "Bye Bye Blackbird" would thus be brought to our attention (even if only as something anomalous in Davis's performance) to be then regarded as a voice of authority under challenge. Second, we could bring to Davis's performance a knowledge or awareness of one of the earlier models, hear that he reverses certain of the key elements of this model, and interpret this as subverting authority. Third, Davis could, through either word or deed, situate himself as in dialogue with what he regarded as an authoritative version of the tune.

With this analysis of Davis's recording of "Bye Bye Blackbird" I do not mean to suggest that Signifyin(g) is a rare occurrence in music, but only that it involves a complex matrix of cultural knowledge and that the listener must understand the process of Signifyin(g) as taking place. When this matrix of knowledge is not in place, what may be left to hear is only double-voiced discourse, or unmediated

79. Although my focus here is on recordings, the same situation would obtain were our experience with live, as opposed to recorded, performances.

authorial discourse. (Indeed, all music could be heard as involved in double-voiced discourse of a quite general kind, in that the conceptual model for each work is in dialogue with the conceptual models for other works.) Double-voiced discourse, as well as Signifyin(g), becomes interesting when tensions between the models become obvious—that is, when the tensions become as important as the models themselves.

Signifyin(g) and Cultural Knowledge

Given the cognitive complexity of the process of Signifyin(g), it is well worth asking why the notion has become a trope among those who work on jazz and popular music. Three reasons come to mind. First, Signifyin(g) offers a clear alternative to the Saussurean model of meaning construction: in Signifyin(g), meaning is something that is not fixed but is created by the listener.[80] Second, Signifyin(g) provides a way of interpreting the cultural practice of jazz and popular music in terms developed to account for the unique profile of one of its most important influences, African American culture. Third, applying Signifyin(g) to music allows music critics to avail themselves of the power and prestige of literary criticism.

Of these three, it is perhaps only the second that has much relevance to music, as opposed to the practice of writing about music. Musical Signifyin(g) is a complex process, distinct from linguistic Signifyin(g) and thoroughly implicated in the dense matrix of cultural knowledge. To explain how it works—when it works—requires not only a theory of Signifyin(g) but also a way to account for musical ontology, an explanation of the framework for discourse provided by cultural theories of information exchange, and a theory of double-voiced discourse. With these in place we can start to see—and hear—how Signifyin(g) shapes musical discourse.

CULTURAL KNOWLEDGE AND MUSICAL ONTOLOGY

Clifford Geertz was skeptical about using descriptions of individual cognitive processes to build an account of culture, and rightly so. Cognitive structure is incredibly complex, and the relationship between individual knowledge and cultural knowledge is not a simple one. Nonetheless, one can discern patterns of consistency in the features selected for defining and evaluating cultural products, patterns that are indicative of cultural knowledge. The approach to cultural knowledge I have developed in this chapter is meant to capture these consistencies and to facilitate a discussion of how cultural knowledge is organized, sustained, and changed. It is not meant as a literal rendering of what someone has in mind in evaluating particular cultural products. The approach is thus an interpretation of culture, but of a

80. This is essentially the approach taken by Robert Walser in "'Out of Notes': Signification, Interpretation, and the Problem of Miles Davis," in *Jazz among the Discourses*, ed. Krin Gabbard (Durham, N.C.: Duke University Press, 1995), 165–88. While my approach to Signifyin(g) is broadly consonant with this treatment of meaning construction, my argument is made from the perspective of research in cognitive science rather than structuralism.

somewhat different sort than those called for by Geertz, for it assumes that culture is what we know, rather than the specific things we do, make, or say.

As members of a culture, one of the things we know is how to categorize sequences of sound events as "music" (or whatever other term is operational in our culture). Knowing that a Beethoven string quartet is music (to return to Geertz's example) means that it conforms to our conceptual model for music, no more and no less. Similarly, John Cage's *4'33"* is music if it conforms to our conceptual model for music; if it does not, we may simply regard it as a rather strange ritual in which a group of people sit in silence for a specified period of time.[81] The conceptual models around which we organize our categories of music are also the means by which we negotiate or resist cultural change, guide performance, and engage in complex patterns of musical discourse. They are, quite simply, the stuff of musical ontology.

Quite obviously, what I offer here is only a beginning. In particular, the account of the conceptual models appropriate to cultural knowledge needs to be refined through further study. Coleman and Kay's study of the meaning of "lie," together with Sweetser's interpretation of that study, offers an interesting example of how relevant empirical research might be conducted. If conceptual models truly have value as a tool for describing cultural knowledge, then it should be possible to develop experimental protocols that test whether and how members of a culture use such models. What will result is not a simple picture of what someone has "in mind" when reasoning about a given situation (which is at best a dubious goal) but a better understanding of the elements of knowledge that make it possible to function as a member of a culture.

Another obvious extension of the work presented in this chapter is to other repertoires, both contemporary and historical. In some cases (for instance, when dealing with a remote historical period), the application may be so speculative as to be useful chiefly in providing a fresh perspective, but in others it will yield surprising results. There are processes every bit as complex and challenging as Signifyin(g) that operate in other repertories—for instance, the intricate patterns of influence and innovation that abound in the music of Gustav Mahler and Arnold Schoenberg—patterns that await only our interest and efforts to discover them.

Perhaps the most intriguing consequence of the argument put forth in this chapter is that, if musical works are cognitive categories, and if music is a cognitive category, then music theory is about the study of categories or—more typically—the conceptual models around which musical categories are organized. Understood this way, music theory immediately escapes the gravitational force field of "the text" that has at times kept the literary criticism of the previous generation earth-bound (even while remaining relentlessly recondite). Thus liberated, music theory's own traditions of high abstraction and unabashed pragmatism may yet find a place in contemporary intellectual discourse.

81. Although I have not tried (or wanted) to develop an overarching conceptual model for music here, it is worth noting in this connection that Cage's four-and-a-half minutes of silence has a score and has been presented in concert numerous times. If these things are important elements of someone's conceptual model of music, they would most likely regard Cage's piece as music.

CHAPTER SIX

WORDS, MUSIC, AND SONG: THE NINETEENTH-CENTURY LIED

On 15 December 1822, the poet Wilhelm Müller noted the publication of a group of songs that took his poems as their texts. In a letter to the composer of the songs, Bernhard Klein, Müller observed, "indeed, my songs lead . . . only *half* a life, a paper-life, black upon white . . . until music breathes the breath of life into them, or at least, when it slumbers within, calls it out and wakens it."[1]

That music could breathe life into poetry is a sentiment also expressed in a eulogy for a composer Müller chose not to address in the foregoing letter, but whose settings have kept Müller's poems from disappearing into the obscure recesses of nineteenth-century German poetry. Speaking of Franz Schubert's Lieder, Josef von Spaun wrote:

> That which moved the poet's breast Schubert rendered true and transfigured in tone in each of his songs as none had done before him. Every one of his songs is actually a poem on the poem that he set to music—and not only for sentiment, which is doubtless at home in songs, but also for all the magic of fantasy, for its supernatural charm and its nocturnal terrors, could he find the perfect moment—yes, even for the lofty seriousness of reflection he had a language.[2]

These two remarkably similar views of the relationship between poetry and music are, without a doubt, as much a testament to the intellectual and artistic life

1. Quoted in Carl Koch, *Bernhard Klein (1783–1832): Sein Leben und seine Werke* (Leipzig: Oscar Brandstetter, 1902), 34, n. 8. The complete text runs as follows: "In der That führen meine Lieder, die zu einem declamatorischen Vortrage, wenige ausgenommen, durchaus nicht geeignet sind, nur ein *halbes* Leben, ein Papierleben, schwarz und weiß—(Ach, wie traurig sieht in Lettern Schwarz auf Weiß das Lied mich an!) bis die Musik ihnen den Lebensodem einhaucht, oder ihn doch, wenn er darin schlummert, herausruft und weckt."

2. "Was des Dichters Brust bewegte, hat Schubert in jedem seiner Lieder treu und verklärt in Tönen wiedergegeben, wie keiner vor ihm. Jede seiner Lieder-Compositionen ist eigentlich ein Gedicht über das Gedicht, das er in Musik setzte; und nicht für Empfindung nur, die im Liede wohl daheim ist, sondern auch für jeden Zauber der Fantasie, ihren überirdischen Reitz und ihre nächtlichsten Schrecken, wußte er den eigensten Augenblick zu finden, ja selbst für den hohen Ernst des Gedankens hatte er eine Sprache." Till Gerrit Waidelich, ed., *Franz Schubert: Dokumente, 1817–1830*, Veröffentlichungen des Internationalen Franz Schubert Instituts, 10 (Tutzing, Germany: Hans Schneider, 1993), 516–17.

and ideals of early nineteenth-century Germany and Austria as they are clear-eyed proposals for a regard of song.[3] And yet they capture something important about the possibilities that arise when words and music come together: under certain circumstances the result is far more than simply the sum of its parts.

The topic of song has fascinated writers on music at least for the last two centuries, and a study of the study of song could be its own book. In a 1992 essay, Kofi Agawu offered a survey of some of this work (as well as his own contribution to it) and identified four basic models for the analysis of song, of which three were fairly well entrenched in the literature on song.[4] The first model derives from the work of Suzanne Langer and operates on the premise that when words and music come together in song, the music wholly absorbs the words. As Langer put it, "Song is not a compromise between poetry and music, though the text taken by itself be a great poem; song is music."[5] The second model proposes that there is an irreducible relationship between words and music; as Lawrence Kramer has put it, "A poem is never really assimilated into a composition; it is *incorporated*, and it retains its own life, its own body, within the body of music."[6] The third model interprets song as a compound structure in which the words carry the primary semantic content and the music colors or enhances what the words signify. Agawu observed that this model is limited because it provides no independent account of the meaningfulness of music.

In reviewing these three models, Agawu was rather too polite, resisting the temptation to note that, within the tradition of song analysis, there have been relatively few attempts to come to terms with how words and music combine to create the phenomena called "song." There are thorough and painstaking analyses of song texts, with cursory mention of the music that sets the text; there are carefully crafted analyses of musical structure, supported at turns by isolated instances of how the words buttress or anticipate this structure; but there are few comprehensive analyses that try to capture how the meaning constructed by the words and the meaning constructed by the music come together to create the meaning associated with a particular song.[7] As an improvement, Agawu proposed a fourth model in which song is construed as a confluence of three independent but overlapping systems: *music* and *words* and *song*. However, he almost immediately withheld full endorsement of this model, noting that it provided no account of a concrete iden-

3. Both must also be situated within the more personal agendas of their authors. Müller's letter is part of an attempt to get the composer to set more of his poems; Spaun's eulogy is part of an attempt to preserve what he viewed as the true legacy of his departed friend.

4. Victor Kofi Agawu, "Theory and Practice in the Analysis of the Nineteenth-Century *Lied*," *Music Analysis* 11 (1992): 3–36.

5. Susanne K. Langer, *Feeling and Form: A Theory of Art Developed from Philosophy in a New Key* (New York: Charles Scribner's Sons, 1953), 152.

6. Lawrence Kramer, *Music and Poetry: The Nineteenth Century and After* (Berkeley: University of California Press, 1984), 127.

7. One analysis that develops a comprehensive account of a song is David Lewin's "*Auf dem Flusse*: Image and Background in a Schubert Song," in *Schubert: Critical and Analytical Studies*, ed. Walter Frisch (Lincoln: University of Nebraska Press, 1986), 126–52. However, Lewin's main interest in this essay is in developing an account of certain remarkable features of this particular song; his study, thus, did not set out to delineate a broad methodological approach to the analysis of song.

tity for song but, instead, allowed song an identity only by default. This led him to muse, "Perhaps, then, what the model points to is song as process, not product. What is interesting, in other words, is not what song *is*, but what it *becomes* in its perpetual striving for a concrete mode of existence."[8]

Nicholas Cook was able to steer a course between the Scylla of emphasizing the text at the expense of the music and the Charybdis of emphasizing the music at the expense of the text, as well as to give an account of a concrete identity for song, by approaching song as an instance of multimedia: words were one medium, music another.[9] However, because Cook defined multimedia as the *perceived* interaction of different media, he tended to regard songs as successful to the extent that the syntax of their words and music remained separate—indeed, in a state of contest. The approach is effective for many songs, and the breadth offered by integrating song analysis into the analysis of multimedia as a whole makes for a very comprehensive perspective. Nonetheless, what is missing is a sense of how, despite their differences, words and music work *together* in song—how music can breathe the breath of life into poetry or create a poem on a poem.

In this chapter, I explore further the nature of song and also the process of conceptual blending. As noted in chapter 2, conceptual blending is a pervasive and often transparent process in which elements from two correlated mental spaces combine in a third.[10] And, as suggested by the examples used in chapter 2, the mental spaces basic to conceptual blends can be set up by music as well as by language. In what follows, I expand on this idea, working on the assumption that music can set up complete discourse structures, which can be correlated with the discourse structure of a text to give rise to a unique domain for the imagination. What I am concerned with, then, are not isolated or very general correlations between music and text but a conceptual blend produced by an entire song.

In the first section that follows, I analyze two settings of Wilhelm Müller's poem "Trockne Blumen" (Withered Flowers), taken from the cycle of poems he called *Die schöne Müllerin* (The Beautiful Miller Maid). The first is by the Berlin composer Bernhard Klein, whom Müller addressed in the letter quoted above; the second is by Franz Schubert. These analyses will allow me to show how different musical environments interact with the same text to produce two quite different conceptual blends, and thus two different songs. In the second section, I turn to Robert Schumann's "Im Rhein" (In the Rhein), from his song cycle *Dichterliebe* (Poet's Love). In "Im Rhein," the music makes possible a conceptual blend whose emergent structure includes a narrative considerably more extensive than that of the text alone. In the third section, I consider two settings of a poem by Joseph von Eichendorff, "In der Fremde" (In Foreign Lands), the first by Schumann, the second by Johannes

10. A focus on the possibilities for meaning construction that arise in this blended space is one of the fundamental differences between the idea of conceptual blending and both Cook's conception of multimedia and Bakhtin's notion of double-voiced discourse.

Brahms. Again, two different songs result, but, in this case, the reasons lie with the generic spaces that structure each conceptual blend.

"TROCKNE BLUMEN"

Wilhelm Müller's "Trockne Blumen"

Müller's *Die schöne Müllerin* had its genesis in the diversions of a group of young artists and intellectuals who gathered at the house of the privy councilor Friedrich August von Stägemann during the autumn and winter of 1816–17.[11] There Müller (1794–1827)—together with the Stägemanns' daughter Hedwig (1799–1891); the artist Wilhelm Hensel (1794–1861); his sister, the poetess Luise Hensel (1798–1876); the publisher Friedrich Förster (1791–1868); and others—put together an informal drama structured around the story of a pretty miller's maid and her suitors. Each member of the group took a part, for which they wrote a verse script. In the enactment of the resulting *Liederspiel*, the participants would recite their verses, using whatever gestures or changes in vocal inflection the situation required in order to tell their part of the story.

The evidence of the poems and anecdotes that survive from the Stägemann circle suggests that its Liederspiel had a thoroughly tragic ending. In what can be reconstructed of the story they developed, the miller's daughter, named Rose (played by Hedwig von Stägemann), was courted not only by the young miller (played by Müller) but also by a country squire (played by Förster), a hunter (played by Wilhelm Hensel), and a gardener (played by Luise Hensel). The miller, after prevailing briefly over the other suitors, falls into despair when the hunter wins the miller maid's affections, and commits suicide. The maid, filled with remorse, then joins him in death.

During the three years after the meetings of the Stägemann circle, Müller, apparently intrigued by the possibilities of the story of the miller maid and her suitors, went on to create his own version of the story, consisting of twenty-five poems under the title *Die schöne Müllerin (Im Winter zum lesen)*, which was first published in 1821.[12] The cycle consists of a verse prologue (in the voice of the poet), twenty-

11. My account of *Die schöne Müllerin* follows Susan Youens's excellent work on the origins and historical context of the cycle, which is reported in three of her publications: Youens, "Behind the Scenes: *Die schöne Müllerin* before Schubert," *19th Century Music* 15 (1991): 3–22; idem, *Schubert: Die schöne Müllerin*, Cambridge Music Handbooks (Cambridge: Cambridge University Press, 1992); and idem, *Schubert, Müller, and Die schöne Müllerin* (Cambridge: Cambridge University Press, 1997). Another important source is Graham Johnson's copious notes for his recording of the cycle. See Johnson, "*Die schöne Müllerin*, The Poems and Their Background," in *Die schöne Müllerin, D795* (Hyperion, [CD] CDJ 33025, 1996).

Although the works I discuss here, both literary and musical, use "trockne" in their titles, the proper word is "trockene," which may be contracted to "trock'ne." For the sake of consistency, I shall use "trockne" throughout.

12. The cycle initially appeared as part of the fancifully titled *Siebenundsiebzig Gedichte aus den hinterlassen Papieren eines reisenden Waldhornisten*. The edition of *Die schöne Müllerin* upon which I have relied and that appears below is from Wilhelm Müller, *Vermischte Schriften*, ed. Gustav Schwab (Leipzig: F. A. Brockhaus, 1830), 1: 1–56.

three poems proper to the drama, and a verse epilogue (again in the voice of the poet), together intended to take about an hour to perform.[13] In poems 1–5, we are introduced to the miller, the millstream, the miller maid, her father, and the group of young workers in his charge. In poems 6–11, we become aware of the miller's growing infatuation with the maiden and the depths of his unrequited love. In poems 12–14, the miller becomes convinced that the miller maid is, as he says in poem 12, "Mine!" Despite this belief, there is absent from the poetic narrative any explanation for what changed his perspective from one of dreamy mooning to a self-assured sense of certain love; the poems provide no evidence that the miller maid has actually returned his love. In poems 15–17, the hunter suddenly enters the scene and, in the confused understanding of the miller, steals the miller maid away. Just as suddenly, the bliss of the preceding poems is replaced by anger, jealousy, and vindictiveness. In poems 18–21, the miller, torturing himself with visions of the hunter and miller maid in fond embrace, gradually begins to dwell more and more on death. It is in poem 21, "Trockne Blumen," that the miller decides to commit suicide, bringing to culmination the thoughts of death and the grave that came to dominate the preceding poems. Poem 22 is a sad dialogue between the miller and the stream, and poem 23 is given to the stream alone, as it gently and eerily caresses the drowned miller. The cycle concludes with an epilogue, which is curiously detached from the passion of the preceding poems, and which attempts to build a bridge from Müller's intense world of fantasy back to the world of the everyday.

The basic story told in "Trockne Blumen," the text and a translation of which are given here, can be seen to proceed in three stages.[14] In the first three stanzas, the miller addresses a collection of withered, moribund flowers that are unaccountably wet. In the second three stanzas, he contemplates the ineffectuality of his tears (the tacit cause of the wetness of the flowers) and the insignificance of his existence in the face of love that has died. This group ends with a stanza that echoes the first stanza of the poem, both in its return to the image of the faded flowers and in the recurrence, in reverse order, of the rhyming pair "gab" and "Grab." Together, these suggest a circular return that closes off the first six stanzas. The final stage of the story commences with the last two stanzas of the poem. These speak of a future in which the miller lies dead in his grave, in which the miller maid recognizes the truth of his love, and in which flowers bloom once more. The poem thus involves sharp contrasts: dying flowers set against blossoming flowers, winter set against spring, and dead love set against true love.

TROCKNE BLUMEN	WITHERED FLOWERS
Ihr Blümlein alle,	All you flowers
Die sie mir gab,	That she gave to me,

13. Müller writes in the prologue, "As it's wintertime I expect you won't regret a brief hour here in the countryside" (as it is depicted in the cycle of poems). ["Erhoffe, weil es grad' ist Winterzeit, / Thut euch ein Stündlein hier im Grün nicht Leid."] Müller, *Vermischte Schriften*, 1: 1.

14. There are other ways to parse the poem, as we shall see later in this discussion. The analysis I offer here is simply for the purposes of drawing out some of the aspects of the poem important for a number of its musical settings.

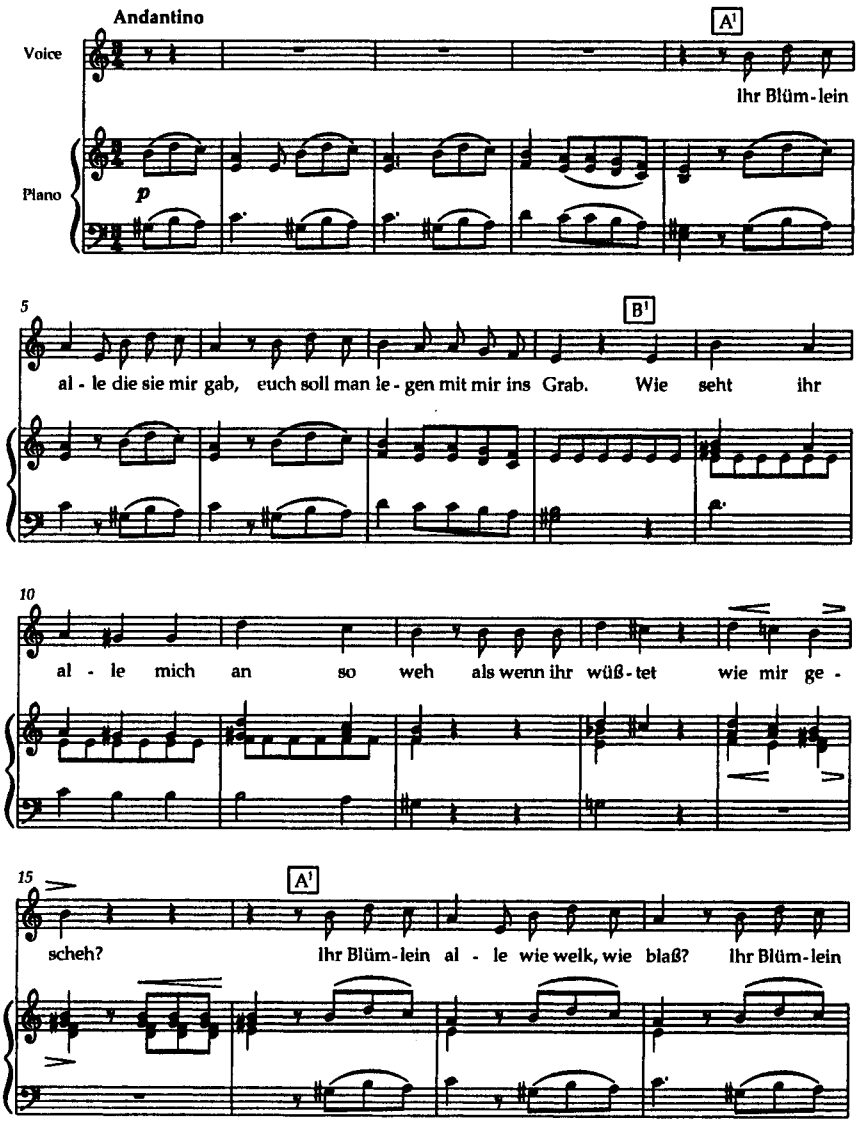
Euch soll man legen	You shall be laid
Mit mir ins Grab.	With me in the grave.
Wie seht ihr alle	Why do you all
Mich an so weh,	Look at me so sadly,
Als ob ihr wüßtet,	As if you knew
Wie mir gescheh'?	What happened to me?
Ihr Blümlein alle,	All of you flowers,
Wie welk, wie blaß?	Why so faded, so pale?
Ihr Blümlein alle,	All of you flowers,
Wovon so naß?	Why are you so moist?
Ach, Tränen machen	Ah, tears do not make
Nicht maiengrün,	The greenness of May,
Machen tote Liebe	They do not make dead love
Nicht wieder blühn.	Bloom anew.
Und Lenz wird kommen	And spring will come
Und Winter wird gehn,	And winter will go,
Und Blümlein werden	And flowers will
Im Grase stehn.	Grow in the grass.
Und Blümlein liegen	And flowers lie
In meinem Grab,	In my grave,
Die Blümlein alle,	All the flowers
Die sie mir gab.	That she gave to me.
Und wenn sie wandelt	And when she walks
Am Hügel vorbei,	Past the mound,
Und denkt im Herzen:	And ponders in her heart:
»Der meint' es treu!«	"His love was true!"
Dann Blümlein alle,	Then all you flowers,
Heraus, heraus!	Come out, come out!
Der Mai ist kommen,	May is here,
Der Winter ist aus.	Winter is over.

One thing immediately evident is that this poem relies, as do most, on conceptual blends. When the miller addresses the flowers, for instance, it is not as plants but as anthropomorphized beings, creatures that can not only look upon the miller but do so with pathos: "Wie seht ihr alle / Mich an so weh, / Als ob ihr wüßtet, / Wie mir gescheh'?" This, of course, is another example of the anthropomorphic blends discussed in chapter 2. Another blend is set up in the fourth stanza, where Müller combines concepts related to the seasons and to romantic love. Thus "maiengrün" becomes both a harbinger of spring and a sign of love's first bloom. Yet a third blend crops up in the seventh and eighth stanzas, when concepts related to the seasons combine with those of life and death: the consummatory "Der Mai ist kommen / Der Winter ist aus" represents both the future turn of seasons the miller envisions

and his rebirth as the eternal lover of the miller maid. The poem is thus a rich discourse structure in its own right, one with intriguing possibilities for pairing with the discourse structures of music.

Bernhard Klein's "Trockne Blumen"

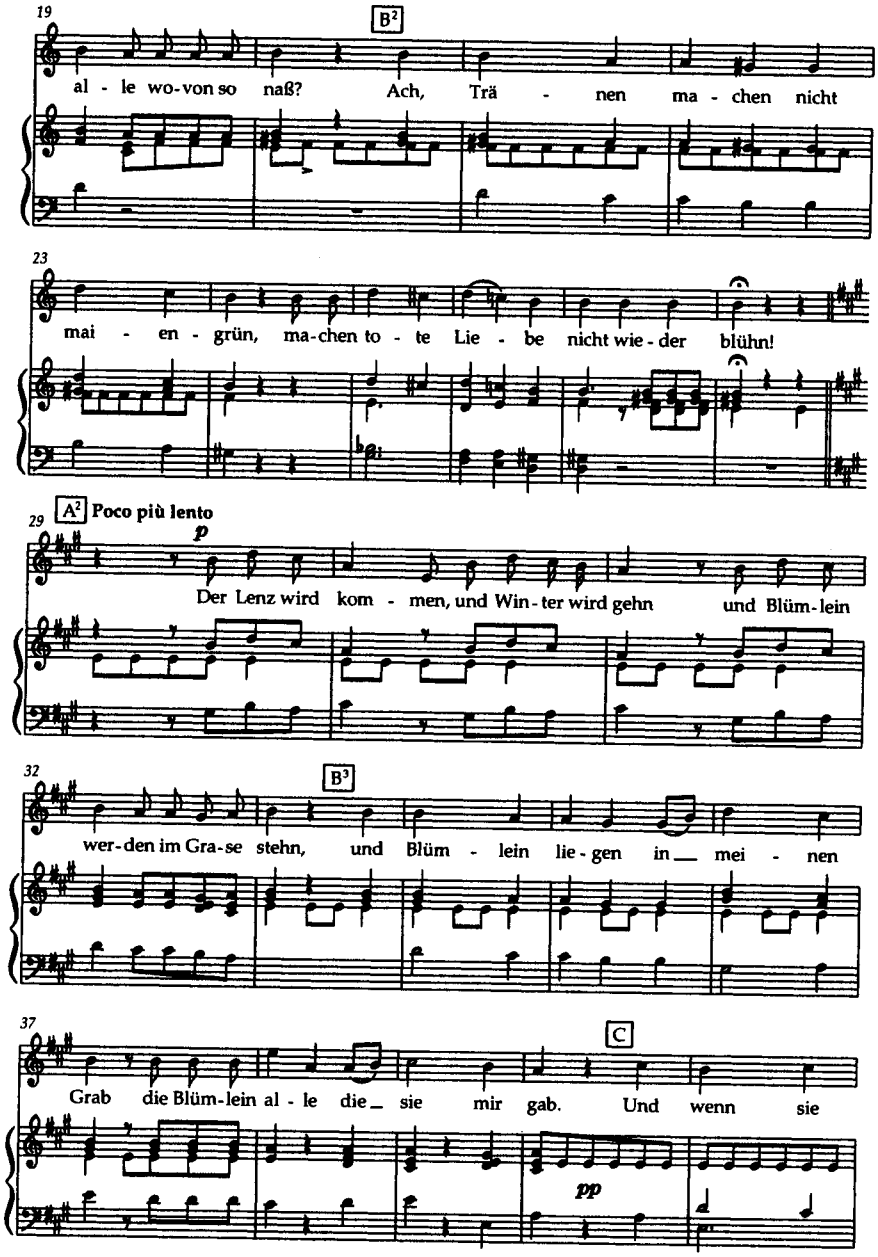
The Berlin composer Bernhard Klein (1793–1832) apparently discovered Müller's poetic cycle shortly after it was published and set "Trockne Blumen" as the last of his five *Lieder und Gesänge mit Begleitung des Piano Forte*. This collection was brought out by E. H. G. Christiani in 1822,[15] and the inclusion of "Trockne Blumen" is all the more remarkable in that the texts for the first four songs involve rather conventional stories of wanderlust and relatively innocent romantic encounters. "Trockne Blumen," as Klein clearly recognized, is a text of quite another order.



Klein's setting, the score for which is given in example 6.1, is guided by his division of the text into four strophes, each comprising two stanzas of the poem. Although the music for each strophe is different, so much material is reused that the song seems more strophic than through-composed, as the formal outline given in table 6.1 indicates.

The song begins with a brief piano introduction that sets out the material used to begin each of the first three strophes. This material, labeled A^1 in table 6.1, consists of three iterations of a motion from dominant to tonic, culminating in a passage in parallel sixths that returns to the dominant. The whole is couched in a spare two- and three-voice texture, with a repetitive melody built up from a compact succession of ascending and descending gestures that circulate around C5 and A4. Although A as tonic is scarcely in doubt, it falls short of attaining a full measure of stability, given the absence of root-position tonic triads in strong rhythmic positions and the emphasis on the dominant harmony at both the beginning and end of each A^1 section. Sections B^1 and B^2 consist entirely in prolongations of the dominant, either by temporarily transforming it into a leading-tone harmony (as in mm. 11–12 and mm. 20–24) or through a pathos-drenched passage that introduces an unprepared $VII^{\frac{4}{3}}$ of IV that leads through IV^6 back to VII, and then to V (as in mm. 13–16 and mm. 25–28). In each of the B sections, the melody struggles upward to D5 three times, only to fall back either to B4 or C♯5. Of these two sections, B^2 is slightly more intense. In it, a repeated F♮4 replaces the repeated E4 that signaled the opening of the B^1 section, giving rise to a VII^{o7} that lasts from m. 20 to m. 24.

In the third strophe, Klein lightens the mood of the music by shifting to the par-



15. Müller is the author of all of the poems of Klein's *Lieder und Gesänge* of 1822; "Trockne Blumen" is the only poem Klein selected from *Die schöne Müllerin*. It is unclear what motivated Klein's choice of poet. In his letter of 15 December quoted above, Müller praised Klein's settings and asked if he would be interested in setting more of his poetry. Given the tone of the letter, it would seem unlikely that Müller was an active participant in the selection of texts for the 1822 collection of songs. I should note, as well, that another Berlin composer, Ludwig Berger, published a setting of "Trockne Blumen" in 1818; analysis of this work, as well as the context for its publication, can by found in Lawrence Zbikowski, "The Blossoms of 'Trockne Blumen': Music and Text in the Early Nineteenth Century," *Music Analysis* 18 (1999): 307–45.

EXAMPLE 6.1 Bernhard Klein, "Trockne Blumen"

allel major. The repeated notes that lent an air of intensity or obsession to the dominant prolongations of the preceding B sections now reappear to keep the music from stalling on the first and second beats of each bar of section A^2. Section B^3 begins with another prolongation of the dominant, but instead of being transformed into a leading-tone harmony in m. 36, as it had at the analogous juncture in sections B^1 and B^2, it now remains a dominant, leading initially to a I^6 in m. 38, and then to the first cadence on A thus far. With the arrival on the I^6 of m. 38, the melody finally reaches E5, preparatory to its arrival on A4 in m. 40.

EXAMPLE 6.1 *(continued)*

(continued)

EXAMPLE 6.1 *(continued)*

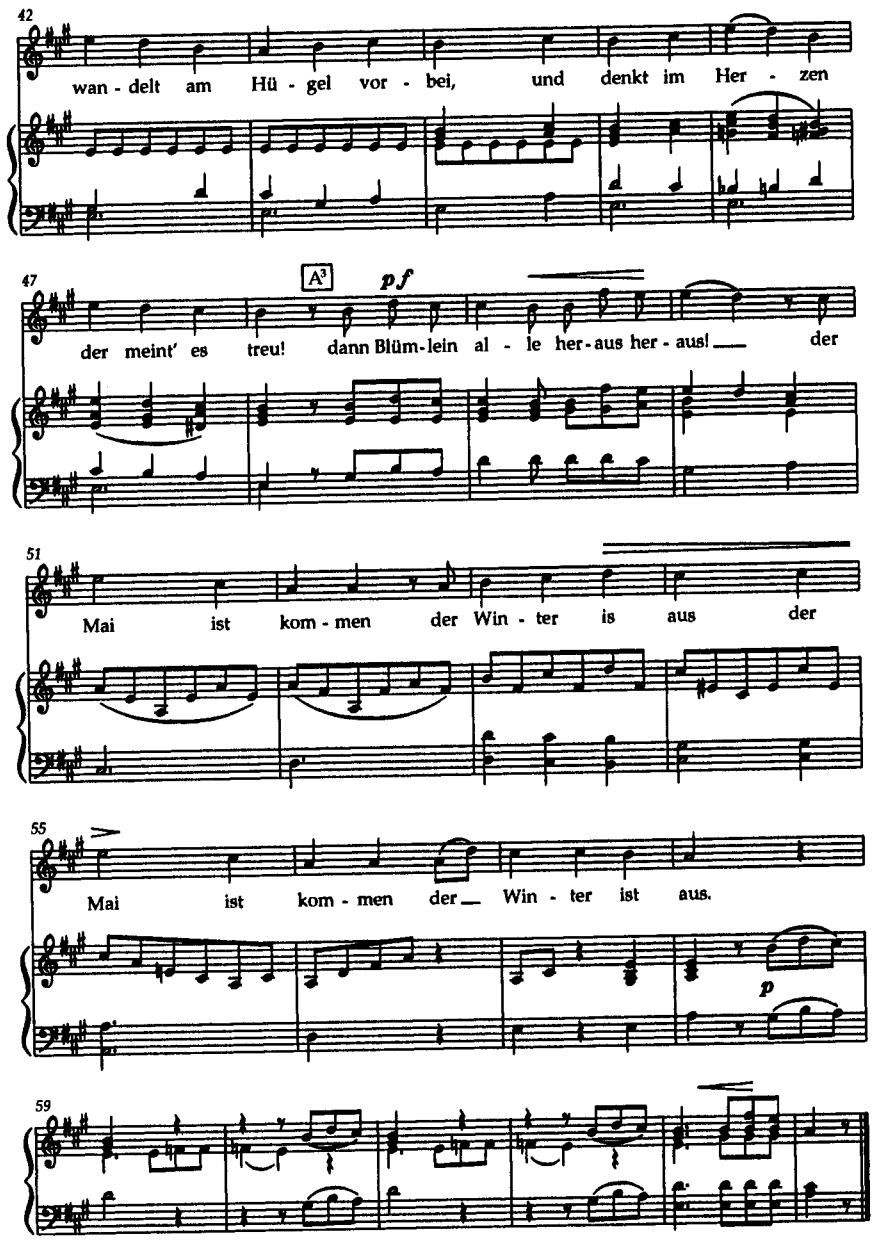


Table 6.1. Formal Outline of Bernard Klein's "Trockne Blumen"

Section and Key	*Text Stanza*	*Musical Material and Melody*	*Measures*
Introduction A minor		A^1, a	0–4
Strophe 1	Stanza 1	A^1, a	4–8
	Stanza 2	B^1, b	8–16
Strophe 2	Stanza 3	A^1, a	16–20
	Stanza 4	B^2, b	20–28
Strophe 3 A major	Stanza 5	A^1, a	29–33
	Stanza 6	B^3, b'	33–40
Strophe 4	Stanza 7	C, c	40–48
	Stanza 8	A^2, a'	48–58
Postlude		A^2, a' (fragment)	58–64

The C section begins another prolongation of the dominant, one whose repeated notes are strongly reminiscent of sections B^1 and B^2. Absent, however, is the relatively active bass line that opened each of the latter sections; it is replaced here by a pedal on E_3. The melody, too, has changed, now peacefully circulating around B_4, with unimpeded ascents to E_5. After m. 45, the intensity of the section increases with the cessation of the repeated notes and the introduction of the chromatic second alto line of mm. 46–47. In m. 48, however, the melodic line that descends from E_5 once again comes to rest on a clear dominant harmony, which leads immediately to the reprise of the A material.

Although section A^3 opens with the same figure in parallel tenths that began the song (adjusted to fit the major mode), the figure now leads toward a dominant-seventh in m. 50 and then to a relatively extensive prolongation of the tonic in mm. 51–55. This prolongation prepares the way for the cadence of mm. 56–58 with which the vocal part concludes. A brief piano postlude follows; it is based on the opening of the A^3 section, but it includes a motion from F♮ to E that recalls the minor mode of the first half of the song.

Thus, Klein's music falls into two distinct parts. The first part, through m. 28, sets out an intense and unstable A minor. Relatively lengthy and obvious prolongations of large-scale harmonic dissonances (such as those associated with the dominant and leading-tone) and sudden interruptions mark the texture, as do persistent repeated notes. The second part, from m. 29 onward, disperses the intensity of A minor and replaces it with a goal-oriented and (for the most part) orderly A major. Here there are also prolongations of the dominant, but of a sort that seem to affirm rather than challenge the viability of tonic. What had been difficult in the first part becomes easy in the second; what had been troubled becomes calm.

This music, together with Müller's text, sets up the conceptual integration network (CIN) diagrammed in figure 6.1. Two observations should be made about the network represented by this diagram, observations that extend to all of the CINs discussed in this chapter. First, as was the case in chapter 2, the diagram represents a kind of analytical snapshot of the elements and relations that make up the network, and that contribute to the emergent structure of the conceptual blend. A

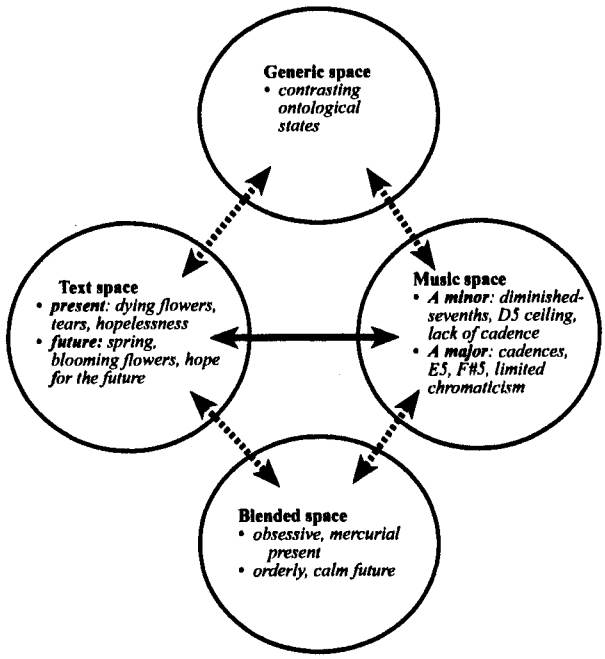

FIGURE 6.1 CIN for Klein's "Trockne Blumen"

fuller account of the way concepts combine within this network would require a series of such snapshots. Second, what I am concerned with here is the *overall* discourse set up by the text and the *overall* discourse set up by the music. Although there are interesting details at more local levels, I am most intrigued by what conceptual blending can tell us about song and by what song can tell us about conceptual blending. Let me expand on this for just a moment before returning to Klein's "Trockne Blumen."

The theory of conceptual blending assumes that there are structural invariances between the input spaces of a blend: these invariances, encapsulated in the elements and relations of the generic space, are what make conceptual blends possible. In the case of songs, the invariances are between the mental space set up by the text and the mental space set up by the music. Put another way, the fact that combinations of text and music can give rise to conceptual blends suggests that there are syntactic correspondences between linguistic and musical discourse. Although the syntax of most nineteenth-century German poetry is usually clear at or below the level of the stanza, the syntax of songs from the same milieu needs to be conceived in terms of the song as a whole, which was construed as a single, if often extended, musical utterance. Because of this, I find it most useful to focus on conceptual blends that encompass the entirety of a given song—that is, blends that arise from the overall discourse set up by the text and the overall discourse set up by the music.[16]

16. This perspective also leads me to regard the poem set by the composer as a text, rather than a poem. Susan Youens, for different reasons, advocates a similar approach; see Youens, *Retracing a Winter's*

What nineteenth-century songs can tell us about conceptual blending stems from the characteristic of musical syntax I have just described. The blend set up by a song (assuming that there are structural correlates between the mental spaces set up by the text and the music) spans at least two or three minutes, involves two different media (with two different, if related, kinds of syntax), and engages us on both emotional and intellectual levels. All these features have the potential to add immeasurably to our understanding of conceptual blending as a general cognitive process.[17]

With these thoughts in mind, let us return to the CIN set up by Klein's song. The generic space for the CIN is structured around the notion of two linked but contrasting ontological states. Such states are often temporally indexed (as past and present or as present and future), but they can be more abstractly represented as theme and variation, or prototype and copy. The delineation of two ontological states often provides the basis for a more extensive interpretive framework. This framework then furnishes an account of the cause for the change of state or an explanation for why one state is to be preferred over another.

Contrast between the two ontological states is supported in Müller's poem by an emphasis on the present in the first four stanzas and an emphasis on the future in the second four stanzas. There is also far less activity described in the first four stanzas than in the second four. Of course, there are exceptions to both of these generalizations. In the first half of the poem, the future is summoned at the end of the first stanza and the past is alluded to in the fourth; the gaze of the flowers and the tears of the miller suggest that the scene is not wholly devoid of activity. In the second half of the poem, the past is evoked briefly in the last two lines of the sixth stanza, the first two lines of which call up the embodiment of lifelessness.

In the mental space of the music, the linked but contrasting ontological states of the generic space are set up by the A minor and A major music of the two halves of the song. These states are linked less by temporal index than by conceptual frame: the A minor music functions as the theme, as it were, and the A major music as the variation. Nonetheless, the A major music *rewrites* the character and syntax of the A minor music. It exchanges the third and sixth scale steps of minor for those of major, provides the first cadences on tonic, avoids the fully diminished seventh chords omnipresent in the first half of the song, and allows the melody to ascend to E5 and F♯5. As a result, it enacts a specific shift of time frame by placing the A minor music firmly in the past and announcing the A major music as the new present. This shift is underlined by the mirrored processes that occupy each half of the song: over the course of the first half of the song, the music becomes more intense

---

Journey: Schubert's Winterreise (Ithaca, N.Y.: Cornell University Press, 1991), 307–12. As will also become clear, I am typically concerned with the story told by the text as a whole, a parabolic level discussed by Mark Turner in *The Literary Mind* (New York: Oxford University Press, 1996), esp. chap. 1.

17. Although it should be clear from the foregoing, let me emphasize that not all songs will set up conceptual blends. Among those songs that do set up blends, some blends will be more successful (that is, lead to more extended elaborations) than others. One example of the latter situation is provided by the third phrase of Brahms's "In der Fremde"; see the discussion of the song later in this chapter.

and darker; over the course of the second half, the music becomes less intense (with the exception of the poignant recollection of mm. 46–47) and brighter.

Correlations between these idealized representations of contrasting ontological states provide an opportunity for the combination of concepts in the blended space, which draws upon elements of the input spaces to create a portrayal of the miller's transformation from a tortured soul into a hopeful and ecstatic one. As was the case in chapter 2, the emergent structure of conceptual blends (including the present one) can be described in terms of the processes of composition, completion, and elaboration.

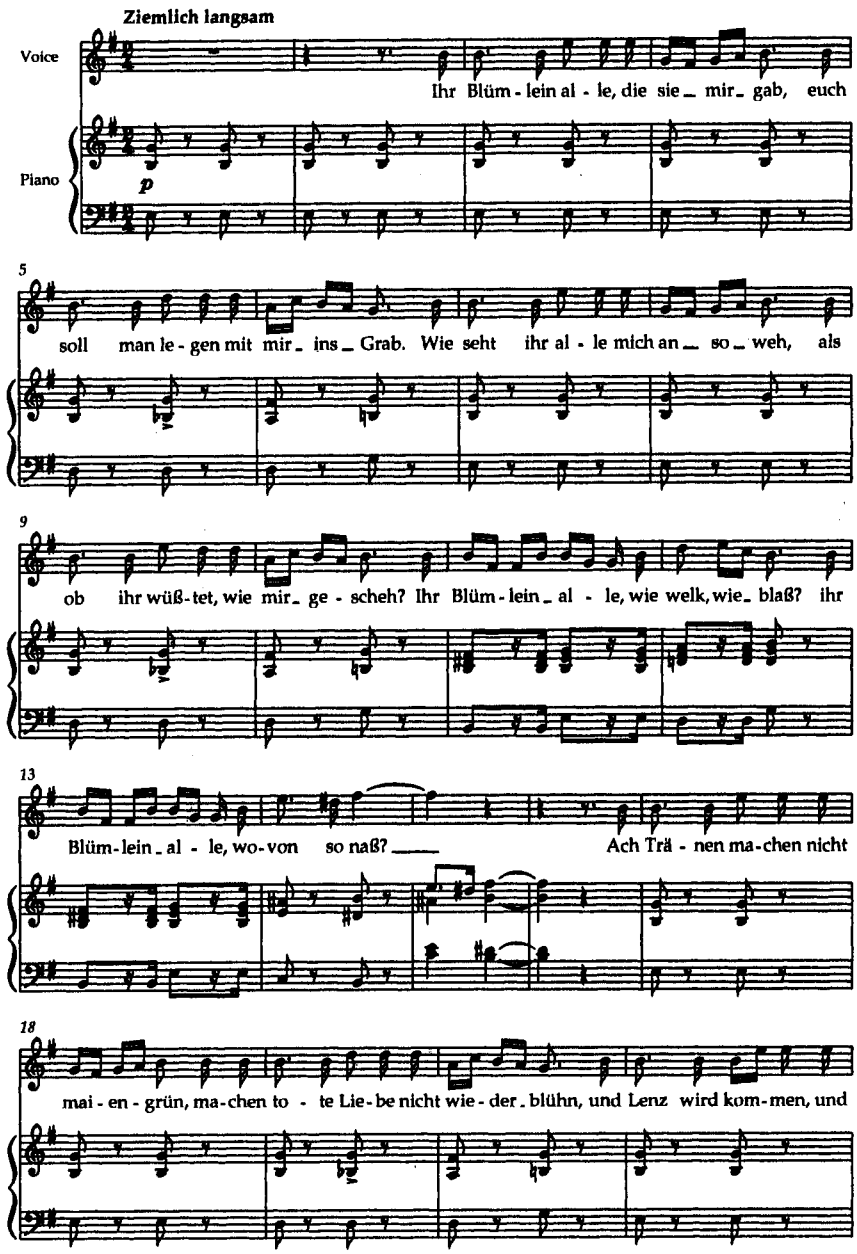
COMPOSITION The combining of elements from the text-space and the music-space is quite straightforward. The enervated present of the first four stanzas and the A minor music combine to create a representation of one ontological state in the blended space: a stark image of the present as dominated by obsessive thoughts, scant opportunity for rest, and a mercurial play of emotions. The active future of the second four stanzas and the A major music combine to create a representation of the second ontological state: what was shadowy has become clear; there is an orderly progress toward goals; and the surroundings are, almost without exception, calm and soothing. The transformation of one state into the other occasions a strange conceptual inversion in this part of the song: the flowers that blossom after the change to A major in m. 29 seem to be the same ones that the miller predicts will lie in his grave (cf. mm. 31–33 and mm. 34–40), even though the latter event, according to the logic of the poem, must *precede* the former.

COMPLETION Building on the context provided by this blend of concepts, we can imagine outward signs of the miller's torment in the first half of the song—a sluggish, depressed body language, accompanied by sudden expressions of anguish as his agony increases—and how, in the second half of the song, these give way to gestures and behavior associated with peacefulness and happiness as the miller contemplates his future. We can also imagine that, overall, the miller grows happier and more at peace with himself as he becomes more distant from his earlier torment. This inference is supported in part by the music of the concluding A^3 section, where the melody breaks through to the high F♯5 of m. 49, a moment followed by the long prolongation of tonic in mm. 51–55 that prepares the singer's final cadence.

ELABORATION Elaboration of the blend suggests that the miller will act in order to make the future he imagines a reality. His "Heraus, heraus!" thus calls forth not only the future's flowers but also the future itself. Elaboration may also provide an explanation for how the state of affairs portrayed in the first half of the song is transformed into the state of affairs portrayed in the second half. Here the music provides a useful guide, for it suggests that the present can be transformed into the future by reinterpreting it, just as the musical materials from A minor were reinterpreted in A major. Thus, the dead love of the present will become the eternal love of the future; the dying blossoms will become living ones. The strange celebration that is enacted in mm. 34–40, as the miller contemplates the flowers that will be laid

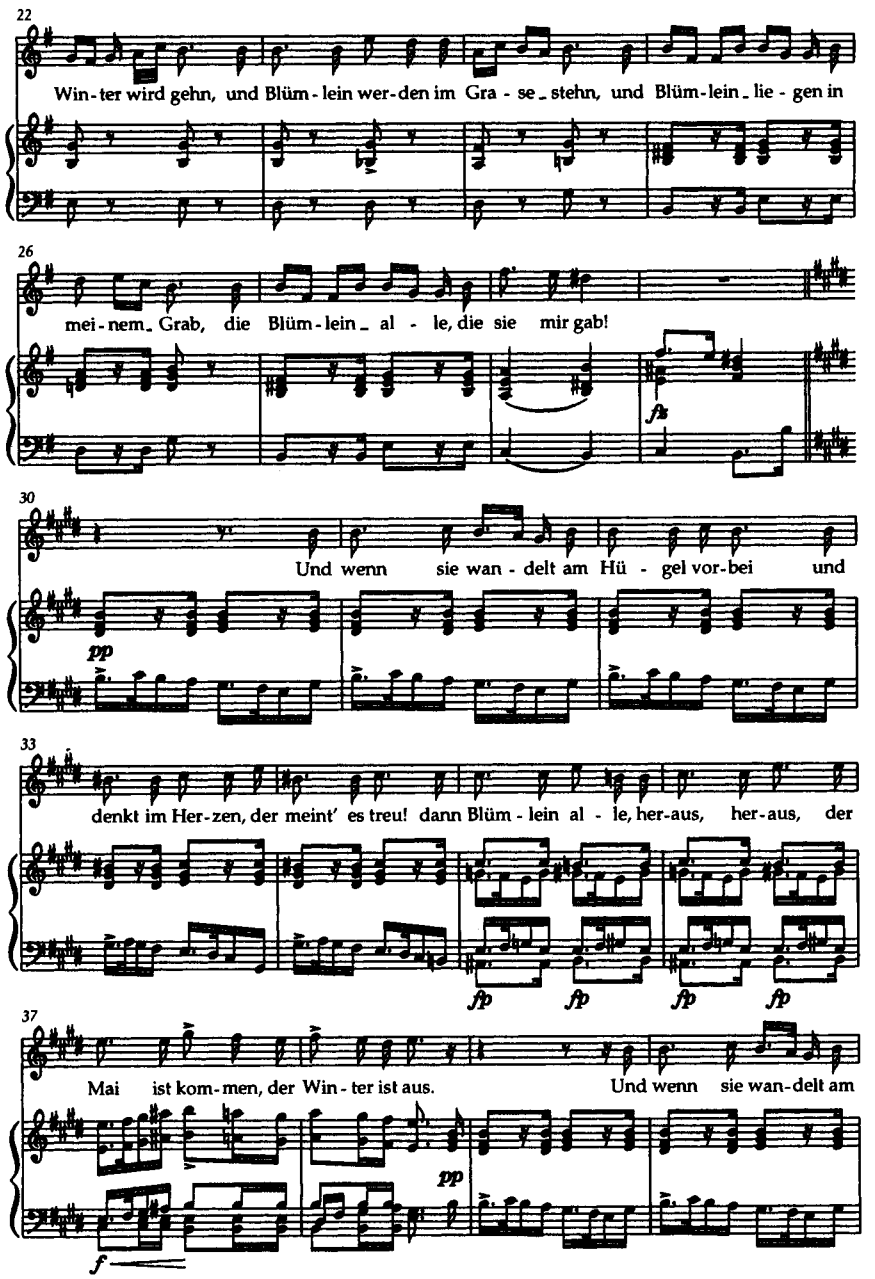
in his grave, then becomes more comprehensible, for in the second half of the song the withered flowers that he holds are transformed into symbols of his eternal love.

Franz Schubert's "Trockne Blumen"



Although the exact circumstances of Franz Schubert's encounter with Müller's *Die schöne Müllerin* are not known, it appears that Schubert came upon the poetic cycle sometime in the first part of 1823 and set twenty of the twenty-five poems during the second half of the same year. The completed cycle was published the following year by the firm of Sauer and Leidesdorf. "Trockne Blumen," the score for which is given in example 6.2, is the eighteenth song in the cycle. Schubert's setting divides the eight stanzas of the poem into a 3 + 3 + 2 grouping. The music in E minor for the first three stanzas is repeated for the second three, after which there is a shift to the parallel major for the final two stanzas. Schubert does not repeat any text in his setting of stanzas 1–6, but he does repeat the last two stanzas in the pattern 7–8, 7–8, 8.

The song begins with the most minimal of piano introductions: two bars of a repeated E minor chord, played *piano*, each eighth-note chord followed by an eighth rest. This pattern continues as the voice enters with a bare melody outlining E minor. With the shift of the bass from E3 to D3 in m. 5, the E minor chord is transformed into a G chord in $\frac{6}{4}$ position. The latter leads to a cadence on G on the second beat of m. 6, coincident with the conclusion of the first stanza of text. The music of mm. 3–6 is then repeated for the second stanza in mm. 7–10, sustaining the spare effects created by the minimal melodic and harmonic materials, but adding the barest hint of forward motion when the voice closes on B4 instead of on G4, as it had in m. 6.



In m. 11, the music becomes more active and its harmonic material somewhat more variegated: the rhythmic pattern of the accompaniment is livelier; the harmonies change every beat; and the melody, as it follows these harmonic changes, becomes more animated. The initial harmonic strategy for the setting of the third stanza is, in compressed form, similar to that used for the first two stanzas: E minor, now preceded by its dominant in m. 11, leads again to G in m. 12. Measure 11 is repeated in m. 13, but this time it is followed by an Italian augmented-sixth chord that leads to the dominant of E minor, while the singer reaches past E5 for the first time to grasp a high F♯5. The piano then echoes this gesture, sustaining the dominant chord for a half cadence on B that lasts through m. 16. Schubert's setting of stanzas 4–6 in mm. 17–29 is virtually identical to the music he provided for the first three stanzas; the only significant change occurs in mm. 28–29, where the E5-D♯5-F♯5 of the melody is restated as F♯5-E5-D♯5.

With the shift to the parallel major in m. 30, the accompaniment becomes yet more active: Schubert adds a lightly tripping bass melody to the animated rhythmic pattern of the right hand. In m. 31, the singer takes up the bass melody, in modified form. With the momentary shift toward C♯ minor in mm. 33–34, however, the melody becomes streamlined once again. The C♯ minor chord in m. 34 yields in the following measure to another augmented-sixth chord. This leads (in m. 37) to a cadential $\frac{6}{4}$, which prepares the first cadence on E in the song. Schubert

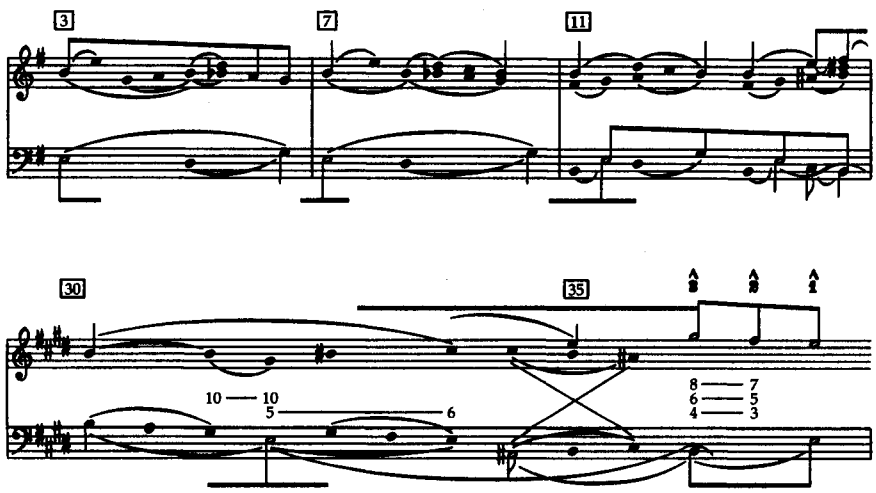
EXAMPLE 6.2 *(continued)*

(continued)

EXAMPLE 6.2 *(continued)*



immediately repeats the whole of mm. 30–38 in mm. 39–47 and then, without pause, repeats the last four bars, with a change of bass and a slight thickening of texture. A six-bar piano postlude, reprising the accompanimental figure of m. 30, concludes the song. In the course of the postlude, the register drops an octave, and the mode shifts to minor for the last four bars.

Although this description cannot do it justice, the effect of the relatively spare musical materials that Schubert employs in this setting is profound. A somewhat more nuanced view of the overall musical discourse can be gained through a middleground sketch of the voice-leading of mm. 1–16 and 30–38, given in example 6.3. As the sketch shows, in the first portion of the song the repeated motions toward G major simply prolong E minor and the initial B4 of the Anstieg. It is only in m. 14 that the music finally begins to move, wrenched from its enervated reiteration of tonic (or the tonic-substitute mediant) by the augmented-sixth chord that leads to the dominant. The augmented-sixth chord also provides the impetus for the continuation of the Anstieg, which is temporarily left hanging on the F♯5 over the dominant. Given the long delay of the continuation of the Anstieg, almost the entirety of mm. 1–29 remains stalled on a prolongation of tonic and B4. Only at the half cadences of mm. 15–16 and mm. 28–29 does the music move away from B4 and momentarily struggle upward toward the Kopfton. With the shift to the parallel major in m. 30 the oppressive harmonic stasis of the first half of the song lifts, and the music begins to move forward, pulled along by the extended dominant preparation of mm. 33–37. Finally, in m. 37, the voice achieves the Kopfton, but as G♯5 rather than G♮5. This accomplishment is followed immediately by the descent of the fundamental line, supported by the first cadence on tonic of the entire song.

Schubert's music falls into two distinct parts in a way that parallels Klein's setting of Müller's poem. The first part, up to m. 29, presents a minimal, washed-out

EXAMPLE 6.3 Middleground sketch of mm. 1–16 and 30–38 of Schubert's "Trockne Blumen"

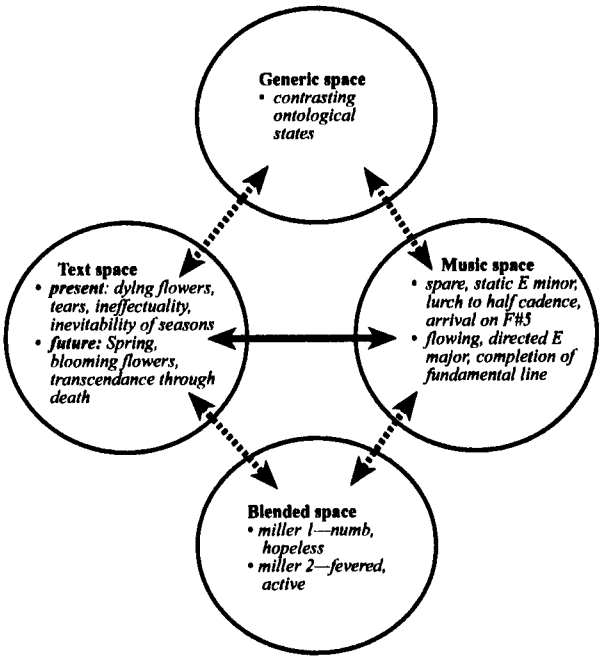


FIGURE 6.2 CIN for Schubert's "Trockne Blumen"

E minor interrupted twice by rather overwrought cadences on the dominant. The second part, from m. 30 on, moves forward, and without so much as a backward look culminates in authoritative and emphatic cadences on E major.

This music, together with Müller's text, sets up the CIN diagrammed in figure 6.2. The generic space, like that for Klein's "Trockne Blumen," is structured around the notion of two linked but contrasting ontological states. However, where in Klein's setting the emphasis is on connections between the ontological states, in Schubert's setting the emphasis is on their incommensurability. Klein's approach takes the point of view of an observer: the undesirable situation represented by the first ontological state can be improved by reconstructing it in terms of the second. Schubert's approach takes the point of view of a participant: recognizing that the first ontological state offers no hope, it is simply abandoned in favor of the second.

The change of emphasis in the generic space reflects a reinterpretation of the elements of the textual space, prompted by Schubert's division of the text into a group of six stanzas followed by a group of two stanzas (which are subsequently repeated). While the ontological states can still be characterized as present and future, the index is now emotional rather than temporal. The present is still occupied with dying flowers, thoughts of the grave, tears, and dead love, but it is also suffused with a sort of numbness, born of the miller's inability to bring about any change in his circumstances. He barely realizes that the tears that moisten the dying flowers are his own; he is powerless to stop them, just as he is powerless to stop the

coming of the seasons, or of his own death. Thus the future of "Und Lenz wird kommen / Und Winter wird gehn" is contained within the present, a leaden emotional domain circumscribed by the echoing rhymes of the first and sixth stanzas. By contrast, the future state called forth by the last two stanzas of the poem is devoid of such dark thoughts: here the miller maid wanders past the resting place of the miller; here spring has truly arrived, and the winter of despair has been banished.

Contrast between ontological states is also apparent in the musical space. Schubert's E minor music is, for the most part, spare and static. After m. 11, it gradually pulls itself into an agitated state, lurches into a half cadence, and then returns to its barren beginning. His E major music, in contrast, exploits and adds to the quickening of pulse that precedes the half cadences of the E minor music, and it drives toward a consummatory cadence that effaces the equivocation and irresolve of the first half of the song. This is music of possibility and completion, of *action*.

Correlations between these idealized representations of contrasting ontological states provide an opportunity for the combination of concepts in the blended space, which draws on elements of the input spaces to create a portrayal of two very different personae for the miller.

COMPOSITION Composition provides the concepts basic to this portrayal. The E minor music and the first six stanzas of text combine to summon a miller who sits in numb contemplation of what seems to be a hopeless predicament. When the gravity of his situation seizes him, he stirs for a moment (responding to the augmented-sixth chords), but even the intensity of torment is denied him and he sinks back into his torpor. The E major music and the last two stanzas portray a quite different miller who, with growing confidence, reaches out toward goals—most particularly, achieving immortality through true love—beyond the grasp of the miller's first persona.

COMPLETION Through completion we can build on what we know about human behavior in such extreme states: we can imagine that in his first persona the miller is virtually inert until, at the moment of his anguish, he half rises, a look of panic on his face; similarly, we can imagine the expansive gestures of the miller in his second persona and perhaps also see the somewhat fevered look in his eyes as he proclaims "Der Mai ist kommen / Der Winter ist aus."

ELABORATION While the emergent structure produced by composition and completion offers a wealth of material to the imagination, it is elaboration that offers the most striking interpretive possibilities. Elaboration of the blend suggests that the transition from the first persona to the second marks a decisive turn in the miller's story. With this transition, the miller has moved beyond merely *entertaining* the thought of death and has now *accepted* the fact of it. The miller will overcome his ineffectuality, he will transform himself, and he will do so through suicide. Supporting this interpretation are the almost frenetic repetitions of the second half of the song (as though the miller still needs to convince himself of the necessity of his

course of action) and the sad turning toward minor of the postlude as the enormity of his decision begins to sink in.[18]

Two Settings, Two Millers

These two settings of Müller's "Trockne Blumen" give us two rather different millers. We first come upon Klein's miller turning over the shards of his shattered love affair and becoming more distraught as he realizes the hopelessness of his predicament. Then there is a sudden shift, and what was dark and foreboding becomes light and promising. The miller's burden has been lifted, for he has found a way to breathe life into dead flowers and dead love: he will welcome death rather than fear it. In contrast, Schubert's miller has two strikingly different personae. The first is emptied out, nearly paralyzed by despair, numbly aware of his misery and his inability to escape it. The second is effusive, expansive in welcoming a future in which the miller is no more. Schubert's miller is, in short, psychotic: at first immobile in the face of death and then feverishly and joyously embracing it.

Are both millers present in Müller's poem? Yes and no. Yes, in that his poem can support these different interpretations, as the CINs above have shown. And yes, in that, from the perspective of the poetic cycle as a whole, the miller is a truly complex character, a quiet psychopath destined for destruction. But no, in that it requires the agency of the music to bring forth these *specific* millers.

The differences between these two millers suggests that a review of the different compositional strategies that brought them into being is warranted so that we may better understand the role of musical syntax in breathing them to life. The similarities between these two settings of Müller's poem are striking: both employ a shift from minor to major mode; both avoid any definitive cadence on the tonic in the first portion of the song; and both make use of relatively delicate textures, especially in the first half of the song.[19] More distinctive are Klein's and Schubert's respective treatments of dominant and tonic. Klein, through extended prolongations, employs the dominant as a tension-generating device, and in consequence the dominant receives more emphasis than the tonic. By contrast, Schubert is sparing with the dominant of his home key, reserving it as a device to pull the music temporarily out of its stasis (in the first half of the song) or using it as part of a normative cadence (in the second half of the song). Tonic, by comparison, is given quite a bit of emphasis, so much so that the first portion of the song becomes threatened with immobility.

The conceptual blends created by Klein's and Schubert's songs, then, are not sim-

18. Further evidence for the moment of this decision is provided by the poetic cycle as a whole. In all of the poems up to "Trockne Blumen," the miller's presence is marked by the use of the first person. After the shift to the third person in "Trockne Blumen," the miller never appears in the first person again.

19. In addition to the similarities between Klein's and Schubert's settings of Müller's poem, both also share features with Ludwig Berger's 1818 setting of the poem, which was mentioned in n. 15; the common features are discussed in Zbikowski, "The Blossoms of 'Trockne Blumen,'" 335. Although such similarities are provocative, no research of which I am aware traces specific patterns of influence between Berger, Klein, and Schubert.

ply a matter of words and music happening at the same time (and thus being "combined" by dint of sharing the same temporal frame). For blending to take place, the mental spaces set up by the text and the music must have a shared topography, reflected in part in commonalities between the syntactic structures of the two media. This shared topography does not exhaust the resources of the input spaces. Indeed, the difference in syntax important to Nicholas Cook's conception of multimedia (discussed at the beginning of this chapter) is no less important in conceptual blending, for it ensures that the stories told by both music and text are compelling in themselves. Nonetheless, common structural features (which may obtain at a different level of structure than those that lead to contest between media) are necessary for conceptual blending to take place.

In the settings of "Trockne Blumen," words and music work together to tell stories that enhance and expand on structural features inherent in the source spaces for each conceptual blend. I now turn to a song by Robert Schumann in which the mental space set up by the music makes possible a conceptual blend whose emergent structure includes a narrative considerably more extensive than that suggested by the text alone.

"IM RHEIN"

In 1840, having established himself as a composer of works for the piano, Robert Schumann turned his energies to song. And formidable energies they were, for by the time the year had ended, he had written over 140 songs. Schumann quite obviously worked at speed: the twenty songs in the original version of his *Dichterliebe* cycle (four were cut before its publication) were written from 24 May to 1 June. Nonetheless, among the songs written that year are some of the most profound and haunting of the nineteenth century, in part because Schumann found ways to combine words and music to create fantastic worlds that extend far beyond those that can be summoned by either words or music alone.

Heine's "Im Rhein"

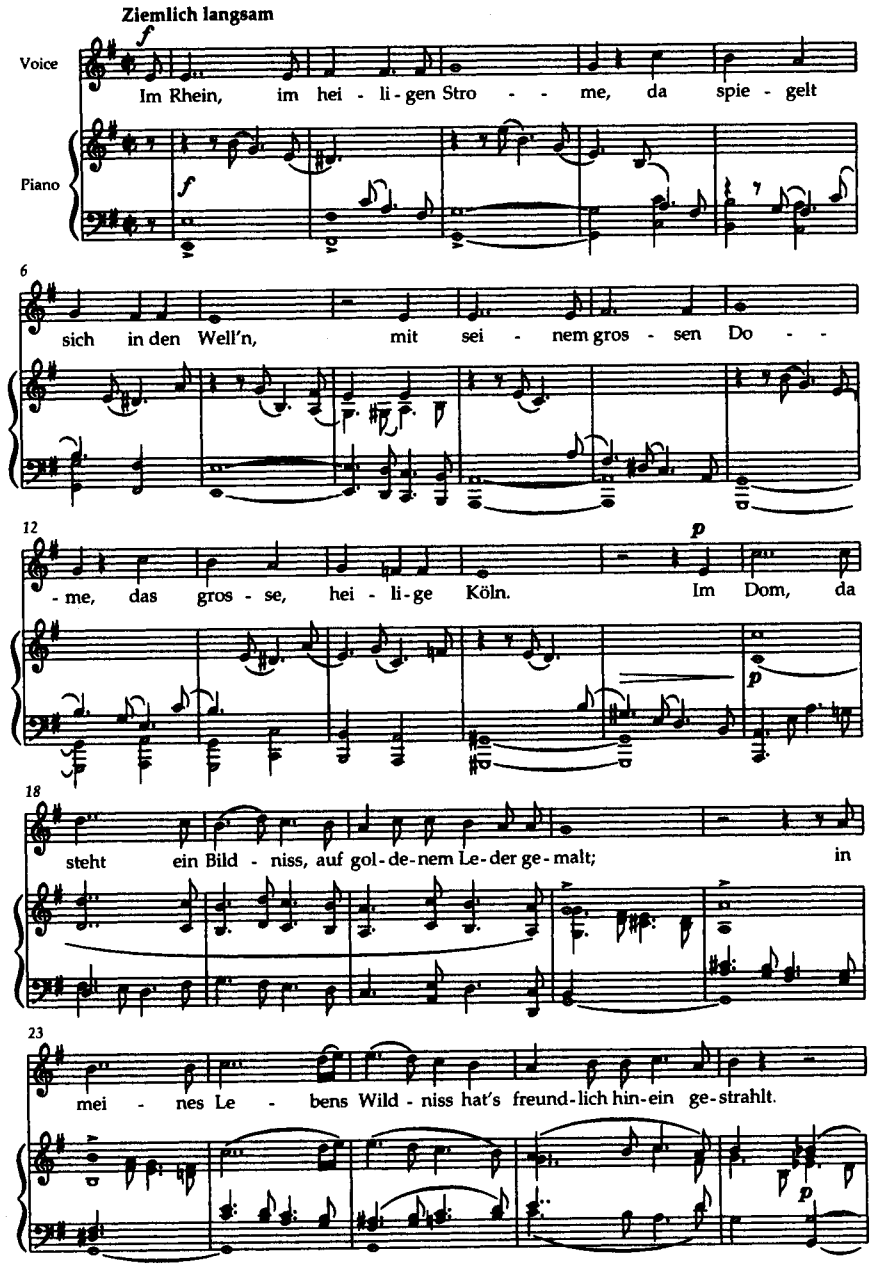
"Im Rhein," the text and translation of which are given here, is the sixth of sixteen songs that make up Schumann's *Dichterliebe*, first published by C. F. Peters in 1844.[20] The text for all of the songs was taken from Heinrich Heine's *Lyriches Intermezzo*, a collection of sixty-five poems published in 1823. Although usually termed a song cycle, *Dichterliebe* is held together not so much by common narrative as by theme: all of the poems deal with romantic love, which is transformed, splintered, or distorted by reminiscence or overheated emotions.

IM RHEIN	IN THE RHINE
Im Rhein, im heiligen Strome,	In the Rhine, in the holy river,
Da spiegelt sich in den Well'n,	There, reflected in its waves,

20. The text for "Im Rhein" given here is from the song as it appears in Clara Schumann's edition of the Lieder of Robert Schumann, but with text repetitions omitted.

Mit seinem großen Dome	With its great cathedral,
Das große, heilige Köln.	Is the great holy city, Cologne.
Im Dom, da steht ein Bildnis,	In the cathedral there hangs a portrait
Auf goldenem Leder gemalt;	Painted on gilded leather;
In meines Lebens Wildnis	Into my life's wilderness
Hat's freundlich hineingestrahlt.	It has shone down kindly.
Es schweben Blumen und Englein	Flowers and cherubs float
Um Unsere Liebe Frau,	Around Our Dear Lady.
Die Augen, die Lippen, die Wänglein,	Her eyes, her lips, her cheeks
Die gleichen der Liebsten genau.	Are exactly like those of my love.

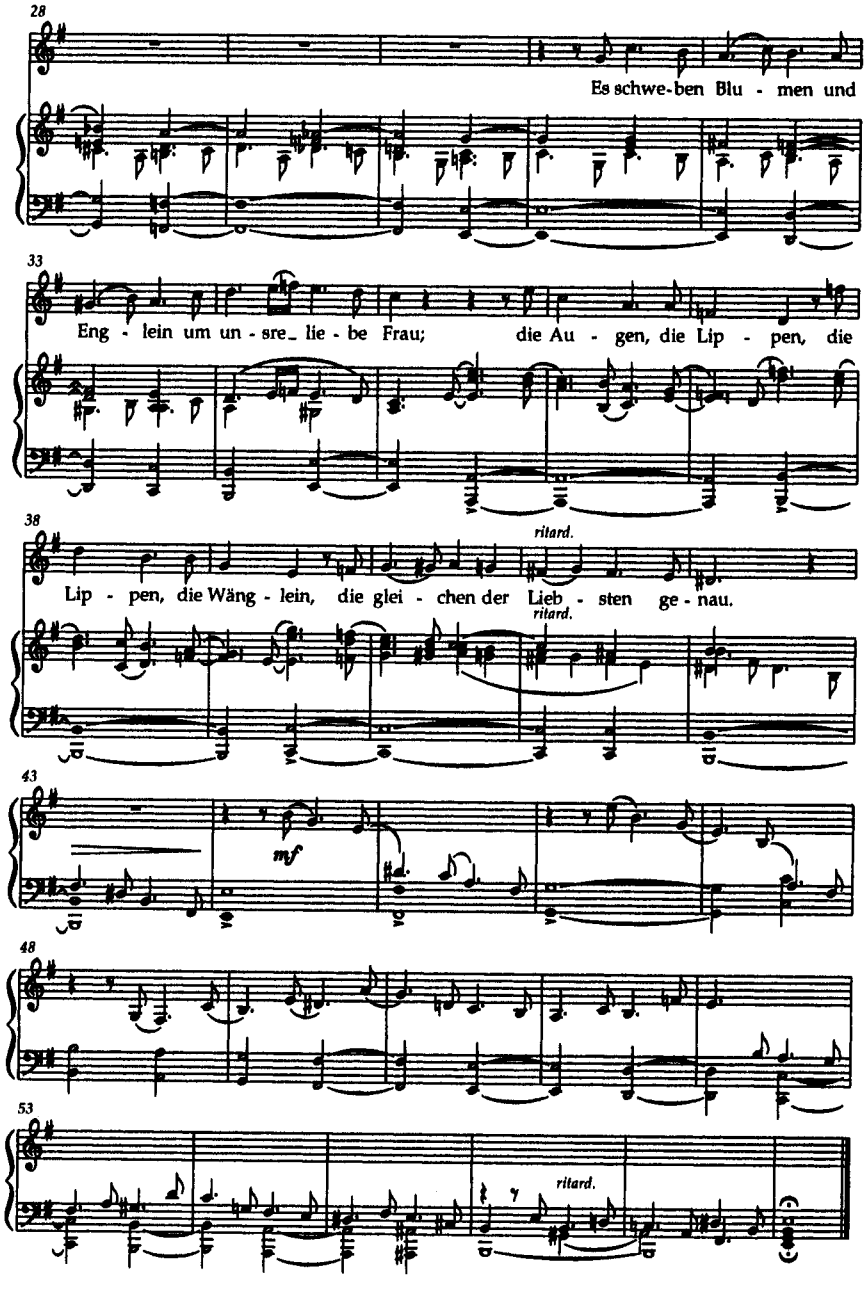
The three stanzas of "Im Rhein" can be divided into two parts. The first part, which comprises the first stanza, summons a broad view of Cologne centered on its cathedral and reflected in the waves of the Rhein. There is a sense of vastness to the perspective (suggested by the repetitions of *groß*), and of the holy (provided by the cathedral and the description of Cologne as the "holy" city).[21] The second part of the poem, which comprises the second and third stanzas, moves inside the cathedral to focus on a portrait within. It is at this point that the presence of a narrator is made explicit and the shifting perspective of the poem acquires an anchor and a rationale. We are here in this city, inside this cathedral, to view a painting of singular importance to the narrator, for its radiance has proved a balm to the troubles of his soul. In the third stanza, the poetic lines become longer, and the narrator takes us inside the painting itself. He begins by describing a heavenly vision of the Madonna, but as he takes us deeper into the painting, the image of the Madonna becomes ever more worldly, until it becomes apparent that the narrator savors this image because it is the exact likeness of his beloved. The poem ends with this sudden shift from the spiritual to the carnal, and we hang in mid-air, suspended both by and within the narrator's vision.



The elegance and power of Heine's unsettling poem stem from two parallel processes. The first is perspectival: we start from the largest scale—the city of Cologne and its cathedral—and then narrow the scope, first to the interior of the cathedral, then to a painting within, and then to specific features of the face portrayed in the painting. The second process is conceptual and affectual: we begin with ideas about vastness and holiness; proceed to the active solace provided by the contemplation of a religious work of art; and then are suddenly confronted with an intense, carnal passion for a lover.

Schumann's "Im Rhein"

Schumann's setting of the poem "Im Rhein," the score for which is given in example 6.4, is in ABA' form. The first sixteen measures, which make up the A section, present a forceful, leaden E minor. Beginning *forte*, the voice (accompanied by the

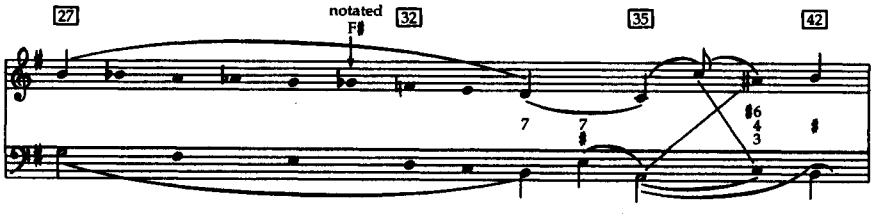


21. Schumann provided additional emphasis on the holy by changing the end of Heine's first line from "im schönen Strome" to "im heiligen Strome."

EXAMPLE 6.4 Robert Schumann, "Im Rhein," from *Dichterliebe*, Op. 48

(continued)

EXAMPLE 6.4 *(continued)*



left hand of the piano in octaves) makes a stepwise ascent from E4 to G4 in m. 4, answered by a stepwise descent from C5 back to E4. At this point, voice and piano part ways. While the voice repeats its melodic material almost exactly (save for the crucial change of the penultimate F♯4 for F♮4), the piano continues the descent initiated in m. 4, sinking to the G1-G2 octave of mm. 11–13. In the second half of m. 13, the bass echoes the voice's descent from C to G of mm. 12–13 but, prompted by the important F♮4 in the voice, it arrives on a G1♯-G2♯ octave instead. This arrival coincides with the final E4 in the voice part and with the completion of the first stanza of the poem. The right hand of the piano fills out, if minimally, the bare texture created by the voice and the left hand; it does so with an accompaniment made up of cascading gestures in a halting pattern of alternating eighth- and dotted-quarter-notes.

The dominant $\frac{6}{5}$ of mm. 15–16, with which the A section concludes, leads to the A minor chord and *piano* of m. 17 that starts the B section. Here, the striding bass of the left hand disappears, replaced by a more fluid and gravitationally liberated adaptation of the eighth/dotted-quarter pattern of the right-hand accompaniment. In mm. 17–21, the voice also abandons its relentless descents and floats gently between D5 and G4; both voice and piano momentarily cadence on G major in m. 21. Although there is a brief struggle in mm. 22–25 as the voice counters the piano's descending figures with an ascent from A4 to E5, once the E5 is achieved the air clears, and the equanimity of the preceding phrase is restored, an effect confirmed by another cadence on G major in m. 27. There follows a brief piano interlude that begins a chromatically harmonized and rhythmically displaced descent through the sixth G2-B1 (the voice-leading of which is shown in ex. 6.5). The voice joins the piano in m. 31, and the completion of the sixth-descent in m. 34 is followed by a cadence on A minor in the following measure. An A minor chord, prolonged through a chromatically inflected voice-exchange (as shown in ex. 6.5), prepares the way for the return to E minor effected by the arrival on the B chord of mm. 42–43.

The return to E minor in m. 44 also marks a return to the material of the A section, which (other than the *mezzo forte* dynamic) is exactly the same as in its first appearance until the left hand of the piano reaches the F♯2-F♯3 octave in m. 49 (as it did in m. 6 of the A section). At this point, the rhythmic displacements of mm. 27–41 reappear, and the bass continues, now in augmentation, to the A1-A2 octave of m. 54. The A1-A2 octave then leads, through A♯, to the dominant of mm. 56–57 and the final cadence.

EXAMPLE 6.5 Linear analysis of mm. 27–42 of Schumann's "Im Rhein"

Schumann's music thus enacts a threefold process. The first part of this process (in the A section of mm. 1–16) establishes an austere, weighty E minor. It is well to note that the tonality is established with minimal reference to the sort of harmonic progressions and disjunct bass motions that are typical of tonal music of the period: there is no cadence on E minor in the entire section, and, moreover, the dominant of E minor is completely absent, its place taken by the leading-tone seventh-chord.[22] The second part of this process (in the B section of mm. 17–43) moves completely, if only temporarily, away from E minor. Here there are definitive cadences, but on G major and A minor. The large-scale instability of this section (a product of its avoidance of the tonal center so unequivocally established in the A section) becomes apparent only gradually. Ultimately, E minor cannot be avoided forever, and the section concludes (in mm. 42–43) with the very first appearance of the dominant of E minor in the entire song. The third part of the process (in the A' section of mm. 44–58), initiated by the definitive return to E minor, reprises the opening music. However, the music is now colored by rhythmic displacements that recall the latter half of the B section and that drive inexorably forward to a final cadence in the lowest practicable register.

This music, together with Heine's text, sets up the CIN diagrammed in figure 6.3. The generic space for the CIN is structured around the notion of exterior and interior domains. In the textual space, the exterior domain is that summoned in the first stanza of the poem: the city of Cologne, with its river and cathedral. The interior domain is that summoned in the second two stanzas: the cathedral and the painting with which the narrator is obsessed. In the musical space, the exterior domain is that of E minor, with its stark octaves and striding phrase rhythm. The interior domain is that of the contrasting (or "not-E-minor") music of the B section, with its more flowing accompanimental pattern, softer dynamic, rhythmic displacements, and large-scale instability.

Correlations between these idealized representations of exterior and interior spaces provide an opportunity for the combination of concepts in the blended space, which draws on elements of the input spaces to create a rich portrayal of the actions of the narrator and the environment within which they take place.

COMPOSITION Composition combines the exterior view of the river, city, and cathedral with the austere E minor music of the A section and suggests a sweeping and somewhat foreboding perspective, surveyed with a deliberative and relentless gaze. In turn, the interior view of the cathedral and the painting within combines with the soothing music of the B section to create a sense of refuge, a surcease from the harsh realities without.

22. It is interesting to speculate on whether Schumann himself would have differentiated between the dominant and the leading-tone chord. The distinction is of more concern to theorists of the period than to composers. Nonetheless, Schumann would most certainly recognize the sharper dissonance created by the leading-tone chord (with or without an added seventh), and it is worth noting that in the E minor portions of "Im Rhein" he favored these over the relative consonance of the dominant chord until m. 42.

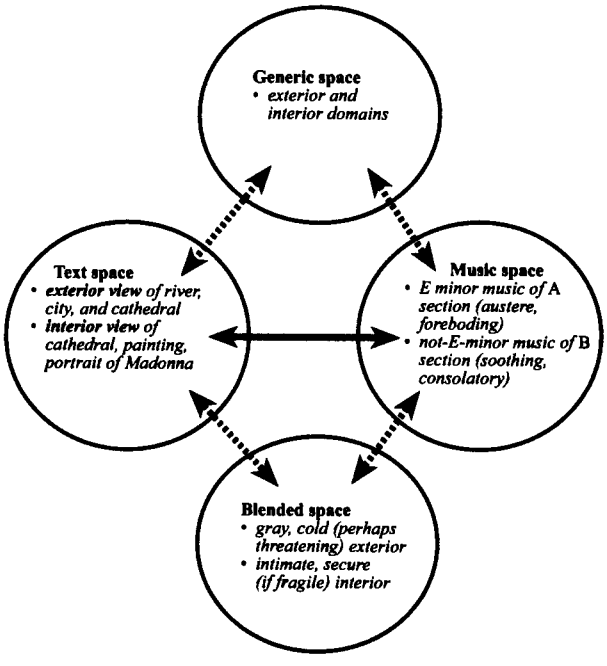


FIGURE 6.3 CIN for Schumann's "Im Rhein"

COMPLETION Completing the image, we can imagine details of each domain: an exterior world gray and cold and in some measure threatening; an interior world intimate and secure, if somewhat fragile. We can also imagine something of the physical and emotional life of the narrator. Outside the cathedral, he is almost certainly self-absorbed, a disheveled figure hurrying to escape the demons that torment him. Inside, he stands rapt, even as the tumult in his mind gradually increases to the point of becoming unbearable.

ELABORATION Our elaboration of the conceptual blend produced by Schumann's setting of Heine's poem might well seek to develop a narrative that could explain the forces that drive the narrator into the cathedral: a personality or perspective that makes life in the outside world intolerable, or a deep obsession with the beloved that renders her both an object of worship and something to be owned and controlled. However, we could also follow the lead of Schumann's music, which, in response to the denouement of the poem, returns to the E minor music of the opening. We are thus returned to the world outside the cathedral and there can see the narrator, now more disturbed than ever, staggering under the weight of his obsession with his lover, just as the music staggers with the rhythmic displacements of mm. 49–55. This furtherance of the narrative by the music suggests that it is the psychic torment of the narrator that is behind the sense of foreboding summoned by the exterior domain, as well as for the irreality of the interior domain. It is an oppressive torment that absorbs all, and among whose fires the narrator

wanders, knowing no rest. The elaboration of the blend, then, suggests a profoundly troubled mind to whom the Rhein represents more than a mirror for a great and holy place: it also offers the means to extinguish the fires that consume him.

Summary

The dark twists and turns of love explored in Heine's *Lyriches Intermezzo* are, in their way, not so very far removed from those Müller captured in his *Die schöne Müllerin*. However, where Müller develops the topic and its ramifications over the course of twenty-three poems, it is Heine's gift to be able to accomplish this in the space of just one. This suggests a mastery of psychological detail—both in understanding his subjects and in what can be asked of his reader—that is altogether impressive. Equally impressive is Schumann's ability to exploit this level of detail by combining Heine's words with music that supports, expands on, and even offers a completion for the story told by the poem. It might be argued that Schumann's setting strips some of the ambiguities from Heine's poem, ambiguities that offer even more possibilities for interpretation than those provided by the song. The point is well taken, for the conceptual blend set up by the song emphasizes certain aspects of the topography of the text space at the expense of others. And yet the gains are considerable, for the conceptual world that emerges from syntactic invariances between Heine's text and Schumann's music is one rich in detail and striking in its immediacy. The challenges and rewards of creating such worlds no doubt fueled the burst of creativity that led to Schumann's amazing output of songs in 1840 and that produced a transformation in the way composers thought about how to organize their musical materials.

"IN DER FREMDE"

The similarities between Klein's and Schubert's settings of "Trockne Blumen" were striking in that Schubert apparently did not know Klein's setting, and Schubert was occupied with developing a song cycle as opposed to creating a single Lied: not only are the musical details of each setting similar, but the generic spaces behind the conceptual blends that each song sets up are almost exactly the same. In Schumann's and Brahms's settings of Joseph von Eichendorff's "In der Fremde," nearly the exact opposite set of conditions holds. Brahms knew and respected Schumann's setting, but he seems to have wanted to show his friend and mentor what he could do with the same material. The result is two songs every bit as different as those of Klein and Schubert, but whose divergences stem from the generic spaces that structure the blends produced by each song.

Eichendorff's "In der Fremde"

"In der Fremde," the text and translation of which are given here, first appeared as the text of an untitled song introduced in the course of Eichendorff's 1833 novella *Viel Lärmen um nichts*.[23] The scene in the novella is a huge and gloomy hall within

23. Joseph Freiherr von Eichendorff, *Viel Lärmen um nichts*, ed. Gerhart Baumann and Siegfried Grosse, Neue Gesamtausgabe der Werke und Schriften (Stuttgart: J. G. Cotta'sche Buchhandlung Nachf.,

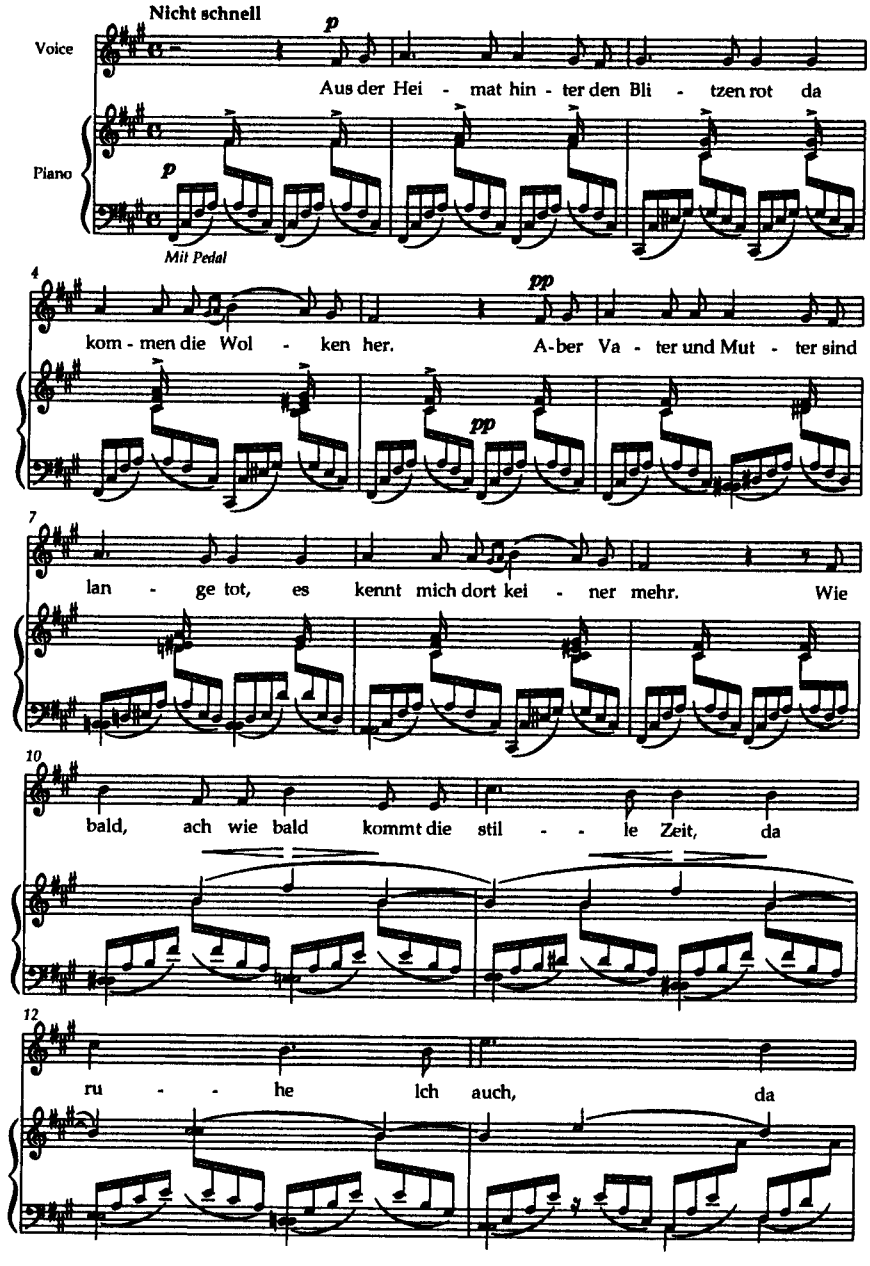
a castle; outside, a storm rages, and, tucked away in a window niche, a young woman sings to her own accompaniment on the guitar. Her song is a deeply sad one, concerned with loneliness and thoughts of a solitary death far from home. The song over, however, she springs up, full of life, to meet her beloved and his friends, who have chanced upon her musings. The scene within which this poem first occurs is thus one of sharp contrasts—between the cold and forbidding interior of the castle, which makes for scant refuge from the storm outside, and the blushing and lively young woman who rushes to embrace her friends.

IN DER FREMDE	IN FOREIGN LANDS
Aus der Heimat hinter den Blitzen rot	From home, behind the red lightning
Da kommen die Wolken her,	There come clouds,
Aber Vater und Mutter sind lange tot,	But Father and Mother are long dead;
Es kennt mich dort keiner mehr.	No one there knows me anymore.
Wie bald, wie bald kommt die stille Zeit,	How soon, how soon will that quiet time come,
Da ruhe ich auch, und über mir	When I too shall rest, and over me
Rauscht die schöne Waldeinsamkeit,	Shall rustle the forest's beautiful solitude,
Und keiner mehr kennt mich auch hier.	And no one here shall know me anymore.

The poem itself offers images and impressions rather than any specific narrative structure. Dominant are the images of nature (in the form of the red lightning, approaching clouds, and promise of the forest's loneliness). Of equal importance is the narrator's profound sense of abandonment (her father and mother are long dead, and she is unknown both in her homeland and in her final place of rest). However, there are also within the poem sharp contrasts similar to those that accompanied its introduction in the novella: the comforting images of the homeland, parents, and sylvan setting are juxtaposed with the ambiguous "here" of the poem, solitude of the forest, and oppressive anonymity of the present surroundings. Nonetheless, connections between the stories told by the poem and the novella were obscured, and some of the ambiguities of the poem were muted, when it was placed by Eichendorff's friend Adolf Schöll in the "Totenopfer" section of an 1837 volume of Eichendorff's collected poetry, at which time it acquired its present title.[24]

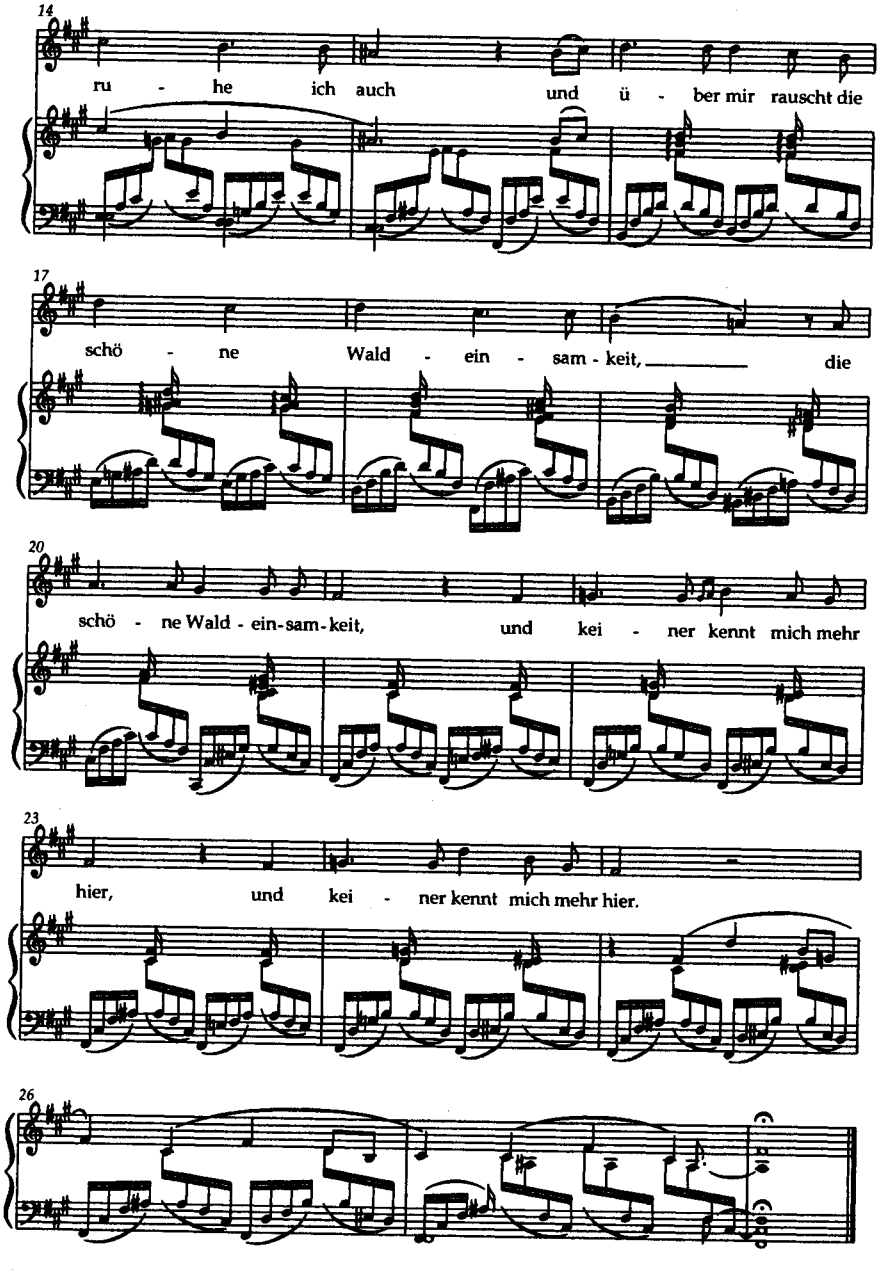
Schumann's "In der Fremde"

It was in Schöll's 1837 edition of Eichendorff's poetry that Schumann (or his fiancée, Clara Wieck) came upon the poem, which he began to set to music on 4 May 1840; the score is given in example 6.6.[25] Although there are indications Schu-



---

1957), 478. The text provided here is the same as that in the novella; some of Schumann's departures from Eichendorff's poem are discussed in the next section.



24. For a discussion of Schöll's role as editor of Eichendorff's work, see Ansgar Hillach and Klaus-Dieter Krabiel, *Eichendorff-Kommentar* (Munich: Winkler, 1971), 1: 47–48.

25. For a stimulating discussion of the songs from Schumann's Op. 39, their ordering in the cycle, and their relationship to the 1837 edition of Eichendorff's poetry, see Patrick McCreless, "Song Order in the Song Cycle: Schumann's *Liederkreis*, Op. 39," *Music Analysis* 5 (1986): 5–40. Dates of the composition of the songs are given in Robert Schumann's *Liederbücher*, which are reproduced in Viktor Ernst Wolff, *Lieder Robert Schumanns in ersten und späteren Fassungen* (Berlin: H. S. Hermann, 1913), 12–19. The same

EXAMPLE 6.6 Robert Schumann, "In der Fremde," from *Liederkreis*, Op. 39 No. 1

EXAMPLE 6.6 *(continued)*

mann intended "In der Fremde" to be the opening song of his Op. 39 *Liederkreis*, when the cycle was first published in 1842 by Tobias Haslinger, "Der frohe Wandersmann" (later published as Schumann's Op. 77 No. 1) appeared in its stead.[26] It was only with the second edition of the Eichendorff cycle, published in 1849 by Friedrich Whistling, that "In der Fremde" made its appearance as the opening song. In revisions to the song, Schumann changed Eichendorff's poem slightly to improve his melody, adding the "ach" in m. 10 and changing the last line of the poem from "Und keiner mehr kennt mich auch hier" to "Und keiner kennt mich mehr hier."[27]

Schumann's setting begins with a flowing accompaniment that continues throughout the song. Although there is no evidence that Schumann referred to Eichendorff's novella in the course of setting this poem, some characteristics of the music seem to fit the image portrayed there of a woman singing to her own accompaniment on the guitar. The running arpeggios in a relatively low register are typical of guitar music, and the melody is folk-like in its simplicity. The first five measures present a thoroughly straightforward F♯ minor, using only tonic and dominant. When the melody is repeated in mm. 6–9, the harmonization becomes a bit richer with the fully diminished seventh chords of mm. 6 and 7, but the basic harmonic framework established in the opening measures remains intact. Beginning in m. 10, however, there is a shift toward A major, and the sound brightens considerably as the higher register of the piano is called into service for the ringing B4-F♯4 fifth of mm. 10–11. A proper arrival on the I^6 of A in m. 13 is thwarted by the melody's temporary escape to E5, and when the outer-voice sixths are retraced in mm. 14–15 (as shown in ex. 6.7), the harmony at the point of arrival is changed to the dominant of B minor (that is, F♯ major) rather than the tonic of A.[28] This not only

sources are correlated with the manuscripts at the Deutsche Staatsbibliothek Berlin in Reinhold Brinkmann, *Schumann und Eichendorff: Studien zum Liederkreis Opus 39*, Musik-Konzepte, 95 (Munich: Edition Text + Kritik, 1997), 80–86. See also Herwig Knaus, *Musiksprache und Werkstruktur in Robert Schumanns "Liederkreis": Mit dem Faksimile des Autographs*, Schriften zur Musik, 27 (Munich: Emil Katzbichler, 1974).

26. "Der frohe Wandersmann" and why Schumann may have included it in the 1842 edition of the *Liederkreis* are discussed in Jon W. Finson, "The Intentional Tourist: Romantic Irony in the Eichendorff *Liederkreis* of Robert Schumann," in *Schumann and His World*, ed. R. Larry Todd (Princeton, N.J.: Princeton University Press, 1994), 156–70.

27. A comparison of the two versions is given in Wolff, *Lieder Robert Schumanns*, 56–57; the revisions are not given in the facsimile provided in Knaus, *Musiksprache und Werkstruktur in Robert Schumanns "Liederkreis."*

28. In my analysis, I have emphasized the sense of departure evoked by mm. 10–14—that is, the firm motion away from minor and the implied cadence on A major. In a compelling analysis of "In der Fremde," David Ferris discusses Rufus Hallmark's reconstruction of one of Schumann's earlier versions of the song; in this version Schumann does indeed cadence on A major. See Ferris, *Schumann's Eichendorff* Liederkreis *and the Genre of the Romantic Cycle* (New York: Oxford University Press, 2000), 111–13. Working from a strongly Schenkerian perspective, Ferris also makes a convincing argument that, in terms of large-scale tonal structure, the move to A major in the final version of the song is, in fact, illusory and is subordinate to an expansion of the subdominant of F♯ minor (pp. 98–106). Although Ferris's reading makes sense of Schumann's overall harmonic and contrapuntal plan, it does not preserve the sense that with the arrival on F♯ major the promised cadence on A major has been subverted. It is this sense of subversion that my analysis, focused as it is on a more surface level of harmonic and contrapuntal activity, attempts to capture.

EXAMPLE 6.7 Linear analysis of mm. 12–15 of Schumann's "In der Fremde"

returns the music to minor but also starts the return to F♯, accomplished in the latter half of m. 19 when a B minor chord is transformed into the leading-tone chord of C♯. The cadence on F♯ minor in m. 21 is followed by eight measures with an F♯ pedal in the bass, over which there are double chromatic neighbors to F♯ (G♮ and E♯), as well as a major third (A♯).

This music, together with Eichendorff's text, sets up the CIN diagrammed in figure 6.4. The generic space, like that for Klein's and Schubert's settings of "Trockne Blumen," is structured around the notion of two contrasting ontological states. Lacking, however, is the notion that there is a smooth or ready connection between the two states: although there is a sense that they are linked in some larger scheme, they are portrayed as basically incommensurate.

Contrast between ontological states in Eichendorff's poem is supported by a marvelously subtle shift of conceptual metaphor. When reference is made to the past or the present, a spatial mapping is used: the past is "there" (the "dort" of the fourth line), the present is "here" (the "hier" of the eighth line). When reference is made to the future, an affective mapping is used: the future is "quiet" (the "stille" of the fifth line) and partakes of "forest-solitude" (the "Waldeinsamkeit" of the seventh line). Each of these mappings is further associated with somewhat more diffuse emotions. The spatial mappings of the past and present are connected with the poignant memory of departed parents and the sense of abandonment that comes with disappearing from memory, with the confused or uncomfortable feelings summoned by the red lightning and approaching clouds, and with the loneliness of an anonymous existence. The affective mappings of the future are connected with a sense of rest and of being in the presence of beauty.

Contrast between ontological states can also be seen in Schumann's music. The F♯ minor music is, for the most part, resolutely secure, yet it is, nonetheless, tinged with chromaticism. Thus, in mm. 1–9, regular cadences appear, but also the fully diminished seventh chords of mm. 6 and 7. Similarly, mm. 20–28 offer the security of the pedal point, as well as the double chromatic neighbors to F♯, which render ambiguous the assertion of major in the final measures. The music of mm. 10–19 tends to be brighter (note the higher register in the piano accompaniment that is especially audible in the right hand of mm. 10–15) and less involved with chromaticism (with the important exceptions of the melodic deflection to A♯ in m. 15 and the fully diminished seventh chord of m. 17). However, in this same passage, convincing cadences are conspicuous only for their absence.

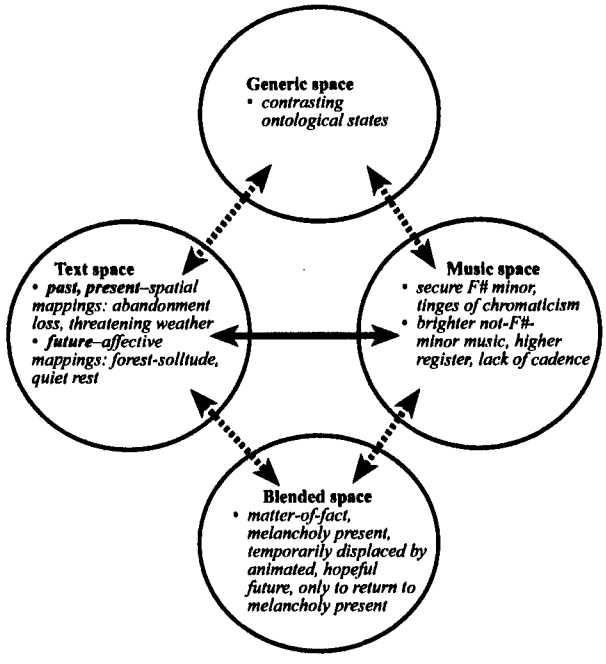

FIGURE 6.4 CIN for Schumann's "In der Fremde"

Correlations between these idealized representations of contrasting ontological states provide an opportunity for the combination of concepts in the blended space. The combination draws on elements of the input spaces to create a portrayal of two worlds, not totally unlike those of "Im Rhein," but framed in emotional rather than architectural terms.

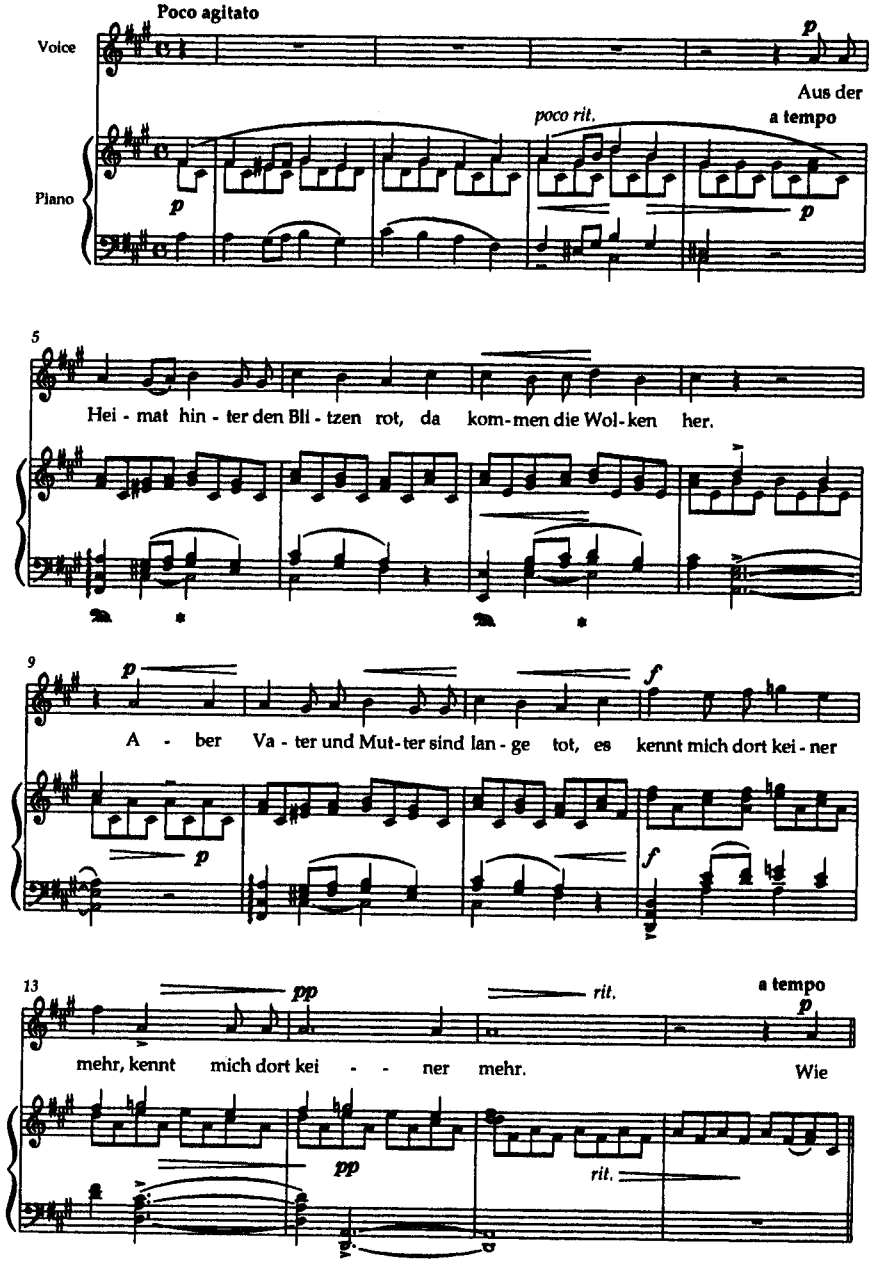
COMPOSITION Composition combines the F♯ minor/major music with the spatially mapped past and present. Evidence that Schumann was aware of the importance of maintaining a consistent musical environment for the first four lines of the poem is provided by his manuscript, for after writing a more varied accompaniment for mm. 6–10 he scratched it out and continued the pattern established in mm. 1–5.[29] The affectively mapped future is first combined with A major and then, with the voice still near the top of its range for the song, B minor. With the repetition of "die schöne Waldeinsamkeit," however, the melody drops, and we return to F♯ and the spatially mapped present.

COMPLETION Following the structure of the blend and our knowledge that a single first-person voice is being projected, we could imagine a singer who begins with almost matter-of-fact observations but who gradually becomes more engaged

29. See the unpaginated "Faksimile des Autographs" appended to Knaus, *Musiksprache und Werkstruktur in Robert Schumanns "Liederkreis."*

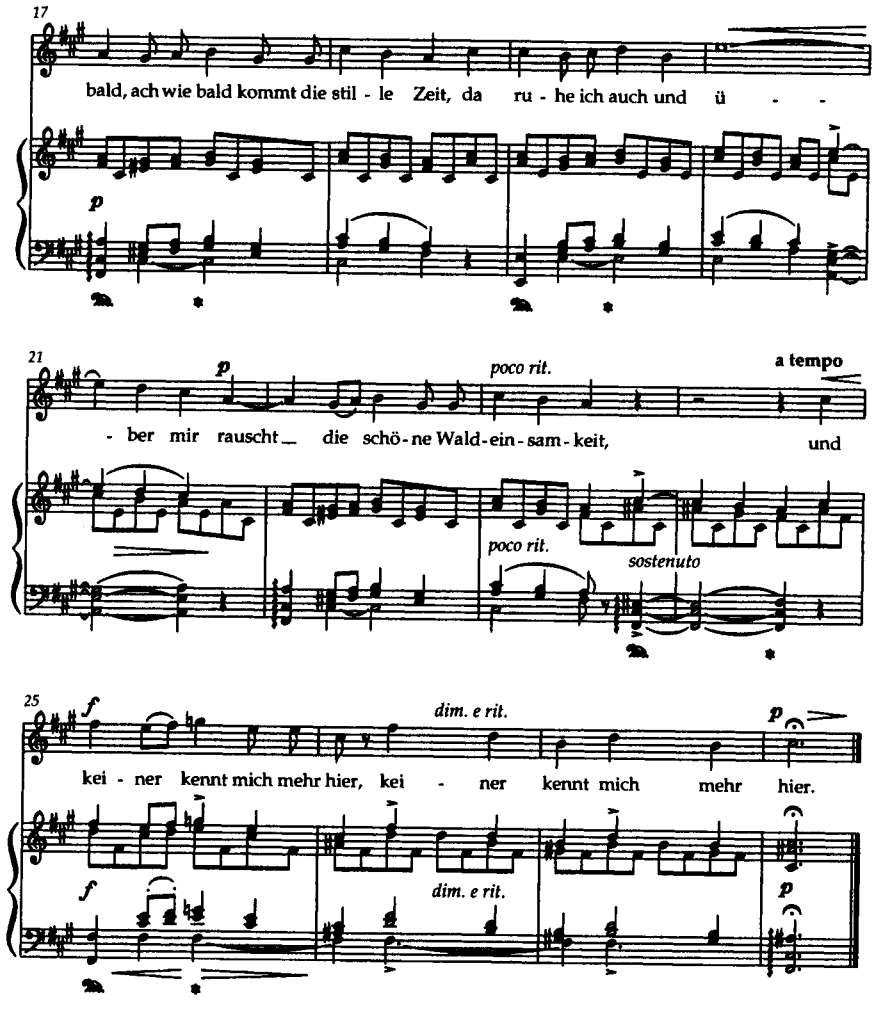
and more melancholy. This melancholy is then rather abruptly displaced (in m. 10) by more animated and hopeful emotions, leading the singer to a higher register and to sing with a fuller voice (in keeping with the profusion of longer note values in the melody). The hopeful attitude cannot be sustained, however, and solitude once again becomes loneliness, the present that is reasserted in m. 21 effectively vanquishing the bright promise of the future.

ELABORATION The imaginary world of Schumann's song is one quite different from that of Eichendorff's original poem. The song sung by the young woman in the window niche is almost folk-like, its regular meter and stylized emotions disturbed only once, by the metrical awkwardness of the sixth line. But this momentary shadow of emotional depth passes, and it is possible to imagine the singer jumping up, the guitar and song flung aside, to greet her friends. Schumann's singer will not be so easily released. The almost formulaic melancholy of the song's opening reveals itself in the end to be inexorable, pulling the energy and hope from the singer and leaving her hollow and forlorn. Schumann's song leaves us with a singer for whom eternity now stretches out as flat and colorless as her present, her spirit struggling as the walls of anonymity close around it.



Brahms's "In der Fremde"

Johannes Brahms was but nineteen when, in November of 1852, he made his setting of "In der Fremde," published the next year by Breitkopf and Härtel as the fifth of his *Sechs Gesänge*, Op. 3; the score is given in example 6.8.[30] "In der Fremde" was the first of the Op. 3 songs that he composed, and it shows clear debts to Schumann: Brahms adopted Schumann's version of the text, the key of F♯ minor, and some important motivic details. Nonetheless, the song is clearly Brahms's own, and nowhere is this more apparent than in the conceptual blend it sets up.



After a short introduction that anticipates the vocal melody without directly stating it (by presenting only elements of the piano accompaniment for the melody), the song proper commences, laid out in four phrases. These phrases have almost identical beginnings, both in harmony and melody, although each ends rather differently. The first touches back upon the tonic at its midpoint (m. 6) and then deflects away to A major. Arrival on A (m. 8) is unsettled by the entrance of the dominant on the second beat (over an A pedal), which supports an echo of the last three notes of the voice part. The second phrase moves at its midpoint to D major (m. 12); its cadence (on the downbeat of m. 13) is as unsettled rhythmically as that of mm. 7–8, but it gains a bit of stability when the fourth line of the poem is repeated (mm. 13–15). Deflection toward A major occurs again in the third phrase (m. 19), but the completion of the cadence is delayed by two beats and the vocal line continues, ultimately eliding with the beginning of the fourth phrase in m. 22. The fourth phrase breaks off momentarily at its midpoint (which, as in all the

30. Brief discussions of the song can be found in Lucien Stark, *A Guide to the Solo Songs of Johannes Brahms* (Bloomington: Indiana University Press, 1995), 15–16; and Eric Sams, *The Songs of Johannes Brahms* (New Haven, Conn.: Yale University Press, 2000), 36–37.

EXAMPLE 6.8 Johannes Brahms, "In der Fremde," from *Sechs Gesänge*, Op. 3 No. 5

EXAMPLE 6.8 *(continued)*

preceding phrases, is marked by an arrival on the tonic), and the mode suddenly changes to major on the last beat of m. 23. Brahms then completes the phrase by recalling the melody of m. 12, but this time harmonized in F♯ rather than D. Within this context, the G♮ in the melody at m. 25 recalls the end of Schumann's setting, an association made stronger when the repetition of the last line of the poem in (mm. 26–28) is set to a melody similar to that which appeared in m. 26 of Schumann's piano accompaniment.

Besides the obvious melodic repetitions engendered by this overall compositional scheme, two additional features bear note. First, the compass of the melody is relatively restricted (from G♯4 to G5, the smallest range of any of the Op. 3 songs). Second, the melody is constantly brought back to A4: each phrase begins on A4, it

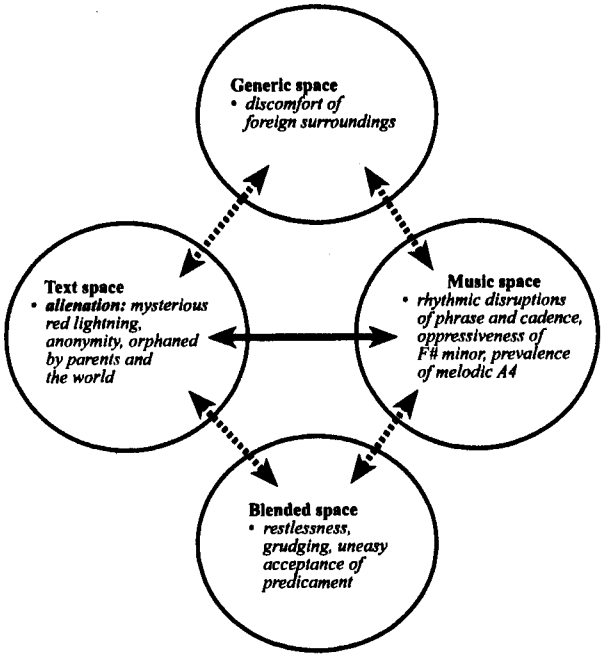


FIGURE 6.5 CIN for Brahms's "In der Fremde"

marks the arrival on the midpoint of each phrase, and the second and third phrases end on it (in the latter case, this brings about the elision of the end of the third phrase with the beginning of the fourth).

This music, together with Eichendorff's text, sets up the CIN diagrammed in figure 6.5. The generic space is structured around the feeling of discomfort attendant on being in alien surroundings. This space is rather unlike those for the other CINs discussed in this chapter in that it does not lend itself as readily to a narrative framework. However, discomfort, by its nature, suggests a dynamic situation (to the extent that we want to return to a state of comfort). This may not quite constitute a narrative in its own right, but it creates an opportunity at least for a minimal story.

Eichendorff's poem supports this sense of discomfort with the ominous portents of the clouds and red lightning, as well as with the isolation and anonymity noted in the fourth and eighth lines. Discomfort is also summoned, if negatively, through the thought that rest is to be found elsewhere.

The discomfort of alien surroundings is suggested musically by the repeated attempts in mm. 4–21 to escape the pitch A4 and the key of F♯ minor. (The accompaniment pattern for the F♯ minor sections also makes use of an insistent C♯4 that starts as a simple bit of rhythmic activation in the introduction, but soon begins to cloy.) Each attempt fails, of course, as it is undercut by insecure cadences and the relentless pull of A4. When a sort of escape is fashioned, at the song's conclusion, one senses that the forces of oppression have been held in abeyance more than defeated. Although the mode changes to major, the G♮5 summons the ♭2̂ that is

more typical of minor; although the melody ends away from A4, it has not accomplished a structural close on F♯4.[31]

Correlations between these idealized representations of discomfort at alien surroundings provide an opportunity for the combination of concepts in the blended space that draws on the elements of the input spaces to create a portrayal of life "in der Fremde."

COMPOSITION Composition combines the images of isolation and the alien in the first four lines of the poem with two successive musical phrases that begin in the same place but move away to end at a distance from the tonic and with the downbeat destabilized. The combination of the last line of the poem and the concluding music is slightly more tenuous: the return of the voice to the high end of its range and the recall of the end of phrase 2 reinforce the portrayal of discomfort, but the sonorous F♯ major chords and pedal point also suggest a sort of reconciliation outside of the basic mapping that structures the CIN.[32]

Although I have not emphasized the failure of elements from the text-space and music-space to combine in my discussions of the process of blending, it is particularly noticeable in the case of lines 5–7 of Eichendorff's poem and mm. 17–23 of Brahms's setting. At this point, the topography of the two spaces is not uniform—more specifically, the text at this point (concerned as it is with contemplation of peaceful rest in the embrace of the forest) does not conform to the structural premises of the generic space. Although words and music certainly co-occur here, they do not combine from the perspective of the CIN diagrammed in figure 6.6. This lack of correspondence may be one reason Brahms's song seems weak here: his text-painting of "über" (as a long, relatively high note that is manifestly "over" the accompaniment) offers rather insufficient compensation for the failure of words and music to work together on a larger scale.

COMPLETION It is through completion of the conceptual blend that Brahms's song takes on a dynamism that extends beyond the rhythmic disruptions and key-area juxtapositions of the music. As noted, we know that states of discomfort cry out for resolution, whether that is provided by shifting position in our chair or moving away from someone who makes us uneasy. When the music of the first half of each phrase is followed by the contrasting music in the second half, it is easy to hear this as a moving away, a physical adjustment to unpleasant circumstances. The sudden shift to major and return of the higher vocal tessitura at the end of the song suggest not so much a final resolution as an uneasy truce: the struggle of the first twenty-odd measures has yielded results, but they can hardly be called definitive.

31. From a Schenkerian perspective, the lack of a clear descent to $\hat{1}$ (through the melodic progression A–G♯–F♯) poses interesting, although by no means irresolvable, problems.

32. It is worth noting that the two lines of the poem most clearly associated with the discomfort of abandonment and alienation—lines 4 and 8—are also the only two that Brahms chose to repeat, thus providing an opportunity to emphasize the composition of elements from the text-space and music-space.

ELABORATION Entering further into the world of Brahms's song, we can see that Brahms's singer is thoroughly within the foreign lands as she sings, and, although her deflections toward major keys suggest an attempt to make herself comfortable in these alien surroundings, she remains an anonymous stranger—she cannot escape the iron grip of F♯ minor, just as she cannot escape her isolation. Nonetheless, Brahms's singer does not despair—at least not yet. Instead, she struggles against her fate, crying out against her anonymity in her highest register, attempting to use her predicament as a lever to gain recognition and a life in this foreign land. Given this text and this music, we can imagine her shaking her fist at fate; if her eyes fill with tears, they are tears of a struggle against destiny.

Summary

With his setting of "In der Fremde" Brahms clearly wanted to demonstrate his independence as a composer, as well as to pay homage to an important friend and mentor. Yet, two other factors are important. The first is raw youth: Brahms at nineteen was no stranger to feelings of alienation and restless energy, and it is hardly surprising that he drew these from Eichendorff's poem. The second are the compositional advances made by Schumann in the *Liederjahr* of 1840: the year bore witness not only to an incredible outpouring of song but also to a new understanding of how musical syntax could be shaped to respond to the possibilities of poetry. Brahms learned the lessons of Schumann's Liederjahr, as well as the many other lessons taught by the music of his century, and he built on them. Where cadence was still a primary articulator of the musical argument for the Schumann of 1840, it became something infinitely more malleable for the Brahms of 1852. Indeed, over the course of Brahms's "In der Fremde," there is not one clear cadence; instead, there are cadences disrupted, so understated as to be almost invisible (as the cadence of m. 23), or assembled out of the bits and pieces of traditional cadential formulae (which is how Brahms brings the song to a conclusion). Brahms, of course, knew when and how to exploit traditional cadential formulae, and he did so with great success in the years that followed, but his setting of "In der Fremde" shows that, when his understanding of a text demanded it, he could create a new set of syntactic possibilities for musical discourse.

CONCEPTUAL BLENDING AND SONG

As part of his anthropological fantasy on the origins of language, Jean-Jacques Rousseau imagined the primordial world that gave birth to the languages of the temperate south. Around the water wells necessary for life in these arid lands people gathered, and young men met young women for the first time.

> Beneath aged oaks, conquerors of years, an ardent youth gradually forgot its ferocity, gradually they tamed one another; through endeavoring to make themselves understood, they learned to explain themselves. There the first festivals took place, feet leaped with joy, eager gesture no longer sufficed, the voice accompanied it with passionate accents; mingled together, pleasure and desire made themselves felt at the same

> time. There, finally, was the true cradle of peoples, and from the pure crystal of the fountains came the first fires of love.[33]

As Rousseau would have it, the language that developed around these aqueous gathering places was not like modern language, but a fusion of words and music:

> Around the fountains of which I have spoken, the first discourses were the first songs; the periodic and measured recurrences of rhythm, the melodious inflections of accents caused poetry and music to be born along with language; or rather, all this was nothing but language itself in those happy climates and those happy times when the only pressing needs that required another's help were those to which the heart gave rise.[34]

In the myth Rousseau offers, music and language don't simply cohabitate; they commingle their syntaxes: the periodic and measured recurrences of rhythm and the inflections of accent are combined in an Ur-language, which, only later, after the Fall or its equivalent, separated into music and language.

In the end, Rousseau's fantasy has more to tell us about the role of language and music in the anthropological speculations of the eighteenth century than it does about the possibility that the two media were once one.[35] But the conviction that music represents a communicative medium to equal language—a conviction Rousseau shared with his old antagonist Rameau[36]—and the idea that the sum of music and language might be greater than its parts are concepts writers like Müller and von Spaun believed were demonstrated, in fairly specific ways, by the nineteenth-century Lied. While it is possible to dismiss such beliefs as products of overheated rhetoric, the fascination composers, audiences, and critics have had with song cannot be ignored. Conceptual blending offers a way to explain why this fascination has been so enduring: under certain circumstances, elements and relations from the mental space set up by the music of a song blend with elements and relations from the mental spaces set up by the text to create a new world for the imagination—a world of supernatural charm, nocturnal terror, and much, much more.

For conceptual blending to occur, the mental spaces that serve as inputs to the blend must have a shared topography. For the songs analyzed in this chapter I have located this shared topography in commonalities between the complete discourse

33. Jean-Jacques Rousseau, "Essay on the Origin of Languages (c. 1763)," in *Essay on the Origin of Languages and Writings Related to Music*, trans. and ed. John T. Scott, Collected Writings of Rousseau, 7 (Hanover, N.H.: University Press of New England, 1998), 314. In my comments on Rousseau's essay, I am more concerned with the idyllic state he imagines than with the overall context relative to which the image is framed. For a probing discussion of this context, see Lydia Goehr, *The Quest for Voice: Music, Politics, and the Limits of Philosophy* (Berkeley: University of California Press, 1998), 98–106.

34. Rousseau, "Essay on the Origin of Languages," 318.

35. For more on the role of language and music in speculations about human origins by French writers of the eighteenth century, see Downing A. Thomas, *Music and the Origins of Language: Theories from the French Enlightenment*, New Perspectives in Music History and Criticism (Cambridge: Cambridge University Press, 1995), chap. 2.

36. Although Rousseau and Rameau both argued that music was the equal to language, for Rousseau this meant melody and for Rameau it meant harmony. This difference of opinion (among other things) was the basis for their debate about musical expression, discussed at the end of chap. 3 in this volume.

structure set up by the music and the complete discourse structure set up by the text. That such commonalities might exist suggests deep correspondences between musical and linguistic syntax. To be sure, these correspondences are, in most instances, of a general sort, outlining as they do constructs like contrasting ontological states (as in the settings of "Trockne Blumen" and in Schumann's "In der Fremde"), exterior and interior domains (as in "Im Rhein"), or discomfort with foreign surroundings (as in Brahms's "In der Fremde"). And yet, such highly abstract constructs still have their power, for they can find realization in manifold concepts associated with both the emotions and the intellect.

Agawu ended his provocative 1992 essay with these words: "We await the development of a syntax of song."[37] The preceding analyses suggest that this syntax is to be found not "in" the song proper, but in the way the constituent media of song—words and music—relate to one another. The syntax of song, then, is a syntax of conceptual blending, through which music breathes life into poetry and poetry breathes life into music, and together they proceed as song.

CHAPTER SEVEN

COMPETING MODELS OF MUSIC: THEORIES OF MUSICAL FORM AND HIERARCHY

Midway in her journey through Wonderland, Lewis Carroll's Alice takes leave of the Cheshire Cat and makes her way toward the house of the March Hare. There she finds a tea party under way—a mad, perpetual tea party, attended by the March Hare, the Mad Hatter, and the somnolent Dormouse. As the party proceeds, Alice's patience begins to wear thin, tried by turnabout word play and abrogated manners, and is stretched to the limit when she finds out that the Hatter's riddle—"Why is a raven like a writing desk?"—is without solution.

> Alice sighed wearily. "I think you might do something better with the time," she said, "than wasting it in asking riddles that have no answers."
>
> "If you knew Time as well as I do," answered the Hatter, "you wouldn't talk about wasting *it*. It's *him*."
>
> "I don't know what you mean," said Alice.
>
> "Of course you don't!" the Hatter said, tossing his head contemptuously. "I dare say you never even spoke to Time!"
>
> "Perhaps not," Alice cautiously replied; "but I know I have to beat time when I learn music."
>
> "Ah! That accounts for it," said the Hatter. "He wo'n't stand beating. Now, if you only kept on good terms with him, he'd do almost anything you liked with the clock."[1]

Exchanges like this are common enough in Wonderland, a place inhabited by creatures whose logic is often as fantastic as their appearance. Nonetheless, the game Carroll is playing at here is less a matter of labyrinthine logic and more a matter of different ways to structure what is putatively the same domain. Alice uses two different cross-domain mappings to reckon with time: time as something to be saved or wasted (mapping from the domain of commodities or substances onto the domain of time); and time as a set of regular motions (mapping from the domain of physiologically defined space onto the domain of time). For the Hatter's cockeyed contribution, Carroll exploits a traditional characterization of time as a human

agent (as in Father Time, or the New Year as a diapered baby), an anthropomorphic mapping that exploits conceptual blends like those discussed in the latter portion of chapter 2. The merry confusion of mappings that results is part and parcel of the imaginary world Carroll constructed—indeed, Wonderland is a maze of interfiliated conceptual blends. However, the scene at the tea party also throws into relief a fundamental conflict between Alice's world and that of Wonderland, which comes to a head in the final chapter. There, Alice responds to the Queen of Hearts's peremptory "Off with her head!" ("Sentence first—verdict afterwards") by dismissing the entire court and courtroom with "Who cares for you? You're nothing but a pack of cards!" At this, Wonderland disappears, and Alice wakes to find herself lying on the bank of the river, with her head in the lap of her sister.[2]

A confusion of mappings similar to the one apparent in Alice's dialogue with the Hatter often arises in music theory. The result, while not quite as entertaining as a turn in Wonderland, can have some of the same flavor. Theorists appear to be talking about the same thing, but they structure their understanding of it in very different ways. Two examples are taken up in this chapter. The first involves musical form, the second musical hierarchy.

During the eighteenth century, the study of musical form emerged as an important basis for discourse about music. Form was regarded as dealing with the very essence of musical works: how musical materials were arranged and correlated over the course of a piece of music. As the study of form developed and was continued through the nineteenth century, theorists worked with two basic—and seemingly opposed—models of musical form, one static, the other dynamic. Musical form, viewed from a static perspective, is reminiscent of architecture (a parallel all the more ironic, given Friedrich von Schelling's characterization of architecture as "frozen music")[3] and typically consists of either a framing structure clad with musical material or relatively abstract containers filled with musical events. Musical form from a dynamic viewpoint is processive and a bit unpredictable: the musical work emerges over the course of time, and musical materials are both the substance of and raison d'être for this emergence. As a further complication, the cross-domain mappings that activated these two models changed during the nineteenth century. Consequently, there are two levels of mapping involved, both of which can breed confusion about just what is meant by musical form: a generic level associated with the two basic models (one interpreting form as static, the other as dynamic); and a specific level associated with the cross-domain mappings that activate the generic models. In the first section that follows, I explore static and dynamic models of musical form that emerged in the eighteenth century and the way these models were transformed by changes in ideology and music education that took place beginning late in that century.

2. Carroll, *The Annotated Alice*, 124.

3. "Architecture, as the music of the plastic arts, thus necessarily follows arithmetical relationships. Since it is music in space, however, in a sense, solidified music, these relationships are simultaneously geometric relationships." Friedrich Wilhelm Joseph von Schelling, *Philosophy of Art*, ed., trans., and intro. Douglas W. Stott, with a foreword by David Simpson, Theory and History of Literature, 58 (Minneapolis: University of Minnesota Press, 1989), 165. See also, on p. 177, the passage that begins "If architecture is indeed solidified music . . ."

The two models of musical hierarchy I deal with in the second of the two sections that follow are a somewhat different matter, for these models were first developed to apply to domains other than music. It was only in the early nineteenth century that they were applied to music, and then to two rather different aspects of musical organization. The first model views hierarchy as a matter of control: each level in a hierarchy (with the exception of those at the extremes) controls the next-lower level and is itself controlled by the next-higher level. This model stretches back at least to the Middle Ages and is most often used to account for tonal organization. The second model of hierarchy relies on a more componential approach: the elements of level A of the hierarchy combine to make up individual elements at the next-higher level (level B of the hierarchy); the elements of level B then combine to make up individual elements at the next higher level (level C of the hierarchy), and so on, until the account of structure is exhausted. This model emerged during the seventeenth century and is most often used to explain music's metrical structure.

When confronted by a maze of mapping like those I have just outlined, mappings that yield contradictory accounts of quite basic musical materials, our inclination may be to throw up our hands and shout the equivalent of "Who cares for you? You're nothing but a pack of cards!" But problems of musical understanding are rarely so easily dismissed. Instead, we must enter into the mad tea party that is music theory, where music theorists from different nations and different historical periods gather around the table to discuss and dispute musical concepts. If we are to make sense of the conversation there, we need to understand how cross-domain mapping shapes this discourse—indeed, as I suggested in chapter 2, how it makes music theory possible.

TWO MODELS OF MUSICAL FORM

There was a certain enviable simplicity to the study of music in the fin de siècle Anglo-American musical world, due in no small part to its near-complete subjugation to the German musical world.[4] Music teachers in Anglo-American circles were either German or trained in Germany, the repertoire studied was almost entirely German, and the theoretical models—developed exclusively with respect to German musical practice—had been formulated by German music theorists of the nineteenth century. Thus the beginning Anglo-American music student of the late nineteenth and early twentieth century learned a tradition of musical study that was almost entirely German. This is not to say, however, that the tradition they assimilated was completely unified. Consider, for instance, the account of musical motives offered by Ebenezer Prout, a prominent music educator in England during the late nineteenth century. Having distinguished between phrases (which end with a cadence) and sections (subphrase units that do not necessarily end with a cadence), Prout makes one further subdivision:

> Every section contains at least two [metric] accents, and can be separated into smaller parts, containing only one accent each. Such parts are called MOTIVES, and correspond

4. By "German musical world," I mean the German-speaking countries of Europe.

> exactly to the *feet* in poetry. Here we have what (to borrow a scientific term) we may call the "protoplasm"—the germ out of which all music springs. A thorough knowledge of the nature of the motive is therefore indispensable to anyone who would understand the fundamental principles of musical form.[5]

Important for Prout's characterization of a motive are the dynamic context provided by metrical accentuation—he will later define motive as composed of a strongly accented note preceded by at least one unaccented note[6]—and the somewhat more abstract notion of a motive as the seed of a musical organism.

Rather different is the approach to motive taken some ten years later by Percy Goetschius, born in New Jersey but educated in Stuttgart, where he first taught. Goetschius situates the motive in an explicitly grammatical context:

> The smallest unit in musical composition is the single tone. The smallest cluster of successive tones (from two to four or five in number) that will convey a definite musical impression, as miniature musical idea, is called a Figure. Assuming the single tone to represent the same unit of expression as a letter of the alphabet, the melodic figure would be defined as the equivalent of a complete (small) word;—pursuing the comparison further, a series of figures constitutes the melodic motive, equivalent to the smallest group of words (a subject with its article and adjective, for example); and two or three motives make a Phrase, equivalent to the complete, though comparatively brief, sentence (subject, predicate, and object).[7]

In contrast with Prout's dynamic account of musical form, Goetschius relies on a highly schematized grammar of musical elements. So formalized is this grammar that it ultimately reduces to a matter of counting measures: "Melodic motives differ in length from one to four measures; by far the most common extent, however, is two measures, and the student will do wisely to accept this dimension and analyze accordingly, unless there is unmistakable evidence to the contrary."[8]

What we have in these excerpts, then, are two markedly different approaches to musical form, voiced through characterizations of motive.[9] Prout's is the more dynamic: music is likened to some sort of organism, and the motive is the seed from which it springs. Goetschius's approach, by contrast, is rather more static: music is but prose in tones, and the motive is simply the smallest intelligible syntactic unit.

6. Prout, *Musical Form*, 31.

7. Percy Goetschius, *Lessons in Music Form: A Manual of Analysis of All the Structural Factors and Designs Employed in Musical Composition* (Bryn Mawr, Penn.: Oliver Ditson, 1904), 19.

8. Goetschius, *Lessons in Music Form*, 23.

9. Although I have chosen to highlight the differences between Prout's and Goetschius's approaches to musical form, Robert Gjerdingen has reminded me that the two theorists knew each other's work and exchanged dedications of their texts. Moreover, not all theorists within the Anglo-American tradition agreed on the importance of motive. For instance, Stewart Macpherson, whose book on form supplanted that of Prout and who was mightily suspicious of overly thorough analyses, wrote, "As an example of a too mathematical conception of analysis may be instanced the stress laid by some theorists upon an arbitrary dissection of the music into certain metrical fragments called motives, a dissection of which usually conveys little or nothing to which the musical sense can respond." Macpherson, *Form in Music: With Special Reference to the Designs of Instrumental Music* (London: Joseph Williams, 1908), 39. A footnote makes clear that in referring to "some other theorists," Macpherson actually meant Prout.

However, two related factors complicate these seemingly neat constructions. First, neither Prout nor Goetschius eschews entirely the approach of the other. Prout is perfectly capable of rendering a crushingly static account of musical form, and Goetschius knows how to enliven his account to make music seem more like an organism than a dry recitation. Second, both of these models of form originate in mappings between language and music (a mapping more obvious in the excerpt from Goetschius, but evident as well in Prout's reference to poetic feet). To untangle matters, we need to begin with theories of musical form developed during the Enlightenment. From there we must proceed to explore how these theories were subsequently reformulated in the first half of the nineteenth century under the influence of political and ideological pressures that transformed the way music was taught.

Grammar, Rhetoric, and Musical Form in the Eighteenth Century

Mappings between music and language go back at least to the Middle Ages. For instance, the ninth-century *Musica enchiriadis* opens with an analogy that anticipates Goetschius by over a thousand years: "Just as the elementary and indivisible constituents of speech (*vox articulata*) are letters, from which syllables are put together, and these in turn make up verbs and nouns, and from them is composed the fabric of a complete discourse, so the roots of song (*vox canora*) are *phthongi* [musical notes], which are called *soni* in Latin. The content of all music is ultimately reducible to them."[10] In the eighteenth century, mappings between language and music flourished and—as an almost inevitable consequence—became more manifold and more complicated. Enlightenment preoccupations with the origins of language and the place of music within systems of human communication led to a number of proposals for how language and music did, or did not, relate to one another.[11] The continued growth of print culture made it increasingly common for music and language to intersect—as score and text—on the printed page, a phenomenon exploited by author-printers such as Samuel Richardson.[12] Finally, a growing middle class fueled a demand for music instruction books, and, within these books, mappings between language and music provided a ready frame of reference for the explanation of fundamental musical concepts. During this period, two mappings from the domain of language onto the domain of music became particularly important for accounts of musical form: the first mapped from grammar onto music, the second mapped from rhetoric onto music.

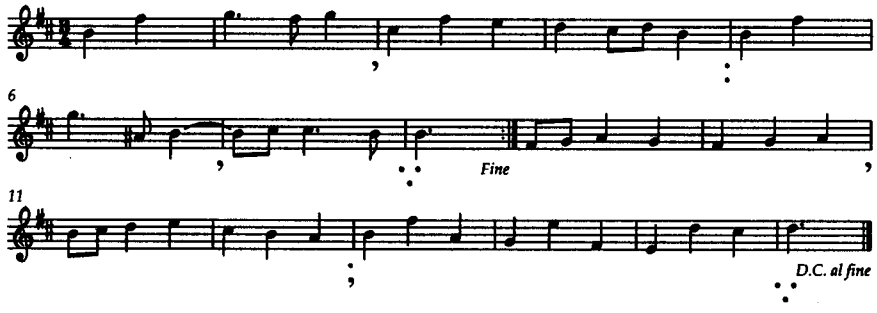
GRAMMAR AND MUSIC Mappings between grammar and music were based on the assumption that music was language-like in its organization—that is, it had structural features analogous to those of language and a normative syntax. The mapping also relied on a familiarity with and respect for grammar acquired through the thorough grounding in the subjects of the Classical trivium—rhetoric, grammar, and logic—that was a common feature of early education in the eighteenth century. Just as every verbal construct, whether spoken or written, can be divided up into clauses, sentences, and paragraphs, the thinking went, so can musical works. This was the basis of Johann Mattheson's account of musical grammar, first proposed in his *Kern melodischer Wissenschaft* of 1737 and subsequently expanded in his *Der vollkommene Capellmeister* of 1739.[13] Mattheson began his discussion with vocal music, showing how the grammar of music had to be in rapport with that of the text: each of the significant divisions in the text had to be supported by analogous divisions in the music. This led Mattheson to a discussion of what things made for effective musical divisions (typically, cadence was the main articulative event) and how such divisions were graded from the barely noticeable to the emphatic.[14]

In a subsequent chapter of *Der vollkommene Capellmeister*, Mattheson argued that knowledge of this sort was even more important for knowing how to write instrumental music. He illustrated his discussion with the minuet shown in example 7.1.[15] Mattheson analyzes the whole as a paragraph, made up of two periods (or *Sätzen*; mm. 1–8 and 9–16), which are divided into a clause (marked by the colon below m. 4), a subclause (marked by the semicolon below m. 12), and phrases (marked by the commas below mm. 2, 6, and 10). Lacking, however, is any explanation for how these analytical decisions were made—why, for instance, mm. 1–4 constitute a clause, while mm. 9–12 constitute a subclause. The reader is left with a clear sense of the importance of grammatical structure to musical works—that grammar is, in fact, a self-evident property of musical works—but with only a few hints as to how the grammatical divisions in music are determined.



A more complete methodology for analyzing musical grammar was provided some fifteen years later by Joseph Riepel in his *Grundregln zur Tonordnung insgemein* of 1755 (the second volume of his *Anfangsgründe zur musicalischen Setzkunst*). Using a thoroughly schematic and comparatively systematic approach to musical organization (written in the dialogue style common in pedagogical treatises of the day), Riepel made explicit connections between grammatical components and musical passages, illustrated through hundreds of examples drawn from or applicable to

13. Johann Mattheson, *Kern melodischer Wissenchaft* (Hamburg: C. Herold, 1737; repr. Hildesheim: Georg Olms, 1976); idem, *Der vollkommene Capellmeister* (Hamburg: C. Herold, 1739; repr. Dokumenta musicologica, 1. Reihe, Druckschriften-Faksimiles, 5, ed. Margarete Reimann [Kassel: Bärenreiter, 1954]).

15. Mattheson, *Der vollkommene Capellmeister*, 223–25; Harriss, *Mattheson's* Der vollkommene Capellmeister, 451–53. For a discussion and analysis of this passage, in a slightly different context, see Ian Bent, ed., *Fugue, Form and Style* (vol. 1 of *Music Analysis in the Nineteenth Century*), Cambridge Readings in the Literature of Music (Cambridge: Cambridge University Press, 1994), 5–6.

EXAMPLE 7.1 Minuet analyzed by Johann Mattheson in *Der vollkommene Capellmeister*, part 2, chap. 13

instrumental music.[16] Riepel based his analysis of the grammatical function of a musical passage on harmonic structure and on the assumption that subdivision of the phrase into even-numbered units was the norm in instrumental music. Although his references to the grammatical structure of speech are explicit, they are also relatively few in number. Subphrase units (which Riepel called *Einschnitte*, and which were usually less than four measures in length) were marked by incomplete harmonic progressions—that is, they ended inconclusively. In contrast, the phrase (the *Satz* or, more frequently, the *Absatz*) was a four-bar unit that provided a complete harmonic progression: it had a conclusive ending. Each Absatz was further characterized on the basis of whether it ended on tonic, on the dominant, or in some other key.[17] By this means, Riepel was able to give an exhaustive (and at times exhausting) account of the different sorts of grammatical structures that might be evinced by music, based on the ways various components could be fit together and modified.

Riepel's approach to musical grammar was adopted by Heinrich Christoph Koch in his *Versuch einer Anleitung zur Composition* (1782–1793), but Koch began his account by returning to the model of speech. After noting the importance of "certain more or less noticeable resting points of the spirit" to those fine arts that attain their goal through speech—namely, poetry and rhetoric—Koch then draws the connection to music.

> Speech . . . breaks down into various sentences [*Perioden*] through the most noticeable of these resting points of the spirit; through the less noticeable the sentence, in turn,

16. Joseph Riepel, *Grundregln zur Tonordnung insgemein* (vol. 2 of *Anfangsgründe zur musicalischen Setzkunst*) (Regensburg: Johann Leopold Montag, 1755), 32–56; idem, *Sämtliche Schriften zur Musiktheorie*, ed. Thomas Emmerig, Wiener musikwissenschaftliche Beiträge, 20 (Vienna: Böhlau, 1996), 138–62.

17. For further discussion of Riepel's approach, see Justin London, "Riepel and *Absatz*: Poetic and Prosaic Aspects of Phrase Structure in 18th-Century Theory," *Journal of Musicology* 8 (1990): 505–19; Nola Reed Knouse, "Joseph Riepel and the Emerging Theory of Form in the Eighteenth Century," *Current Musicology* 4 (1986): 46–62; and John Walter Hill, "The Logic of Phrase Structure in Joseph Riepel's *Anfangsgründe zur musikalischen Setzkunst*, Part 2 (1755)," in *Festa musicologica: Essays in Honor of George J. Buelow*, ed. Thomas J. Mathiesen and Benito V. Rivera, Festschrift Series, 14 (Stuyvesant, N.Y.: Pendragon Press, 1995), 467–87.

> breaks down into separate clauses [*Sätze*] and parts of speech [*Redetheile*]. Just as in speech, the melody of a composition can be broken up into periods by means of analogous resting points, and these, again, into single phrases [*Sätze*] and melodic segments [*Theile*].[18]

However, Koch also saw limits to the applicability of mapping from the grammar of speech onto the grammar of music. After a long and thoughtful passage in which he pursues the notion that musical phrases are organized around subjects and predicates as are those of speech, Koch turns away from the model. He writes, "I am abandoning this comparison because, as already mentioned, subject and predicate cannot be differentiated enough in melodic sections. We must content ourselves with learning how to determine, through feeling, the presence or absence of resting points of the spirit and the nature of sections with regard to their completeness."[19] As did Riepel, Koch assumes subdivision of the phrase into even-numbered units to be the norm. He uses harmonic structure—specifically, the harmony with which each phrase ends[20]—to determine the divisions of musical grammar. And he builds larger musical structures by modifying and concatenating musical phrases.

Mappings between grammar and music of the sort evident in the work of Mattheson, Riepel, and Koch allowed writers in the eighteenth century to give detailed accounts of musical organization and to indicate how composers manipulated musical materials to create unique musical statements that nonetheless conformed to certain basic syntactic principals.[21] The mapping yields a characterization that emphasizes the static rather than the dynamic—what Koch came to call the "mechanical" aspect of music in the introduction to the second volume of his *Versuch*.[22] Each unit of musical grammar can be contemplated and discussed separately,

18. Heinrich Christoph Koch, *Introductory Essay on Composition: The Mechanical Rules of Melody, Sections 3 and 4*, trans. Nancy Kovaleff Baker, Music Theory Translation Series (New Haven, Conn.: Yale University Press, 1983), 1. The source from which Baker's translation is drawn is the second volume of Koch's *Versuch einer Anleitung zur Composition* (Leipzig: Adam Friedrich Böhme, 1787; repr. Hildesheim: Georg Olms, 1969). I have adapted this and the following quotation to restore Koch's somewhat unwieldy locution "resting points of the spirit" ("Ruhepuncte des Geistes"), which preserves the subjective aspect of determining music-grammatical divisions.

19. Koch, *Introductory Essay on Composition*, 6, translation adapted. In a note to this passage, Koch explains that he abandoned strict comparisons between the phrases of speech and melody because his treatise is intended for beginning musicians who wish to learn composition, and "these seldom have either grammatical knowledge of speech or familiarity with that part of logic which explains the different types of phrases and their closures."

20. Koch writes, "The essential difference between an internal phrase and a closing phrase depends on nothing more than the essential difference of ending formulas." Koch, *Introductory Essay on Composition*, 7.

21. As noted in chap. 2, it is through mappings such as these that theorists bring an integrated system of terms and structural relations to bear on particular problems of musical understanding. In chap. 2, the problems discussed had to do with ways to characterize tonal organization. Here the problems relate to how musical materials should be organized to create meaningful utterances.

22. Nancy Kovaleff Baker and Thomas Christensen, eds. and trans., *Aesthetics and the Art of Musical Composition in the German Enlightenment: Selected Writings of Johann Georg Sulzer and Heinrich Christoph Koch*, Cambridge Studies in Music Theory and Analysis, 7 (Cambridge: Cambridge University Press, 1995), 140.

and each can be fit together with other such units to create a complete statement at the level of a paragraph or higher. The perspective, then, is inherently constructivist: mapping grammar onto music isolates the building blocks of music and describes how they fit together to create coherent structures.

The account of musical form produced by this mapping is one that tends to emphasize complete, free-standing structures, as well as a synoptic view of such structures.[23] What is incomplete is ungrammatical; what is ungrammatical is incomplete. This is a view of basic materials well suited to pedagogy—mappings from grammar to music are invariably connected with lessons in composition—but one that has little to say about the process of constructing grammatical statements that are both complete and compelling.

RHETORIC AND MUSIC One of the principal uses of mappings from rhetoric to music during the eighteenth century was to describe how to go about composing music and the laying-out of musical materials in particular. Mattheson, in his *Das neu-eröffnete Orchestre* of 1713, offers the following analysis: "A [musical] composition comprises three things: Inventio (*Erfindung*), Elaboratio (*Ausarbeitung*), [and] Executio (*Ausführung* or *Aufführung*), which seem to display a close relationship to oratory or rhetoric. The last two things can be learned; the first has no competent master."[24] Of course, Mattheson is being somewhat disingenuous here, since the three techniques he mentions—and, for that matter, the very term "composition"—are all derived from the teaching of Classical rhetoric and were only secondarily applied to music. Twenty-six years later, in *Der vollkommene Capellmeister*, Mattheson expanded this plan to include a total of five stages: Inventio (*Erfindung*), Dispositio (*Einrichtung*), Elaboratio (*Ausarbeitung*), Decoratio (*Schmückung* or *Zierde*), and Executio (*Ausführung* or *Aufführung*).[25] In this more extensive application of rhetoric to music, Mattheson also drew on the structural categories of rhetorical theory to characterize the parts of a musical work (as distinct from the process of creating the work). These he identified as the Exordium (*Eingang*), Narratio (*Bericht*), Propositio (*Antrag*), Confirmatio (*Bekräfftigung*), Confutatio (*Wiederlegung*), and Peroratio (*Schluß*). Mattheson then used these categories to analyze the music of a *da capo* aria by Benedetto Marcello, but the result was at best a mixed success:

23. As I understand it, this synoptic view of the musical work does not recover what Michel Foucault calls the "simultaneity" of thought: musical works, whether "paragraphs" or "chapters," must still unfold in the temporal series specified by their grammar. The synoptic function instead reflects the taxonomy of forms basic to grammatical systems. There is an immediacy to such taxonomic units—be they phrases or paragraphs, books or symphonies—that is independent of the time it takes to traverse the individual syntactic components they comprise. On the simultaneity of thought, see Foucault, *The Order of Things: An Archaeology of the Human Sciences* (New York: Vintage Books, 1973), 83.

24. "Es gehören sonst zu einen Composition dreyerley: Inventio, (Die Erfindung) Elaboratio, (Die Ausarbeitung) Executio, (Die Ausführung oder Aufführung) welches eine ziemliche nahe Verwandschafft mit der Oratorie oder Rhetorique (Rede-Kunst) an den Tag legt; Die beyden lezten Stücke können erlernet werden; zum ersten hat sich noch kein tüchtiger Maitre." Johann Mattheson, *Das neu-eröffnete Orchestre* (Hamburg: Printed for the author, 1713; repr. Hildesheim: Georg Olms, 1993), 104.

25. Mattheson, *Der vollkommene Capellmeister*, 235; Harriss, *Mattheson's* Der vollkommene Capellmeister, 470.

the aria simply did not provide an adequate target for mappings from the traditional structure of oratory.[26]

Where Mattheson's mappings between *grammar* and music pointed to a fruitful model for characterizing musical organization, his proposed mappings between *rhetoric* and music never flourished in the same way. One problem was that the structural model of an oration used in Classical rhetoric was simply too rigid for music—indeed, there was every sign that it was coming to be regarded as too rigid for speech as well.[27] Another problem was that the flexibility of musical semantics made it difficult to develop hard and fast rules for what counted as a Propositio, a Confirmatio, or any of the other elements of an oration: it was clear to Mattheson and other theorists that music had meaning, but just how this meaning corresponded with the figures and processes of Classical rhetoric proved difficult to specify.[28]

The account of the *process* of composition afforded by rhetoric was given new promise when it was incorporated into the theory of aesthetics promulgated by Johann Georg Sulzer in his *Allgemeine Theorie der schönen Künste*, first published in two large volumes in 1771 and 1774. Sulzer drew on Classical rhetoric to develop a general characterization of the creative process, reflecting his belief that art shared with rhetoric the goal of moral improvement. According to Sulzer, the artist first discovers the ideas necessary to a work of art through invention. After the ideas have been discovered, the artist then realizes them through a three-stage process: *Anlage* (layout), *Ausführung* (realization), and *Ausarbeitung* (elaboration).[29] Of these, the latter two stages are identical with those identified by Mattheson in *Das neu-eröffnete Orchestre*. Sulzer's first stage corresponds with the second stage—Dispositio (*Einrichtung*)—of the expanded plan presented in *Der vollkommene Capellmeister*. (Of Sulzer's treatment of Mattheson's first stage—Inventio—more presently.)

The approach to composition outlined by Sulzer, while promising, was also very

26. Mattheson's analysis is in *Der vollkommene Capellmeister*, 237–39 (pp. 472–76 of the Harriss translation). For discussion, see Mark Evan Bonds, *Wordless Rhetoric: Musical Form and the Metaphor of Oration*, Studies in the History of Music, 4 (Cambridge, Mass.: Harvard University Press, 1991), 82–90; and Peter Hoyt, "Review of Mark Evan Bonds, *Wordless Rhetoric*," *Journal of Music Theory* 38 (1994): 127–29.

27. For further discussion of the limitations of rhetorical models, see Hoyt, "Review of *Wordless Rhetoric*," 130–33.

28. The problem is, if anything, more intractable at the level of individual rhetorical figures, as is evident in the complicated and occasionally redundant system set up by Joachim Burmeister in the early seventeenth century; see Burmeister, *Musical Poetics [1606]*, trans. Benito Rivera, Music Theory Translation Series (New Haven, Conn.: Yale University Press, 1993). For his part, Mattheson attempts no formalization of rhetorical figures, preferring to describe a few of them, indicate the applicability of many more, and then move on; see *Der vollkommene Capellmeister*, 243–44 (pp. 482–84 of the Harriss translation).

Although locating the specifics of rhetorical structure in musical discourse is challenging, the importance of rhetoric for all manner of thought and expression—even beyond the eighteenth century—should not be underestimated. For a discussion of the importance of rhetoric in scientific discourse, for instance, see Jeanne Fahnestock's recent *Rhetorical Figures in Science* (New York: Oxford University Press, 1999).

29. My summary of Sulzer's aesthetic theory and translation of the German terms for the stages in the compositional process are taken from Thomas Christensen's introduction to Sulzer's writings in Baker and Christensen, *Aesthetics and the Art of Musical Composition*, 3–24.

abstract, and it lacked specifics where music was concerned. These were supplied by Koch in the second and third volumes of his *Versuch*, in which he endeavored to show how Sulzer's three-stage process could be implemented with musical materials.[30] Where Sulzer was vague, having attempted to give an account of composition adequate for all the fine arts, Koch was specific, providing a detailed account of just what was involved at each stage of the compositional process, which he illustrated with an analysis of an aria from Carl Heinrich Graun's highly popular cantata *Der Tod Jesu* of 1755.[31] Making Sulzer's framework for the compositional process specific for music also provided a further justification for the technical language of musical grammar developed by Koch, for Koch believed it was by the conscious manipulation of this grammar that the beginning composer could create an aesthetically satisfying final work.

Mappings between rhetoric and music allowed music theorists like Mattheson and Koch to describe the compositional process in terms of distinct stages, which made it possible to give specific advice about how the novice composer should proceed along the way. Inasmuch as this process was construed as analogous to that undertaken in other art forms, music was placed on a parallel with sister arts to which it had formerly been but a poor cousin. Mapping from rhetoric to music also allowed music—more specifically, untexted music—to be regarded as a medium with persuasive powers similar to that of oratory. Although the trope of music as oratory was common at least since the Renaissance, preoccupations with the relationship between language and music during the Enlightenment revivified the analogy and put into relief the dynamic aspect of music: here was a type of oratory that not only unfolded over time but also was conducted in the pure language of tones—what Mattheson called *Klang-Rede* (sound-speech).

The view of the compositional process and its product afforded by mapping from rhetoric to music also highlighted the essential mystery of musical creation. This is plainest in the quotation from Mattheson's *Das neu-eröffnete Orchestre*—"invention is the process that knows no competent master"—but it is also evident in Sulzer's discussion of invention in the *Allgemeine Theorie* and in Koch's adaptation of that discussion in his *Versuch*. At first Sulzer maintains that invention is a capacity that can be improved through diligent and careful practice: "The power of invention, like the power of judgment, is a natural and inborn faculty that all men possess in proportion to their own genius. And just as one may turn to reason to aid one's power of judgment, so can one's talent for invention be augmented, in as much as it might be treated, like logic, as a part of philosophy."[32] Sulzer's initial suggestion for accomplishing this augmentation is to turn to rhetoric, urging the artist to exploit the rules and methodology that rhetoricians had developed for the express

30. Koch's realization of Sulzer's plan is discussed in Ian Bent, "The 'Compositional Process' in Music Theory 1713–1850," *Music Analysis* 3 (1984): 29–55; and by Nancy Kovaleff Baker in her introduction to Koch's writings in Baker and Christensen, *Aesthetics and the Art of Musical Composition*, 111–43. Koch was apparently unaware of Sulzer's work when he prepared his first volume, published in 1782.

31. Koch's analysis of Graun's aria can be found in translation in Baker and Christensen, *Aesthetics and the Art of Musical Composition*, 163–76.

32. Baker and Christensen, *Aesthetics and the Art of Musical Composition*, 56.

purpose of discovering useful ideas. But as attractive as such an orderly process is for the ever-moralizing Sulzer, he ultimately realizes that it is not the most productive where invention is concerned. Better to be constantly occupied with one's art, for one will surely stumble upon good ideas this way. As Sulzer ruefully admits,

> The most important inventions probably do not arise through the first deductive manner described above, but rather by the second way: the main subject appears only dimly at first to the artist; he recognizes its importance and takes time to think about its contents so it can be set in its proper light. This is how a famous composer told me he worked. He had more than once saved material that he heard by chance to use as a theme or subject for a composition. He never could have invented anything as good had he decided ahead of time to look for something having the identical character of expression.[33]

In this Koch agrees, writing, "Theory will never be able to invent a truly effective means to indicate just how the beginning composer should contrive that a beautiful melody arises in his soul."[34] However, once inspiration strikes and invention has commenced, the composer must work with haste to capture the whole in a plan of the sort Koch developed for Graun's aria. The plan in place, the composer may then proceed to the more mechanical side of musical composition.

The mystery surrounding invention, together with the focus on purely musical meaning afforded by mapping the structures of rhetoric onto music, suggests an independence for music adumbrated by Koch's reflections on the value of theory. Music, now more than simply materials to be manipulated, is something that arises in the soul of the composer. Although the full flowering of the idea that music was an autonomous medium would have to wait until the turn into the nineteenth century, we can see its seeds in eighteenth-century mappings from rhetoric to music. These provided a view of music as a powerful and highly dynamic medium with the potential to shape the thought of those who listened to it.[35]

GRAMMAR, RHETORIC, AND MUSICAL FORM It has been traditional and convenient to think of grammar and rhetoric as separate subdomains of language. Of the two, grammar is the simpler and more basic, necessary for proper communication but not the stuff to turn heads. Grammar, reckoned this way, is thus pure syntax, a careful if static ordering of linguistic units. By comparison, rhetoric is more complex and subtle, persuasive because it has true semantic force. As the means by which the passions can be moved, it is truly dynamic.[36] Nonetheless, the

33. Baker and Christensen, *Aesthetics and the Art of Musical Composition*, 61.

34. Baker and Christensen, *Aesthetics and the Art of Musical Composition*, 186.

35. For a discussion of the emergence of the idea that music was an autonomous art form, see Lydia Goehr, *The Imaginary Museum of Musical Works: An Essay in the Philosophy of Music* (Oxford: Clarendon Press, 1992), chap. 6; and Bellamy Hosler, *Changing Aesthetic Views of Instrumental Music in 18th-Century Germany*, Studies in Musicology, 42 (Ann Arbor, Mich.: UMI Research Press, 1981).

36. When Michel Foucault sought to characterize the distinct functions of rhetoric and grammar, he seemed rather deliberately to invert this traditional perspective, arguing that rhetoric is spatial and that grammar distributes that spatiality in time—that is, rhetoric is static and grammar is dynamic (Foucault, *The Order of Things*, 84). However, "spatial" here refers to the simultaneity of thought—to its essential and ongoing polyphony. Grammar distributes this spatiality in time only by freezing fragments of it so

distinctions between the two are hardly as clear-cut as this traditional perspective would have it, and nowhere is this more evident than when they are mapped onto music.

Returning briefly to Riepel, his classification of cadence types provides a case in point. In distinguishing between an Absatz that ends with a "garbled cadence" (*verstümmelter Schluß*) and one that ends with a "complete cadence" (*vollständiger Schluß*), Riepel uses the rhetorical term "enthymeme" for the first, and "syllogismus" for the second.[37] Descending momentarily into the labyrinth of rhetorical terms, we can discover that enthymeme refers to an incomplete syllogism, one in which either the major or minor premise of the syllogism is left implied. A syllogismus, by contrast, calls on the audience to draw an obvious conclusion, the major and minor premise having been stated.[38] Although the mapping between these two terms and the musical phenomena to which Riepel would have them apply is less than perfect, what is important is the implication that each of the grammatical components is imbued with semantic value—syntax has its semantic function. Indeed, as I argued in chapter 4, the manipulation of musical syntax is one of the principal means by which musical semantics is created.

Careful attention to the grain and texture of discourse about music is thus necessary to determine which of these metaphorical mappings is used to structure a given theory of music. Generally speaking, eighteenth-century writers used grammar to emphasize things that do not change in music—suitably defined, an Einschnitt is always an Einschnitt, an Absatz always an Absatz. The same writers used rhetoric to emphasize how music functions in time, either in the challenges it presents a composer attempting to deploy musical materials or in the reaction of a listener persuaded by a musical argument. Grammar gave a view of musical form that was static, and rhetoric gave a view of musical form that was dynamic. Significant, however, is the context relative to which these characterizations were made. As the dynamic view offered by rhetoric began to be more important for those who thought about music, and as the cultural context for thinking about music changed, mappings from language began to give way to other possibilities for conceptualizing music.

Formal Theory in the Nineteenth Century

Over the course of the nineteenth century, the two basic models of musical form that emerged in the eighteenth century remained in place. Musical works could be regarded as manufactured things that comprised discrete—and inherently static—components, or as instances of quasi-abstract communication that unfolded dynamically in time. However, explicit mappings from language to music faded as they

---

that they can be ordered, much as musical materials, isolated from their becoming, are transformed into basic building blocks for the beginning composer.

37. Riepel, *Grundregln zur Tonordnung insgemein*, 59; idem, *Sämtliche Schriften zur Musiktheorie*, 153.

38. These definitions are drawn from Gideon Burton's online *Silva Rhetoricæ*, at http:/humanities.byu.edu/rhetoric/silva.htm.

were absorbed into musical nomenclature or replaced by other mappings that served a similar purpose. Instrumental in this process were the context within which music was taught and the intellectual framework relative to which music was conceptualized. Beginning in the final years of the eighteenth century, music instruction was taken over by institutions concerned as much with the advancement of the state as with education. In consequence, the move toward a complete and comprehensive curriculum that arose in furtherance of the former objective brought with it the development of integrated courses of study that employed both static and dynamic accounts of music. At around the same time, music came to be thought of in organicist terms, and, as a result, even the most basic and isolated of musical materials were imbued with dynamic characteristics. Hence, the conceptual metaphors for musical form established in the eighteenth century—form as static, or form as dynamic—remained in place, but they were activated by a number of different linguistic metaphors.

THE PARIS CONSERVATOIRE AND THE BERLIN UNIVERSITY During the eighteenth century, music education in the French- and German-speaking countries was carried out in a diffuse manner. Students typically studied with a local music master or at a school associated with a church, and there were few if any efforts at centralized music instruction. As a result of various political upheavals, this situation began to change in the late eighteenth century, and music education, together with instruction in other topics, began to be more closely controlled by the state.

The circumstances of music education changed most rapidly in France. After the 1789 revolution, numerous educational reforms were proposed, focused largely on efforts to create a utilitarian educational system and to promote deductive reasoning for the arts and sciences; some of these were at least partially enacted.[39] As a consequence of the diminishing role of the church after the revolution, the system of *maîtrises*—the music schools associated with the major cathedrals—collapsed, leaving two principal options for music instruction: the School of the National Guard (a product of the revolution) and the Old Regime's School of Singing (founded in 1784 with the intent of providing a reliable supply of singers for the Académie Royale de Musique, known familiarly as the Opéra). To realize the goal of conserving a French national music that was free from the influence of Italy and Germany, the Republic in 1795 consolidated the faculty and power of these two schools and formed the Conservatoire National de Musique et de Déclamation. The institution, as originally envisioned, was to provide free training for musicians (especially those destined for military service or the Opéra). It was also to serve as official arbiter of music used for state functions or music that was to be sanctioned by the state. The Conservatoire also became the source of the first national music theory, for its original charter included the provision that the texts used therein would be written by its faculty. Because of the political power that eventually

39. A thorough account of changes in music education after the French revolution is given in Cynthia M. Geselle, "The Institutionalization of Music Theory in France: 1764–1802" (Ph.D. diss., Princeton University, 1989), 235–306.

accrued to the Conservatoire, the texts that it adopted became the core of a national music curriculum.

The first texts adopted by the Conservatoire were models of practicality, simplifying those notions that were deemed unnecessarily complex and striving toward uniformity of method. As time went on, however, the faculty went beyond the highly utilitarian education envisioned by the original reformers and developed a sophisticated pedagogy that embraced virtually all aspects of musical thought. As an example, the pedagogy created by Antoine Reicha, who was appointed professor of counterpoint at the Conservatoire in 1817, extended from his *Traité de mélodie* of 1814 through the *Cours de composition musicale* (?1816–18) to the *Traité de haute composition musicale* of 1824–26.[40] In these texts, Reicha, with the zeal of a geometer and the passion of an artist, strove to provide a systematic approach that extended from the most basic aspects of musical structure—expressed through a grammar of music analogous to that of Koch—to a full account of the largest forms. Thus was institutionalized an approach to music that began with isolated components and culminated in large forms conceived as dramas enacted in sound.[41] Within this course of study, musical form was presented as both static and dynamic. In the early stages of the pedagogical plan, form was static, consisting of various components that could be assembled to create musical compositions. In the later stages, it became thoroughly dynamic, as this perspective yielded to one that accommodated, even if it did not completely sanction, the artistic license necessary to create works such as Mozart's Overture for the *Marriage of Figaro*.[42]

Changes to the German universities were not as sudden as those that led to the formation of the Conservatoire, but they were motivated by pragmatic and political concerns similar to those that shaped France's new educational system. There had developed in Germany over the course of the eighteenth century the perception that a university education served no useful purpose. This notion, together with efficiencies imposed by French rule and the growing financial burden presented by universities whose traditional sources of financial support had begun to erode, contributed to the disappearance of over half the German universities during the Napoleonic era.[43] As a way of countering this general disintegration, a delegation of professors from the University of Halle, which had been suspended by Napoleon in 1806, approached King Friedrich Wilhelm III in the late summer of 1807 and asked

40. Reicha's *Cours de composition musicale* ultimately replaced Charles-Simon Catel's *Traité d'harmonie*, which had been approved by the General Assembly of the Conservatoire in 1801 as the Conservatoire's main harmony text.

For a discussion of affinities between Reicha's account of the *grande coupe binaire* (now conventionally called sonata form) and drama, see Peter Hoyt, "The Concept of *Développement* in the Early Nineteenth Century," in *Music Theory in the Age of Romanticism*, ed. Ian Bent (Cambridge: Cambridge University Press, 1996), 141–62.

42. For a discussion of the range of Reicha's analytical perspective, which included the Overture from the *Marriage of Figaro*, see Ian Bent's commentary on one of the analyses from Reicha's *Traité de haute composition musicale*, in *Music Analysis in the Nineteenth Century*, 1: 152–53.

43. Theodore Ziolkowski, *German Romanticism and Its Institutions* (Princeton, N.J.: Princeton University Press, 1990), 228. My account of the history of German universities owes much to chap. 5 of this book, which is given over to a consideration of the institution of the university during the time of German Romanticism.

that their university be reestablished in Berlin. The king was apparently receptive to the idea and is reported to have responded that "the state must replace through intellectual powers what it has lost in the way of physical powers."[44] Loosely modeled on the ideals associated with the University of Jena when Friedrich Schiller, Johann Gottlieb Fichte, and Friedrich von Schelling lectured there, the University of Berlin was conceived as an institution combining faculties in the sciences, medicine, and the humanities. It was to be unified by a central faculty of philosophy professing an "encyclopedic" approach to knowledge. The university formally opened in October 1810 with a faculty that included Fichte and Friedrich Schleiermacher.

By the time the composer and music theorist Adolph Bernhard Marx was offered a chair at Berlin in 1830, much of the spirit of the Romantic university had faded to a memory.[45] What remained were a faculty that included Hegel in its ranks (who began lecturing at Berlin in 1818) and the notion that the university was an institution by, of, and for the state. Marx's encyclopedic approach to music theory resembled Reicha's sweeping attempt to provide a complete account of musical knowledge in his three treatises. In 1837, Marx published his four-volume *Die Lehre von der musikalischen Komposition, praktisch-theoretisch*. This comprehensive tract, which went through six full or partial editions during Marx's lifetime, presented a graduated course of study that began with the simplest of musical materials and forms and proceeded to the most complex.[46] However, where the pedagogy of Reicha's treatises was conceptualized around the models of language and drama, Marx adopted a different model, one closely associated with the same Romantic idealism that had shaped the structure of the University of Berlin. This was the model of organicism.

ORGANICISM As has often been noted, organicist models, which map features from principally vegetative domains onto inorganic or artificial domains, flourished among early Romantic philosophers and writers.[47] The model was, however, also in use during the late eighteenth century. Our friend Sulzer, as part of his more practical remarks on invention, advises the artist faced with an intractable situation to put the work to one side for a short while. Gradually, solutions will present themselves, until a way is found where none was thought to exist.

44. Ziolkowski, *German Romanticism*, 287.

45. An account of Marx's place at the University of Berlin can be had in Scott Burnham's introduction to Adolph Bernhard Marx, *Musical Form in the Age of Beethoven: Selected Writings on Theory and Method*, ed. and trans. Scott G. Burnham, Cambridge Studies in Music Theory and Analysis, 12 (Cambridge: Cambridge University Press, 1997), 5–6.

46. For overviews of the content of Marx's *Die Lehre* and discussions of the educational context within which it was embedded, see Burnham's introduction to *Musical Form in the Age of Beethoven*, 7–11; and Mark Spitzer, "Marx's 'Lehre' and the Science of Education: Towards the Recuperation of Music Pedagogy," *Music and Letters* 79 (1998): 489–526.

47. A thorough account of the role of organicist models in theories of invention during the eighteenth and nineteenth centuries (framed in terms of the memorable phrase "vegetable genius") can be found in Meyer Howard Abrams, *The Mirror and the Lamp: Romantic Theory and the Critical Tradition* (Oxford: Oxford University Press, 1953), 198–225.

> It is one of many remarkable secrets of psychology that apparently clear thoughts can, when one turns to them for deeper contemplation, refuse to be developed or comprehended in a clear way. But when they are left alone they will by themselves grow in greater clarity, much as that period in which plants germinate unnoticed and all at once burst into full bloom. Some concepts will gestate little by little in our mind, so to speak, and extract themselves from the mass of obscure ideas into the clear light. Every artist must rely upon such fortunate moments of genius, and if he cannot always find what he diligently seeks, he must await with patience that moment when his thoughts ripen.[48]

Here the mystery of invention, which Sulzer also connected with rhetoric, is explained in terms of an organicist model: ideas are seeds, and, given time and a little care, they will put forth complete and fully articulated intellectual constructs—the flowers of invention—that could never be produced by more mechanical means.

The perspective evident in Sulzer's account of unconscious psychology had a profound effect among German thinkers of the late eighteenth and early nineteenth centuries. These proponents of "nature philosophy," including Fichte, Schelling, Jean Paul Richter, and August Wilhelm Schlegel, embraced the newly emerging biological sciences, finding in them a source of concepts that could replace those derived from Cartesian or Newtonian mechanics. It was this model that Marx absorbed and adapted for the characterization of musical form.

In the first volume of *Die Lehre*, after a few preliminaries, Marx begins the journey that would culminate in a consideration of the most exalted compositional forms of his day with a brief contemplation of the relationship between a major scale and its tonic. He observes that no note within the scale provides the sense of repose that the tonic does: pausing on any other note is unsatisfying and demands further motion. This observation leads Marx to a principle basic to all music, the main terms of which are placed in typographical relief on the page:

> In this we have found the opposition that thoroughly permeates all of music:
> Rest and Motion
> Tonic and Scale.[49]

Marx extended this opposition to apply to all aspects of musical form, formulated as the dynamic impulse *rest—motion—rest*. For Marx, this basic pattern is truly comprehensive: it governs the modest four-measure phrase, as well as the entire expanse of sonata form.[50]

48. Baker and Christensen, *Aesthetics and the Art of Musical Composition*, 63.

49. "Hierin haben wir einen durch die ganze Tonkunst wirksam hindurchgehende Gegensatz,
Ruhe und Bewegung
Tonika und Tonleiter
gefunden." Adolph Bernhard Marx, *Die Lehre von der musikalischen Komposition, praktisch-theoretisch*, 4th ed. (Leipzig: Breitkopf and Härtel, 1841–47), 1: 27.

50. This characterization is from Burnham's introduction to Marx, *Musical Form in the Age of Beethoven*, 9.

It was in locating a source for this impulse that Marx turned to an organicist perspective that resonated not only with his era but also with the characterization of invention that had been offered by Sulzer some sixty-five years earlier. However, where for Sulzer the idea is the seed, for Marx it is the motive: "The motive is the primal configuration [*Urgestalt*] of everything musical, just as the germinal vesicle, that membranous sac filled with some fluid element (or perhaps with solid bodies), is the primal configuration of everything organic—the true primal plant or primal animal. The motive, this conjunction of two tones or some other unities, simply *is*."[51] Marx's mapping from the organic domain to the musical domain makes possible an account of form that extends from little more than a pair of notes to entire symphonies. Evident throughout is an approach to musical form that is not only dynamic (through the progression *rest—motion—rest*) but also motivated by the forces latent within the most basic of musical materials. According to Marx, the motive, as the essential organic entity, offers something that can connect with the composer's spirit. Should the spirit adopt the motive, the composer's intellect will then come into play, shaping the motive to create works of art.[52] The organicist perspective that Marx employs thus serves as a way to characterize the dynamic aspect of musical form and as a launching point for the pedagogy of composition. It also fulfills the promise of eighteenth-century theorists who first suggested that music was an independent domain of meaning and expression: in the organicist perspective of the early nineteenth century, the fully autonomous work of music is born.[53]

As heady as was the intellectual environment associated with the organicist perspective basic to his conception of form, Marx's *Die Lehre* was, as its full title announced, both theoretical and practical. In his discussion of the basic elements of musical form, Marx notes a certain confusion regarding the notion of a period, which is formed from two fundamental elements (the *Gang* and the *Satz*) derived from the motive: "If, in my compositional method, I associated the period with the fundamental forms, it was only for reasons of method, in order to keep this important and ubiquitously hard-working form constantly before the student's eyes from the very beginning."[54] Marx's pedagogy, shaped by the practical exigencies of a system of education intended to work the will of the state, had its static building blocks, as well as its dynamic idealism. Although Marx could always trace these building blocks back to their organic origins, they nonetheless represented basic components of a student's education and, at least for the beginner, of the musical work.

51. Marx, *Musical Form in the Age of Beethoven*, 66. This passage is from Marx's 1856 essay "Form in Music."

52. Marx, *Musical Form in the Age of Beethoven*, 66–67.

53. Although my interpretation of the origin of the fully autonomous work of music is somewhat different from that of Lydia Goehr, this is due mostly to the somewhat different focus of my approach. I am concerned here not simply with the idea of a fully autonomous work but with the complex of ideas represented by organicism that allowed music theorists to articulate the notion of an autonomous work on both a practical and a theoretical level. Goehr's interpretation can be found in *The Imaginary Museum of Musical Works*, 159–75.

54. Marx, *Musical Form in the Age of Beethoven*, 68.

That the high abstraction of Marx's theory caused problems, at least for some theorists, is suggested by the approach to motive taken by Hugo Riemann. Riemann, as editor of the ninth edition of Marx's *Die Lehre* (which appeared in 1887), was well acquainted with Marx's conception of a motive. Nonetheless, in his *Musik-Lexikon* of 1882, Riemann began his definition of a motive by mapping from yet another domain: "Motive means in music, as it does in architecture, the most basic characteristic parts of an artistic structure."[55] Riemann goes on to distinguish between rhythmic motives, melodic motives, and harmonic motives, all conceived in architectural terms. Although the dynamic impulse basic to Marx's conception of motive would appear to have vanished, in other of his works it is evident that Riemann has simply transferred it to metric structure, which he construed as having, as its essence, the impulse *upbeat-downbeat*.[56] This construal gave Riemann a way to represent the musical dynamism that Marx had developed through an organicist metaphysics in more concrete terms. To the extent that the student or reader understands the basic experience of musical rhythm, so will he or she understand the dynamic impulse basic to music.

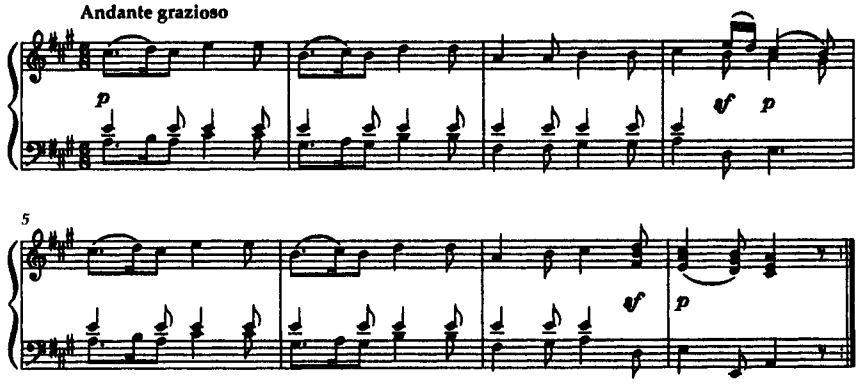
MODELS OF MUSICAL FORM To all appearances, Ebenezer Prout and Percy Goetschius are a bit like Alice and the Mad Hatter (although I shall not venture to say which theorist takes which role), seeming to talk about the same thing but doing so in very different terms. But where Alice and the Hatter are engaged with the elusive topic of Time, Prout and Goetschius are dealing with the rather more humble matter of Motive. And where the Hatter is as surely a denizen of Wonderland as Alice is not, Prout and Goetschius draw their ideas about motive and form from the same pool of German music scholarship.

As we can now see, Prout's approach is informed by the work of Marx and Riemann: he conceives of motive in terms of both metrical accentuation and organicism, although in the end it is the former that is foregrounded in his theory while the latter remains safely in the background. Goetschius, in contrast, conceives of motive in almost exclusively grammatical terms. His approach resembles, first and foremost, that of Reicha (whose three treatises were translated into German by Carl Czerny and published in a four-volume French-German bilingual edition in 1832). To a lesser extent, it resembles that of Koch (whose work was not as widely known in the nineteenth century). Thus, Goetschius's method is shaped not only by a grammatical approach to musical form but also by a pedagogy that was thoroughly pragmatic. Just as Reicha's theory of form was part of a larger program of complete instruction in music for a nation intent on building its musical identity, so Goetschius's manual was part of a series of texts intended to fulfill the same function in the New World.

Beyond being able to sort out the lineages of Prout's and Goetschius's ideas

55. "*Motive* nennt man in der Musik wie in der Architektur die letzten charakteristischen Glieder eines Kunstgebildes." Hugo Riemann, *Musik-Lexikon* (Leipzig: Verlag des Bibliographischen Instituts, 1882), 605.

56. Hugo Riemann, *System der musikalischen Rhythmik und Metrik* (Leipzig: Breitkopf and Härtel, 1903), 13–18.



about motive and form, however, we now also have a better grasp on the different sorts of conceptual work done by the mappings they employ. Mappings that yield a static account of musical form put into relief the explicitly conceptual side of music: they rely on our ability to isolate musical events or series of musical events and put them into categories. Members of the categories can then be compared with one another, as can the categories themselves. The view that results is of music as material that can be shaped and manipulated, whose meaning is neatly contained in discrete packages. Mappings that yield a dynamic account of musical form put into relief the experiential side of music: music as something to be lived through, which may move us or not, but which in all cases resists packaging into neat conceptual containers. Here meaning is at best only imperfectly contained and is in constant danger of overflowing the crude boundaries of ontological necessity.

As the examples drawn from the ways musicians characterized form in the eighteenth and nineteenth centuries show, the cross-domain mappings we use in our theories of music are more than simple curiosities of language, for these mappings have everything to do with our understanding of how music is organized, along with what counts as music in the first place.

TWO MODELS OF MUSICAL HIERARCHY

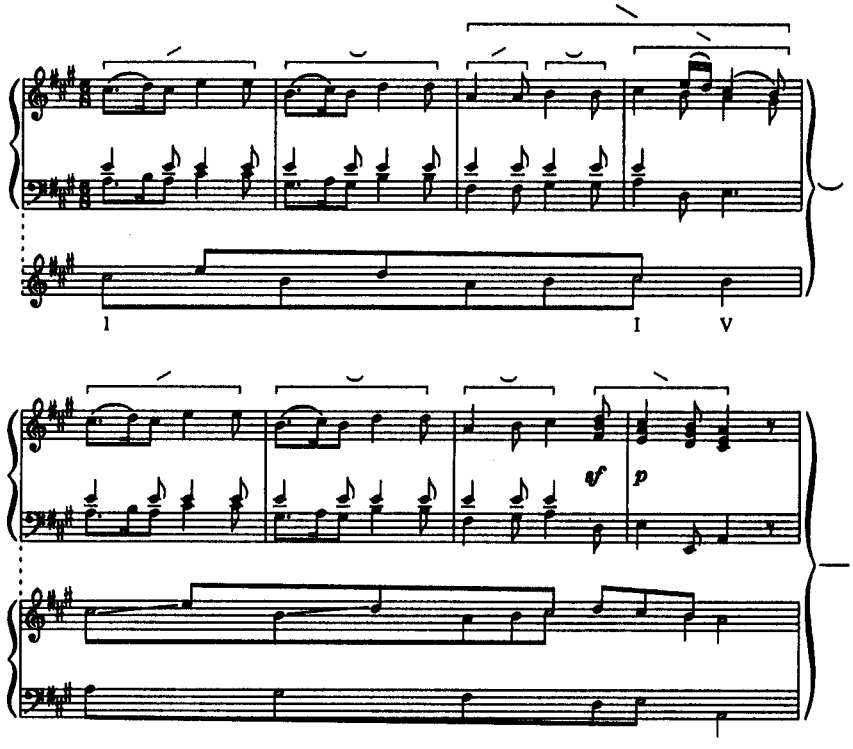
As I attempted to show in the preceding pages, descriptions of musical form have occasioned a number of cross-domain mappings, operating on both the specific and generic level. The situation with musical hierarchy is somewhat different, in part because hierarchy was not deemed an attribute of musical works as such but was instead used to characterize the organization of musical materials. Consequently, explicit discussions of hierarchy rarely appear in accounts of works of music but instead form the context for those accounts. As an example, let us consider three contemporary analyses of the same passage: the first eight measures of the theme from the opening movement of Mozart's Piano Sonata in A major K. 331. All three analyses deal with the rhythmic structure of the passage (the score appears in ex. 7.2).

EXAMPLE 7.2 W. A. Mozart, Piano Sonata in A major K. 331, first movement, theme, mm. 1–8

Edward Cone's analysis of the theme appeared in his *Musical Form and Musical Performance* of 1968. The analysis comes just after the introduction of a striking metaphor for the melodic and harmonic shape of a musical phrase: Cone likens the shape of a phrase to a game of catch:

> If I throw a ball and you catch it, the completed action must consist of three parts: the throw, the transit, and the catch. There are, so to speak, two fixed points: the initiation of the energy and the goal toward which it is directed; the time and distance between them are spanned by the moving ball. In the same way, the typical musical phrase consists of an initial downbeat (/), a period of motion (⌣), and a point of arrival marked by a cadential downbeat (\).[57]

This metaphor then provides the framework for his analysis of the rhythm of Mozart's theme, a portion of which is given in example 7.3. Cone rejects a simple alternation of strong and weak measures of the sort posited by Riemann on the basis of harmony. Cone asserts, rather, that the first and fifth measures of the period should be considered strong because of the firm statement of tonic. The fourth and eighth measures should also be deemed strong because of the emphasis provided by the cadences. A consideration of the motivic structure of the period enables Cone to refine this analysis. The first phrase consists of two individual sequential measures followed by a two-measure unit. The shape of the two-measure unit duplicates the shape of the phrase in miniature: it consists of two half-measure units followed by a full measure. As we see in example 7.3, the internal dynamic of the two-measure unit is the same as that of the complete phrase. The second phrase begins with the same sequential measures as the first, but in m. 7 the compression that prepares the closing cadence brings the rise from A4 to C♯5 into prominence. Cone's hearing of this rise as a third member of the sequence prompts him to assign it the same rhythmic symbol as the second member of the sequence, heard in m. 6. Voice-leading concerns and the forward energy of the *sforzando* cause Cone to group the final eighth note of m. 7 with the cadential material of m. 8; this constitutes the closing downbeat.



Although Leonard Meyer's analysis of this theme appeared after Cone's (he presented it first in one of the Ernest Bloch lectures he gave at the University of California at Berkeley in 1971), his methodology is essentially the same as that which he had developed with Grosvenor Cooper over a decade earlier. Cooper and Meyer understood rhythmic structure to be perceived as "an organic process in which smaller rhythmic motives, while possessing a shape and structure of their own, also function as integral parts of a larger rhythmic organization."[58] Rhythmic relationships are analyzed as patterns of beats, in which a stable accent and one or more weak beats are grouped together in different ways; these low-level, foreground patterns combine with one another in various ways to form more extended rhythmic groupings. In this way the musical surface gives rise to a hierarchy of rhythmic groupings.[59]

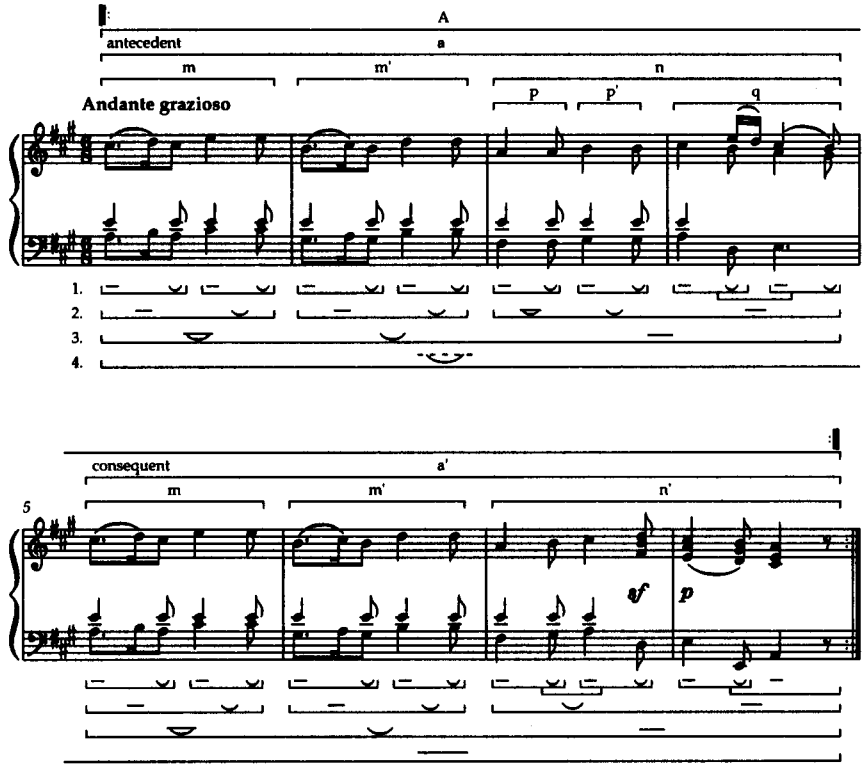
59. Leonard B. Meyer, *Explaining Music: Essays and Explorations* (Berkeley: University of California Press, 1973; repr. Chicago: University of Chicago Press, 1978), 27–28. Meyer's Bloch Lectures of 1971 form the basis for *Explaining Music.*

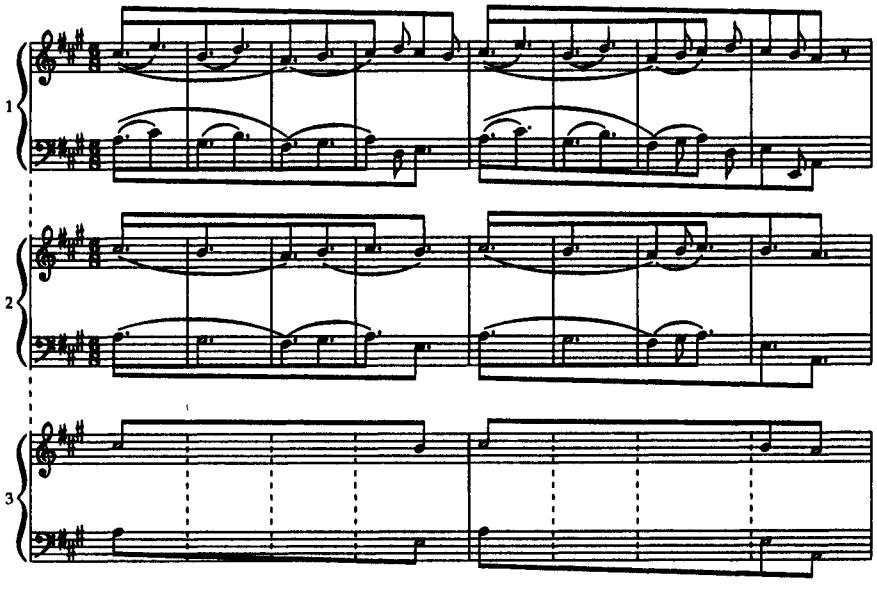


EXAMPLE 7.3 Edward Cone's analysis of the opening theme of Mozart's Piano Sonata K. 331, mm. 1–8

Meyer's analysis of the opening period of Mozart's theme is given in example 7.4. The first level of the analysis starts at the half-measure level of the music, important for Meyer because the ♩♫♫ patterns of the first two measures of each phrase do much to determine the grouping and accentual pattern of the complete bar. In mm. 3 and 4, Meyer's analysis on level 2 corresponds closely with Cone's reading: although the symbols are slightly different (Meyer's indication for a retrospectively weak accent replacing Cone's symbol for an initial downbeat), on this level as well as the third and fourth, the analyses for the most part agree. The main difference between the two is that Cone *starts* his analysis at what for Meyer is the third level of a rhythmic hierarchy.

In his article "The Theory and Analysis of Tonal Rhythm" (1978), Robert Morgan noted that, although both Cone's and Meyer's work reflected the influence of Schenker's theory of tonal music, their analyses of Mozart's theme were still beholden to certain aspects of metrical dogma. For his part, Morgan proposed considering the theme from a more consistently Schenkerian viewpoint. Morgan noted that Schenker's theory supplied a method for locating points at which structural motions originate and terminate; his idea was to correlate these points of structural origin and termination with the points of principal accent through which the larger rhythm of a passage is regulated. In Morgan's analysis, the first phrase of the theme

EXAMPLE 7.4 Leonard B. Meyer's analysis of the opening theme of Mozart's Piano Sonata K. 331, mm. 1–8



is governed by the overall motion from C♯5 and A3, in m. 1, to B4 and E3 in m. 4 (see ex. 7.5, level 3). This overall motion is articulated on the next level (level 2 of ex. 7.5) by a motion down to A4 and F♯3 in m. 3. Although the A could be seen as the completion of a third span from C♯5, the bass F♯3 and the acceleration away from A4 to B4 on the second beat of m. 3 prevent closure.

Up to this point, Morgan's analysis agrees, in most respects, with the analyses by Cone and Meyer. Morgan does not, however, believe the first beat of m. 4 should be heard as accented relative to the second beat. The acceleration of m. 3 continues into m. 4, in his view, carrying the music forward to the arrival of the bass on the dominant on the second beat. This arrival, according to Morgan's analysis, serves as the rhythmic goal and closing accent of the phrase. From Morgan's perspective, then, the rhythm of this phrase is not a matter of strong and weak beats or strong and weak measures; it is created rather by an articulated tonal process that moves between the two points defined by the outer-voice frame.[60]

The acceleration in the first phrase is answered by an even greater acceleration

60. Robert P. Morgan, "The Theory and Analysis of Tonal Rhythm," *Musical Quarterly* 64 (1978): 446.

EXAMPLE 7.5 Robert Morgan's analysis of the opening theme of Mozart's Piano Sonata K. 331, mm. 1–8

in the second, for the consequent phrase must go through the dominant to arrive on the tonic. That arrival gives a different character to the closing accent of the second phrase; for Morgan, it is the difference in character between the two closing accents, and not some analogy to two large beats, that is responsible for the upbeat-downbeat effect created by the pairing of antecedent and consequent. Implicit in this analysis is the notion that accent refers to a *point* of emphasis, which also leads Morgan to reject Cone's and Meyer's reading of the rhythm of mm. 3 and 4 as a diminution of the overall rhythm of mm. 1 through 4. If mm. 3 and 4 supply the downbeat for mm. 1 and 2, they must represent an arrival, but in fact the point of arrival occurs only at the end of the unit. Morgan does not believe m. 3 can simultaneously be both an arrival and a departure.

Although these three analyses converge on a number of points, their divergences reflect two different models of musical hierarchy. The first model, which gives rise to what I call *chain-of-being hierarchies*, does a good job of capturing the harmonic and scale-degree dependencies typical of the harmonic organization of instrumental music of the late eighteenth century. The second model, which gives rise to what I call *atomistic hierarchies*, does a good job of capturing the regularity and nesting of accentual patterns typical of musical meter during the same period. Because both models are associated with what appears to be a common set of structural relations—called "hierarchy"—we might be misled into thinking that they are simply variations of each other. Such is not the case, however, for these models developed at different times in history, and with reference to different domains. These differences are reflected in the structure of the models and also in the ways they have been applied to music.

Historical Models of Hierarchical Organization

The principal mark of chain-of-being hierarchies is a conception of the universe as a precisely arranged system of interdependent levels or degrees of existence extending from a Supreme Being down to the lowliest organism. Although this concept is part of an incredibly rich collection of ideas—one writer has suggested that the history of chain-of-being hierarchies is, in reality, a history of Occidental thought[61]—only a few central aspects need concern us here.

The ingredients for this complex of ideas came from Plato and Aristotle; Aristotle's connection of "powers of the soul" with levels of being in *De anima* proved particularly influential. It was in Neoplatonism, however, that these ideas first appeared fully organized into a coherent general scheme.[62] Crucial to this organization was Plotinus's idea that the perfection of the One included a superabundance which, overflowing, was the source of the Many. According to Plotinus, this generation of the Many from the One could not come to an end as long as any possible variety of being in the descending series was left unrealized.

One of the principal ways the Neoplatonic cosmology was transmitted to the Middle Ages was through Macrobius's *Commentary on the Dream of Scipio* (which dates from the late fourth to early fifth centuries A.D.). In a passage expanding on the revelation presented to Scipio that minds are given to man out of the eternal and divine fire of the stars, Macrobius writes:

> Accordingly, since Mind emanates from the Supreme God and Soul from Mind, and Mind, indeed, forms and suffuses all below with life, and since this is the one splendor lighting up everything and visible in all, like a countenance reflected in many mirrors arranged in a row, and since all follow on in continuous succession, degenerating step by step in their downward course, the close observer will find that from the Supreme God even to the bottommost dregs of the universe there is one tie, binding at every link and never broken. This is the golden chain of Homer which, he tells us, God ordered to hang down from the sky to the earth.[63]

61. C. A. Patrides, "Hierarchy and Order," in *Dictionary of the History of Ideas: Studies of Selected Pivotal Ideas*, ed. Philip P. Wiener (New York: Charles Scribner's Sons, 1973), 2: 434.

62. Concerning the complex of ideas associated with the great chain of being and Neoplatonism, see Arthur O. Lovejoy, *The Great Chain of Being: A Study of the History of an Idea* (Cambridge, Mass.: Harvard University Press, 1936), 61; concerning *De anima*, see p. 58.

63. Ambrosius Aurelius Theodosius Macrobius, *Commentary on the Dream of Scipio*, ed. and trans. William Harris Stahl (New York: Columbia University Press, 1990), 145. It is also in Macrobius (pp. 185–200 in the Stahl translation) that we find a detailed discussion of the harmony of the spheres, as well as the legend of Pythagoras and the blacksmith's shop. The connection between harmony and order found in Macrobius was an important one, and it may have contributed to the application of a metaphorical chain-of-being hierarchy to music. However, it is also striking that the image of a ladder is used in both domains. In the Middle Ages, the hierarchical organization summoned by the Great Chain of Being was commonly represented by Jacob's Ladder; see Paul G. Kuntz, "A Formal Preface and an Informal Conclusion to *The Great Chain of Being*: The Universality and Necessity of Hierarchical Thought," in *Jacob's Ladder and the Tree of Life: Concepts of Hierarchy and the Great Chain of Being*, ed. Marion Leathers Kuntz and Paul Grimley Kuntz, American University Studies, Ser. V, Philosophy, 14 (New York: Peter Lang, 1987), 6. Also, some early mnemonic diagrams show the gamut as notes on a ladder; see Karol Berger, *Musica Ficta: Theories of Accidental Inflection in Vocal Polyphony from Marchetto da Padova to Gioseffo Zarlino* (Cambridge: Cambridge University Press, 1987), 9–10.

The notion of a Great Chain of Being proved a concise and powerful model through which humans could give order to their universe. It also provided a model through which the distribution of power could be accomplished and justified. The model is quite evident in ecclesiastical hierarchies: power flows from the top down, in the same way that being and soul flow from the Godhead down through the various levels of being, from highest to lowest.

Inherent in the Neoplatonic scheme is a tension between the self-sufficiency of the One and the multitudinous abundance of creation it gives rise to: it is a paradox that the One needs nothing else and yet produces everything else. Giordano Bruno, writing in the sixteenth century, reveled in this paradox.[64] Yet it was also Bruno who, by combining the concept of atomism with the comprehensive organization provided by the Neoplatonic scheme, inspired a way of thinking about hierarchical organization that would eventually compete with the Great Chain of Being.

For Bruno, atomism was a metaphysical principle that provided the basis for a demonstration of the underlying unity of all nature.[65] This view was especially influential in England, where Bruno lived from 1583 to 1585 and where two factors combined to transform his vague, metaphysical scheme into a compelling account of order. The first factor came in the form of a challenge to the model for the distribution of power provided by the application of a chain-of-being hierarchy to the social sphere. In a social chain-of-being hierarchy, the power of any individual is linked, as an essential property, to the level occupied by that individual within the system: the higher the level, the greater the power over others. A refutation of this model can be seen in Thomas Hobbes's *Leviathan* of 1651. Hobbes argued that all humans were basically equal in the faculties of body and mind: all had approximately equal power over others. Because of this equality, the natural state of individual humans was one of competition. Only by imposing a social order on humans from without, in the form of a common power "to keep them all in awe," was it possible to overcome the natural state of virtual or actual war.[66] Thus the properties ascribed to each member of a society (which result in equal measures of power for all members) are different from those according to which societal order should be established (which result in unequal measures of power): the properties of the individual are independent of the properties of the system.

The second factor important in the development of an alternative view of hierarchical organization was the increased presence of mechanical devices in people's lives.[67] These machines provided thinkers of the time with practical models of the organization of nature. Among the most important of these was the mechanical clock. As Gideon Freudenthal has observed: "In the construction of the mechanical clock it was possible to produce complicated movements by an appropriate disposition of gears and a driving force. The task of science [in the seventeenth and eighteenth centuries] can be interpreted as the attempt to discover in a limited area

and to a limited extent the principles of construction of the divine clock."[68] The model of a clock is one that appears consistently in the dispute between Isaac Newton and Gottfried Wilhelm Leibniz on the ultimate nature of matter. Of particular interest are the different methodological approaches used by Newton and Leibniz. Leibniz held to what had become, by the early eighteenth century, a traditional Baconian methodology: scientific inquiry should seek to disassemble the divine clock, piece by piece, never speculating beyond what could be observed. Although Newton was in sympathy with this methodology, it was inadequate for a purely mechanical account of physics, since the ultimate workings of the clock—its atomic structure—could not be observed. Newton's solution, given in the final Query appended to the fourth edition of his *Opticks*, was a practical one that divided scientific theorizing into two halves.[69] The first half is analysis: "This Analysis consists in making Experiments and Observations, and in drawing general Conclusions from them by Induction, and admitting of no Objections against Conclusions, but such as are taken from Experiments, or other certain Truths."[70] The second half is synthesis or composition, in which the various inductive generalizations produced by analysis are organized into a logical system based on a limited number of essential principles. In the case of the divine clock, synthesis of necessity played a larger role than analysis (which led Leibniz to accuse Newton of arguing from hypothesis rather than from observation). However, Newton believed this exception to his overall methodology was justified by the potential results:

> To derive two or three general Principles of Motion from Phænomena, and afterwards to tell us how the Properties and Actions of all corporeal Things follow from those manifest Principles, would be a very great step in Philosophy, though the Causes of those Principles were not yet discover'd: And therefore I scruple not to propose the Principles of Motion above-mention'd, they being of very general Extent, and leave their Causes to be found out.[71]

In other words, the scientist simply had to assume that the general principles produced by synthesis held, even on levels that could not be directly observed: the mechanical workings of the divine clock were assumed to be consistent throughout.

When combined with the independence of elemental and systemic properties proposed in the social sphere, this approach developed into a new conception of hierarchical order, which I call an atomistic hierarchy. In contrast to a chain-of-being hierarchy, an atomistic hierarchy can be built from the bottom up, its organization governed by a set of general principles that obtain no matter what the

specific attributes of a given level. It is a concise and concrete account of organization, and one that, through applications in physics, chemistry, and biology, has had an enormous influence on how humans view their world.

Structural Features of Chain-of-Being and Atomistic Hierarchies

Each of these models of hierarchy offers a different view of how the world is organized. The fundamental conceit of chain-of-being hierarchies is to regard a domain as a huge organism pervaded by a force, the origins of which are mysterious.[72] "Being" and "political power" are both examples of such forces. The mysterious force behind any chain-of-being hierarchy manifests itself as properties instantiated in varying degrees by the elements of the domain. In a traditional Great Chain of Being, for instance, a rock has the property of *substance*, a tree has the properties of *substance* and *life*, and an insect has the properties of *substance*, *life*, and *mobility*. The domain can be organized into a hierarchy in which any given level is distinguished by a specific set of properties that embody aspects of being. These properties include all of the properties that distinguished lower levels, plus properties unique to the given level: trees include *substance* and add *life*; insects include *substance* and *life* and add *mobility*. Inclusion within the hierarchy is thus of properties, but not elements.

The fundamental conceit of atomistic hierarchies is to regard a domain as an extended mechanism operating according to a limited set of general principles. The laws of classical physics are an example of one such set of principles. All of the actions and properties of elements within the domain, from the smallest to the largest, and from the most simple to the most complex, follow these general principles. Thus subatomic particles and planets both conform to the same principles. Classes of elements may be distinguished according to common conformance with the general principles of the system. The actions and properties of electrons, protons, and neutrons on the atomic level are by no means identical, but they can be distinguished from the actions and properties of atoms on the molecular level. In addition, all of the elements within a given class have the shared property of combining into units: electrons, protons, and neutrons combine to form atoms, and atoms combine to form molecules. The domain can be organized into a hierarchy in which each level is a conformance class whose elements combine into units that constitute the elements of the next higher level in the hierarchy. This process continues recursively until the limits of the system are reached. Inclusion within the hierarchy is thus of elements, but not properties.

The unique features of each of these models of hierarchy can be characterized in terms of relationships that are established between the general, abstract property of "energy" and the CONTAINER schema. "Energy" takes form as either the mysterious

72. While the parallels with the ideology of organicism that blossomed in the late eighteenth century are intriguing, it should be remembered that the organicism associated with chain-of-being hierarchies dates back at least to the Middle Ages. Accordingly, the mysterious origins of the power behind chain-of-being hierarchies is somewhat different from the mystery associated with Romantic organicism since the former is an essential property of the model where the latter would be better described as accidental.

force of a chain-of-being hierarchy or the power that drives the mechanism of an atomistic hierarchy. For both models, the CONTAINER schema provides the basic internal structure of the levels that make up the hierarchical system.

In a chain-of-being hierarchy, the energy proper to the system (that is, "being" or "political power") is distributed unequally throughout the system. Systemic organization is consequently based on the amount of energy (interpreted as "properties of being" or "extent of political power") each element of the system has. The containers (or hierarchical levels) that articulate this organization group elements according to their amount of energy (or systemic properties). Although chain-of-being hierarchies often offer vivid and dynamic accounts of organization, hierarchical structure (based on the contents of the containers that make up the hierarchy) is, in fact, relatively abstract.

In an atomistic hierarchy, energy is distributed throughout the system according to a fixed set of general principles. Systemic organization is consequently based on the way different elements of the system manifest these principles. The containers (or hierarchical levels) that articulate this organization group elements according to common conformance with the general principles. The generality of the organizing principles of atomistic hierarchies means that the principles can seem somewhat removed from actual experience, although hierarchical structure (based on the contents of the containers that make up the hierarchy) is, in fact, relatively concrete.

Given these structural attributes, each model has a slightly different potential as a source domain. A chain-of-being hierarchy will map these predicates onto a target domain:

- The target domain is pervaded by a mysterious force.
- This force manifests itself as properties instantiated to varying degrees by the elements of the domain.
- The domain can be organized into a hierarchy, in which each level is distinguished by a unique set of properties.
- Each level of the hierarchy includes all of the properties of the next lower level and adds new properties unique to that level.
- The higher levels of the hierarchy more completely manifest the mysterious force (and are thus more perfect) than the lower levels of the hierarchy.

Because chain-of-being hierarchies have often been used to structure natural and human domains, applying the model to other domains may suggest that elements of that domain have natural or anthropomorphic aspects, even though these are not necessary entailments of the mapping.[73]

An atomistic hierarchy will map these predicates onto a target domain:

- The target domain is analogous to an extended mechanism.
- This mechanism operates according to a limited set of general principles.
- All of the actions and properties of elements within the domain follow these general principles.

73. As the analyses at the end of chap. 2 suggest, factoring anthropomorphism into the application of chain-of-being hierarchies to different domains would quickly lead to a dense and highly interconnected network of correlated domains.

- Classes of elements may be distinguished according to common conformance with the general principles and the shared property of combining into units.
- The domain can be organized into a hierarchy, in which each level represents a conformance class.
- The elements on each level of the hierarchy combine to form units; these units constitute the elements of the next higher level in the hierarchy.
- The recursive combination of elements into units continues until the limits of the system are reached.

Because atomistic hierarchies have often been used in scientific explanations, applying the model to other domains may suggest that a "scientific" approach is being used, even though this is not a necessary entailment of the mapping.

Given the different structural attributes each model of hierarchy will map onto a target domain, it follows that each provides a different model for reasoning about the target domain. Nowhere is this clearer than in the first thoroughgoing applications of these models to the domain of music during the early nineteenth century.

Mapping Models of Hierarchy onto Music

CHAIN-OF-BEING HIERARCHIES AND TONAL THEORY Early in his *Cours complet d'harmonie et de composition* of 1806, Jérôme-Joseph de Momigny presents a C major scale arranged as two symmetrical tetrachords:

G a b C
C d e F

Momigny reminds his readers that the three main notes of the scale are G, C, and F. He goes on to stress the centrality of tonic, providing a telling image in the process: "The tonic triumphs over all the other notes. It is [tonic] who plays the premier role in *le Ton*. It is the center of gravity, the purpose of all purposes, the end of all ends; in a word, it is to [tonic] that the scepter of the musical empire is entrusted."[74] At the beginning of the chapter in which this passage occurs, Momigny linked his concept of *Ton* to that of hierarchy;[75] with his image of tonic holding the scepter, he leaves no doubt as to what sort of hierarchy he has in mind.

74. The complete passage is as follows: "J'ai déjà dit que ce sont là les trois Notes principales du Ton. La TONIQUE l'emporte sur toutes les Notes. C'est elle qui joue le premier rôle dans le Ton. Elle est le centre de gravité, le but de tous le buts, la fin de toutes les fins; en un mot, c'est à elle que le sceptre de l'empire musical est confié." Jérôme-Joseph de Momigny, *Cours complet d'harmonie et de composition, d'après une théorie neuve et générale de la musique* (Paris: Chez l'auteur, 1806), 1: 47. The image is used again on p. 81 of the same volume.

Although the early nineteenth-century notion of *Ton* can be considered to be approximately equivalent to the modern notion of "key," there are also differences between the two concepts; specifically, *Ton* has a dynamic quality lacking in "key." For this reason, I shall not use the latter as a translation of the former.

75. "*Ton* is the hierarchy, the order established between the notes of a genus and a mode." ["Le Ton est la hiérarchie, l'ordre établi entre les Notes d'un genre et d'un mode."] Momigny, *Cours complet d'harmonie et de composition*, 1: 47.

A similar, if less colorful, image may be found in the fuller explanation of order in music that he offered twelve years later in the second music volume of the *Encyclopédie méthodique*. This order, which Momigny claims is purely metaphysical, consists in a natural hierarchy of seven notes that are arranged according to the authority of the one called tonic.[76] As Renate Groth has noted, this is essentially the same definition of order given over two decades later by François-Joseph Fétis; the most important difference is that Fétis assigned it the name *tonalité*.[77]

By mapping a chain-of-being hierarchy onto the domain of music, Momigny creates a very specific notion of *Ton*. The origin of *Ton* is mysterious—Momigny never gets more specific than claiming that it is "metaphysical."[78] The notes organized by *Ton* occupy different levels, according to their directive force; Momigny establishes these levels through various musical propositions. Perhaps most important, notes are regarded as agents with powers proportional to their status within the hierarchy: the properties characteristic of *Ton* increase as one ascends toward tonic. Thus, even though Momigny identifies dominant as the generator of the scale (based on the presence of a minor seventh in the overtone series), he argues that it must be regarded as subservient to tonic, for the authority of tonic cannot be challenged.[79]

The conception of tonal organization produced by mapping a chain-of-being hierarchy onto music was a powerful one. We see it not only in Momigny's early formulation of the concept of *Ton* but also in the persuasive account of tonal organization presented in the first and third volumes of Heinrich Schenker's *Neue musikalische Theorien und Phantasien*. As presented in Schenker's *Harmonielehre* of 1906, the mysterious force that pervades the domain of music is that of nature, manifested through the overtone series. Earlier, in chapter 3, in a discussion of conceptual models as the basis for theories, I quoted a central passage from the *Harmonielehre* on Schenker's organicist approach to the overtone series and pursued its application to his approach to musical analysis. The same passage and related discussion is directly relevant to our present concerns, and we turn to them again here. In Schenker's conception, every tone within the musical domain is possessed of the urge to produce endless overtones, much as living beings have procreative urges.[80] Beginning with a single tone, Schenker creates a community of tones arranged in

76. Jérôme-Joseph de Momigny, "Musique," in *Musique*, Series 36 of *Encyclopédie méthodique, ou par ordre de matières*, ed. Nicolas Étienne Framéry, Pierre Louis Ginguené, and Jérôme-Joseph de Momigny (Paris: Chez Madame veuve Agasse, 1818), 2: 179.

77. Renate Groth, *Die französische Kompositionlehre des 19. Jahrhunderts* (Wiesbaden: Franz Steiner, 1983), 58.

78. On this use of "metaphysical" (which can also be seen in the work of Fétis), see Thomas Christensen, "Fétis and Emerging Tonal Consciousness," in *Music Theory in the Age of Romanticism*, ed. Ian Bent (Cambridge: Cambridge Univesity Press, 1996), 37–56.

79. Momigny, *Cours complet d'harmonie et de composition*, 1: 49–51, 47–48.

80. "It is self-evident that the urge to produce unending generations of overtones belongs to every tone in equal measure. One might also compare this urge to that of animals, for it appears in fact to be in no way inferior to the procreative urge of a living being." ["Es ist selbstverständlich, daß den Trieb, Generationen von Obertönen ins Unendliche zu zeugen, jeder Ton in gleichem Maße besitzt. Man darf, wenn man will, auch diesen Trieb einem Animalischen vergleichen, denn er scheint in der Tat dem Fortpflanzungstrieb eines Lebewesens durchaus nicht nachzustehen."] Heinrich Schenker, *Harmonielehre*, Neue musikalische Theorien und Phantasien, 1 (Stuttgart: J. G. Cotta'sche, 1906), §14, p. 42.

hierarchical order, with the notes closest to the source-pitch having priority over those more remote.[81] The tonal system that results is a manifestation of the desire of the source tone to rule over others and to extend this rule as far as possible.[82]

In *Der freie Satz*, from 1935, Schenker retained this conception of tonal organization and, by emphasizing the organicism latent in this conception, built from it an account of the coherence of entire works of music. He did this by proposing that the transformation of the musical source (now the Naturklang, or chord of nature) proceeded through discrete levels from background to foreground. The background represented an abstract, initial working-out of the tendencies of the chord of nature through the Ursatz, or fundamental structure; the foreground represented the musical work as we conventionally think of it.[83] Schenker makes clear that this foreground emanates from and is controlled by the background.[84] Thus the hierarchical organization of music is not restricted to the ordering of single tones into a scalar system, but manifests itself as a series of transformations that steadily enrich musical content. In Schenker's vision of the relationship between structural levels, a version of the Neoplatonic cosmogony central to the original Great Chain of Being continues to echo: "Between fundamental structure and foreground there is manifested a rapport much like that ever-present, interactional rapport which connects God to creation and creation to God. Fundamental structure and foreground represent, in terms of this rapport, the celestial and the terrestrial in music."[85]

81. Schenker, *Harmonielehre*, §§17–18, pp. 54–55.

82. "But now, what does 'relationship' mean in the life of the tone and what in this context would be implied by the intensity of living life to the fullest? The relationships of a tone are its system. Once the egoism of the tone manifests itself in such a way that the tone (rather like a human) might rule over its fellow-tones rather than be ruled by them, then these very systems provide the means for satisfaction of this egoistic love of power. A tone rules over others when it subjugates them to the relationships outlined in the systems above." ["Nun aber, was soll denn Beziehung heißen im Leben des Tons und was soll hier wohl Intensität des Sichauslebens bedeuten? Beziehungen des Tones sind seine Systeme. Äußert sich der Egoismus des Tones darin, daß er, hierin einem Menschen ähnlich, lieber über seine Mittöne herrscht, als daß er von ihnen beherrscht wird, so sind ihm zur Befriedigung dieser egoistischen Herrschsucht eben in den Systemen die Mittel zur Herrschaft geboten. Ein Ton herrscht über die andern, wenn er sich dieselben nach den in den Systemen geschilderten Verhältnisse unterwirft."] Schenker, *Harmonielehre*, §38, pp. 106–07.

83. Robert Snarrenberg has recently pointed out what I would characterize as competing conceptual models in the usual translations of Schenker's terms (e.g., "fundamental structure" for "Ursatz"); see Snarrenberg, "Competing Myths: The American Abandonment of Schenker's Organicism," in *Theory, Analysis and Meaning in Music*, ed. Anthony Pople (Cambridge: Cambridge University Press, 1994), 45–52.

84. "All the foreground diminutions, including the apparent 'keys' arising out of the voice-leading transformations, ultimately emanate from the diatony in the background." Heinrich Schenker, *Free Composition (Der Freie Satz)*, ed. and trans. Ernst Oster, New Musical Theories and Fantasies, 3 (New York: Schirmer Books, 1979), §4, p. 11. ["Ist doch alle Vordergrund-Diminution, einschließlich der scheinbaren Tonarten aus den Stimmführungsvervandlungen, zuletzt eben aus der Diatonie im Hintergrund erflossen."] Heinrich Schenker, *Der freie Satz*, Neue musikalische Theorien und Phantasien, 3 (Vienna: Universal-Edition A. G., 1935), §4, p. 32.

85. Schenker, *Free Composition*, 160 (Passage E). "Aehnlich wie von Gott zum Geschöpf zu Gott eine Fühlungnahme waltet, stets ineinanderlaufend, stets gegenwärtig, wirkt sich eine Fühlungnahme auch zwischen Ursatz und Vordergrund aus als gleichsam einem Jenseits und Diesseits in der Musik." Schenker, *Der freie Satz*, 18.

ATOMISTIC HIERARCHIES AND METRICAL THEORY A rather different view of musical order is presented by Gottfried Weber in his *Versuch einer geordneten Theorie der Tonkunst*, which appeared in a number of editions in the early nineteenth century. In the course of introducing this particular view, Weber focused not on the organization of pitches but on the organization of musical rhythm. For Weber, rhythm depends on regularity, and the mechanical nature of this regularity is revealed in his breathless definition:

> If . . . a symmetrical measured division of the times is found in a piece of music, *i.e.* the time is distributed into exactly equal general divisions, and these are again divided into equal parts, and the latter are farther separated into equal smaller quotas or proportional parts, &c. and the duration of the tones in relation to one another is exactly measured according to such divisions of time, so that a general division always appears as a symmetrically arranged group of several smaller portions of time, and these taken together as a smaller subordinate group of yet smaller parts, and the accent is also symmetrically apportioned amongst all these divisions of time—then the music is measured and rhythmical.[86]

This mechanical notion of rhythm is accompanied by a mechanical notion of time-keeping: Weber emphasizes the importance of inventions like the metronome and devotes a lengthy footnote to instructions for constructing a pendulum that will accomplish the same thing.[87]

Weber follows his digression into the mechanics of time-keeping with a detailed account of the rules by which musical measures are constructed, first dividing the measure into its constituent parts and then building measures according to symmetrical patterns of accent. He then proceeds to further levels of rhythmic organization:

> But there is still a *higher* symmetry than this. That is to say, as parts of times taken together form small groups, so also can several groups taken together be presented as parts of a larger group, of *a greater* or *a higher rhythm*, of *a rhythm of a higher order.*
>
> We may go still farther, and to such a greater rhythm we may annex moreover a second and a third, so that these two or three together constitute again a still higher rhythm. Thus, *e.g.* in the following passage, two measures taken together constitute a small rhythm, two of these, taken together, constitute again a rhythm of a higher species, and again two of the latter taken together, constitute a capital or principal rhythm.[88]

> The construction of the members of the larger rhythms is a symmetry proceeding more by the great; it is perfectly similar to that involved in the structure of measures, except that it is simply on a larger scale. As a measure consists of two or three parts,

86. Gottfried Weber, *Theory of Musical Composition, Treated with a View to a Naturally Consecutive Arrangement of Topics*, ed. John Bishop, trans. James F. Warner (London: Robert Cocks, 1851), 1: 62 [§47].

87. Weber, *Theory of Musical Composition*, 1: 68–71 [§51].

88. Weber, *Theory of Musical Composition*, 1: 85 [§68].

> so two or three measures form the parts of a greater rhythm, and several such rhythms are again parts of a still higher group.
>
> Hence the measures are distinguished from one another in such higher rhythms, in respect to their greater or less internal weight or accentuation, in the same way the parts of the measure are distinguished among themselves; *i.e.* the heavy or accented *measures* assume a prominence above the lighter, as do the heavier *parts* of the measure above the lighter.[89]

What Weber has described, of course, is an atomistic hierarchy of metrical groups: beats combine into measures, measures combine into groups of measures, and so on up through a series of hierarchical levels.

Mapping an atomistic hierarchy onto the domain of musical rhythm emphasizes the regularity of accentual pattern often associated with the concept of meter. By turning rhythm into a machine, Weber can describe its organization with three basic principles: (1) all units of rhythm are either accented or unaccented; (2) these units are grouped into cyclic patterns of accent that form symmetrical groups; (3) the groups of one level constitute the units of the next higher level. All of the objects within this domain must conform to these principles, but not necessarily in exactly the same way. Although accent or nonaccent applies to both beats and groups of measures, with beats, the property lasts for but an instant, whereas with groups of measures, the property lasts for the duration of the group. No limit is specified for the hierarchy that results, although Weber does not develop levels beyond those shown in his example.

The approach to musical rhythm proposed by Weber became standard during the nineteenth century, although subsequent theorists often added interesting complications. Moritz Hauptmann, for instance, imposed a Hegelian interpretation on metrical groupings, which permitted him to frame the basics of meter and harmony in the same terms.[90] By the time of Riemann's *System der musikalischen Rhythmik und Metrik*, the hierarchical structure represented by Weber's "capital or principal rhythm" was presented as the normative framework (*normatives Grundschema*) of rhythmic organization: beats formed measures, which in turn formed duple groups, which combined into two half-phrases of four measures each, which joined to create the eight-measure phrase.[91]

Reasoning about Music through Chain-of-Being and Atomistic Hierarchies

Chain-of-being and atomistic hierarchies developed at different points in the history of Western thought to explain two different domains of human experience. These differences are reflected in the basic structure of each type of hierarchy, and they result in two distinct models for reasoning about the world. When these mod-

90. Moritz Hauptmann, *The Nature of Harmony and Metre*, trans. W. E. Heathcote, 2nd ed. (London: Sonnenschein, 1893; repr. with a new forward by Sigmund Levarie, New York: Da Capo Press, 1991), 189–91.

91. Riemann, *System der musikalischen Rhythmik und Metrik*, 196–98.

els are mapped onto music they yield different inferences about how musical materials are organized, which lead to different ways to analyze music. If our reasoning is guided by a chain-of-being hierarchy, we infer that each musical work constitutes a domain pervaded by a mysterious force. Musical analysis consists in explicating the way different musical elements embody this mysterious force. By this means, the proper place of these elements in the musical hierarchy can be determined and an account of musical structure can be produced. If our reasoning is guided by an atomistic hierarchy, we infer that each musical work operates like an extended mechanism. Musical analysis consists in identifying the basic components of this mechanism and explicating the principles according to which it works. The view of musical structure that results is of a hierarchy of distinct yet interrelated substructures that, combined, constitute the musical work.

With these two models for reasoning in mind, let us now return to the three analyses of the rhythmic organization of Mozart's little theme discussed at the opening of this section and consider in more detail how these two models of hierarchy condition and constrain musical analysis.

Conceptual Models and Music Theory

According to the Schenkerian paradigm Robert Morgan adopts, tonality is characterized by the property of control: within a tonal composition, every pitch controls or is controlled by other pitches. Pitches located at the foreground have only the property of being controlled. Pitches located at middleground levels control pitches at lower levels and are themselves controlled by pitches at higher levels. Pitches located at the background level are governed only by restrictions placed on the Ursatz by the chord of nature.

Morgan's correlation of rhythmic organization with this account of tonal organization has two important entailments for the conception of musical rhythm. First, rhythm becomes a matter of motion between structurally significant events. The initiation and completion of each rhythmic motion is marked by the appearance of the pitches that control a given span; the character of the rhythmic motion will reflect relationships between these controlling pitches. Thus the first rhythmic motion of Mozart's theme begins with the Kopfton in m. 1 and ends with the appearance of $\hat{2}$ in m. 4; the motion has the character of an antecedent because a complete motion from $\hat{3}$ to $\hat{1}$ has not yet been achieved (see ex. 7.5). Second, the type of accent assigned a given musical moment will tend to be unequivocal. Emphasis, as an articulation of rhythmic motion, follows from hierarchical structure: emphasized pitches will be those located at higher levels of the tonal hierarchy. Because the location of a given pitch within the hierarchy is not equivocal, the emphasis it receives will not be equivocal. Thus m. 3 cannot have both an upbeat accent and a downbeat accent at the same time but must be given a rhythmic reading that matches the overall tonal structure.

Although Leonard Meyer's treatment of Mozart's theme certainly takes account of tonal structure, his rhythmic analysis begins, as noted, at the musical surface. The accentual groups of the first (surface) level of the hierarchy become the elements of the second level of the hierarchy, the accentual groups of the second level

become the elements of the third level, and so on up through four levels of hierarchical organization (see ex. 7.4).[92] From Meyer's perspective, rhythmic organization, insofar as it is metrical, is independent of tonal organization, since the elemental patterns of metrical accent can be specified in the absence of pitch. The overall rhythmic character of a passage results from an interaction between tonal organization and patterns of metrical accent occurring on a number of hierarchical levels. The emphasis accorded a given musical event can only be reckoned in context. On level 2 of Meyer's hierarchy, m. 3 is (as a whole) accentually weak; on level 3, it is one component of a strong accent; and on level 4, it is a subcomponent of a weak accent. The property of accent is consequently different on each hierarchical level, since the accent proper to each level pertains to different spans of musical events.

The differences between these two accounts of the rhythmic structure of Mozart's theme follow in part from the way each model of hierarchy constrains reasoning about music. From the perspective of a chain-of-being hierarchy, the musical surface is the least important of all levels. Given the way musical events are assigned to hierarchical levels, any polysemous reading of such events is little more than analytical dithering. From the perspective of an atomistic hierarchy, there can be no grand plan of musical organization that does not originate with the simplest and most readily apprehended of musical materials. Nonetheless, there is a bit more to the story. The constraint these models impose on our reasoning goes beyond the inferential possibilities provided by their relational structure and penetrates to the very core of what counts as relevant phenomena for theorizing and analysis. Indirect evidence for this constraint is supplied by the way each model of hierarchy is mapped onto music. Chain-of-being hierarchies have been mapped almost exclusively onto the domain of musical pitch—they have generally not been mapped onto the domain of musical meter. Atomistic hierarchies, on the other hand, have been most often mapped onto the domain of musical meter—mapping them onto the domain of pitch has not met with wide acceptance.[93]

Explaining how this constraint works requires that we briefly revisit the procedures of cross-domain mapping discussed in chapter 2, with particular attention to the Invariance Principle. According to this principle, for those portions of the source and target domains involved in a cross-domain mapping, the mapping preserves the image-schematic structure of the target domain, and it imports as much of the image-schematic structure from the source domain as is consistent with this preservation. Mapping a model of hierarchy onto music will preserve aspects of our musical experience and structure these by importing the relationships between

92. In the complete analysis Meyer actually adds two additional levels of hierarchy, although the sixth and final level is somewhat speculative; see Meyer, *Explaining Music*, 39.

93. Eugene Narmour's recent attempts to map an atomistic hierarchy onto pitch have met with only limited success, and the application has not been widely adopted. See the in-depth treatment of the issue in Narmour, "Some Major Theoretical Problems Concerning the Concept of Hierarchy in the Analysis of Tonal Music," *Music Perception* 1/2 (1983–84): 129–99; Narmour discusses mm. 1–8 of the first movement of Mozart's Piano Sonata in A, K. 331, on pp. 160–98. In some recent analyses, Narmour reads musical structure as only quasi-hierarchical and thus better dealt with in terms of networks. See Narmour, *The Analysis and Cognition of Basic Melodic Structures: The Implication-Realization Model* (Chicago: University of Chicago Press, 1990).

"energy" and the CONTAINER schema embodied by this model. When we take a chain-of-being hierarchy as the source domain, we preserve our sense that some aspects of music are more important than others, and we import a model of systemic organization in which energy is distributed unequally and hierarchical levels group elements according to their amount of energy. This mapping works well for the asymmetrical pitch relations typical of tonal music but less well for the measured domain of metrical rhythm. When we take an atomistic hierarchy as the source domain, we preserve our sense that some aspects of music are regular and recurring, and we import a model of systemic organization in which energy is distributed equally and hierarchical levels group elements according to common conformance with general principles. This mapping works well for the measured domain of metrical rhythm but less well for the asymmetrical pitch relations typical of tonal music. Thus the image schemata that ground our conceptual models also facilitate mapping these models onto novel domains, subject to the limitations of the image-schematic structure of both domains.

Additional evidence for the part played by image schemata in conceptual models and cross-domain mapping is suggested by Edward Cone's analysis of Mozart's theme, which combines aspects of the approaches demonstrated by Morgan's and Meyer's analyses. For Cone, as for Morgan, musical rhythm involves motion between points of tonal stability. The first and fifth measures of the theme should be strong because of the firm statement of tonic; the fourth and eighth measures should also be strong because of the emphasis provided by arrivals on important harmonies. However, Cone, like Meyer, is also interested in the contribution of the musical surface to our understanding of musical rhythm as a whole. Cone's overall interpretation of the rhythmic structure of the opening eight measures is thus shaped by meter, motivic structure, and surface accents. What guides Cone's analysis is his concept of musical energy—it was this that prompted his comparison of a musical phrase to a game of catch. The path of energy that marks the transit of the ball in the game of catch is the analogue for the path of musical energy constituted by a given passage in a work of music. Starting with the concept of energy rather than with a model of hierarchy allows Cone to tap into both models of hierarchy and draw from each what he needs. By this means, he can forge a single account of musical rhythm that recognizes both hierarchic paradigms but which is restricted to neither. Thus, Cone's analysis demonstrates a conceptual blend, the generic space of which focuses on the notion of energy common to both models of hierarchy.

According to the approach I have developed here, the discrepancies between these three analyses of Mozart's theme reflect the role of conceptual models in theories of music. At work are two different models of hierarchical organization. One maps a chain-of-being hierarchy onto music and highlights one set of aspects of the musical domain. The other maps an atomistic hierarchy onto music and highlights a different set of musical aspects. Two of the analyses—those by Robert Morgan and Leonard Meyer—rely on relatively straightforward mappings, one from each model of hierarchy. Where the structure of the models of hierarchy diverge, there the musical analyses based on these models will also diverge. The third analysis, by Edward Cone, blends the two mappings by focusing on commonalities between their image-schematic structure. By focusing on these commonalities, Cone puts

some distance between his interpretation and notions about hierarchical organization and produces yet a third analysis of Mozart's theme. The discrepancies between the three analyses are thus not the result of different opinions about what constitutes the theme of the first movement of Mozart's sonata, nor are they a consequence of analytical inconsistencies. Rather, they follow from the structure of these two conceptual models and the way they are employed in accounts of music.

COMPETING MODELS OF MUSICAL FORM AND HIERARCHY

The foregoing represents an attempt to sort out why musicians—reasonable, highly experienced musicians—disagree about such things as musical form and musical hierarchy. As I have endeavored to show, such disagreements can be traced to competing models of musical structure. Much as Alice and the Hatter have different ideas about what time is, so music theorists have different ideas about the properties of musical form and the structure of hierarchical relationships. The analyses I offer should help explain why this is so. If one is thinking about musical form in terms of grammar or building blocks, it may not be immediately evident how music achieves its rhetorical effects or seems to grow from within. If one is thinking about musical relationships in terms of dominance and control, musical meter may appear to be something of a cipher, for meter provides only weak demonstrations of these properties.

More interesting, however, is the way these models reflect back on the theorists who employ them, much as Alice's models of time reflect the world of a seven-year-old girl in Victorian England, while the Hatter's model of time reflects the world of Wonderland. Theorists who focus on a static model of musical form are almost invariably occupied with a very basic level of music pedagogy. Dynamic models only start to make real sense once a level of artistry has been achieved—that is, once the student can speak and understand the language of music with some fluency. Not surprisingly, then, the two models begin to overlap and intertwine in confusing and interesting ways in the early nineteenth century, for the institutionalization of music education required a bit of both perspectives. Nation building required the mechanisms of rationalized instruction and of artistic exegesis, the first to guarantee a future, the second to celebrate a past. Similarly, theorists who focus on atomistic hierarchies are convinced that we enter music from its surface and only later can penetrate to its depths by understanding the general laws that connect them both. Theorists who make recourse to chain-of-being hierarchies, on the other hand, are convinced that surfaces are illusions—the real truth of music lies hidden in mysterious powers that guide compositional creation like an unseen hand. These summaries are too reductive, of course, but they make in brief the point toward which this chapter has argued at length: the models we choose for our characterizations of music tell us at least as much about ourselves as they do about music.

COGNITIVE STRUCTURE, THEORY, AND ANALYSIS

Let us return to Proust's *A la recherche du temps perdu* and to the encounters between listener and music described within. The introduction to this volume was framed around the moment when Charles Swann first hears the Andante of a sonata for violin and piano by Vinteuil at the bourgeois salon of the Verduins. As that moment unfurled, Swann moved from vague and unformed impressions to active understanding: he began to conceptualize music. Now, a year later, Swann again encounters the same fictitious composition, this time at a soirée at the Marquise de Saint-Euverte's. Over the course of this year, Swann has become obsessed both with the Andante—especially as represented through the fragment he calls "the little phrase"—and with Odette, the courtesan whom he had also first come to know at the Verduins. At the moment we find him, Odette has left him, and he finds himself surrounded by people who, if they knew of his love for her, would only trivialize it. Then, unexpectedly, the musicians commence the sonata, and Swann finds himself enraptured once more. Where in his first encounter the sonata had amounted to not much more than pleasant sensations, it is now a full-fledged discourse, speaking in a beautiful and paradoxical language: "Ever since, more than a year before . . . the love of music had, for a time at least, been born in him, Swann had regarded musical *motifs* as actual ideas, of another world, of another order, ideas veiled in shadow, unknown, impenetrable to the human mind, but none the less perfectly distinct from one another, unequal among themselves in value and significance."[1] The ideas that enthrall Swann—distinct yet shadowy, perfectly clear yet impenetrable—are musical concepts; the discourse to which he attends is musical discourse. What began as a sketchy, provisional transcript has blossomed into a theory of musical organization that is robust enough to reach out to the transcendental.

The process that led to this transformation (as described in chap. 1) begins with categories of musical events, of which the *motifs* (or motives) upon which Swann focuses are a good example. Musical motives show a number of similarities to basic-

1. Marcel Proust, *Swann's Way* (vol. 1 of *Remembrance of Things Past*), trans. C. K. Scott Moncrieff and Terence Kilmartin (New York: Vintage Books, 1981), 379–80.

level categories, offering an effective compromise between efficiency and informativeness. The variability of motives, as they are shaped to the exigencies of musical context and compositional process, matches perfectly the variability of Type 1 categories; our impression that there is a motive reflects the conceptual models around which such categories are organized. Of course, motives of the sort typical in late nineteenth-century music, of which the little phrase is intended to be a paragon, represent only one possibility for musical categories. Categories might also be organized around a harmonic structure or a ground bass, around a two-voice contrapuntal pattern or a persistent rhythmic figure. As the analysis of atonal music has suggested, musical categories might even involve relatively abstract relationships, which are obscure at first but which emerge with repeated listenings.[2]

As I proposed in chapter 1, we can construe musical concepts as equivalent to musical categories. Although such concepts may be affiliated with language, language is not necessary for their creation or maintenance. The paradox presented by Proust—that musical ideas are "ideas veiled in shadow, impenetrable to the human mind, but none the less perfectly distinct from one another"—is simply a reflection of the limits of language. Musical concepts are of another world, another order, because they extend into a domain that is beyond words.

One of the principal ways musical concepts are related to other concepts—musical and otherwise—is through the process of cross-domain mapping. A bit before the passage quoted above, the little phrase is first a kind of superhuman agent transformed into sound (whose presence is itself likened to the perfume of a flower), then the words this spirit speaks, then an almost corporeal lover, and finally once again a comforting spirit:

> Swann felt its presence like that of a protective goddess, a confidante of his love, who, in order to be able to come to him through the crowd and to draw him aside to speak to him, had disguised herself in this sweeping cloak of sound. And as she passed, light, soothing, murmurous as the perfume of a flower, telling him what she had to say, every word of which he closely scanned, regretful to see them fly away so fast, he made involuntarily with his lips the motion of kissing, as it went by him, the harmonious, fleeting form. He felt that he was no longer in exile and alone since she, who addressed herself to him, was whispering to him of Odette.[3]

This dense field of overlapped mappings cannot, of course, quite summon the acoustic reality of the little phrase (which exists, after all, only in Proust's imagination), but it does select certain aspects of the musical domain as targets. The little phrase is distinct enough from the surrounding materials that it can be likened to a person emerging from a crowd; it has a measure of delicacy about it, both in its

2. I am thinking especially here of the work of David Lewin, who has a knack for discovering intriguing musical relationships, characterizing them through impressively abstract formulations, and managing to create analyses of compelling immediacy. On the possibility of hearing these formulations, Lewin comments, "One should not ask of a theory, that every formally true statement it can make about musical events be a perception-statement. One can only demand that a preponderance of its true statements be potentially meaningful in sufficiently developed and extended perceptual contexts." Lewin, *Generalized Musical Intervals and Transformations* (New Haven, Conn.:Yale University Press, 1987), 87.

3. Proust, *Swann's Way*, 378.

overall aesthetic shape and in its lack of assertiveness; despite this delicacy, the substance of its communicative force is such that it evokes response not simply in words but in deeply intimate gestures. If, after this description, the little phrase still remains elusive, we can nonetheless generate a fairly clear sonic picture of what it involves. Proust's mappings have thus constructed an image of this imaginary music, selecting musical concepts—vague and ill formed, to be sure, but convincing nonetheless—from the general field of possible musical constructs.

It is through similar, if more prosaic, mappings that we structure our understanding of music, building up the integrated systems of terms and relations through which we describe our experience with and conceptions of music. Such cross-domain mappings have their ultimate grounding in embodied experience (as we observed in chap. 2). In turn, our experiences with music allow us, on occasion, to map from the musical domain onto other domains. For instance, in the passage just cited, music (as represented by Vinteuil's sonata) provides a model according to which a succession of fleeting impressions—the movement of a person's body, the scent of a flower, the brush of a kiss, a scattering of forms—can be construed as constituting an indivisible whole. Just as the sonic materials proper to a musical work appear and disappear and yet always remain part of "the work," so the fleeting impressions noted by Swann are, in truth, but some of the disparate threads out of which his love for Odette is woven.[4]

The possibility of mapping structure both to and from the musical domain contributes to the process of conceptual blending, in which elements from two correlated mental spaces are blended together in a third mental space. This offers a further interpretation of Swann's encounter with the little phrase, for what appears before him is a blend of features drawn from the human and sonic domains—a protective goddess who has disguised herself in a sweeping cloak of sound. Just such a blend seems to have been intended by Proust, who goes on to write that Swann "had no longer, as of old, the impression that Odette and he were unknown to the little phrase. Had it not often been the witness of their joys? True that, as often, it had warned him of their frailty."[5] As the story continues, the little phrase becomes fully personified, engaging in dialogue with Swann, offering sage advice, and leading him to transports of the spirit. What Proust is relying on, of course, is the sort of anthropomorphic blend he also employed in his description of Swann's lilac trees, and which Tovey employed so strategically in his analysis of Beethoven's Sixth Symphony (both discussed in this volume in the latter portion of chap. 2).

The musical concepts produced by categorization and the structural relationships produced by cross-domain mapping come together in conceptual models, which provide the basis for reasoning about music. Swann relies on two models. Of these, the first yields a view of music as a type of discourse structure: musical motives are regarded as ideas that are shaped into a communicative medium by the way they are organized in time and with respect to other musical ideas. The sec-

4. This is particularly apparent because Proust's allusion to "the perfume of a flower" is anticipated a few pages earlier by Swann's detailed recollection of the chrysanthemum Odette gave him early in their romance.

5. Proust, *Swann's Way*, 378.

ond model yields a view of the nonlinguistic as supernatural. Words, as proper to human discourse, are necessarily mortal; those things that escape words are consequently immortal; things that are immortal exist only outside the natural world. These models are then combined into a theory of music appropriate to Swann's moment of clairvoyance, following the perspective developed in chapter 3. According to this theory, musical discourse is a suprahuman mode of communication, something evident as the two musicians conclude the performance that had summoned the little phrase and Swann's rapture.

> Swann dared not move, and would have liked to compel all the other people in the room to remain still also, as if the slightest movement might imperil the magic presence, supernatural, delicious, frail, that was so soon to vanish. But no one, as it happened, dreamed of speaking. The ineffable utterance of one solitary man . . . breathed out above the rites of those two hierophants, sufficed to arrest the attention of three hundred minds, and made of that platform on which a soul was thus called into being one of the noblest altars on which a supernatural ceremony could be performed.[6]

This is a theory of music rather different from the others I have discussed, not the least because where specifics are wanted we find only sweeping generalities. Nonetheless, the theory of music that Swann has developed in his efforts to understand the effect of Vinteuil's sonata is in truth but a manifestation of a portion of the broader theory of aesthetics Proust sought to develop in *A la recherche du temps perdu.* Within this theory, music was to occupy the same place accorded it by Schopenhauer: as a pure expression of the will.[7] Necessary to this perspective is the conceit that absolute music somehow exists outside the domain of human cognition.

The perspective relative to which I have framed this book, of course, is that music, "absolute" or otherwise, is wholly within the domain of human cognition. In making this argument, I have focused not on the most basic aspects of musical cognition—the level where raw data is taken in by the auditory processing system and transformed into electro-chemical information within the brain—but on a relatively high level of cognition accessible to our conscious thoughts. My emphasis has been on how general cognitive capacities (like those for categorization, cross-domain mapping, and the construction and maintenance of conceptual models and theories) are specified for music. Indeed, understanding something as music—as opposed to the hammering of a woodpecker, or an agreeable if not particularly interesting succession of sounds, or just noise—is intimately bound up with directing these general cognitive capacities to the specific task of making sense of patterned sound.

This approach to music cognition makes it possible to give a fairly detailed account of how M. Swann (and M. Proust, for that matter) conceptualize music. It also provides a perspective on broader problems of musical understanding, four of which I treated at length in the second part of this book.

6. Proust, *Swann's Way*, 383.

7. On this point, see Jean-Jacques Nattiez, *Proust as Musician*, trans. Derrick Puffett (Cambridge: Cambridge University Press, 1989), chap. 4.

MUSICAL SYNTAX The idea that musical works could be woven from relatively limited bits of musical materials—motives—was one that gained currency around the time that composers became increasingly interested in the resources of purely instrumental music—that is, around the middle of the eighteenth century. As such, the idea that motives are important for musical discourse is hardly a new one, even if it did not assume prominence in music theory treatises until the mid-nineteenth century. Viewing a motive as a cognitive category has the practical benefit of explaining why we construe diverse motive forms as "the same," despite their manifold differences. The perspective becomes really interesting, however, when we start to consider relationships among the members of a category of motives, for these offer a way to explain the way the musical syntax specific to a given work emerges over time. As the composer deploys now more, now less typical members of the category, we not only develop a more complete sense of the structure of the category but also come to see how typicality correlates with overall compositional design. This syntactic strand could be woven together with those spun from harmonic and formal syntax to create a rich, multileveled discourse (as we saw in the analyses of works from the eighteenth century presented in chap. 4).

The same approach also provides a way to explain how the musical topics so important in eighteenth-century instrumental music emerged. As we saw in the first movements of two Beethoven string quartets, categories of motive forms were distinguished by how they were used in the course of a movement. In the case of a motivic category used only for beginnings, for instance, this property then becomes part of the conceptual model for the category of motive forms: in addition to its other attributes, the category now acquired the attribute "used only for beginnings." This change has the consequence of giving the category a semantic value: within the context of this movement, the motive means "this is a beginning." As a result, a musical topic, even if of a very local and restricted sort, has been born. For eighteenth-century music, this process is of interest chiefly for answering the riddle of how musical topics were created in the first place and for understanding the interplay between locally generated signs and established topics. For music with a less-clearly defined tradition, such as that of the twentieth century, the process is of rather more interest, for it offers a way to explain how each individual piece generates a semiotic system. Indeed, it is in part through establishing and manipulating categories of musical events that composers of the twentieth century create musical meaning. We can also see the part this process plays in helping us understand an unfamiliar repertoire: by attending to the specifics of musical syntax, we can begin to understand the process of meaning construction of which this syntax is a part. In a manner of speaking, music teaches us how we should listen to it.

The dynamic approach to musical syntax made possible by considering relationships among the members of musical categories (and among categories themselves) is one that is well suited to developing an account of large-scale rhythm—that is, rhythm at the phrase level or above. The challenge of theorizing large-scale rhythm has been to develop a model that is more than simply an adaptation of metric theory or a reinterpretation of large-scale harmonic theory. One way to develop such a model is to construe relationships among category members in dynamic terms. For instance, if we return to the compositional strategies discussed in chapter

4, we could use cross-domain mapping to correlate the typicality of category members with stability, and atypicality with instability. Applied to the opening measures of the Allegro from Mozart's "Dissonance" Quartet, what emerges is a large-scale pattern that begins with stability (in mm. 23–26), moves to instability (beginning in m. 27), returns to stability (in mm. 31–34), moves somewhat more quickly to instability (beginning in m. 35), returns (after a brief hiatus) to stability (in m. 44), and then finally dissolves into instability (after m. 48).[8] The pattern could be further applied to each subsequent episode involving the motive, producing a dynamic account of the movement as a whole.

MUSICAL ONTOLOGY That an exploration of musical ontology might yield significant insights into the structure and character of cultural knowledge might at first seem surprising, for as common as music is, it is still not the central business of human culture. However, because music is resolutely ephemeral, knowledge of it is, in most cases, preserved only in human cognitive structure. We can know what Greek pottery of the fifth century B.C. was like, because some of it has been preserved into the present era. The same cannot be said of Greek music. Theoretical and other writings give us hints about the character of Greek music, but direct experience of it is impossible. Music, where it is not preserved through some artifactual means, exists solely in the conceptual models and theories of the members of a musical community. In consequence, giving an account of the basis for determinations of musical identity—what it means for something to be considered an instance of music—means giving an account of the cultural knowledge upon which such determinations are based.

Although it is easy to hold up the Western preoccupation with "the score" as the acme of musical objectification, the notion of a musical object is not a consequence of artifacts like scores but is instead an offshoot of the conceptual models we use to structure our understanding of what we hear. Because these models are, for the most part, completely transparent, we take them for the way things are: conceptual models are part and parcel of what counts as reality (as noted in chap. 3). Our impression that "music" is an objective category, and that there are musical objects, is simply a consequence of the cognitive efficiency conceptual models represent.

In that the conceptual model relative to which we make determinations of musical ontology captures the things our culture deems most important about patterned sound (or the place patterned sound occupies in our culture), our theories of music are consequent to these models: what counts as "music" determines what counts as "music theory." One prominent example of this was provided by the Greek music theories of antiquity discussed in the introduction. However, more subtle examples are available as well: for Rameau, "music" meant French music, and it was relative to that national tradition of musical expression that his theory was framed. Similarly,

8. The changing pattern of stability and instability I have outlined very much resembles the pattern that occurs at the level of the beat, specifically in the context of what Harald Krebs calls metric dissonance. The principal difference is that the pattern as I have described it is expanded to encompass entire musical phrases. This theory of metric dissonance is most fully worked out in Krebs, *Fantasy Pieces: Metrical Dissonance in the Music of Robert Schumann* (New York: Oxford University Press, 1999).

for Schenker "music" meant music from the German-speaking world, and it was to this repertoire that his theory was directed. This conception of musical ontology can be extended to other repertoires, like jazz (as noted in chap. 5). There we observed that certain jazz musicians of the 1950s and 1960s regarded the harmonic possibilities of a tune (that is, the potential for the harmonic template of the tune to be reconstituted through the modification or substitution of harmonies) and its overall affect as more important than the bare pitch structure of its melody or the basic syntax established by its harmonies. In consequence, the theory of music that issued from this practice—a theory woven throughout the interviews and quotations that form the fabric of Paul Berliner's *Thinking in Jazz*—was centrally concerned with ways to create and layer the multiple musical discourses made possible by a particular harmonic pattern.[9] For this music, it was far less important to develop an explanation of the imperatives of melodic or harmonic syntax, since these were assumed to be almost totally dependent on local context.

MUSIC AND OTHER DOMAINS According to at least some definitions, language and music are quite separate domains. The distinction is eminently sensible: when we want to know if supper is ready, we expect a response in words, not a musical phrase ending with a deceptive cadence. Nonetheless, inasmuch as both language and music are products of human cognitive processes, it also seems sensible that they will rely on some of the same cognitive capacities. For example, evidence from conceptual blending suggests that they both employ similar discourse strategies. Admittedly, these strategies, as represented by the generic space of a conceptual integration network, are rather abstract, so elemental as to be almost simplistic. And yet there is strong evidence that such simple stories are basic to human cognition and communication—indeed, as we observed in chapter 2, Antonio Damasio has argued that they are involved with consciousness itself.[10] In situations where linguistic discourse and musical discourse are simultaneous and structured by the same basic strategy, concepts from the mental spaces set up by each can combine in a third mental space: a conceptual blend. Situations of this type were demonstrated by the analyses of songs in chapter 6. And, as we saw with Brahms's "In der Fremde," if a uniform topography between the constituent spaces in a conceptual integration network is lacking, conceptual blending will not occur. The combination of words and music in such cases may be pleasant enough, but it will not realize the full potential of these conjoined media.

A basic conceptual blend involves four coordinated mental spaces (as noted in chaps. 2 and 6). However, as Tovey's analysis of Beethoven's Sixth Symphony shows, conceptual blending may involve any number of mental spaces. It is fairly easy to imagine songs that might involve multiple spaces—for instance, if the song makes

9. Paul F. Berliner, *Thinking in Jazz: The Infinite Art of Improvisation*, Chicago Studies in Ethnomusicology (Chicago: University of Chicago Press, 1994).

10. For an overall account of the importance of abstract discourse structures to human cognition, see Mark Turner, *The Literary Mind* (New York: Oxford University Press, 1996). The approach Antonio Damasio takes in his *The Feeling of What Happens: Body and Emotion in the Making of Consciousness* (New York: Harcourt Brace, 1999) is notable for the empirical evidence and level of neurophysiological detail that he brings to bear.

reference to a well-known myth, or if, as in the case of Schubert's "Trockne Blumen," there are strong parallels between the situation described in the words and details of the composer's life.[11] Even more intriguing are the possibilities offered by opera, which can easily engage—and often revels in—simultaneous musical, linguistic, theatrical, gestural, and scenic discourse. Various kinds of musical multimedia—music and film, music and dance, music and visual images—offer further possibilities for exploring conceptual blends involving multiple spaces. In each case, where a uniform topography between the spaces set up by these media obtain, conceptual blending can occur. What is potentially intriguing about the blends that can be set up by the coordination of these diverse media are the views of discourse structure that will result, so that the syntax of music will shed light on the syntax of other media, and they on music. While differences between the media are essential to the experience of multimedia, as Nicholas Cook has suggested, the deep commonalities between the discourse structure of various media offer new ways to think about musical structure.

COMPETING MODELS OF MUSICAL STRUCTURE The theory of music developed by Charles Swann, while useful for making a reconciliation with what he imagined to be the end of his love affair, offers hardly any explanation for why the little phrase works the magic that it does or how Vinteuil's sonata can hold three hundred Parisian socialites enthralled. Where we long to discover more about its syntax, or its place within a tradition of similar works, or the means by which it sprang forth from the mind of its creator, Swann's theory gives us only obscurantism and effusion. That this should be so is a direct consequence of the conceptual models his theory employs. Given the assumption that music is a type of discourse structure (rather than, say, some sort of organism or mechanism), Swann's theory places an emphasis on the message rather than the medium and on temporal constraint as an essential element of musical experience. Music has things to tell us, but the disappearance of these messages is practically coincident with their emergence. Given the assumption that nonlinguistic discourse is supernatural (rather than something humans make use of regularly), we cannot expect to make much sense of the things music tells us; we can only be grateful that we have been able to hear them at all. Of course, Swann's—and Proust's—theory of music is a product of a particular cultural and historical moment, one that sought to explain how humans could participate in the divine even while they were forever shut off from it. Other cultural and historical moments—including our own—will seek other explanations, employing the categories, cross-domain mappings, conceptual models, and theories that resonate with them most deeply and constructing a vision of music that best fits with their vision of the world as a whole.

Theories of music, then, are not so much about truth as about a particular perspective on what aspects of patterned sound are rewarding or important to attend to; they are equally concerned with the integration of this perspective into a larger

11. Although this biographical correlation does not figure in my consideration in chap. 6 of Schubert's song, I touch on these parallels in Lawrence Zbikowski, "The Blossoms of 'Trockne Blumen': Music and Text in the Early Nineteenth Century," *Music Analysis* 18 (1999): 340.

view of human society and culture. Similarly, music does not offer us an unmediated vision of the truth—despite what M. Swann believes—but a truth assembled from the possibilities of patterned sound and human cognitive capacities.

Most of my discussion has focused on cognitive structure and theory, and I have had relatively less to say about analysis—especially analysis as the object of a separate domain of inquiry. The reason for this apparent imbalance, as mentioned in the introduction to this volume, is that while analysis is essential for making claims about musical structure explicit, it is not independent of theory: every analysis relies on some theory of music.[12] For that matter, I am somewhat doubtful about making a meaningful distinction between description (as a more or less passive reporting of the relevant features of a work) and analysis (as a thorough contextualization of aspects of musical structure), since decisions about what counts as "relevant features" and "musical structure" rely equally on some theoretical understanding about music. It seems more promising to distinguish between ad hoc theories and extended theories, as I did at the end of chapter 3. This distinction is based on the kind of problems a theory engages, its place within a tradition of inquiry, and the degree to which it is rendered systematic. Generally speaking, descriptions or analyses based on extended theories are more interesting than those based on ad hoc theories, for extended theories draw much more deeply on our cognitive capacities and cultural knowledge.

Although analysis has been a bit of a dark horse, it has hardly been out of the running. Indeed, it has been present throughout the course traced by the preceding pages: in the analyses by Schoenberg, Tovey, Rameau, Schenker, Mattheson, Meyer, Cone, and Morgan I have discussed, and in the analyses I myself have presented. In the case of earlier writers, I have been most interested in what their analyses have to say about their theories of music. My own analyses, of course, are based on the theory that our understanding of music is shaped by our cognitive capacities and that these are visible at every turn in our encounters with music. Through our theories and analyses, we thus shed light not just on music but on the fascinating mysteries of human thought.

The abiding mystery I have sought to explain is the one embodied in M. Swann's first encounter with Vinteuil's sonata: how it is that we can make some sort of sense of an unfamiliar music almost immediately and yet have this same work provide continued reward in our further experiences with it. Music, as revealed by Proust's vignette, is thus simultaneously immediate and complex, transparent and opaque. The solution I have offered is that our understanding of music relies on cognitive capacities that we use throughout our daily lives. The cognitive processes behind categorization, cross-domain mapping, conceptual models, and theories would all be operational had we never heard a note of music. Doubtless, our lives would be immeasurably impoverished had this unlikely turn of events transpired,

12. Among the first to draw this distinction was Edward T. Cone in "Analysis Today," *Musical Quarterly* 46 (1960): 172–88. This essay can also be found in Paul Henry Lang (ed.), *Problems of Music Analysis: The Princeton Seminar in Advanced Musical Studies* (New York: W. W. Norton, 1960), 34–50; and Cone, *Music, a View from Delft: Selected Essays* (Chicago: University of Chicago Press, 1989), 39–54.

but not only because we would have never been exposed to what Proust characterized as "another world, another order, ideas veiled in shadow, impenetrable to the human mind, but none the less perfectly distinct from one another." We would also have never had these cognitive capacities stretched and transformed by the challenge of listening to the play of patterned sound. Nor would we have taken what we learned in our encounters with that domain back to our understanding of the world as a whole. And we would never have had the opportunity to extend our conceptualization of music into theories of music—theories that, in the webs of relations they build both within and without music, offer their own topic for intellectual investigation. Conceptualizing music, seen in this way, is thus both a celebration and an exploration of the means by which our minds go out to meet the world.

Recordings

This reference list makes use of the following abbreviations: CD = compact disc; LP = 33 rpm record; 78 = 78 rpm record.

Bennie Krueger's Orchestra. "Bye Bye Blackbird." Brunswick, [78] no. 3186, 1926.

Benny Goodman Sextet. "I Got Rhythm." In *Benny Goodman*. CBS Records, [LP] P5 15536 CP, 1981.

Bobby Short. "Bye Bye Blackbird." In *Bobby Short*. Atlantic, [LP] 1230, 1956.

Charlie and His Orchestra. "Bye Bye Blackbird." In *Charlie and His Orchestra: German Propaganda Swing 1941–1942*. Harlequin, [CD] HQ CD 03, 1990.

Charlie Parker and others. "I Got Rhythm." In *Bird: The Complete Charlie Parker on Verve*. Verve/Polygram Classics, [CD] 837 142-2, 1988.

Chick Webb and His Little Chicks. "I Got Rhythm." In *Spinnin' the Webb: Chick Webb and His Orchestra*. GRP Records, [CD] 513678L, 1994.

Derek Bailey, Pat Metheny, Gregg Bendian, and Paul Wertico. *The Sign of 4*. Knitting Factory Works, [CD] KFW 197, 1997.

Don Redman and His Orchestra. "I Got Rhythm." In *Don Redman and His Orchestra, 1931–1933*. Classics, [CD] 543 Classics, 1990.

Eddie Cantor. "Bye Bye Blackbird." In *Songs by Eddie Cantor from* The Eddie Cantor Story. Capitol, [LP] L-46, 1954.

Fletcher Henderson and His Orchestra. "Yeah Man." In *Fletcher Henderson, Developing an American Orchestra, 1923–1937*. Smithsonian Collection, [LP] R 006, 1977.

Fred Rich and His Orchestra. "I Got Rhythm." In *1930—You're Driving Me Crazy: Portrait of a Year in Music*. Phontastic, [CD] PHONT CD 7618, 1992.

Freddie "Schnickelfritz" Fisher and His Orchestra. "Bye Bye Blackbird." Decca, [78] no. 25357/3788, 1941.

Gene Austin. "Bye Bye Blackbird." Victor, [78] no. 20044-B, 1926.

George Gershwin. "I Got Rhythm." In *Gershwin Performs Gershwin: Rare Recordings 1931–1935*. Musical Heritage Society, [CD] 512923A, 1991.

George Gershwin and Ira Gershwin. *Girl Crazy*. Elektra Nonesuch, [CD] 79250-2, 1990.

Jimmy Dorsey and His Orchestra. "I Got Rhythm." In *Jimmy Dorsey and His Orchestra*, Vol. 2: *1942–44*. Hindsight Records, [LP] HSR-153, 1980.

Johnny Maddox. "Bye Bye Blackbird." In *Tap Dance Rhythms*. Dot, [LP] DLP 3008, 1955.

Lester Young with the Kansas City Six. "I Got Rhythm." In *The Tenor Sax: Lester Young, Chu Berry and Ben Webster: The Commodore Years*. Atlantic, [LP] SD 2-307, 1973.

Marlene Fingerle and Arthur Schutt. "Medley: 'I Know That You Know,' 'Baby Face,' 'Bye Bye Blackbird.'" In *Song Hits of 1926*. Songs of Our Times. Decca, [LP] DL 5170, 1950.

Miles Davis. *'Round about Midnight*. Columbia, [CD] CK 40610, 1987.

Peggy Lee. "Bye Bye Blackbird." In *Songs from* Pete Kelly's Blues. Decca, [LP] DL 8166, 1955.

"Pete Kelly and His Big Seven" (Matty Matlock and others). *Pete Kelly's Blues*. BMG Special Products; [CD] DRC12081, 1998.

Red Nichols and His Five Pennies. "I Got Rhythm." In *Rarest Brunswick Masters, 1926–1931: Red Nichols and His Five Pennies.* MCA Records, [LP] MCA 1518, 1982.

Red Norvo and His Swing Sextette. "I Got Rhythm." In *Red Norvo.* Time-Life Records, [LP] STL-J14, 1980.

Sidney Bechet and the New Orleans Feetwarmers. "Shag." In *Sidney Bechet.* Time-Life Records, [LP] STL-J09, 1980.

ACKNOWLEDGMENTS

The editors would like to thank the authors, all of whom entered into this project with great enthusiasm, professionalism, and efficiency. They did more than write their individual contributions. They willingly engaged with other authors and ourselves to develop and refine a coherent and cross-referring set of papers which, as a result, is considerable greater than the sum of the parts. Crucial to this process was the contribution of a number of referees. Each chapter was reviewed by a least two experts in the field, and their perceptive comments helped authors to refine and update their contributions. Among those who participated in the review process were Emmanuel Bigand, Anne Blood, Warren Brodsky, Claudia Bullerjahn, Alfred Cramer, Ian Cross, Jane Davidson, Walter Dowling, Andrew Gregory, David Hargreaves, Antoine Hennion, Anthony Kemp, Carol Krumhansl, Andreas Lehmann, Jerrold Levinson, Justin London, Clifford Madsen, Peter Martin, Eugene Narmour, Bruno Repp, John Rink, Martin Stokes, William Forde Thompson, Magnus Widesheim, Suzanna Widmer, and Dolf Zillman. In addition, several of the authors provided comments on parts of the book.

We are particularly grateful for the help and support of colleagues at Oxford University Press, for receiving the initial proposal warmly, and encouraging the project at all stages. Martin Baum, our Editor, has taken a close personal interest in all aspects of the project, and his constant attentiveness and readiness to act on behalf of the project has meant a great deal to us.

We acknowledge the support of our respective institutions. Patrik Juslin's work was supported by the Bank of Sweden Tercentenary Foundation. John Sloboda was enabled to devote time and resources to the project by the award of a semester of sabbatical leave under the Keele University Research Investment Scheme.

Finally, we wish to acknowledge two individuals, now retired from full-time academic positions, without whom this project would have been inconceivable. Leonard B. Meyer's brilliant work in the 1950s is the foundation on which almost everything else in this book rests, directly or indirectly. We are delighted that he has supported this project with a contribution which is as fresh and innovative as anything that he has written. Alf Gabrielsson is, in many ways, the father of modern psychological investigations into musical emotions. He was publishing pioneering empirical work relating to emotion and musical expression in the early 1970s, long before any other contributor to this book. He has been profoundly influential for many researchers, not least the editors of the current volume—Juslin through many years of direct collaboration at the Uppsala University, and Sloboda through two decades of collegial support in activities such as the organization of scientific meetings, the nurturing of scholarly scientific bodies, and tireless contributions to the editorial work of books and journals. We salute these two giants, and hope that this book will add to the recognition of their important contributions to the furthering of knowledge.

FOREWORD

It has often been claimed that music is the language of the emotions. One can interpret this claim in either of two senses. On the one hand, it could be taken to mean that music provides an iconic representation of the affective 'movements of the soul' which is more appropriate to the dynamic flow of emotional experience than symbolic description through verbal labels (which imply steady states). On the other hand, the claim that music is the language of the emotions can also be understood as commentary on the nature of music, specifically the suggestion that music cannot be composed, performed, or listened to without affective involvement. In consequence, the privileged relationship between emotion and music has been the object of much scholarly discussion as well as empirical research. Not surprisingly, then, the topic has been addressed by many different disciplines - philosophy, musicology, literature, psychology, acoustics, anthropology, and neurosciences - as well as by practising musicians, composers, and performers alike.

Given its multifaceted nature, the relationship between music and emotion is a topic of central concern for the emerging domain of affective science. The current volume, edited by Patrik Juslin and John Sloboda, will have a major role in establishing the topic as a core research area in this multidisciplinary domain of scientific inquiry. It attempts no lesser feat than bringing together the various concerns with the affective nature of music that have so far been spread over a wide variety of journals and book publications in different disciplines. For all practical purposes, this material has been inaccessible to the non-specialist. In addition, the volume provides a state-of-the-art overview of current thinking and a synthesis of the major research results to date. The editors succeed admirably on both counts.

Following an overview of the various perspectives that have been adopted by the disciplines concerned with the emotional expressiveness and the affective impact of music, the contributions are grouped with respect to their focus on the composer, the performer, and the listener. In an extensive introduction, that helps to structure the issues and define fundamental concepts, as well as in a final commentary, Juslin and Sloboda pull together the various strands and work toward an integration of the different themes. Among the contributors, all established experts in their respective areas, are two of the eminent pioneers in the study of music-emotion relationships - Alf Gabrielsson and Leonard Meyer. This volume is a fitting tribute to their vision.

Given the multitude of perspectives provided in this book and the ensuing enlargement of the horizon for scholars and researchers in the highly specialized disciplines concerned with this topic, one can expect a quantum jump in the sophistication of affective science research on music and emotion. It is equally to be hoped that the fascinating questions and hypotheses detailed in the pages of this volume will recruit a new generation of multidisciplinary-minded researchers to the study of a phenomenon that has intrigued mankind since the dawn of time.

Klaus R. Scherer

PART I

INTRODUCTION

CHAPTER 1

MUSIC AND EMOTION: INTRODUCTION

PATRIK N. JUSLIN AND JOHN A. SLOBODA

Questions about music and emotion have occupied human beings ever since antiquity. It is a topic of considerable interest to laymen and experts alike. Some sort of emotional experience is probably the main reason behind most people's engagement with music. Emotional aspects of music should thus be at the very heart of musical science. It is all the more remarkable then that this topic has been seriously neglected during the last decades. None of the recent books on music psychology, or emotion psychology, have treated emotional aspects of music other than sparingly, despite the fact that some emotion theorists have argued that studies of music might be helpful also in understanding emotions more generally (Gaver & Mandler 1987). The most authoritative handbook of music psychology to appear thus far, *The psychology of music* (Deutsch 1999), does not include a chapter on emotion. Similarly, the most extensive handbook on emotion yet to appear, *Handbook of emotions* (Lewis & Haviland-Jones 2000), also does not contain a chapter on music.

Still, it is probably true that most people experience music—somehow, somewhere—every day of their lives, often with an accompanying affective response of some sort (e.g. nostalgic recognition of a favourite song on the radio while driving a car, frustration directed at the music at the shops, joy when listening to an excellent performance at an evening concert, a sad mood created by the soundtrack of a late night movie). As noted by Dowling and Harwood (1986), 'music arouses strong emotions in people, and they want to know why' (p. 202). However, despite the ubiquity of emotional responses to music, it seems that, for a long time, such reactions have defied psychological explanation.

Without wishing to forestall the different conceptualizations of emotion in this book, it may be useful to provide a preliminary description of how affect is differentiated from other psychological phenomena that occur in relation to music. When an individual engages with music, either as performer, listener, or composer, a very broad range of mental processes and contents may be engaged. The present book focuses on those musical processes and mental contents that have an *evaluative* component. We contrast such phenomena to those processes and contents that are primarily descriptive or *representational.*

Examples of representational processes would include the determination, or awareness, of such properties of a piece of music as metre, rhythm, tonality, harmony, melody, form, and style (whether accomplished explicitly or implicitly). Such representational processes are central to the recognition, identification, and performance of

music. They are the focus of the study of music perception and cognition, and, as such, have dominated the scientific literature on musical activity for the last century or more (Deutsch 1999; Sloboda 1985).

Examples of evaluative processes would include the determination, or awareness, of music as eliciting liking or disliking; preference; emotion and mood; and aesthetic, transcendent, and spiritual experiences. We use the term evaluative because it is typical of such processes that they are both *valenced* and *subjective*. Valence refers to the tendency to attach differing degrees of positivity or negativity to whatever is being experienced or processed. Subjectivity refers to the fact that such experiences are affected by labile personal factors such as attitudes, associations, and goals. There is, of course, no absolute dichotomy between representational and evaluative processes. Rather they represent extremes of a continuum. Representation can incorporate evaluative components (particularly in situations of ambiguity, with which music abounds). For instance, hearing the lower rather than the upper line of a two-part invention as 'foreground' may involve preference grounded in subjectivity (this particular listener perhaps prefers focusing on lower parts because he or she is a bass player). Affect can also incorporate representational aspects, especially where some aspect of what is being experienced is deeply embedded culturally or biologically. For example, listeners within a particular culture may have no option but to hear organ music as 'churchy'—with all the emotional connotations that brings—thus appearing to be an 'objective' characteristic of the music. One of the key issues for musical science is to better understand the relationship between the representational and affective processes. Do affective responses always take representations as their starting point, and if so, what other factors moderate between representation and outcome? Unfortunately, musical affect has been the poor relative of contemporary musical science (Sloboda 1995).

1.1 The slow progress in the study of music and emotion

Why has the field of music and emotion been so slow to catch up with the other domains of musical science, such as music cognition or musical development? We believe that there are several reasons for this neglect—some that the domain of music and emotion has in common with the field of emotion as a whole, and some that are particular to the music domain. One problem, which has impeded progress in understanding emotions in general, is the difficulty involved in studying emotions in the laboratory (Plutchik 1994, Chapter 1). This is also true of emotional reactions to music, which are difficult to observe under laboratory conditions.

Another reason for the slow progress in the field of music and emotion is the dominant influence of so-called *cognitive science* (Gardner 1985) on psychology in general and music psychology in particular, which has led to a strong emphasis on cognitive aspects of musical behaviour—both in perception (Deutsch 1999; Dowling & Harwood 1986) and performance (Gabrielsson 1999; Palmer 1997). This is illustrated through the titles of some of the main scholarly organizations for music that exist around the world. Most of them contain the word 'cognition'. None contain the word 'emotion' (e.g. Society for Perception and Cognition of Music, European Society for the Cognitive Sciences of Music, International Conference for the Perception and Cognition of

Music). And whereas studies of music cognition have been guided by a common 'paradigm'—the information-processing approach—the study of music and emotion has not yet benefited from any unifying paradigm. Indeed, a number of authors have expressed doubts that current theories of emotion are adequate for dealing with music. Thus it seems to us that the study of musical emotion is pretty much in its 'pre-paradigmatic' phase, to borrow from Kuhn's (1962) terminology. There is still plenty of disagreement in the field about many issues, and at present, it seems that the field is best served by a multiplicity of approaches. A lack of a unifying theoretical framework may explain why no psychologist has attempted to write a book on the topic: it has been too difficult to present a coherent story based on the available literature. However, one important goal for future research could be to try to reach some degree of consensus concerning a common set of concepts, definitions, and methodologies for the study of music and emotion. Indeed, we hope that this very book may contribute to that goal by summarizing a variety of theoretical perspectives and methods in a systematic fashion, highlighting areas of agreement whenever possible.

One reason why many researchers have been reluctant to study musical emotions is that it is a very difficult topic. Most of the early studies in the field were concerned with matching emotion labels to excerpts of music, and for about 50 years, it appeared as if the field would not move beyond such studies. There was no sense of direction in this early work, despite the pioneering studies by Kate Hevner (1935) and others. Perhaps frustrated by a lack of theories and by some difficulties inherent in describing responses to music in words, many researchers simply abandoned the field. Part of the reason for this was also the behaviourist era of the 1940s and 1950s, during which the study of emotions and other 'inner' mental processes were seen as less than scientific. Since then, we believe, there has been a tendency for many researchers to think that the problem of music and emotion is so complex that they would prefer to avoid it altogether—rather than dealing with the problem inadequately, it is better not dealing with it at all. This view has, of course, not improved the state of affairs. As a result, there has been limited progress in the field.

A final reason for the neglect of emotion comes from the fact that much academic study of music takes as paradigmatic a very particular way of listening to music and talking about it that is enshrined in the narrow 'classical concert culture' where, as described by Frith (1996) and others (Cook 1998; Small 1999), audiences are taught to listen 'silently and respectfully' with minimum bodily movement or emotional expression (until the end). 'Appreciation' of music is often taken to mean having an intellectual understanding of the history and form of the musical composition, rather than an articulated emotional response. Even where emotions are valued, they tend to be those rarefied (transcendent or spiritual) forms that are related to 'higher' abstract and aesthetic properties of works, rather than the everyday or full-blooded emotions. As a consequence, there have been few academic discourses available in which to frame and articulate a relevant understanding of the emotions. Such discourses have mainly been relegated to 'the discourse of the hallway' (e.g. Frith 1996), those informal 'off-duty' moments when academics allow themselves to say what they feel about the music they study. It is in the context of increasingly viewing the whole music of the world's cultures as worthy of study (including taking account of the discourses and practices surrounding music making in these diverse

cultures) that the possibility of making emotion more central to disciplined talk about music may be increasingly enabled.

1.2 Purpose and organization of this book

The present book is, to the best of our knowledge, the first scientific anthology ever devoted specifically to musical emotions. Why should it appear now? Along with a renewal of interest in emotional phenomena in general (e.g. Ekman & Davidson 1994; Lewis & Haviland-Jones 2000) there has been a new surge of interest in music and emotion. Music and emotion is once again at the forefront of music psychology, as reflected in innovative and exciting research all over the world. After a long time of regarding music and emotion as an 'off-limits' topic, scientists are returning to the field to address what may be the most exciting aspect of musical behaviour: its affective consequences. Today, it is almost becoming fashionable again to study emotion. For instance, in August 2000, 94 out of 310 papers (30 per cent) presented at the Sixth International Conference of Music Perception and Cognition (Woods *et al.* 2000) contained the word 'emotion' in the text (as verified by applying a search engine to the CD rom version of the proceedings). By contrast, visual inspection of the proceedings of the First International Conference in the same series (Japanese Society of Music Perception and Cognition 1989) yields only 11 out of 94 papers (12 per cent). The peak of this renaissance is yet to come, we believe.

This book can be characterized by two words. The first word is 'change'. The concept of emotion is intimately related to changes—in particular to significant changes in the social environment (cf. Oatley 1992). Music, too, is about changes. Music takes place in time, in a constant flux. Emotional responses to music are often induced by particular kinds of changes in the music. The field of music and emotion itself has gone through some dramatic changes over the last decade. One of the most significant changes is the increasing diversity of topics, approaches, and methods involved. Another significant change is the increasing concern with theories of music and emotion. Both of these trends are evident in the present volume.

The second word that can be used to characterize this book is 'interface'. Emotions have been conceptualized as the interface between the inner world of goals and plans, and the outer world of objects and events (cf. Scherer 1985). Emotion has also been described as the point where nature meets nurture (Oatley 1992, p. 14)—this is evident in many of the contributions to this volume. Moreover, much of what is interesting about music and emotion takes place at the interface between performance and perception (Juslin 2000). Last but not least, this book represents an interface between researchers from different disciplines. Recent years have seen some important developments in diverse approaches to music and emotion.

Unfortunately, current work is largely scattered across different publications. It is thus difficult to get a sense of the progress in the field, or to grasp what questions researchers are currently debating. The purpose of the present book is to bring together some of the leading researchers of the field for an up-to-date look at the relationship between music and emotion. Fundamental questions addressed by this book include: Why does music induce emotions in its listeners? Are the emotions we experience in

relation to music different from the emotions we experience in everyday life? Why are different pieces of music associated with different emotions? Are performers able to communicate specific emotions to listeners? Do emotional responses to music vary as a function of the cultural context? How do emotional responses to music affect the brain and body of listeners?

The purpose of the book is both summative and formative. We aim to summarize what is currently known about music and emotion, but we also aim to stimulate further research in promising directions that have been little researched. The focus is on theory and research on music and emotion rather than practical applications. We believe that, with a few exceptions in the context of music therapy, performance anxiety, and film music, the field of music and emotion has not yet reached a stage where it can provide a consistent body of knowledge for application to a wide range of practical problems (this is incidentally another reason why we prefer to think of the field as being in a 'pre-paradigmatic' phase). However, we believe that the present book covers every major approach to the study of music and emotion.

This volume is organized into four sections following this introduction. The first section provides multidisciplinary perspectives on music and emotion from philosophy, musicology, psychology, biology, anthropology, sociology, and therapy. The next three sections of the book provide research reviews that focus on the composer, the performer, and the listener, respectively. Although, in practice, most musical situations involve some combination of composition, performance, and listening, research has largely tended to focus on one or two of these aspects. (Most research has focused on the listener, and the least on the composer.) Therefore, we have assigned the remaining chapters into sections according to whether their primary focus lies on the composer, the performer, or the listener.

1.2.1 Multidisciplinary perspectives

Arguably, emotion is first and foremost a psychological concept (e.g. given the 'mentalistic' nature of the construct and its relation to behaviour). It is not surprising then that the majority of studies on music and emotion to date are psychological. However, the study of music and emotion often transcends the traditional lines of enquiry, and we believe that much can be learned from other perspectives as well. The chapters in Part II of the book are intended to stimulate further research and collaboration in areas that—in some cases at least—have been little studied previously. The chapters are ordered to reflect both historical primacy (philosophy and musicology are arguably the oldest disciplines to consider emotion and music) and also a progression from the more individualist perspectives (as epitomized by psychology and biology) to social and cultural perspectives (as reflected in anthropology and sociology).

One important problem that has plagued theory and research on music and emotion is conceptual confusion. Therefore, an important contribution to the study of music and emotion from philosophy could lie in its ability to resolve conceptual problems. In Chapter 2, Davies provides a discussion of philosophical perspectives on music and emotion. After outlining the nature of academic philosophy and discussing philosophical perspectives on emotions, Davies considers three philosophical problems with respect to music and emotion: The first problem concerns the fact that music is often perceived as

expressive of emotion—despite the fact that music is not a sentient being. The second problem concerns the listener's emotional response to music in such instances where the listener's response mirrors the music's, despite a lack of beliefs that usually underlie such a response. The third problem concerns why listeners enjoy and revisit pieces of music that, on their own account, incline them to feel sad. In addressing these problems, Davies scrutinizes the major philosophical theories of music's expressiveness—music as symbol, expression theory, arousal theory, music as virtual persona, contour theory—involving the works of Langer, Kivy, Levinson, and Davies himself. Davies further explores the idea that music is a universal language of emotions, and mentions some critical issues that need to be considered in regard to this notion. (This touches upon one of the recurring themes of the book, i.e. the relationship between biological universals and cultural specifics.) Davies' philosophical discussion is framed by a set of constraints that an acceptable theory of music's expressiveness should satisfy, according to Davies. One of these constraints is that the theory must explain how—despite their manifest differences—our non-primary use of emotion words to describe responses to music relates to these words' normal application to the emotions of sentient creatures.

Philosophical concerns about emotion in music have been expressed for almost as long as people have thought about music. Musicological thinking, surveyed by **Cook and Dibben in Chapter 3**, also has historical roots stretching back for many centuries (indeed, it could be argued that musicological and philosophical approaches have only been separable in the last three centuries or so). Cook and Dibben's treatment of musicological approaches to music and emotion in Western art music and popular music focuses on theoretical frameworks aimed at understanding how music can embody, express, arouse, or otherwise signify emotional states. Cook and Dibben begin with a historical sketch, tracing some of the developments in thinking about music and emotion that still exert an influence on modern thinking, for instance the ancient notion that music can both represent and induce emotions. An important observation is that our views on musical emotions, throughout history, have been much shaped by contemporary conceptions of emotion in general (e.g. the eighteenth-century affect as a rationalized emotional state, in contrast to the nineteenth-century emotion as personal and spontaneous expression). Cook and Dibben then review a selection of classic music-theoretical approaches to musical emotion (many of which were influenced by linguistic models), including the 'doctrine of affections' and the theories by Cooke, Tagg, Meyer, and others. This leads them to propose that the fundamental problem in musicological approaches to music and emotion is 'to talk about both the emotion and music in a sustained manner'. Cook and Dibben suggest that Hatten's neo-semiotic approach is the most comprehensive attempt to integrate expressive and structural analysis within a coherent critical practice. Cook and Dibben conclude by discussing a 'performative' approach in which music-analytical practices are understood less in terms of how the music *is* and more in terms of how it *might* be heard; the implication is that musicological knowledge actually may shape our perceptions of music. Thus, as Cook and Dibben note, the very act of saying that a certain piece of music is expressive in a certain way well lead us to hear it in that way.

Contemporary psychological approaches to music and emotion have been very much influenced by philosophical and musicological debates. In **Chapter 4, Sloboda and**

Juslin describe the essentials of a psychological approach to the study of music and emotion. They suggest that a central aim of psychology is to understand the mechanisms that intervene between music reaching a person's ears and an emotion being perceived, or experienced, by that person as a result of hearing that music. Other important aims involve understanding the roles of emotion in composing and performing music. First, Sloboda and Juslin review the major approaches to conceptualizing emotion in psychology: categorical, dimensional, and prototype approaches. They also show that there are certain underlying and objectively observable characteristics that are present in the set of phenomena we normally describe as 'emotions', and that these same characteristics seem to apply also in the case of music. Then, they consider two primary sources of emotion in music, namely *intrinsic* and *extrinsic* sources. Intrinsic sources are those that are non-arbitrarily embedded in structural characteristics of the music and that contribute to the creation, maintenance, confirmation, or disruption of schematic expectations. Extrinsic sources are of two kinds: (i) iconic sources which come about through some formal resemblance between a musical structure and some event or 'agent' carrying emotional tone; and (ii) associative sources which are premised on arbitrary and contingent relationships between the music being experienced and a range of non-musical factors, which also carry emotional messages of their own. Sloboda and Juslin suggest that failure to see the many ways that music may represent and induce emotions has contributed to the controversies that have characterized the field of music and emotion. No single theory is likely to be able to account for all emotional responses to music. Sloboda and Juslin conclude by suggesting some directions for future research, noting in particular that the psychological approach has tended to ignore the social context of musical behaviour.

Chapter 5 by **Peretz** outlines a biological approach to music and emotion. This approach is very much rooted in psychology, and uses data from the brain to shed light on the cognitive organization of musical experience. It should be noted that a biological approach to music and emotion may entail evolutionary perspectives, physiological perspectives, or neuropsychological perspectives. It is the last of these that is the focus of Peretz' chapter (an evolutionary perspective is provided by Juslin in Chapter 14, and physiological evidence is reviewed by Scherer and Zentner in Chapter 16). Neuropsychological studies are burgeoning at the moment, with a variety of brain-imaging techniques that can be used to investigate the effects of music on the brain, such as positron emission tomography (PET), functional magnetic resonance imaging (fMRI), and event-related potentials (ERPs). Peretz reviews studies that may shed light on the brain substrates underlying emotional responses to music. Peretz also suggests promising future directions for research, showing what questions, in particular, such studies of music and emotion are most likely to answer. Peretz concludes that emotional appreciation of music is best conceived as the product of a specialized cortical arrangement that is shared by most members of a given musical culture.

Psychology and neuropsychology focus on emotion as experienced and perceived by the individual. The remaining chapters of this section consider musical emotion from a broader social perspective, beginning in Chapter 6 where **Becker** presents perspectives on music and emotion from music anthropology: the study of modes of music making as a means of cultural expression. Becker challenges some of the unexamined

'ideologies' and presuppositions that have dominated Western theorizing about music and emotion and that—as she demonstrates—do not apply for most of the world. This includes the common view of the listener as inwardly focused and isolated. Becker introduces the concept of 'habitus' of listening to describe the listening habits and expectations that listeners within a particular culture 'accumulate largely unawares'. These habits reveal implicit assumptions in the listening context about what music 'means', what it is for, how it is to be perceived, and what might be 'appropriate' responses. Becker goes on to consider anthropological views on emotion, and reviews evidence of cultural differences in the expression of, motivation for, and interpretation of emotion in relation to musical events. However, she also notes that, through experience and empathy, we can come to understand differing emotional reactions to different kinds of music. Becker then presents examples of different kinds of habitus of listening from her fieldwork and that of others. Becker suggests that autonomic arousal is a human universal related to music making. This leads her to the main theme of her chapter: a plea for a move to transcend the dichotomy between 'scientific universalism' and 'humanistic particularity'. In particular, Becker suggests that biological and cultural approaches to music and emotion may be brought together by understanding music listening as a process in which the relationship between music and emotion extends beyond the minds and bodies of individuals. She argues that this process can be viewed as 'biological', since both performers and listeners undergo a learning process in which they imitate physical and mental gestures that transform both their inner structures and their relationships to everything beyond the boundaries of the body.

The social context of musical behaviour is also central to **Chapter 7** in which DeNora presents a sociological perspective on music and emotion. Sociology is concerned with investigating forms of social organization and the relations of these forms to social action, whether 'macro' (large-scale institutions) or 'micro' (interactional processes). DeNora first considers the recent rediscovery of emotion in sociology, which has been linked to sociology's traditional concern with social contexts. (A concern with the social context of music making is another recurring theme in the present book.) Then she describes how the focus of sociological studies of music has changed over the last decade, from preoccupations with music's production—music as an object shaped by social relations—to concerns with how it is consumed and what it 'does' in social life. Within this 'new' sociology of music, she observes, music is conceptualized as a device for the constitution of emotive action in and across a range of social settings. (DeNora traces the origins of this development to the writings of Theodor Adorno and ethnographic studies in the 1970s.) One of the most promising trends in the 'new' sociology, according to DeNora, is the discovery of how music can be used by, and on behalf of, actors as a resource to construct self-identity and to create and maintain a variety of emotions. DeNora illustrates this point by reviewing some recent work by Hennion and herself concerning the uses of music in everyday life. Based on in-depth interviews, these studies reveal that listeners are not merely passively affected by music, but rather are actively constructing their own ability to be moved. Moreover, the studies reveal how people use music to regulate, enhance, and change qualities and levels of emotion. They show considerable awareness about the music they 'need' to hear in different

situations and at different times to influence aspects of themselves and their self-concepts. Such uses of music are based on the listeners' perceptions of what they believe the music to 'afford', for instance associations that listeners have made between certain musical materials and extramusical features. DeNora suggests that there may be a useful bridge here between sociology's focus on associations that listeners forge between music and emotions, and musicology's traditional focus on ways in which musical structures lend themselves to particular interpretations.

Ending this section is a contribution which shows how music embedded in a context of social interaction can become an agent of therapy or healing. **Chapter 8** by **Bunt and Pavlicevic** considers the role of music in music therapy, with a particular focus on improvisational music therapy. First, they give a general background to music therapy, discussing different forms of music therapy and showing how the different sources of emotion described by Sloboda and Juslin in Chapter 4 may be observed in clinical practice. A critical aspect to the generating and receiving of emotion in music therapy is the direct experiencing of emotion within the listener or player, as well as the recognition of emotion within the music itself. Therapists' abilities to make emotion judgments from musical improvisations were explored in a study summarized by Bunt and Pavlicevic. The therapists listed a large number of musical parameters that aided the process of judging the emotions (Bunt and Pavlicevic note that these are common features of many musical improvisations made by patients of all ages). Moreover, Bunt and Pavlicevic show how recent work in developmental child psychology by Trevarthen, Trehub, Papoušek, and others, and in particular Stern's so-called 'vitality affects', can provide reference points in understanding the subtle interplay between the personal and the musical in improvisational music therapy. They suggest that the primary locus of any therapeutic change lies in the interpersonal musical relationship built up between therapist and patient. Examples from their own practice show how Pavlicevic's concept of dynamic form can be used to understand how the relationship between the therapist and the patient is defined in real-time improvisations. This chapter complements the scientific perspectives offered by the previous chapters by providing unique insights from clinical practice.

We believe that this multidisciplinary section makes at least two things clear. First, it suggests that multidisciplinary approaches are called for—perhaps even necessary—to make real progress in understanding the relationship between music and emotion in all its richness and complexity. Second, it calls for some humility. Given the broad range of domains that intersect with the study of music and emotion—from brain imaging to sociological studies to analyses of musical structure—we cannot expect any one individual to be able to address the topic from all angles simultaneously. The key word is 'collaboration'. The first section of the book presents a challenge to the reader, with its wide range of disciplines, theories, concepts, and methods. Many of the traditional views on music and emotion are certainly challenged. However, we believe that the reader who is willing to accept this challenge will be rewarded with a fresh look on the topic, and that he or she may be able to look at the other contributions of the book in the light of these multidisciplinary statements.

1.2.2 The composer

In Part III, the focus is on the composer and—in particular—the materials or 'building blocks' that the composer can work with. In subsequent sections, the contributions examine emotion as communicated and experienced by the performer, and finally by the end-recipient, the listener.

One of the fundamental emotion dimensions which studies of music listening have identified is *arousal*. The notion of arousal is crucial to **Simonton's Chapter 9**, which links this concept to the act of music composition. In other chapters of the book, the authors have reviewed evidence based on such methods as philosophical enquiry, experiment, observation, brain imaging, interview, and structural analysis. In this chapter, Simonton adopts yet another approach called 'historiometrics', which involves the adaptation of psychometric methods to analyse data about historic individuals. In the case of classical composers, Simonton includes both biographical information about their lives and content-analytical information about their works. Simonton has been using this particular technique to study creativity and aesthetics in classical music. Although this research programme was not directed specifically at investigating musical emotion, some of the empirical results clearly have a bearing on this topic. Simonton begins by defining his concept and measure of 'melodic originality' in musical compositions, and goes on to show that this simple measure—which incidentally seems to encompass more compositional aspects than just melody alone—may be related to a piece's 'arousal potential' as perceived by listeners. Pieces of music scoring high on 'melodic originality' should sound more unpredictable, interesting, or complex (and thus yield more uncertainty, to elaborate on Meyer's views in Chapter 15) than melodies scoring lower. Simonton refers to experimental work that supports this hypothesis, and there is a clear link to Meyer's theory that emotional arousal reflects the violation of musical expectations. Simonton goes on to demonstrate that the relation between arousal potential and aesthetic impact is curvilinear, in accordance with the 'Wundt curve', and that the most popular classical works in the real world are those that evoke an optimum arousal level. However, due to 'habituation', the response to an arousing stimulus will often diminish. Therefore, as Simonton illustrates, composers have a tendency to increase their use of melodic originality as their careers progress. Moreover, Simonton argues (boldly) that the degree of melodic originality also reflects the emotional life of the composer at the time of a work's composition, such that the melodic originality (and hence the 'arousal potential') is larger during periods of life stress. Indeed, Simonton finds a positive relationship between measures of melodic originality and an index of life stress for ten eminent composers of classical repertoire (after controlling for confounding factors). Simonton also discusses the 'Swan song' phenomenon (i.e. the idea that composers exhibit a 'late life' compositional style). Simonton concludes that 'melodic originality', at least to some extent, forms part of the composer's tools for expressing emotions in music. However, he also observes that composers have a great deal more in their 'expressive tool kit' than just the choice of pitches.

Additional aspects of the expressive tool kit that composers can use to express various emotions are dealt with in **Chapter 10**, in which **Gabrielsson and Lindström** present a review of studies—from the end of the nineteenth century to the present day—that have attempted to specify the expressive properties of various elements of

musical structure usually indicated in the musical notation of a piece of music (performance aspects are reviewed in Chapter 14 by Juslin). This is, in fact, the domain within which most of the traditional studies of music and emotion tend to fall. Gabrielsson and Lindström first describe different methodological approaches used in studies of expression in music since the late nineteenth century, including different response formats: free description, adjective checklists, adjective ratings, and continuous response (reviewed by Schubert in Chapter 17). Studies also differ with regard to musical stimuli, ranging from brief and simple sound sequences to recordings of entire musical compositions. Then, Gabrielsson and Lindström review findings about the expressive properties of different musical elements, such as interval, mode, rhythm, tempo, melodic direction, harmony, timbre, and form. This review uncovers a number of relationships between musical elements and particular emotions, but also indicates several gaps and ambiguities in the results. In particular, few investigations have considered potential interactions among different elements. Gabrielsson and Lindström conclude by suggesting directions for future research, emphasizing the need to explore more sophisticated manipulations of melody, rhythm, timbre, and harmonic progression. Even so, the findings reviewed by Gabrielsson and Lindström provide a rich source of music-emotion relationships that have been used, or could be used, in a variety of practical contexts such as music therapy or film music.

In Chapter 11, Cohen considers an applied compositional domain that has a substantial history: the use of music in film. This complements Chapters 8 and 13 which explore applications of knowledge about emotion in the context of music therapy and performance anxiety. The purpose of Cohen's chapter is to address the question of what contribution music makes to the emotional impact of film. Cohen argues that music is one of the strongest sources of emotion in film and intends to open doors to further empirical work that explains why this is so. Cohen begins by establishing a context for discussing emotion in music and film. Then, she presents a historical perspective on film music, from the use of music in silent film to the advent of the sound film in the late 1920s. Cohen also reviews empirical research that has investigated the effects and functions of music in film. These functions of film music include masking extraneous noises, providing continuity between shots, directing attention to important features, inducing mood, communicating meaning and furthering the narrative, enabling the symbolization of past and future events through the technique of leitmotiv, heightening the sense of reality, and adding, as an art form, to the aesthetic effect of the film. Cohen also presents a cognitive framework for understanding musical phenomena of relevance to soundtracks. Finally, she considers the role of the composer as the ultimate source of musical emotion in film, discussing conditions and requirements associated with composing music for film. A hypothesis of Cohen's chapter is that the capacity of music to accomplish its emotional task may be based on the ability of music to simultaneously carry several kinds of emotional information in its harmony, rhythm, melody, timbre, and tonality. Real life often entails multiple emotions, simultaneously and in succession. Miraculously, yet systematically, Cohen argues, this 'emotional polyphony' can be represented by the musical medium.

1.2.3 The performer

In Part IV of the book, the focus is on the role of emotion in the performance of music. In **Chapter 12, Persson** makes an excursion into the subjective world of the performer, outlining exploratory research into the 'phenomenology' of emotion in musical performance. This includes such issues as performance motivation and interpretation, and the learning and conceptualization process of constructing musical meaning. Persson acknowledges that there is little previous research in this area, but notes that the present chapter might serve as a basis for future research and provide a preliminary understanding of how performers construe the subjective aspects of musical performance. Persson's overview is based on qualitative and quantitative research by himself and others, as well as on published interviews with famous performers. Persson considers the motivational basis for becoming a performer, asking what made certain individuals choose a musical career. Although a variety of reasons are suggested, a significant finding from Persson's research is that many performers are motivated primarily by a 'hedonic' motive—treasuring music as a means to control and induce positive emotional experiences by means of playing (this theme is also evident in Chapter 6 by Becker). Persson then considers the roles of emotion in interpretation, discussing imagery, conceptualization of musical meaning, and so-called self-induction to altered states of awareness. He concludes by suggesting directions for (much needed) further research concerning the subjective world of performers.

As noted by Persson in Chapter 12, one important reason for performing music is that it induces positive emotions in the performer. In **Chapter 13, Steptoe** considers the flip side of the coin: While performance of music often generates strong positive emotions, it may also induce *negative* emotions in the performer, such as distress and anxiety. Such emotions may impair the quality of performance, and could also have debilitating effects on the performer's career. Steptoe reviews the psychological and medical literature on performance anxiety and also considers other negative emotions related to music performance as a profession, such as social tension, worries about job security, boredom, feeling separated from family, and so forth. Furthermore, Steptoe argues that research on performance anxiety would benefit from regarding performance anxiety as a form of situational stress response, which is similar in certain respects to problems such as social phobia or academic examination stress. By analogy with other work on stress, Steptoe suggests, it may be useful to separate distinct components of performance anxiety. One such component is affect, which forms the central experience of performance anxiety for many musicians. However, there are other important aspects as well, including cognitive responses (e.g. disturbances in information processing), changes in behaviour, and physiological responses. Steptoe reviews some promising treatment methods that have been devised for stress management, and argues that the incorporation of these principles into the training of musicians could be very beneficial.

Numerous studies have investigated emotional expression in pieces of music (these studies are reviewed by Gabrielsson and Lindström in Chapter 10). However, only recently have researchers begun to study how different aspects of the *performance* affect the emotional expression of a piece of music. This topic is reviewed by **Juslin** in **Chapter**

14. He provides a review of empirical studies of communication of emotion in music performance, and outlines a theoretical framework suitable for organizing the findings. The review of studies focuses on two aspects of the communicative process, namely how well performers succeed in conveying a particular emotional interpretation to a listener, and what acoustic means they use to do this. The relationships between variables in the performance and emotion categories (e.g. sadness) and dimensions (e.g. arousal, activity) are described, with emphasis on 'expressive contours' and so-called 'mixed' emotions. Then, Juslin outlines a theory to account for the origin of the 'code' used by performers. Following the biological approach to music and emotion discussed by Peretz in Chapter 5, Juslin suggests an evolutionary perspective on performers' expressive skills. He argues that the acoustic code of performers reflects both innate 'brain programmes' for vocal expression of emotions, and social learning (for example, learning of links between cues and extramusical aspects through analogies). He further argues that the code used by performers today may be linked—in functional ways—to important cultural activities of the past. Juslin also describes a Brunswikian 'lens model' than can serve to illustrate how music performers communicate emotions to listeners by combining a number of uncertain but partly redundant cues in the performance. The lens model makes it possible to quantitively relate performance to perception in order to better understand the functional relationships between expression and recognition of emotion. Finally, possible mechanisms for the induction of emotion by expressive performance are discussed by Juslin.

1.2.4 The listener

In the final part of the book, the focus is on the listener. The contributions are ordered to reflect the progression of Part II (multidisciplinary perspectives). This progression begins with a musicological (and philosophical) contribution, moving to two chapters concerned with the explanation and measurement of individual response, and ends with two contributions which emphasize the effect of social context on listener response.

One of the most influential analyses of musical emotion was given by Meyer (1956) in his book, *Emotion and meaning in music.* In Chapter 15, Meyer revisits his theory to provide an updated version of his view on music and emotion. The focus of Meyer's essay is on the role of uncertainty in listeners' emotional responses to music. First, Meyer provides a number of distinctions for the field of music and emotion, observing that the field has lacked conceptual specificity and precision (another theme recurring throughout this book, see, for example, Chapters 4 and 16). Then, he points out that researchers have tended to focus on emotions as states rather than processes. Consequently, Meyer notes, researchers have underestimated the importance of succession in explaining emotional responses to music. In fact, the heart of the emotional experiences of music lies, he argues, in processes that can be understood in terms of creation and minimization of uncertainty (the role of uncertainty is also discussed by Juslin in Chapter 14, but whereas Juslin focuses on the 'textural' resolution of uncertainty via parallel 'cues' to emotion, Meyer focuses on the 'successive' resolution of uncertainty in musical 'episodes'). Meyer distinguishes between 'native' processes (which

reflect constraints that are inherent in the human mind and body, e.g. the gestalt laws) from 'syntactic' processes (which depend on learning, having internalized the constraints of a particular style). Both 'native' and 'syntactic' processes generate uncertainty (about what will happen, when it will happen, and how it will happen). Uncertainty, in turn, generates arousal and schematic implications that are disrupted, delayed, or confirmed. Ultimately, Meyer observes, this process reflects the human need to envisage in order to choose. But whereas we try hard to avoid uncertainty in everyday life, in the arts—including music—we frequently cultivate and relish a considerable amount of uncertainty. But uncertainty itself is not an emotion, according to Meyer. Uncertainty is rather one of the sustaining conditions for emotions. The uncertainty is a function of the amount of information the mind is required to process. Therefore, as the number and strength of implied musical alternatives increase, so does the uncertainty.

Scherer and Zentner in **Chapter 16** present a theoretical framework for studying emotional effects of music in which they include very stringent criteria for distinguishing different kinds of affective response: mood, emotion, preference, attitude, personal trait, and interpersonal stance. Scherer and Zentner propose that we should theoretically define the effects of music on the listener in the form of 'rules', which specify the relative contribution of different features (such as musical structure, performance, listener personality and mood, and context). The bulk of their chapter deals with production rules, outlining those mechanisms that can be theoretically expected to produce, or induce, changed emotional states in the listener (e.g. appraisal, memory, empathy, or proprioceptive feedback). Scherer and Zentner suggest that it is important to clarify exactly which type of state can be produced by music and what criteria should be used to determine the presence of the respective states empirically. Then, they review the literature pertinent to this issue, and examine the effects of music on cognition, physiological arousal, motor expressive behaviour, action tendencies, and subjective experience. Scherer and Zentner argue that, ideally, the claim that music can induce emotions should be instantiated by studies showing that listening to a piece of music reliably leads to a *synchronization* of cognitive, physiological, expressive, motivational, and experiential processes. Few studies of this kind are currently available, although Scherer and Zentner review a large number of studies of separate components, which provide preliminary evidence of emotional responses. One theme in the chapter is that researchers should be open to new ways of conceptualizing affective responses to music. Scherer and Zentner also suggest that an important goal for future research might be to develop a vocabulary of emotion specifically for the domain of music. They conclude by making suggestions for theoretically based and methodologically sound future research on emotion production.

One of the themes of Meyer (Chapter 15) is that researchers have tended to underestimate the importance of succession in explaining emotional responses to music. Following this lead from Meyer, **Schubert** (in **Chapter 17**) presents an overview of recent attempts to address this problem by means of 'continuous response methodology'. The comprehensive research agenda proposed by Scherer and Zentner (Chapter 16) also requires the development of such methodologies. First, Schubert considers different response formats used in continuous response research—checklists, open-ended formats, and rating scales—noting some of the problems associated with particular

formats. He argues that rating scales based on emotion dimensions like *valence, activity,* and *arousal* are most useful in continuous measurement of emotional response. Schubert goes on to discuss the different uses of continuous response methods in the literature: validation of various response formats, comparative investigations (e.g. comparing the responses of musically trained and untrained listeners), stimulus-response investigations (i.e. exploring which musical parameters predict changes in response), and system-dynamics investigations (i.e. studying the dynamic nature of emotional responses over time). Schubert also provides a critical discussion of problems concerning the design, validity, and reliability of continuous response instruments (e.g. the coding of musical features, response coding, synchronization of music and response, sampling rate, lag structure, and statistical analysis). Schubert argues that researchers using continuous response methods must become more aware of the analytical problems created by continuous response data, and suggests some solutions for dealing with these problems. He concludes that the main advantages of continuous response methodology—the abilities to study moment-to-moment changes in the relationship between musical structures and emotional responses and the 'lag' structure of listeners' response to music—are yet to be fully exploited by researchers.

Scherer and Zentner argue in Chapter 16 that future work on the emotional effects of music must pay greater attention to motivational constructs that are specific to music (e.g. 'why do people listen to music?'), because these are the motivational urges that need to be taken into account when we attempt to assess goal conduciveness or obstruction in cognitive appraisals of musically induced emotions. A fresh perspective on this motivational terrain, the uses and functions of music in everyday life, is provided in **Chapter 18 by Sloboda and O'Neill.** They build on the foundation laid out by DeNora in Chapter 7, pointing out that music is a cultural resource in the social construction of emotions. Music, they observe, is heard in a particular place and time, with or without other persons being present, and with other activities taking place at the same time. Thus, an account of emotional responses to music must recognize the interaction among these different factors. The purpose of Sloboda and O'Neill's chapter is to discuss research on habitual and routine modes of engagement with music, including as much of the social context as possible. By definition, everyday uses of music are difficult to study in the laboratory. Further, they tend to be unmemorable and, hence, unsuitable for retrospective report of the kind used by Gabrielsson (in Chapter 19). The solution adopted by Sloboda and O'Neill is called the 'experience sampling method'. This involves the use of electronic pagers that subjects carry with them during the waking hours, along with a booklet that they fill in on each paging. A study by Sloboda and coworkers using this method indicated that there was a 44 per cent likelihood of music being experienced in any 2-hour period—confirming the common claim that music pervades everyday life. More importantly, the study showed how music was used in a wide range of everyday activities. One of the working assumptions made by Sloboda and O'Neill is that music can have different 'emotional functions' in different situations, and they present evidence that listeners use music to manage their moods in a number of different ways. Indeed, this deliberate use of music to achieve specific psychological outcomes can be described in terms of 'self-therapy'—a practice partly corresponding to the professional uses of music to that same end in music therapy (see Bunt and

Pavlicevic, Chapter 8). One notable finding from Sloboda and O'Neill's pager study is that the majority of episodes that involved music resulted in the listeners feeling more positive and alert. That is, music made them feel better. However, Sloboda and O'Neill also review evidence of negative emotions in memories of childhood experiences, often related to an evaluative context and hence reminiscent of the negative emotions experienced by some adult performers (Chapter 13). Sloboda and O'Neill conclude that musical activities are enmeshed in a social and cultural world which involves a number of 'hidden' practices and assumptions about musical activity. Only by uncovering the 'hidden' meanings of these practices, Sloboda and O'Neill argue, can we hope to gain a better understanding of emotional responses to music in everyday life.

In **Chapter 19, Gabrielsson** reviews findings about emotional reactions to music based on free phenomenological description of strong experiences of music. Gabrielsson begins by discussing the notion of *peak experience*, made famous by the humanistic psychologist Abraham Maslow. Gabrielssson then describes his research project on strong experiences of music (SEM), the purpose of which was to get some sense of what phenomena are contained in such experiences, and to study how SEM are related to the properties of the music, the individual, and the situation. Gabrielsson is also concerned with the long-term consequences of such experiences. To address these questions, Gabrielsson adopts an approach involving written self-reports by listeners of their strongest experiences of music. Content analysis of several self-reports yielded an overall classification of SEM into physical and behavioural aspects, perceptual aspects, cognitive aspects, emotional aspects, motivational aspects, existential/transcendental aspects, and developmental aspects. In the present chapter, Gabrielsson explores in depth the emotional aspects, providing a large number of examples of emotional reactions to music from the listeners' reports. The examples include so-called 'basic' emotions as well as 'aesthetic' and 'transcendental' emotions. These descriptions provide fascinating glimpses into the peak experiences that many people treasure. Gabrielsson notes that positive emotions dominate in the reports, often in the form of euphoria that borders on ecstasy, but that there are also examples of strong negative emotions. Finally, Gabrielsson considers some implications of these findings for theories of emotional responses to music, and also mentions certain problems associated with retrospective, verbal description of music experience, such as memory distortions and individual differences in verbal fluency.

1.3 Concluding remarks

The peer-reviewed contributions of the present book will reveal how much progress there has been in this field since Meyer's (1956) classic book, *Emotion and meaning in music*. Besides providing research overviews, many of the chapters also set forth significant paths for future theory and research. *Music and emotion* may thus serve many functions. First, it may provide a research source for what is currently known about music and emotion. Second, it may serve as a starting point for investigating the field. Third, and as already noted, it can be a source of interdisciplinary dialogue. The chapters in this volume represent the history of the study of music and emotion, its present state, and its future. This scope is reflected in the age range of the contributors. At the

time of writing, the youngest of the contributors is 30 years old and the oldest is 82 years old. Throughout the work on this book we have often been struck by the enthusiasm with which the authors have shared their ideas about music and emotion; we hope that this enthusiasm will come through in their contributions.

Last but not least, we would like to describe one of our personal reasons for bringing together this anthology. We are dedicating this book to Alf Gabrielsson to coincide with his retirement in June 2001. Alf has made an enormous contribution to the field of music research—both as a researcher and as a teacher—as many of his colleagues would be willing to attest. Of more direct relevance for the present volume, Alf was one of the (relatively few) people who repeatedly stressed the importance of studying emotional aspects of music, long before it became fashionable to do so. We sense an increase of interest in affective processes in music at the moment and hope that the twenty-first century will be the time when the domain of music and emotion finally catches up with the other domains of musical science. This would surely help us to gain a better understanding of the manifold ways that music enriches all of our lives.

PART II

MULTIDISCIPLINARY PERSPECTIVES

CHAPTER 2

PHILOSOPHICAL PERSPECTIVES ON MUSIC'S EXPRESSIVENESS

STEPHEN DAVIES

2.1 Philosophy and its method

Sometimes philosophy seems to psychologists to be psychologizing in a fashion that is uninformed and unrestrained by empirical data. (That's alright, sometimes psychology looks to philosophers like unskilled philosophizing!) As this is the only chapter by a philosopher, I begin with an introduction outlining the nature of academic philosophy.

For most questions, one (or more) of the following strategies supplies the answer: fact finding, scientific theorizing, calculating, voting, and legislating. The natural and social sciences rely on the first three of these methods. Some questions are not satisfactorily resolved by their use, however. The issues these questions present are neither empirical nor merely matters of opinion—they are 'philosophical'. 'Philosophy' comes to connote the recalcitrant residue of questions which remain after all the (other) branches of knowledge and taste have taken the questions they are equipped to answer. The fact that philosophical questions are immune from empirical data suggests, perhaps, that they arise from deep conceptual confusions or subtleties, and that it is the purpose of philosophy to untangle these knotted skeins.

Some of the questions of philosophy are distinctive to it, such as many of those addressed by metaphysics, ethics, and logic. But, also, philosophical queries are generated by consideration of foundational issues in all areas and disciplines, and so there is philosophy of art, of science, of mathematics, of feminism, of medicine, of mind, and so on.

Some classic examples of philosophical questions are these: What is truth? Is causality a natural relation or, instead, merely how constant conjunction sometimes is interpreted by human observers? What is identity? Is more than one consideration (such as merit and need) relevant to justice and, if so, are these different aspects mutually commensurable? How is the good to be characterized? What is time? A few moment's reflection should make clear that the answers cannot be settled by an investigation looking at the sorts of facts tested by science. The usual scientific methods of enquiry typically presuppose certain answers to such questions, and the use of such approaches thereby prejudges the outcome of the study. To take another case, how could science analyse the nature of scientific facts without begging the outcome? And another: if empirical facts

underdetermine the explanatory theories we apply to them, we cannot choose between theories, as we will want to do in distinguishing pseudo-science and psycho-babble from legitimate disciplines, solely by citing the facts, because what counts as a fact and how it is significant is disputed between the contested theories. Also, if we are indeed enmeshed in some subtle confusion about a topic, we may be confused in how to describe and respond to (further) empirical evidence.

To say that philosophical method is non-empirical is not to imply that philosophy is indifferent to the facts of science. Philosophical analyses must be consistent with the facts, or with interpretations of what these are. But philosophical analyses must go beyond the facts in resolving the problems, paradoxes, and inconsistencies they can seem to generate. What is needed often is not more facts, but a clarification of the issues raised by those that are available. The most familiar notions can produce conceptual puzzles, and then it is not more facts but a deepening of our current understanding, or new interpretations of the resident data, that is needed. Sometimes philosophical investigations are suggestive of new empirical questions, and here science takes over again. At other times, a grasp of unexpected conceptual connections or distinctions enables us to overcome the mental cramps that formerly afflicted us.

To bring out their non-empirical nature, philosophical puzzles often describe two things that are alike in their appearance or empirical features but which strike us as conceptually very different, and then asks what makes that difference. For instance, Descartes wondered how he knew he was not presently dreaming, given that he could dream that he was dreaming. Others have explored how we are to describe the distinction between one's arm's being moved and the action of one's moving one's arm, or how Marcel Duchamp's ready-mades could be artworks where their lookalike, unappropriated counterparts were not.

It could be that nothing hangs on how we answer the philosophical questions before us. In that case, we will come to see that it is for us to decide which way to go, since there is no truth of the matter to be discovered. And it can be that, on examination, philosophical questions turn out to be nonsensical. But it cannot be assumed from the beginning, however, that all philosophical questions are empty, trivial, or silly. In many cases, how we propose to resolve a philosophical question can have far-reaching implications for other cases, for overall consistency within our folk practices, for the power and fecundity of our explanatory models, and for coherence and consistency in our theories.

Not all philosophical questions are weighty. 'Is the karaoke singer a co-performer with the people on the accompanying DVD?' is a philosophical question that provokes us to consider the individuating conditions of performances and recordings, but it is not in the same league as 'what is the meaning of life?' And not all weighty questions are as exciting as this last. Also, the significance of the topic under discussion is often not apparent in the examples in terms of which it is discussed. These frequently are mundane or commonplace, either because it is appropriate to begin with uncontroversial paradigms or to avoid illustrations that attract attention to themselves, rather than to what is at issue. Philosophers who discuss the expression of emotion in music regularly offer the slow movement of Beethoven's *Eroica* as illustrating musical sadness. This does not mean they deny that other pieces are expressive, or that other emotions can be

expressed in music. Instead, it indicates that even such a humdrum case already presents in a graphic form the puzzle that troubles the philosopher.

Sometimes, Anglo-American analytical philosophy, which is the approach of this chapter, is contrasted with continental philosophy. The differences are largely matters of degree or style. In terms of the philosophy of music, Continental approaches sometimes describe an entire metaphysical system and consider music in order to locate it within that system; or they view music in terms of larger sociopolitical or psychological models of human behaviour, such as Marxist or psychoanalytic ones; or, again, they approach it from the perspective of general theories that are semiotic, structuralist, or deconstructionist. And when they do focus on music as such, they are likely to emphasize the subjective response and the phenomenology of musical experience. By contrast, analytic philosophy is less theory-driven and politically motivated. It is centred on perceived 'problems' or 'questions', rather than on a canon of works by great philosophers. The approach is (often) piecemeal, tackling issues one by one as their relevance emerges. The focus falls on interpersonal judgments and public criteria, rather than the idiosyncratic or personal.

In what follows, I concentrate on philosophical discussions of music's expressive character. An obvious question asks how music could be expressive of emotion, which is how we seem to experience many pieces, when it is non-sentient. Depending on how we answer this first query, we are led to others. For instance, if we argue that expressive predicates apply only metaphorically to music, we might then be puzzled at the strength of the response music is capable of eliciting from the listener.

The topic on which I focus, that of music's expressiveness, has been a dominant one in music aesthetics, but many subjects not covered here have also attracted detailed examination by philosophers. These include the ontology of musical works (Goehr 1992; Gracyk 1996; Levinson 1990), performances and their relation to works (Godlovitch 1998; Thom 1993), the notion of 'authentic' performance (Davies 1987; Kivy 1995; Levinson 1990), musical representation (Davies 1994; Kivy 1988), ways in which music can be said to be meaningful and the kind of understanding it invites (Davies 1994; Kivy 1990; Levinson 1990, 1997*a*), music's value (Budd 1995; Davies 1994; Goldman 1995*a*; Higgins 1991; Kivy 1990, 1997), and music's social significance and ethical dimension (Goehr 1998; Higgins 1991). For recent collections covering many of these topics, see Alperson (1994, 1998), Robinson (1997), and Hjort and Laver (1997).

2.2 Ways in which music's expression of emotions is philosophically problematic

In this chapter I consider three puzzles, the first of which has dominated philosophical discussions about music and emotion over the past two decades. It observes that purely instrumental music is not the kind of thing that can express emotions.[1] Music is not

[1] The focus falls on instrumental music simply because the problem of music's expressive powers is at its most acute where music is divorced from words, narrative, and drama.

sentient and neither is its relation to occurrent emotions such that it could express them. The second problem concerns the listener's response, where this mirrors the music's expressive character. When listeners are saddened by the music's sadness, apparently they lack the beliefs that normally underpin such a reaction; for example, they do not think the music suffers, or that the music's expressiveness is unfortunate and regrettable. The third perplexity concerns negative responses elicited by music, such as the sad one just mentioned. Why do listeners enjoy and revisit works that, on their own account, incline them to feel sad? (For a summary of philosophical approaches to these three topics and more besides, see Levinson 1997*b*, 1998.) Before addressing these puzzles, it is useful to examine philosophical theories regarding the nature of the emotions.

2.3 Theories of the emotions

It was once thought, by Descartes for instance, that emotions involve the subject's awareness of the perturbations of his or her animal spirits. It was the dynamic structure of this inner motion, along with the feeling of pleasure or displeasure with which it was apprehended, that distinguished the various emotions. Call this the 'hydraulic theory' of the emotions. In this view, emotions are experiences passively undergone by the subject; they are only contingently connected to their causes and to their behavioural manifestations; they are essentially non-cognitive.

In the latter half of the twentieth century, an alternative account, usually called the 'cognitive theory', has been developed (see Lyons 1980; Gordon 1987; Solomon 1976).[2] This allows that emotions possess a phenomenological profile, but regards this as only one element among several, all of which are necessary and none of which is sufficient alone for an emotion's occurrence. Emotions may be characterized by physiological changes, but, more importantly, they are object-focused. Emotions are directed toward their objects. This means they are usually outward facing, as when I fear the lion that is before me, though the emotion's object also may be one's own sensations or emotions, as when I am alarmed by how tense I feel or where I am ashamed that I am angry. Moreover, emotions involve the categorization of their objects; for instance, if the emotion is one of fear its object must be viewed as harmful, and if the emotion is one of envy its object must be viewed as something both desirable and not already controlled or possessed. In addition, they include attitudes toward their objects; for example, though I judge you to be injured, my emotional response will depend on whether this is a source of concern, satisfaction, or indifference to me. Also, particular emotions find expression in typical behaviours; if I pity you I will try to comfort you and to change your situation for the better, and if I fear you I will fight, flee, or seek protection.

Philosophers disagree in the versions of the cognitive theory they espouse. Some insist that emotions require a belief in their objects' existence, while others think that cognitive

[2] The term 'cognitive' has a somewhat different meaning in philosophical theories of emotion than it has in psychological theories. In the latter, the term implies a focus on underlying information-processing mechanisms, whereas in philosophical theories, it refers to beliefs, imaginings, thoughts, intentions, desires, and like states of consciousness.

attitudes, such as make belief, also can play the role of securing the emotion's object. Some hold that emotions can be individuated in terms of their sensational patterns, without reference to the emotion's propositional component, whereas others regard its cognitive ingredient as crucial to its identification. (For a useful summary of the literature, see Deigh 1994.)

Many of these disputes can be resolved by acknowledging that emotions do not constitute a homogenous class. For instance, some, such as disgust, might be primitive, automatic responses that are not susceptible in their operation to changes in the subject's cognitive state, whereas others, such as patriotism, are marked more by their self-conscious, intellectual content than their sensational character. Even if there is a continuum of cases between these extremes, it is useful to distinguish between emotions (such as jealousy, hope, and remorse) in which the cognitive elements are prominent, malleable, and sophisticated from those (such as lust, fear, and disgust) in which the cognitive elements may not be present to awareness and the reaction is inclined to be automatic and inflexible.[3]

Some further distinctions that may be useful are those between emotions and moods, and between emotions and mere sensations (or mere feelings). These distinctions are drawn roughly within folk psychological discourse along the following lines. Moods are not object-directed and involve rather general feelings. There can be moods of dread, depression, and happiness, but not of embarrassment or remorse, because these latter lack a distinctive experiential character and are distinguished more in terms of what is cognized about their objects. Meanwhile, emotions may involve bodily sensations but are not reducible to them. A person who sits too close to the fire might experience exactly the same sensations as another who is acutely embarrassed, but it is only the latter who feels an emotion.

2.4 Constraints on the theory

Before outlining philosophers' theories of musical expressiveness, it is helpful to consider the desiderata that an acceptable theory must satisfy.

We could not account for the interest and value of expression in music, or for the emotional responses music calls from the listener, unless terms like 'sad' and 'happy' retain their usual meanings in connection with music's expressiveness. So a principal

[3] Griffiths (1997) argues that the emotions do not form a 'natural kind' and that the cognitive theory applies to only some. He is impressed by experimental data supposedly showing that the neural structures dealing with the emotions are modular and cognitively opaque, thereby generating evolutionarily adaptive quick, dirty, and conservative reactions to affective stimuli. (For work on this wavelength, see LeDoux 1998.) But it seems to me that the cognitive theory is not so easily dismissed. Propositional attitudes—beliefs, desires, intentions—can be in play without being held before the mind. Yesterday I believed that the earth is round, though I did not bring the relevant thought to consciousness at any time. Nevertheless, though I suspect the experimental data referred to by Griffiths might be interpreted in ways consistent with cognitivism, as I have just indicated, later I argue that some of the most common emotional responses to music's expressiveness do not fit the cognitive model.

task will be to indicate how, despite their manifest differences, music's expressing an emotion parallels the default case in which a person expresses an emotion they feel. In other words, an account explaining and justifying our attribution to music of predicates such as 'sad' and 'happy' must make clear how this non-primary use relates to these words' normal application to the occurrent emotions of sentient creatures.

As I see it, this constraint quickly rules out three approaches to the topic. It will not do to attempt to reduce music's expressiveness to a catalogue of technicalities and compositional devices. Even if it is true that all, and only, music in minor keys sounds sad, it cannot be that 'sounds sad' *means* 'is in a minor key'. Even if one can make sad music by composing it in the minor key, there must be more to the analysis of music's expressiveness than acknowledgment of this, for it is by no means clear how the music's modality relates to the very different kinds of things that make it true in the standard case that a person is expressing sadness. Musical features ground music's expressiveness, and it is interesting to discover what features those are, but identifying them is, at best, only an initial step toward an informative theory of musical expressiveness.

Another of the disallowed strategies claims that music's expressiveness is metaphorical and declines to unpack the metaphor.[4] The claim here is not merely that, as a figure of speech, music can be described metaphorically. It is, rather, that the music itself is metaphorically expressive. While this last assertion obviously locates expressiveness squarely with the music, its meaning is quite mysterious. The idea that musical expression is metaphorical must itself be a metaphor, since metaphor primarily is a linguistic device depending on semantic relations for which there is no musical equivalent. This approach indicates what is puzzling about music's expression of emotions—that it is hard to see how emotion terms could retain their literal sense when predicated of music, though clearly their application to music trades somehow on their literal meaning—but it offers no solution to that puzzle.

Also unacceptable is the theory insisting that music's expressiveness is *sui generis*; that is, of its own kind and not relevantly comparable to the default case in which occurrent emotions are expressed. That approach is not offering a theory, but, rather, is rejecting the philosophical enterprise that seeks one. I do not deny that, when it comes to expressiveness, music does its own thing. This is only to be expected: its medium is that of organized sound, not that of a biological organism evolved and educated to engage emotionally with its environment. What I repudiate is the suggestion that an analysis of music's expressiveness can avoid addressing if and how the musical medium realizes a kind of expressiveness that is equivalent to the biological one.

2.5 The qualified listener

One assumption common to the theories discussed below should be made explicit: listeners must be suitably qualified if they are to be capable of detecting and appreciating music's expressiveness. (Unprepared listeners may miss, or misidentify, the music's

[4] In its strongest version, the theory denies the possibility of analysing the crucial metaphor. For theories to which this claim is central, see Goodman (1968) and Scruton (1997).

expressive character.) Qualified listeners are at home with the type of music in question, with its genre, style, and idiom. They know when the melody begins and ends, and when the piece is over. They can recognize mistakes and can distinguish predictable from unusual continuations. They may not be able to articulate this knowledge, most of which is acquired through unreflective exposure to pieces of the relevant kind. Indeed, the majority of qualified listeners have no formal music education and are not familiar with the musicologist's technical vocabulary (Davies 1994; Kivy 1990; Levinson 1996).

2.6 First problem: the expression of emotion in music

When we say that something expresses an emotion, usually we mean that it publicly betrays or indicates a state that it feels. People's tears express their sadness only if they are experiencing sadness. Therefore, only sentient creatures can express emotions. Musical works are not sentient, so emotions cannot be expressed in them. Yet many of them do express emotions such as sadness and happiness. How could that be?

2.6.1 Music as a symbol

A first theory suggests that music operates as a symbol or sign, the import of which is purely associative and conventional. Though it bears no natural relation to an emotion, it comes to denote or refer to an emotion, and then to characterize it, by virtue of its place within a system. In this view, music picks out and conveys something about emotions after the manner of linguistic utterances; that is, through combining elements according to rules with the function of generating and communicating a semantic or propositional content (Coker 1972). Musical signs, like linguistic ones, are both unlike and opaque to their referents.

Quasi-vocabularies sometimes have been described for music in its relation to the emotions, and music is highly organized according to quasi-syntactic rules governing the well-formedness of musical strings (Lerdahl & Jackendoff 1983; Meyer 1956), yet there is not a semantics in music. Without that, the parallel with linguistic and other symbol systems collapses. It is not the case that music points or refers to emotions which it then goes on to describe. There are no plausible equivalents in music to predication, to propositional closure, or to any of the other functions and operators that are essential to the meaningful use of linguistic and other truth-functional systems.

An alternative theory would have it that music refers to the emotions not within the framework of a symbol system, but as a result of *ad hoc*, arbitrary designations and associations. For instance, certain musical gestures or phrases happen to be linked saliently with texts expressive of a given emotion and retain that connection over many years, so that purely instrumental music comes to be heard as expressive when it includes the relevant gesture or phrase (Cooke 1959). Or music of certain kinds is linked with rites or events that otherwise are emotionally charged, and these ties persist, becoming commonplaces of musical expressiveness. In this theory, expressiveness involves techniques like those followed by Wagner in his use of leitmotiv, except that the relevant conventions are available to many composers and occur in many works, so widespread and entrenched are the associations that underpin them.

There is no denying that some aspects of music's expressiveness—for instance, the links between instruments and moods, as between the oboe and bucolic frames of mind, the organ and religiosity, or the trumpet and regality or bellicosity—seem to be arbitrary and conventional in ways that may depend on historical associations. Such cases notwithstanding, this last account is no more plausible or attractive than the first. It reduces music's expressiveness to something like brute naming; it indicates how music might refer to an emotion but not how it could characterize it.

These theories regard expressive music as referring beyond itself. As with language or signs relying on arbitrary associations, features intrinsic to the music are of interest only in so far as they happen to be relevant to its role as a symbolic vehicle. Though the music mediates contact with the emotion that is symbolized, listeners should not be distracted by its intrinsic qualities from pursuing its referential target. Because it is radically different from the emotions it symbolizes, it is opaque with respect to them, yet the music is of interest only in its symbolic import.

This account is seriously at odds with the phenomenology of listeners' experiences of music's expressiveness. Registering music's expressiveness is more like encountering a person who feels the emotion and shows it than like reading a description of the emotion or than like examining the word 'sad'. While the dinner bell might, through association, lead us to salivate, we do not think of it as tasty. By contrast, we experience the sadness of music as present within it. Emotion is transparently immediate in our experience of music and our awareness of its expressiveness is not separable from, or independent of, our following the music's unfolding in all its detail. Moreover, the listener's connection is not with some general, abstract conception of the emotions, but with a specific and concrete presentation.

Any theory of musical expressiveness must acknowledge and respect the phenomenological vivacity and particularity with which music presents its expressive aspect. Here, then, is a further constraint on acceptable theories of music's expressiveness, and it is one that is failed by the theories discussed so far. Music is not merely a vehicle for referring beyond itself in a fashion that largely ignores the intrinsic and unique character of its individual works.

The semiotic theory can respond to this objection if the link between music and emotion is transparent because it is natural, not arbitrarily conventional. Here is a first suggestion: there is a synaesthetic quality to certain timbres. The trumpet's upper notes are bright and the clarinet's low register is dark; the tone of the celesta is ethereal, while high string harmonics are brittle. Even if these connections are widely made, however, they lack the temporally extended complexity that could account for music's expressiveness. They might contribute to the work's emotional ambience, but they could not generate it.

A stronger form of natural connection is that of similarity, and this is emphasized in theories regarding music as an iconic or exemplificatory symbol. If music vividly resembles the emotions it expresses—indeed, if it depicts them in virtue of these resemblances—then it would be natural to respond to the symbol much as we respond to that for which it stands. Iconic symbols (such as representational paintings) are more transparent to their referents than are signs that rely on arbitrary associations or symbol systems (such as that of a natural language) to establish the connection. We regularly talk of pictures as if we are in the presence of what they depict, though this is not to say

we are deceived by them. We do not react to linguistic descriptions in the same way. Both Langer (1942) and Goodman (1968) have suggested that music is symbolic precisely because it is experienced as resembling or exemplifying what it denotes.

What is it about the emotions that music resembles? Not their thought components if, as was just argued, purely instrumental music is not equipped to convey the contents of proposition. It has been suggested that expressive instrumental music recalls the tones and intonations with which emotions are given vocal expression (Kivy 1989), but this also is dubious. It is true that blues guitar and jazz saxophone sometimes imitate singing styles, and that singing styles sometimes recall the sobs, wails, whoops, and yells that go with ordinary occasions of expressiveness. For the general run of cases, though, music does not sound very like the noises made by people gripped by emotion. A more plausible source of resemblance lies in the music's dynamic structure than in its sound as such. We experience movement and pattern in music; we hear in music a terrain shaped by ongoing interactions between its parts, which vary in their highness, complexity, teleological impetus, energy, texture, inertia, tension, and so on. If music resembles an emotion, it does so by sharing the dynamic character displayed either in the emotion's phenomenological profile, as Addis (1999) maintains, or in the public behaviours through which the emotion is standardly exhibited.

The first of these suggestions assumes that the phenomenological profile of some emotions is distinctive enough to provide for their individuation. I am doubtful both that cognitively rich emotions, like hope or jealousy, survive being divorced from their cognitive elements and that there is anything to distinguish the internal dynamics of bursting with joy from blowing one's top. Moreover, to suggest that music symbolizes the 'general form of emotions' (Langer 1942), not particular kinds or their instances, enfeebles the account. To those who have abandoned the hydraulic in favour of the cognitive theory of the emotions, it is more promising to compare music with the outward expressions of emotions than with their experiential shape. A number of emotions have standard behavioural expressions that are partly constitutive of their nature, rather than dispensable concomitants, and these have distinctive dynamic physiognomies. A downcast bearing and slow movements go with sadness, whereas joy is upbeat and lively. Sometimes we can tell what a person is feeling from the carriage of their body, without knowing the cause of their feeling, their cognitive state, or the object of their emotion.

A fatal problem remains in explaining music's expressiveness in terms of this or any other resemblance between music's features and properties displayed by emotions: in the normal case, the pertinent behaviours are expressive only if they stand in the relevant relation to an instance of the appropriate emotion. Someone might always display the behaviour without feeling the way their behaviour leads us to suppose. In that case, no occurrent emotion is expressed. And if a given physiological state is not accompanied by relevant thoughts, attitudes, desires, or behavioural dispositions, the experience of that state would not normally be regarded as an emotion. No matter how powerful the resemblance, the analogy fails to go through, since it cannot be supposed that music experiences or undergoes the emotions expressed in it.

Theories regarding music as a sign or symbol referring to the emotions accept the conclusion of the argument with which I commenced: occurrent emotions cannot be expressed in musical works. They look for some other, more abstract, way music can

connect with the affective life. But semiotic theories inevitably leave a gap between music and emotion. In consequence, they do not do justice to the direct and unmediated fashion in which emotional expression imposes itself on our experience of the music.

2.6.2 Experiencing subjects: composers, listeners, and imagined personas

Most theorists accept that only sentient creatures can express occurrent emotions, but deny that this counts against music's expressiveness. They hold that, when emotion is expressed in a piece of music, that piece stands to a sentient being's occurrent emotion as expressing it. Accordingly, they seek a sentient being whose emotion is given expression by the music. The prime candidates are the composer (or performer) or a persona represented in the music. Alternatively, they maintain it is the occurrent feelings of the listener, ones caused by his or her attention to the music, that license the judgment that the music is expressive.

The *expression theory* analyses the music's expressiveness as depending on the composer expressing his or her occurrent emotion through the act of composition. The chief difficulty for this theory is conveyed by O. K. Bouwsma's aphorism: 'The sadness is to the music rather like the redness to the apple, than it is like the burp to the cider' (1950, p. 94). In other words, we experience music's expressiveness not as a residue of feelings discharged in the compositional process but as resident in its nature.

The expression theory seems to be empirically false as not all expressive music is written by composers who feel emotions and try to express them. A more philosophical point is this: in the default case, sadness is expressed by weeping and the like, not by musical composition. The connection between the composer's emotions and the work he or she writes is by no means as natural or transparent as that between his or her emotions and the behaviours, like weeping or whooping, that vent them. So, even if composers sometimes express their emotions in the works they write, this fact, rather than accounting for the music's expressiveness, needs to be explained. Indeed, in the most plausible account, the composer appropriates the music's expressiveness in order to make the connection with his or her own emotions. In other words, the composer is like the person who expresses his or her feelings, not by showing them directly, but by making a mask that wears an appropriate expression. Just as the mask is expressive whether or not it is used in this sophisticated act of self-expression, so too is the music. If composers occasionally match the expressiveness of the music to their own feelings, that is possible only because the music can present expressive aspects apart from its being appropriated in this fashion.[5] (For further criticism of the expression theory, see Davies 1987, 1994; Goldman 1995*b*; Kivy 1989; Tormey 1971.)

The *arousal theory* explains the music's expressiveness as its propensity to evoke the corresponding emotion in the listener. What makes it true that grass is green is that it

[5] Similar arguments can be ranged against the version of the expression theory that identifies the performers as the ones who express their emotions through their rendering of the music. Performers need not feel the emotions they present, and when they do, there is matching rather than direct expression.

arouses certain experiences in (human) observers under standard conditions; grass's greenness is its causal power to bring about appropriate experiences. Similarly, what makes it true that music is sad or happy is its causal power to bring about these or related responses in the listener (Matravers 1998).

I doubt that the correspondence between listeners attributing sadness to music and their experiencing feelings or emotions of sadness in response to it is sufficient to make the arousal theory plausible. In the case of colour, the experience inevitably goes with the judgment and the two are pulled apart only when the observer or the conditions of observation are abnormal. The 'standard conditions' for music to produce its effects are those in which a qualified listener pays attention to the music. Those conditions are often satisfied. When they are, the arousal of a response in listeners who correctly judge the music to be expressive is not nearly as regular as the arousal theory requires. And it is unconvincing to claim that the relevant feelings, or dispositions to them, can be so weak as to escape the listener's notice. In fact, we have a clear sense of the music's expressive character as quite distinct from our (very variable) responses to it. This is not to deny that the music sometimes can cause an emotional reaction. What is denied is that this reaction is what makes it true that the music is expressive. Normally, we regard the connection as reversed: it is because the expressiveness is apparent in the work that we are moved by the music.

Many theorists (but cf. Beever 1998) would subscribe to the following proposition: if we were never moved by music, we would not find it expressive. This involves no commitment to the arousalist's programme for analysing music's expressiveness, though. Usually the conditional is regarded as reversible: if we never found music expressive, we would not be moved by it. In other words, it identifies the close and mutual dependence of our experience of music and the judgments we make concerning its features; it does not imply that one takes explanatory precedence over the other.

Expression and arousal theories go hunting for an experiencing subject to whom the music might stand, either as the expression of his or her (the composer's) occurrent emotion or as the cause of his or her (the listener's) emotion-like response. Instead of actual persons and emotions, perhaps we should consider imagined ones. In the case of works generating fictional worlds, such as novels and films, we engage imaginatively with characters inhabiting that world. Maybe music's expressiveness connects to fictional or make-believe experiences of emotion. There are two possibilities. In the first, listeners imaginatively ascribe emotions to themselves on the basis of their make-believe engagement with the world of the work. In the second, listeners make believe that the work generates a fictional world to which they are external observers; they imagine of the music that it presents a narrative concerning the emotional life of a persona.

Both views are presented by Walton (1988), but it is his version of the first that I will consider. He suggests that a passage is expressive of sadness if the listeners imagine of their hearing of it that it is a cognizance of their own feeling of sadness. Listeners take their awareness of their auditory sensations to be an awareness of their own feelings, and it is these feelings that the music can be said to express.

Even if one charitably allows that awareness of music's expressiveness could be as self-centred and introspective as this, the theory remains implausible. Reflecting on one's auditory sensations is not plainly similar to experiencing emotions, so it is difficult

to see how what one imagines can be connected back to and controlled by the music, so that, ultimately, it is the music's expressiveness that is revealed.

The thesis that, in hearing expressiveness in music, we sometimes imagine a persona who is subject to a narrative that unfolds in the music, is widely supported (Budd 1985; Karl & Robinson 1995; Ridley 1995; Vermazen 1986; Walton 1988, 1990). The idea could be offered as a heuristic—as a way of helping people recognize the music's expressiveness—or as a claim applying only to particular works. The strongest position insists that this manner of hearing is always required for appreciation of the music's expressiveness. Levinson (1996) comes nearest to the strong position by defining musical expressiveness such that a passage is expressive of an emotion if, and only if, it is heard (by appropriately experienced listeners) as the expression of that emotion by an imagined human subject, the music's persona.

A first objection denies that all qualified listeners imagine a persona as a condition of their awareness of the music's expressiveness. They might be able to say what it would be suitable to imagine, even if they do not imagine it themselves, but they do this in terms of an awareness of the music's expressive character that is not mediated by the imagination. Besides, I contend that what the listener imagines is too little constrained by the course and detail of the music to provide a theory regarding music's expressiveness as an objective property, which is what Levinson intends. In the case of novels and films, a great deal of information about the fictional world is conveyed to the audience, even if its members must entertain the reality of this world. Those data control what is to be imagined, and why and how, in following the story. Because it does not convey a definite propositional or depicted content, and hints at such things (if at all) only in the vaguest and most general fashion, purely instrumental music cannot direct and channel the content of the listener's imagining (Davies 1997). For instance, what is to determine how many personas he or she should make believe, or the background of relations that might hold between different personas? Inevitably, what is imagined reveals more about the listener than about the music's expressiveness.

2.6.3 The contour theory

A final view, the *contour theory*,[6] abandons the attempt to analyse music's expressiveness as depending on its connection to occurrent emotions. It observes that certain behaviours, comportments, and physiognomies are experienced as expressive without giving expression to, or being caused by, occurrent emotions. Some faces, gaits, or movements are happy-looking. They present an emotion characteristic in their appearance. St Bernards are sad-looking dogs, but this is to say nothing about how they feel. The use of emotion terms to name the expressive characteristics of appearances is secondary, but it bears an obvious connection to those terms' primary use: the behaviours that display an emotion characteristic unconnected with an occurrent emotion are the same (or very similar) to the

[6] Kivy's version of the theory (1989) often is called 'cognitivism' as a way of acknowledging his commitment to a cognitive theory of the emotions, especially as these concern the listener's response. His theory of music's expressiveness does not invoke the cognitive theory of the emotions, however, because it denies that the music expresses occurrent emotions.

ones that, where the emotion is occurrent, give direct and distinctive expression to it. Only those emotions that can be recognized solely on the basis of the outward expressions that betray them have corresponding emotion characteristics in appearance.

Turning now to music, the contour theory proposes that pieces present emotion characteristics, rather than giving expression to occurrent emotions, and they do so by virtue of resemblances between their own dynamic structures and behaviours or movements that, in humans, present emotion characteristics. The claim is not that music somehow refers beyond itself to occurrent emotions; music is not an iconic symbol of emotions as a result of resembling their outward manifestations. Rather, the claim is that the expressiveness is a property of the music itself. This property resides in the way the music sounds to the attuned listener, just as happy-lookingness can be a property displayed in a creature's face or movements. Because music is a temporal art, its expressive character is revealed only gradually, and can be heard only through sustained attention to its unfolding. It takes as long to hear the music's expressive properties as it takes to hear the passages in which those properties are articulated.[7]

Consider Fig. 2.1. The car and the puppet are happy looking, and the dog and the weeping willow are sad looking. These attributions apply to the appearances the depicted items present, not to occurrent emotions. Only the dog is sentient, and there is no reason to think it feels as it looks. (Besides, dogs do not display feelings of sadness, when they have them, in their *faces*.) These looks present emotion characteristics because they resemble bearings or expressions which, were they shown by people under appropriate circumstances, would express those people's occurrent emotions. I maintain that, when we attribute emotions to music, we are describing the emotional character it presents, just as we do when we call the willow sad or the car happy. In the case of music, this 'appearance' depends on its dynamic topography, as this unfolds through time. In general, music resembles gaits, carriages, or comportments that are typically expressive of human occurrent emotions, rather than facial expressions.

In discussing the theory that regards music as an iconic symbol or depiction of emotions, I have already considered objections to the view that music resembles expressions of the emotions. I concluded that the resemblance claim is at its most plausible when it compares music's dynamic pattern to that apparent in non-verbal, behavioural expressions of emotion. Yet even if this is accepted, a further objection notes that resemblance alone could not ground music's expressiveness. Resemblances, which are symmetrical and, anyway, can be found between music and many things besides expressive appearances, are insufficient to explain why we experience music as powerfully expressive of emotion.

One might reply, as Kivy does, that we are evolutionarily programmed to 'animate' what we perceive. Or one might simply say 'yet this is how we hear it', without committing oneself to an account of the mechanisms and triggers that underlie the response. Not just music, but many things, are experienced as redolent of emotions, despite lacking

[7] In outline, this is the theory presented in Kivy (1989), as well as in Davies (1994), though the terms in which it is formulated are closer to my account than Kivy's. As observed earlier, Kivy is more inclined than I to find an expressive resemblance between music and the human voice (see also Juslin, this volume). For further discussion of our differences, see Davies (1994) and Kivy (1999) and for critical commentaries, see Goldman (1995*b*), Levinson (1996, 1997*b*), and Madell (1996).

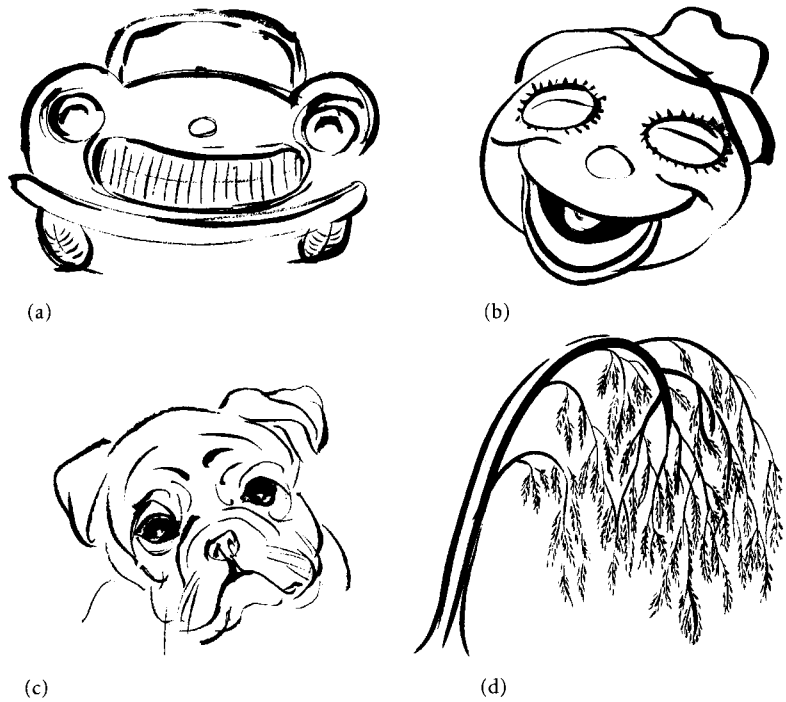

Figure 2.1 Appearances with various emotion characteristics: (a) car, (b) puppet, (c) dog, and (d) weeping willow.

the feature one would assume to be crucial; namely, sentience. There can be no denying that crude representations of the human face can be emotionally compelling in their expressive power, though such responses are not strictly entailed by the resemblances that can be found. Consider the masks of comedy and tragedy, or a simple drawing such as Edvard Munch's 'scream' face.

If these last observations are not fully satisfying, that does not reflect more badly on the contour theory than on other analyses. For instance, the arousalist is reduced ultimately to saying 'simply, this is how music affects us'; and philosophers who regard music as an iconic symbol, or as calling on us to make believe a narrative about a persona, are no better equipped than the contour theorist to go beyond the perceived resemblances that are central to their accounts of music's expressiveness.

A different line of objection doubts that the contour theory can explain the significance we attach to expressiveness in music, or the energy with which music engages our emotions. What can we learn from, and why should we be moved by, mere appearances of emotion that are not expressions of occurrent, deeply felt emotions? One answer draws attention to the fact that music is intentionally and ingeniously designed to be as it is. Though expressiveness is a property of the piece's sounds, we encounter it not as an accident of nature but as deliberately created and used, which adds considerably to its potential importance. Another response could question if it is true that music is valued

as a source of knowledge about the emotions, rather than for the experience it provides, where this experience takes in much more than only its expressiveness.

2.6.4 Universalism

The contour theory, more than any other, lends itself to the idea that music is a universal 'language of the emotions'; that is, to the suggestion that expressiveness can be recognized cross-culturally. If, as some psychologists have claimed (Ekman 1980), certain emotions have characteristic appearances that are universally understood, and if music is experienced as expressive as a result of its recalling these same appearances in its dynamic character, then cross-cultural appreciation of music's expressiveness should be possible. And perhaps it is sometimes. When the musical systems of different cultures are parallel (for instance, in their principles of scalar organization and modalities), there may be sufficient transparency to allow members of one culture to correctly recognize expressiveness in the music of the other culture. Many Westerners can access sub-Saharan African music, and not only because it provided the seeds from which a number of popular Western musical types emerged.

Often, though, the music of one culture is expressively opaque to outsiders. There are several reasons why this can be so. The emotions appropriate to given circumstances can differ, so that one group sees death as an occasion for sadness where another views it as a cause for joyous celebrations. Until one appreciates the belief systems that determine the significance of the social settings in which emotions are situated, and then recognizes the connection of music with all this, it will not be a simple matter to read off expressiveness from foreign music. Even if music's expressiveness implicates 'natural' resemblances to behaviours that are transcultural in their import, these then are structured according to historically malleable musical conventions of genre and style, so that they are no longer apparent to those who lack familiarity with the culture's music. To take a crude example, whether a given pitch is 'high', 'middle', or 'low' depends on the range that is deemed available for use, and that can vary arbitrarily from musical type to type. The contour theory, no less than other analyses, supposes that qualified listeners can become such only by immersing themselves in the kinds of music that are their focus, and that listeners have no guaranteed access to the properties of foreign music, including its expressive ones, until they become appropriately experienced.

2.7 Second problem: mirroring responses to music's expressiveness

People often respond emotionally to musical works. While there is nothing odd about a listener being moved by the work's beauty, it is strange that he or she should respond with sadness to the sadness it expresses. The listener's sad response appears to lack beliefs of the kind that typically go with sadness. When I am sad because the dog has died, or because it is raining on your parade, or because you are depressed, I believe the death of the dog, or the rain, or your depression, are unfortunate occurrences, but when the sadness of the music makes me feel sad I do not believe there is anything unfortunate about the music. Moreover, the response to another's emotion often does not mirror it. Another's anger is as likely to produce in me fear, or disappointment, or irritation, as

it is likely to precipitate my anger. Yet the listener is not as liable to feel pity, or compassion, or evil delight at the music's sadness as he or she is liable to feel sadness. How is the listener's response appropriate to the music?

The problem is not a general one. Many of our emotional reactions to music conform neatly to the cognitivist model. We can marvel at the music's complexity, and be shocked by its discordant novelty. These responses, in taking the music as their object, involve beliefs or thoughts of the kinds that normally accompany marvelling and shock. The problem case is the one in which listeners mirror in their reactions what the music expresses; where they are saddened by sad music, or cheered by happy music.

Kivy (1989) denies the problem's existence: people are mistaken when they claim to be saddened by sad music.[8] They are moved by the music, certainly, but not to sadness. This explains why concert audiences neither display nor act as if they are sad about the music; simply, that is not how they feel. People are not often wrong about the identity of their emotions (cf. Griffiths 1997), however, and Kivy's position will fail so long as some people sometimes react to the music's expressiveness by mirroring it in their own feelings. For these reasons, and by appeal to their own experience, most philosophers reject Kivy's stance (for discussion, see Davies 1994; Goldman 1995*b*). Any alternative theory that can deal with the problem without denying the phenomenon will be preferable.

If the listener believed music expresses a sadness felt by its composer (or performer), there would be no special puzzle about his or her reaction, for such beliefs are appropriate to a sad response. In this case, however, the object of the response would not be the music, but the composer or performer. When we react to a person's emotional state, our response is directed to them, not to their expressive behaviour as such, even if it was this behaviour that alerted us to their condition. This account does not after all address the problem case, that in which the listeners' responses are solely to the music's expressive character. To have this reaction, they need not believe that the music expresses emotions experienced by its composer; it can be sufficient that they acknowledge the music's expressive appearance, without supposing this to be connected to anyone's occurrent emotions.

According to the theory in which a persona is the human subject of the imaginary act of expression we hear as going on in the music, the problem response can be approached as follows: if that response is directed to the persona, then it will be targeted at the music, for it is in the world of the music that the persona is imagined to exist. And if we hear the persona as undergoing the emotional vicissitudes outlined in the music, then we entertain thoughts about the situation of the persona that are appropriate for mirroring reactions. Admittedly, these thoughts are make believed, not believed, but if this presents no special difficulty in accounting for our reactions to fictional characters (as argued in Carroll 1998), then the response also is unproblematic in the musical case. So long as the cognitive theory of the emotions allows that the cognitive connection between the emotion and its object can be secured by the imagination in some cases, as

[8] Addis (1999) agrees that listeners are not aroused to sadness by sad music. He differs from Kivy, though, in holding both that they are aroused to a uniquely musical experience—a kind of stirring—and that this response does not take the music as its intentional object, though it is caused by the music.

unfortunate and the rest. Nevertheless, if I am roused to an emotion under those circumstances, it will be a mirroring one, because, in the absence of relevant cognitions, it is only through a kind of contagion or osmosis that my feelings are engaged.[9]

2.8 Third problem: negative responses

Yet if we accept that music expressive of negative emotions sometimes produces an echo in feelings experienced by the listener, another problem emerges. People avoid sad experiences where they can, because these are unpleasant. Those who are under no duty to listen to sad music often choose to do so. They report that such music gives rise to a negative emotional response, yet they offer this in praise of the music. Rather than fleeing, they are attracted to the music, and they willingly return to it, despite predicting that it will again make them feel sad. Given that music lovers are not masochists, how is this to be explained?

For Kivy (1990) there is again no problem. Listeners to sad music do not experience negative feelings, or if they do, these are of the ordinary kind—as when one is disappointed in the poverty of the work's ideas, or by its execrable execution—and provide reason for avoiding the emotion's object, the work, or the performers, in the future. Those who think that music can lead the listener to a negative, mirroring response cannot avoid the issue, though. Three argumentative strategies are available.

The first notes that there can be much to enjoy about musical works that arouse negative emotions; for instance, the work's beauty, the composer's treatment of the medium, and so forth. In addition, because it lacks 'life implications', one can savour and examine one's response, thereby coming to understand the emotion better while being reassured of one's own sensitivity (Levinson 1982). In this view, the negative elements are outweighed by positive ones. We listen to music that arouses negative emotions because it also does much more, and the overall balance is on the credit side.

The position is not entirely convincing in its present formulation. If we can get the same or similar benefits from works that do not make us feel unhappy, we should prefer them. We should shun skilful, interesting works that make us feel sad in favour of equally skilful and interesting works that make us feel happy. To reply to this objection, the original view can be developed (as in Levinson 1982) by arguing that at least some of the benefits cannot be obtained from works other than those that are liable to induce negative feelings. The Aristotelian position, according to which we are better off for purging negative feelings in the context of art, pursues this line, as does the theory that our experiences of artworks educate us about the emotions in a setting that insulates us from the practical demands and dangers of

[9] The view presented here requires rejection or revision of the cognitive theory of the emotions sketched earlier, since it countenances emotions that lack the appropriate beliefs or make beliefs, the desires, and behavioural dispositions that would follow from these, and the relevant emotional object. As indicated, Matravers (1998) and Addis (1999) also argue that the mirroring response takes the music as its emotional object. Of course, this is not to deny that the music is the focus of attention and perceptual object of the response, which is a point apparently missed by Madell (1996).

the real world. In this connection, it is also often held that the feelings experienced in regard to artworks are muted and undemanding compared to equivalents provoked by real-world situations.

These ways of addressing the objection are more convincing in the discussion of our reactions to narrative and representational artworks, not instrumental music, I find. If the response to music lacks the cognitive content of emotions, it is difficult to see how it could be a source of education or insight, or how it is easier to tolerate than similarly unpleasant feelings caused by real-world phenomena. If music does not generate a contentful fictional world, the reaction to its expressive properties is not less a response to 'real-world' features than is, say, that in which an especially vivid shade of lime green induces sensations of dyspepsia in its observer.

The second approach to the issue derives from Hume (1912), who argued of the experience of tragedy that its negative aspects are transformed to positive ones through the delight taken in the narrative's construction, the natural attractiveness of representation, and so on. It is far from clear, though, what is the character of this conversion, or how feelings such as sad ones could remain sad while becoming intrinsically pleasant. Perhaps what Hume was driving at is better articulated by the third strategy, which offers the strongest possibility for justifying the interest of someone whose sensitivities incline him or her to negative feelings on hearing music in which negative emotions are presented.

Even if we accept that the negative aspects of experience are unpleasant, and that this gives a reason for avoiding them, it is plain that, for many, this reason is not always overriding. For music, that which is negative often is integral to the whole. Provided our desire to understand and appreciate the work is strong enough, we may be prepared to face those negative elements. The experience that results is not just good on balance; it is not as if the work would be better if we could ignore its negative aspects, for then we would not be engaging with it as such. In other words, experience of, and reaction to, music's negative expressiveness, where that expressiveness is important to the work, is something to be accepted if our goal is to understand and, through understanding, to appreciate the music. There is nothing irrational in pursuing that goal, though the experience to which it gives rise can be unpleasant in parts.

There is a different way of getting at the same point. It simply is not true that people always duck the avoidable negative aspects of life. These are recognized as essential components of many things we like and value. They come along with the territory, not solely as something to be endured but also as contributing to its being the territory it is. This is true of the most important components of our lives: intimate personal relationships, child rearing, self-realization, career. To achieve a fulfilling life, the individual must honestly and seriously face these in all their dimensions, both positive and negative. Yet it also is true of the way we live generally, even apart from the big issues of survival and flourishing. Thousands of amateurs train for endurance races, such as marathons and triathlons. Other hobbies and activities, in which the challenge of the negative is no less central, are pursued with the same passionate commitment by other people, though they are under no compulsion to do so. Against this background, surely it is safe to deny there is a special problem about the fact that people willingly engage with something so rewarding as music, though they know that doing so will expose

them to expressions of negative emotions, which are liable to cause feelings that are unpleasant to experience.[10]

CHAPTER 3

MUSICOLOGICAL APPROACHES TO EMOTION

NICHOLAS COOK AND NICOLA DIBBEN

3.1 Defining musicology

Writing about music may well go back as far as writing itself, but to speak of 'musicology' before about 1800 is to court anachronism. In the centuries before then, there were in the West two broadly distinct traditions of writing about music: on the one hand more or less practical manuals addressed in general to (and generally by) composers and performers, and on the other hand more or less speculative writings that, to modern eyes, can at times resemble cosmology with a musical vocabulary. The emergence of 'musicology' (a term not used in English until the twentieth century, but borrowed from the earlier French term *musicologie*) can, then, be traced to two circumstances: first, the new relationship between compositional theory and practice that resulted from a general growth in historical awareness and the establishment of a canon of 'masterworks'; and second, the increasing systematization of what in the course of the nineteenth century became known (especially in Germany) as the human sciences.

In its original form, and to some extent still in common British parlance, 'musicology' means simply the study of and knowledge about all aspects of music, taking in, for example, the systematic approaches to musical organization collectively known as 'music theory'; American usage of the term is distinctly narrower: in Joseph Kerman's words, 'the study of the history of Western music in the high-art tradition' (Kerman 1985, p. 11). In the 1990s, however, the self-imposed limitations of this version of musicology were seriously challenged by the so-called 'new' musicology (a development foreshadowed by Kerman's critique of the traditional discipline's formalist and positivist tendencies). There is, then, no single, universally accepted definition of the discipline's scope.

This poses problems in determining the scope of this chapter. A genuinely inclusive treatment of musicological approaches to emotion would not restrict itself to the work of 'musicologists' in any narrow sense, but might encompass the views of performers, composers, aestheticians, and others who wrote on music before 1800; similarly, it might take in not only present-day musicological writing but also the ethnomusicological, philosophical, psychological, or sociological perspectives that inform it. (It might also recognize the existence of other traditions of systematic thinking about music, other musicologies, outside the Western orbit.) But that would take a book and not a chapter! More modestly, then, we discuss here a selection of musicological or

music-theoretical approaches to the expression of emotion in Western 'art' and popular music, most of them written since 1950, emphasizing in particular those that set out general frameworks within which to understand how specific pieces of music embody, express, arouse, or otherwise signify emotional states. (We recognize, and readers should be aware, that other authors might well have made a different selection.) Bearing in mind the likelihood that many of our readers will be unfamiliar with the discipline, however, we precede this with a whistlestop tour of thinking about music and emotion since around 1600: this will serve as much to contextualize musicology as to identify issues and points of reference that will be drawn on later in the chapter.

3.2 A historical sketch

While comparatively little is known of the nature and practice of ancient Greek music, classical writings about music have formed a constant point of reference for subsequent theorists and have accordingly exerted a lasting influence. One could almost frame a history of thinking about music and emotion in terms of the two principal functions which the Greeks ascribed to music: on the one hand *mimesis* (the imitation or transformation of an external reality) and, on the other, *catharsis* (the purification of the soul through emotional experience). The first term values music for its representational function, in this sense embracing it within the theory of knowledge, whereas the second locates music's value in the effect it makes upon the experiencing subject. At issue are two fundamentally different conceptions of what sort of thing music is. As might be expected, however, such philosophical concerns did not greatly impinge upon the practice of working musicians, who were less likely to discuss issues of music's emotional powers than simply to take them for granted; a comprehensive history of pre-musicological approaches to emotion would have to be extracted from a multitude of oblique references hidden in the nooks and crannies of a wide range of texts.

The rise of opera around 1600, with which we begin this overview, was associated with a long period of ascendancy in the idea of music as *mimesis*. (It is perhaps not irrelevant that the Florentine *camerata* responsible for this development saw themselves, however misguidedly, as reconstructing the practices of ancient Greek drama.) The function of music in baroque opera is to reflect or heighten the expression of the emotions signified by the words and presented by means of staged action; we can talk of the music 'expressing' emotion just to the extent that the emotion is located not within the music as such, but within an external reality (whether actual or imagined) which the music references. Music, in short, represents reality, just as language does. It is not surprising, then, that baroque musicians borrowed wholesale from contemporary thinking about language, seeking to understand even instrumental music as a form of discourse and, in particular, applying to it the principles of classical rhetoric: an eighteenth-century example is Mattheson (1981), who traced the operation in music of such rhetorical devices as repetition, variation, or counterstatement, seeing them as serving to project or heighten emotional content in the same way that, in language, the devices of rhetoric colour or inflect propositional content. And in each case the aim was persuasion: just as legal or political orators would seek to persuade their listeners of the case being presented, so musicians

sought to convince audiences of their emotional veracity. Like actors, musical performers had themselves to feel the emotions they wanted to convey to their listeners: as C. P. E. Bach put it in his *Essay on the true art of playing keyboard instruments*, 'A musician cannot move others unless he too is moved' (Bach 1974, p. 152).

During the seventeenth and eighteenth centuries, vocal music—that is, music allied to words—was understood as the paradigm case for music in general. It was through heightening verbal signification that music itself acquired meaning; purely instrumental music by contrast had no meaning, or at best signified at second hand, functioning as a more or less pale reflection of texted music. Unsurprisingly, then, music fared badly in the formulation of the eighteenth-century discipline of aesthetics; music can arouse emotions, Kant admitted, but it amounts to no more than 'a play with aesthetic ideas . . . by which in the end nothing is thought'. (He added that the pleasure it creates 'is merely bodily, even though it is aroused by ideas of the mind, and . . . consists merely in the feeling of health that is produced by an intestinal agitation corresponding to such play'.[1]) It is in this light that the much vaunted rise around 1800 of autonomous instrumental music has to be understood: the point is not that people did not play purely instrumental music up to that time, but that it was not the paradigm case for music that it became by the middle of the nineteenth century. Lydia Goehr has characterized this conceptual transformation as a conjunction of a '*formalist* move which brought meaning from the music's outside to its inside' and a '*transcendent* move from the worldly and the particular to the spiritual and the universal' (Goehr 1992, p. 153).

The formalist move to which Goehr refers is most famously represented in the writings of the Viennese critic Eduard Hanslick, the first edition of whose short book *On the musically beautiful* appeared in 1854. In describing the 'content' of music as 'tonally moving forms' (Hanslick 1986, p. 29), Hanslick was claiming that questions about musical meaning, which had long been formulated in terms of representation, should be reformulated as questions about the intrinsic properties of the music itself. The clearest indication of what is at stake here is to be found in those later writers, such as the turn-of-the-century Viennese theorist Heinrich Schenker, who sought to build systems of musical analysis on Hanslickian foundations: commenting on C. P. E. Bach's prescriptions of how the improviser is to excite or soothe the passions, Schenker claims that 'One must not seek in Bach's word 'passions' [*Leidenschaften*] what certain aestheticians of the doctrine of affections bring to it . . . [Bach] means by it simply the consequences of a change in diminution: pure musical effects which have nothing in common with the amateurishly misunderstood and so grossly exaggerated ideas of the aestheticians' (Schenker 1994, p. 5).[2] (This development of the scope of musical analysis, in effect elaborating on the structural potential of 'tonally moving forms', might be seen as a definitive rebuttal of Kant's dismissive reduction of music to the level of intestinal

[1] This passage (from Kant's *Critique of judgement*) is quoted and discussed by Kivy, who scornfully encapsulates Kant's image of music as 'the sonic counterpart of Tums for the tummy' (Kivy 1993, pp. 258–9).

[2] The passage in Bach's *Essay on the true art of playing keyboard instruments* to which Schenker refers is on pp. 438–9 of Mitchell's translation (Bach 1974).

agitation.) It is in this sense that, as Goehr puts it, meaning was brought from the music's outside to its inside.

Released from its representational function, music is no longer seen as describing specific emotions within specific situations (the Count's mounting jealousy in Act 1 of Mozart's *Marriage of Figaro*, say), but rather as abstracting the essence of phenomena; this is the move from the particular to the transcendental of which Goehr speaks. Just as in the work of early romantic artists like Caspar David Friedrich, personal emotions are subsumed within a generalized aesthetic yearning for the universal and the spiritual; for the influential writer E. T. A. Hoffmann, writing in the early years of the nineteenth century, music's power lay precisely in its ability to transcend the conditions of ordinary existence, a view echoed in Hanslick's statement that the composer creates 'something which has no counterpart in nature and hence none in the other arts, indeed none in this world' (Hanslick 1986, p. 74). Seen in this light, music, once the poor relation of the visual and literary arts, could be considered uniquely privileged within the aesthetic hierarchy: the very lack of specificity that formerly consigned it to a subordinate role was now construed as an infinite suggestiveness. It is precisely because of its lack of direct reference to the specifics of everyday existence that the art historian Walter Pater (1910, p. 135) wrote that 'All art constantly aspires to the condition of music'.

But it is at this point that the story takes a series of unexpected turns, which between them can be seen as accounting for the fragmented and in many ways contradictory nature of present-day thinking about music, and particularly about musical meaning. For no sooner had music made itself independent of the word than the word began to re-establish itself, only this time outside rather than inside the musical text. It was during the nineteenth century that the consumption of music began to be routinely surrounded by a variety of informative and interpretative texts: programme notes, music appreciation texts, and, today, CD liners, broadcasts, and magazines. This development was largely associated with the reception of Beethoven's instrumental music, and in particular the increasingly idiosyncratic, not to say erratic, works of his late period. Some contemporary listeners put their hermetic style down to the composer's now profound deafness. Others felt that, behind the music's apparent contradictions (such as the consistent mixing of genres in the Ninth Symphony) there must lie some intention, some deeper message. And so there emerged a plethora of commentaries on the music, each attempting to work from the musical text to the meaning assumed to lie behind it. The most influential of these commentaries understood the music in autobiographical terms. In 1828, for example, Franz Joseph Fröhlich published a review of the Ninth Symphony, interpreting it as the expression of Beethoven's struggle with deafness and his ultimate transmutation of suffering into joy (Wallace 1986). Fröhlich even brought this interpretation to bear upon the bar-by-bar details of the music: bars 1–30 of the first movement, he explained, represent in succession tender longing, heroic strength, pathos, and a vision of joy—all of them complementary aspects of Beethoven's own, complex personality.

Commentaries of this kind, which maintained their popularity among the concert-going public during the remainder of the nineteenth century, set up a number of striking paradoxes. The first we have already referred to by implication: in Scott Burnham's words, 'music no longer in need of words now seems more than ever in need of words' (Burnham 1999, p. 194). Secondly, and related to this, music now vindicated as the most

abstract of the arts is explained in the most concrete terms; it is worth observing how the music programme tradition which runs from Berlioz and Liszt to Richard Strauss (and from there, arguably, into film music) in effect brought such explanations back within the music itself, so setting itself up in opposition to the prevailing aesthetic of autonomous instrumental music. Thirdly, meaning now understood as located within the musical text (the very term applied to such commentaries, 'hermeneutics', is borrowed from traditions of biblical exegesis) is explained through the construction of an authorial persona whose experiences the music represents. Most telling of all, however, is the manner in which music is now construed as an expression of what might be termed bourgeois subjectivity.

As presented in baroque and classical opera, emotion belongs to the public sphere; to put it another way, it is conceived dramatically. The paradigm of nineteenth-century literature, by comparison, is the novel, where emotion subsists in private, subjective experience, to which the various characteristic devices of the novel give the reader access. In the same way, the emotion which nineteenth-century commentators read into Beethoven's music belongs to the private sphere, unmistakably so when Wagner describes the Ninth Symphony as Beethoven's attempt to reach out from the solitude of his deafness: 'When you meet the poor man, who cries to you so longingly, will you pass him on the other side if you find you do not understand his speech at once?' (Wagner 1899, p. 203). Music is still understood as expression, just as under the principle of *mimesis*, but this now takes the form of self-expression, the attempt of the artist to make contact with others and, so to speak, with himself or—more rarely—herself. However dated its origins, this is a concept that has never really lost currency in the years since the 1820s, though it is nowadays perhaps most evident in popular music: music videos, for instance, promise the fan a means of intimate access to the star, while the values of authentic self-expression are central to the carefully constructed persona of an artist like Bruce Springsteen (Cavicchi 1999).[3] It is in the contrast which Adorno once drew between the emotional qualities of Schoenberg's music and the earlier model of dramatic representation, however, that the idea of music as self-expression reaches its apogee: 'Passions are no longer simulated', he wrote, instead, 'genuine emotions of the unconscious—of shock, of trauma—are registered without disguise through the medium of music' (Adorno 1973, pp. 38–9). For the composer, then, and perhaps for the listener too, music provides something akin to the purification of the soul through emotional experience that the Greeks associated with it, and so assumes the function of *catharsis*.

Nowadays, formalism and hermeneutics are seen as opposite ends of the critical spectrum. But as we have explained, it was not always so: formalism, the idea that music is autonomous and should be understood in its own terms, was originally associated with the sense of music's other-worldliness and consequent spiritual value. Nor did Hanslick seek to deny music's emotional powers, although later formalists often read him this way. (Hence his statement in the foreword to the eighth edition of *On the musically*

[3] For a study of the bourgeois subject that takes in both romantic *Lieder* and rock, see Bloomfield (1993); for an example of popular music which problematizes this expressive norm, see Dibben (2001).

beautiful—published in 1891, 37 years after the book's first appearance—that 'I share completely the view that the ultimate worth of the beautiful is always based on the immediate manifestness of feeling' (Hanslick 1986, p. xxii).) He did, however, seek to qualify its ability to represent specific emotions, putting forward an early version of what is nowadays called the cognitive theory of the emotions (Kivy 1993, pp. 270, 284; see also Davies, this volume). You cannot feel love, Hanslick claims, without thinking of the loved one; the emotion is inextricably tied up with its object. But depending on the circumstances 'its dynamic can appear as readily gentle as stormy, as readily joyful as sorrowful, and yet still be love'. His point is that 'music can only express the various accompanying adjectives and never the substantive, e.g. love itself' (Hanslick 1986, p. 9). But how does it do this? In order to answer this question, Hanslick asks another (p. 11):

> What, then, from the feelings, can music present, if not their content? Only that same dynamic . . . It can reproduce the motion of a physical process according to the prevailing momentum: fast, slow, strong, weak, rising, falling. Motion is just one attribute, however, one moment of feeling, not the feeling itself.

His conclusion, then, is that it is these purely musical motions, and not the feelings with which they may be associated, that must form the focus of any meaningful theory or criticism of music.

It would be possible to argue that what Hanslick means is that only when you can fully explain music in *motional* terms is there any point in trying to do so in *emotional* ones. Because you can never fully explain anything in the arts, however, that is a recipe for infinite deferral. At all events, and whatever Hanslick himself may have intended, he laid the foundations for a formalism that grew in strength during the later part of the nineteenth century and survived through the greater part of the twentieth, according to which issues of musical meaning and expression were regarded as off limits for purposes of serious academic discussion. This change in the nature of formalism coincided with the development of increasingly abstract and powerful methods for musical analysis (through the work of not only Schenker but also Schoenberg and Hindemith in the first half of the twentieth century, for example, and Babbitt, Forte, and Lerdahl in the second half), the aim of which was to provide complete and self-sufficient explanations of music in exclusively structural terms. That did not necessarily entail a denial that music might have emotional powers. Lerdahl and Jackendoff (1983, p. 8) specifically state that

> To approach any of the subtleties of musical affect, we assume, requires a better understanding of musical structure. In restricting ourselves to structural considerations, we do not mean to deny the importance of affect in one's experience of music. Rather we hope to provide a stepping stone toward a more interesting account of affect than can at first be envisioned.[4]

But the practical effect is, of course, the indefinite postponement of consideration of music's expressive qualities to which we have already referred. In what follows, we shall consider the viability of the separation that this implies between structural analysis and expressive interpretation. For now it is worth just noting its apparent similarity to the traditional piano teacher's advice formulated by Ralph Kirkpatrick as 'Learn the notes

[4] Cf. Edward T. Cone's claim that 'If verbalization of true content—the specific expression uniquely embodied in a work—is possible at all, it must depend on close structural analysis' (Cone 1982, p. 233).

and then put in the expression'; tellingly, Kirkpatrick continues, 'My admonition is to learn the notes and understand their relationships, and then to draw the expression out' (Kirkpatrick 1984, p. 128).

By the 1980s there was a growing view that this narrowness of analytical purview, coupled to a parallel reluctance to enter upon aesthetic interpretation on the part of music historians, had resulted in an apparently unbridgeable schism between the concerns of professional musicologists on the one hand, and those of practically everyone else who had an interest in music on the other: as Kerman put it, 'Along with the preoccupation with structure goes the neglect of other vital matters—not only the whole historical complex . . . but also everything else that makes music affective, emotional, expressive' (Kerman 1985, p. 73). In this context one can see the 'new' musicology that followed as less new than revisionary, aiming to reinstate something of the more generous purview of musical interpretation as practised in the middle of the nineteenth century. Indeed one of the vehicles of the 'new' musicology was the revival of a self-styled hermeneutic criticism tacitly modelled on the nineteenth-century version.[5] Leo Treitler has made the acid observation that such criticism is 'not different in form or verisimilitude from the sort of nineteenth-century hermeneutic that interpreted Beethoven's Ninth Symphony in images drawn from Goethe's *Faust*' (Treitler 1999, p. 370).[6]

There is a crucial difference, however, for the 'new' musicological revival of hermeneutics was supplemented by a strain of social critique deriving primarily from the work of Adorno. It was most conspicuous in the work of Susan McClary, who gained a great deal of notoriety through her critical interpretations of the war-horses of the symphonic repertory: most famously, she likened parts of the Ninth Symphony to a rapist's murderous fantasy (McClary 1991, pp. 128–9), contrasting what she saw as the violent and misogynous emotions expressed by Beethoven's music with the altogether more accommodating and socialized expression found in the music of the contemporary but (arguably) homosexual Schubert. One might see this as a frivolous or mischievous application of traditional hermeneutical procedures, involving the construction of a clearly unhistorical compositional persona (and McClary has been criticized on precisely these grounds). But that is to miss her substantial point, which is that music serves to express not only personal emotions but also social ideologies, in this case a characteristic attitude to women or, more generally, to sociocultural differences. While many aspects of McClary's work have been subject to critique, the broadened musicological purview represented by her work has been widely accepted. And as a result, the long marginalized topic of musical meaning has become central to the discipline.

3.3 Some classic approaches

As we have seen, one strand which has dominated thinking about musical expression is a reliance on linguistic models. The notion of a shared musical 'language' is particularly

[5] See, for instance, Kramer (1990), along with McClary (1991), one of the key texts of the 'new' musicology; for a brief overview, focusing on issues of gender representation, see Cook (1998a, Chapter 7).

[6] The reference is to the programme note that Wagner drew up for his 1846 performance of the symphony in Dresden.

prominent in baroque music treatises which, influenced by newly rediscovered Greek and Roman doctrines of oratory and rhetoric, provided instruction on how the composer was to 'move' the 'affections' or emotions of the listener.

A primary aesthetic goal in baroque music was to achieve stylistic unity based on the representation of a single emotion—a phenomenon exemplified by the da capo aria, so called because its final section repeated the first one da capo, 'from the top'. Affections were conceived as typified and static attitudes of mind, expressed in music through specific figures and compositional techniques identified and discussed in contemporary theoretical sources (one of the earliest was Burmeister's *Musica Autoschediastike* of 1601). The approach derived from the rhetorical concept of *decoratio*, that is, rules and techniques for embellishing the ideas of an oration and infusing it with passion. Applied to music, devices such as melodic repetition, fugal imitation, and the use of dissonance were invoked in order to explain and justify irregular contrapuntal writing, in much the same way that nineteenth-century commentators proposed hermeneutical explanations for the idiosyncracies of Beethoven's style. Gesturing was also part of rhetorical delivery (itself an object of study for politicians, ministers, and actors), and was theorized in the form of treatises on gestures in everyday life, and on rhetorical delivery and opera acting (Fig. 3.1) (Solomon 1989). The

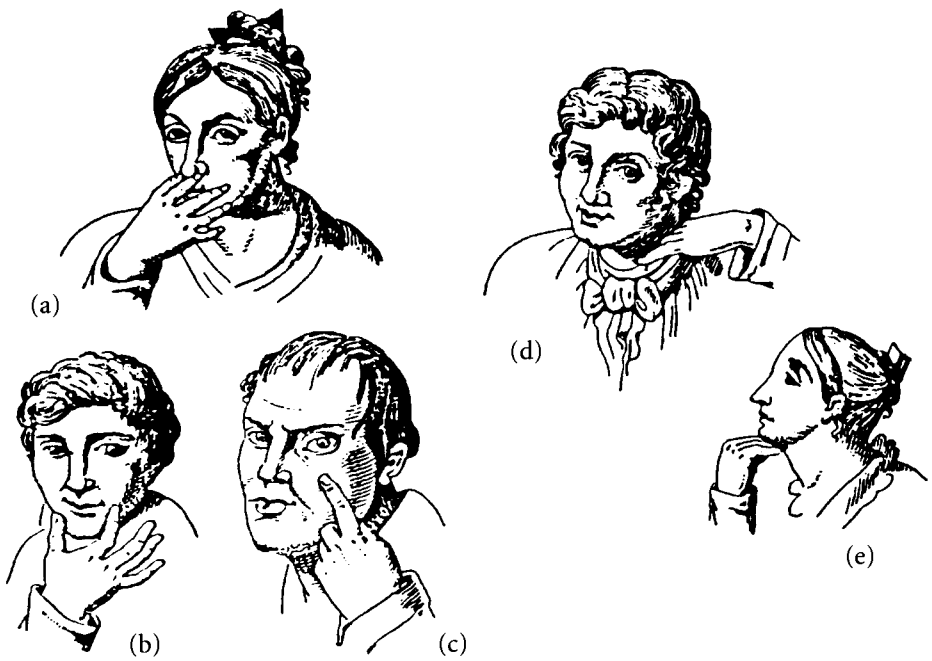

Figure 3.1 Gestures with the hand and face: (a) astuteness, (b) beauty, (c) carefulness, (d) deception, and (e) the negative (from Andrea di Joria, *La mimica degli antichi investigata nel gestire napoletano*, Napoli, 1832, reproduced in Solomon 1989).

precise bodily gestures and movements associated with the representation of specific attitudes of mind outlined in these texts seem perversely static and unreal from the standpoint of nineteenth- and twentieth-century constructions of subjectivity; in the same way, the da capo aria has long been criticized for the artificial nature of its return to the opening, as if emotions could be repeated to order. All this reflects a fundamental shift of conception: whereas the eighteenth-century affection is a rationalized attitude of mind, the nineteenth-century understood emotion as a personal and spontaneous expression or experience. (The listeners of Fig. 3.2, eyes turned away from the performers or head buried in hands, embody the migration of emotion from the outer to the inner world.)

In the later part of the eighteenth century, there was a shift from the earlier emphasis on *decoratio* to a lexicon of affective types or 'topics', as they have been termed by Ratner (1980); this was linked to an increasingly dynamic view of musical expression, whereby a single piece might encompass different emotions, or the transition between one emotion and another. (For contemporary listeners this was one of the most striking and innovatory features of Mozart's operatic arias and ensembles.) Basing his work on contemporary treatises as well as the study of musical texts, Ratner showed how classical compositions evoked, often in kaleidoscopic succession, a more or less fixed repertory of melodic, rhythmic, textural, and other types, each of which had its own specific connotation. Such types might refer, for example, to particular dances (minuet, gigue),

Figure 3.2 Beethoven playing for his friends (lithograph by Albert Graefle, c. 1877).

styles (the 'brilliant' style, the 'Turkish' style), compositional procedures (the 'learned' style), or extramusical associations (the hunt).

This notion of an affective lexicon has been further developed by means of semiotic theory, in relation to both 'art' music (Agawu 1991; Allanbrook 1983) and popular music (Tagg 1982); it has also been interpreted in terms of cognitive theory (Gjerdingen 1988). All such approaches understand expressive meaning as the product of historical usage: music signifies through reference to established syntactical types (the V–I progression and motivic liquidation that encode closure in a Mozart string quartet, say), to other music and its circumstances of performance (the parade ground, for instance, in the case of an orchestral march), or to some kind of extramusical reality. It is crucial to such approaches that these meanings were deliberately employed by composers and understood as such by contemporary audiences. For example, Agawu (1991, p. 31) cites a letter from Mozart to his father in which he discusses his compositional strategy in the opera *Die Entführing aus dem Serail*, and the likely impact of particular features on the audience. Mozart refers specifically to his use of the 'Turkish' style to create a comic effect during the scene in which Osmin expresses his rage, as well as to the use of syntactical features such as a change of key and metre at the end of a particular aria in order to surprise his audience.[7]

Because of the assumption that musical meaning results from historical sedimentation, the application of any given lexical approach of this kind is necessarily restricted to a specific repertory. By contrast, the aim of Deryck Cooke's *The language of music*, first published in 1959, is to provide not only a lexicon of but also an explanatory basis for the emotional meanings of Western 'art' music in general (and perhaps even, as we shall see, for music as a universal phenomenon). In Cooke's words, his book 'attempts to show that the conception of music as a language capable of expressing certain very definite things is not a romantic aberration, but has been the common unconscious assumption of composers for the past five-and-a-half centuries at least' (Cooke 1959, p. xi). He locates his basic expressive lexicon in the tonal and intervallic 'tensions' embodied in specific scale steps and the patterns of motion between them, seeing other musical dimensions such as timbre and texture as 'characterising agents', that is, as merely modifying the tensions established through pitch, time, and dynamics (Cooke 1959, pp. 37–8). He substantiates his theory by citing large numbers of extracts taken from vocal works, the texts of which embody similar expressive meanings. The assumption is that the emotional associations of particular musical formations apply equally when these formations occur in autonomous instrumental music. After going through this process with each of the different scale steps, he draws up a summary of what he terms 'the basic

[7] Such lexicons had a kind of after-life in early cinema history, in the form of the cue sheets, manuals, and handbooks that provided guidance to the performers, usually pianists, who accompanied silent films. These volumes contained both transcriptions from the classical repertoire and originally composed music, categorized according to the narrative situations and emotions engendered by it (see also Cohen, this volume). One of the earliest anthologies (*Motion picture piano music: Descriptive titles to fit the action, character or scene of moving pictures*, cited in Marks 1992, p. 68) contains 51 short pieces with titles such as 'Aged Colored Man, Aged Persons, Ancient Dance, Andante, Antique Dance, Apparitions', listed alphabetically.

expressive functions of all twelve notes of our scale', beginning as follows (Cooke 1959, pp. 89–90):

> *Tonic:* Emotionally neutral; context of finality. *Minor Second:* Semitonal tension down to the tonic, in a minor context: spiritless anguish, context of finality. *Major Second:* As a passing note, emotionally neutral. As a whole-tone tension down to the tonic, in a major context, pleasurable longing, context of finality. *Minor Third:* Concord, but a 'depression' of natural third: stoic acceptance, tragedy. *Major Third:* Concord, natural third: joy'

Philip Tagg's (1982) application of semiotic theory to popular music is reminiscent of Cooke's approach in both concept and method. He identifies a range of signs in popular music, equating particular emotions, moods, and meanings with particular harmonies, melodies, timbres, and so forth, and referring to them as 'musemes' or minimal units of musical meaning; the term is based on 'phoneme', and is thus a further illustration of the indebtedness of theories of musical emotion to linguistic models.[8] Tagg verifies his interpretations in two ways. The first of these is what he calls 'inter-subjective comparison', by which he simply means establishing the consistency of attributions of meaning to the same music played to different respondents. The second and better known is what he terms 'inter-objective comparison' (IOC): this means the substitution for a given museme of others drawn from comparable expressive contexts, especially ones involving words, in order to confirm their semantic equivalence. (Again the reference to texted music provides a link with Cooke's method.) Tagg demonstrates his theory through the detailed analysis of specific pieces of music, the most extended examples being his analyses of the *Kojak* TV theme tune and the Abba hit *Fernando.* The readings that result are more complex than Cooke's in that they do not simply bring to light emotional contents but attempt to define an attitude towards the ostensible meaning of the lyrics: in the case of *Fernando,* for instance, Tagg concludes that the music gives the lie to the revolutionary sympathies expressed by the words.

There are a number of criticisms which can be levelled equally at Cooke and Tagg.[9] One is that both their methods are heavily dependent upon extramusical aspects, particularly accompanying lyrics or other programmatic elements. Although such elements are obviously important where present, how do we know what happens in music from which they are absent and the connotations of which are therefore less clear (Middleton 1990, p. 234)? How confident can we be that what applies in the one case applies in the other? (Does music derive its emotional meanings from purely historical associations with certain texts, or were those texts associated with the music because of some

[8] Tagg's concept of sign, however, is broader than Cooke's: as well as 'style indicators', which refer to compositional 'norms', and 'genre synecdoche', referring to a 'foreign' style and hence to the genre and culture to which it belongs, Tagg identifies 'anaphones', which share a structural homology with the sonic, kinetic, or tactile events that they signify, and 'episodic markers', which designate structural functions (Tagg 1992).

[9] See, for example, Middleton (1990), Davies (1994, with many references), and Shepherd and Wicke (1997). Scruton (1997, pp. 203–8) offers a trenchant critique of the parallel between music and language implicit in Cooke's approach.

emotional quality inherent in the music?) Related to this is an objection which applies to all lexical approaches to musical meaning: the emotional or other signification of musemes may vary according to the musical contexts within which they are articulated (in other words, it may not be possible to draw so confident a distinction between the 'semantic' and the 'syntactical' aspects of music).[10] Lexical approaches, in short, may endow the music with a false semblance of semantic fixity.

Other criticisms apply to one method but not the other. For example, one problem with Tagg's IOC technique is that it is so laborious, if it is to be done properly, as to verge on the impractical. As Allan Moore (1993, p. 158) puts it, 'it is so time-consuming that I have never seen it properly undertaken in equivalent studies' (other than by Tagg, that is to say). Again, Tagg has been criticized for drawing comparisons between contemporary popular styles and the European 'art' repertory, so implicitly assuming that they form part of a common cultural tradition (Middleton 1990, p. 234). This may be a reasonable assumption in the case of some film and television music: several commentators have traced the appropriation of semantic elements from late nineteenth- and early twentieth-century 'art' music by the Hollywood film industry (Eisler [and Adorno] 1947; Flinn 1992). Analyses of popular music also sometimes reveal the influence of 'art' traditions. An example is Walser's linkage of heavy metal music with the ideologies and even some of the performance practices of nineteenth-century Romanticism (Walser 1993). However, it would be clearly wrong to claim that traditions such as blues, rock, rap, or dance music derive primarily from 'art' music. So it becomes necessary to define just what the relevant frame of reference is for any particular repertory or piece, and that of course raises questions of who is doing the defining and to what ends. Nor is that the only problem. If you set out to identify the different stylistic traditions within which different musemes operate, how are you going to decide where to stop? (Are there specific musemes applicable to popular music? Or to pop but not rock? Or just to dance music? house? garage? jungle? Bristol jungle?)

Such problems may not be insoluble in principle, but they are certainly hard to solve in practice. In such a context, there is something very tempting about Cooke's attempt to derive the emotional expression of music directly from natural principles. As we have seen, he explains expression in terms of intervallic tensions, and he explains intervallic tensions in terms of basic acoustic principles, specifically the overtone series. 'That the major third should be found to express pleasure should surprise no one', he writes, since it appears 'early on in the harmonic series: it is nature's own basic harmony, and by using it we feel ourselves to be at one with nature' (Cooke 1959, p. 51). He admits that tradition builds on tradition, that is, that there is a historical element in musical meaning, but he insists that traditions arise in the first place because of the natural principles built into the music (Cooke 1959, pp. 40–1); for him, then, there was emotional mean-

[10] Cf. Jenefer Robinson's criticism (also voiced, for example, by Anthony Newcomb) that 'most philosophical theorists of musical expression have either ignored or underemphasized . . . the fact that the musical expression of complex emotions is not a function of a few isolated measures here and there, as in Kivy's examples in *The corded shell*; rather it is very often a function of the large-scale formal structures of the piece as a whole. We cannot understand the expression of complex emotions in music apart from the continuous development of the music itself' (Robinson 1998, p. 19).

ing in music before texts were associated with it. And, of course, principles like the overtone series do not vary from one culture to another. It is in this sense that, although limiting his examples to Western 'art' traditions, Cooke implicitly sets out a universal model of emotion in music: the laws of nature apply in China and in Africa as they do in Europe and America, and therefore the same principles should govern musical expression. Such thinking has become deeply unfashionable, because of its potentially essentializing and ethnocentric nature, and few present-day scholars would probably be prepared to sign up to this aspect of Cooke's theory. (Approaches to emotion and meaning in the ethnomusicological literature, while falling outside the scope of this chapter, are almost invariably rooted in the 'thick' description of specific cultures and contexts.[11]) Perhaps the most telling symptom of Cooke's ethnocentricity, however, lies in the way in which he unquestioningly identifies meaning with the expression of personal emotion—in which he understands it, in short, in terms of bourgeois subjectivity. A strong argument could be made that Cooke's approach, valid as it may be for Schubert or Schumann, is misleading in relation not just to Chinese or African music, but to Monteverdi's and Handel's too.

Despite the difficulties to which we have referred, Cooke's work was important in placing emotion firmly within the musicological agenda, and in attempting to do so on a principled basis. Much the same might be said of Leonard B. Meyer (1956), whose first book, *Emotion and meaning in music*, appeared 3 years before Cooke's (indeed, Kivy has described it, perhaps rather sweepingly, as 'the book that taught many of us for the first time that you can talk about music without talking nonsense' (Kivy 1987, p. 153)). Whereas Cooke attempted to ground the emotional expression of music in natural-scientific principles, thereby as it were short-circuiting cultural mediation, Meyer drew upon a range of sources in psychology. His overall interpretation of musical structure, which he has continued to develop in the ensuing 40 years (cf. Meyer, this volume), is based on gestalt principles: listeners are drawn to perceive musical patterns as wholes, as tending towards closure, and compositional techniques can be understood as ways of both stimulating and challenging such perceptions. In essence, Meyer sees music as setting up expectations in the listener (or, to put it another way, implications in the music) which are in general fulfilled or realized, but often only after postponement or apparent diversion. It is here that Meyer's approach to emotion comes in. The basic principle, which Meyer also drew from contemporary psychology, is that 'Emotion or affect is aroused when a tendency to respond is arrested or inhibited' (Meyer 1956, p. 14). To take a very simple example, a dominant seventh chord implies resolution; the longer resolution is postponed the more affect will be created, and if when it comes the resolution is to *vi* (an interrupted cadence), further postponing the return to *I*, there will be a further heightening of affect. Because the implications created by any given piece of music, and the manner in which they are or are not realized, fall clearly within the domain of structural analysis, the result is that emotion is incorporated within the latter. In effect, the analysis of musical emotion plugs into that of musical structure.

[11] For representative examples—one chapter-length, one book-length—see Tolbert (1994) and Feld (1982). See also Becker (this volume).

For all its neatness, however, this approach creates a number of difficulties. One concerns the relationship between emotions as normally understood—hope, joy, grief, and so on—and the kind of undifferentiated affect or feeling tone (in effect a unidimensional variable) that Meyer's theory predicates. Some commentators have doubted whether Meyer's theory can properly be considered as pertaining to the emotions at all (e.g. Budd 1985). Davies (1994, p. 288), by contrast, observes that 'for Meyer the possibility of the listener's differentiating the feeling tone is a real one', and he elaborates and justifies Meyer's position by arguing that the feeling tone can itself take on a kind of mimetic function:

> There are, within any culture, groups of emotions having a common pattern of behavioral expression. For instance, the dynamics of the behavioral expressions of sadness, grief, disappointment, and regret are similar and can be distinguished from the behavioral expressions of joy, happiness, and enthusiasm. Music can be heard as imitating the dynamics of behavior. As listeners we hear these dynamics and imagine that the music is through them expressive of, say, sadness. In so doing we (imaginatively) make the music the emotional object in terms of which our feeling tone can be differentiated.

In saying this, Davies is invoking the Hanslickian idea that feelings are characterized by specific dynamic qualities. As we saw above, Hanslick argues that music cannot specify love, but through its motional qualities it can specify such adjectival properties as the joyful or sorrowful quality of love. In effect, Davies is suggesting that Meyer's undifferentiated affect conveys such adjectival properties, which we are led to attribute to the music itself (that is why it is common, if arguably misleading, to talk of the music being happy or sad, as if it were a sentient being). Since Hanslick's day the idea that music expresses emotion through somehow mirroring the dynamics of our inner life has become a commonplace in writing on the topic; the classic formulation is Langer's claim that 'there are certain aspects of the so-called "inner life"—physical or mental—which have formal properties similar to those of music—patterns of motion and rest, of tension and release, of agreement and disagreement, preparation, fulfilment, excitation, sudden change, etc.' (Langer 1942, p. 228).[12] When we said that music 'somehow' mirrors the dynamic of inner life, however, we meant to signal a crucial vagueness in such thinking: without entering into details, the problem lies in specifying what sort of entity the 'dynamics of our inner life' might actually be, or how it might be measured. In the absence of adequate answers to these questions, the appeal to such impalpable dynamics has little explanatory force.

A second line of criticism is that Meyer's approach is too narrow and exclusive. Davies, for instance, complains that it 'overemphasizes the status of the unpredictable at the expense of the structural significance of similarity' (Davies 1994, p. 289), while Keil (1994) similarly complains that it ignores the significance of repetition and performance skills. Underlying these complaints is a suspicion that, through incorporating them within a psychologically based theory, Meyer is lending a spurious

[12] Davies (1994, pp. 123–4) offers a critique, along with an extensive though by no means complete listing of similar claims by other writers (p. 230, n. 33). The basic approach, of course, links with earlier ideas of music 'moving' listeners' affections.

generality to principles grounded in the modernist aesthetic, with its valorization of innovation and the unique. This charge would be not altogether fair, because the link he makes between psychological principles and musical meaning is not a simple or direct one. For one thing, Meyer recognizes the extent to which listeners' expectations reflect not only the properties of the musical stimulus but also the culturally specific stylistic codes that are acquired through enculturation. For another, he took pains to explain on the very first page of *Emotion and meaning in music* (1956) that the kind of musical meaning we have so far discussed is not the only one: he distinguishes 'embodied' meaning, which is the result of the realization or frustration of expectation, from 'designative' meaning, which involves reference to objects, concepts, or events outside music (a distinction corresponding to Jakobson's 'introversive' and 'extroversive semiosis'; see Jakobson 1971, pp. 704–5), emphasizing that the latter reflects not just culture-specific associations but the listener's personal experiences and disposition, too. Nevertheless, embodied meanings play a far larger role in Meyer's work than designative ones, and it is not hard to see why, for his theory *explains* musical meaning (rather than simply acknowledging its existence) only to the extent that it can be reformulated in terms of relationships between musical elements. Or to put it another way, explaining meaning means translating it into music-structural terms; it is a one-way process. There is something symbolic in the fact that Meyer's first book is the only one he wrote specifically about musical emotion and meaning, the others all focusing on issues of structure and style.

3.4 Structural and expressive vocabularies

The basic problem we have diagnosed in Meyer is that of talking about both the emotion and the music in a sustained manner: you may start off talking about the emotion, but you seem to end up talking about the music in more or less the usual way. Of the admittedly limited amount of musicological or music-theoretical work in this area since 1956, much is open to the same criticism. So it is of interest to consider a more recent critique of such work by a professional philosopher (Kivy 1993). Kivy takes as his starting point a critical reading of Schumann's Second Symphony by a writer loosely associated with the early stages of the 'new' musicology (Newcomb 1984). Newcomb's essay is a good example of the revival of a hermeneutical approach to which we previously referred, and indeed sets out to reconstruct a nineteenth-century perception of Schumann's symphony (which was more highly rated in its own time than is generally the case today). Newcomb attempts to achieve this through consideration of the expressive trajectory of the piece, which he characterizes as 'suffering leading to healing or redemption', and relates these emotional characteristics to the difficult circumstances of Schumann's life as he sketched the work. He also points out that many other compositions from around the same period exhibit a similar trajectory (an example to which we have already referred being the 'transmutation of suffering into joy' in Beethoven's Ninth Symphony), and suggests that we might think of this as a 'plot archetype', in other words a generic category in terms of which individual instances may be understood.

Kivy (1993) applauds Newcomb's aims (indeed he sees in them the seeds of a 'new music criticism'), but identifies what he sees as serious methodological failings. In

particular, Kivy objects that Newcomb is trying to add an additional, interpretative layer to structural analysis, whereas the whole project of interpreting autonomous instrumental music is built on a fallacy. 'Pure' music cannot represent anything, Kivy claims, and therefore the symphony cannot contain the meaning Newcomb ascribes to it; in other words, as soon as Newcomb started talking about Schumann's biography, he stopped talking about the music. (As a musicologist rather than a philosopher, Newcomb might very well reply that nineteenth-century listeners clearly *did* interpret the music in just this way, and that the question of whether they were philosophically justified in doing so is irrelevant to an exercise in historical reconstruction.) But in that case, you might ask, how *are* we to build emotional expression into music criticism? Kivy (1993, p. 316) replies:

> The new way is not to amplify criticism by adding interpretation to analysis but, rather, by amplifying analysis itself. For once one ceases to see expressive properties of music as semantic or representational properties, it becomes clear that they are simply *musical* properties: they are phenomenological properties of music, and as such a proper subject of musical analysis.

In other words, he is saying, when we analyse music we should analyse its expressive properties alongside its structural ones. And he offers some examples of what he has in mind. In Mozart's 'Dissonance' Quartet, he says, the relationship between the dark, anguished character of the introduction (which gives the quartet its soubriquet) and the light, sunny character of the allegro that follows creates an effect of strong, expressive resolution; take away the expression and you weaken the resolution. Or again, there is an expressive difference between a Haydn symphony movement that goes from tonic minor to relative major to tonic minor (that is, from dark to light to dark), and one that ends in the tonic major (so that its overall trajectory is from dark to light). Because these are directly experienced aspects of the music, Kivy concludes, 'an analysis . . . that leaves out the expressive contrast, is incomplete in a musically non-trivial way' (1993, p. 319). But does this solve the problem of how to talk about both the music and the emotion in a sustained manner? The answer turns on whether Kivy has identified expressive properties as distinct from structural ones, or whether he is simply talking about structural properties but giving them expressive names. In the Mozart case, is the effect of resolution created by the passage from dark to light actually different from that created by the passage from the dissonance of the opening to the diatonicism of the main movement? Or are these just different ways of talking about the same thing? (If so, then in what sense are you leaving out the expression in speaking only of dissonance and diatonicism?) Again, in the Haydn case, just what does it mean to speak of the passage from dark to light over and above what it means to speak of the passage from minor to major? If the conclusion is that the one terminology can be simply substituted for the other, then there must be a suspicion at least that Kivy's 'new music criticism' is just the old music criticism with an updated (some music theorists might say outdated) vocabulary.

Of course, it might just be that Kivy applies his expressive terminology in too literal a manner. That, at any rate, is suggested by the comparison with another study, this time a collaboration between a philosopher and musicologist, which interprets Shostakovitch's Tenth Symphony as 'a progression from dark to light or struggle to victory' (Karl &

Robinson 1997, p. 166). In using these terms, the authors are not referring to anything as simple as a major or minor mode, or dissonance versus consonance. They are referring to the composite properties of a complex musical structure, and, indeed, their main purpose is to show how the large-scale musical unfolding of the third movement is central to the construction of its expressive message, which they see as one of hope (and more than that, false hope). While their argument begins with structural analysis and ends with expressive analysis—the same sequential approach that Kivy criticized in Newcomb—it would not be fair to describe Karl and Robinson as simply building expression onto structure, like icing on a cake. The very characterization of complex, large-scale passages as 'light' or 'dark' stimulates the attempt to explain these expressive qualities in terms of the music's structural properties; again, the authors set out what they call the 'cognitive content' of hope (which involves looking forward to, and striving towards, a happier but uncertain future) and then match the structural properties of the music against these criteria, in effect using them as an analytical framework. In this way their interpretative strategy involves what they describe as 'a complex interplay among a variety of different sorts of observations' (1997, p. 170), both formal and expressive. There is, however, a certain ambiguity at this point. On the one hand, the authors write that 'we consider this dichotomy [between the formal and the expressive] ill-conceived, because often the formal and expressive threads of a work's structure are so finely interwoven as to be inextricable' (1997, p. 176). On the other, they claim that 'the formal and expressive elements of musical structure are so thoroughly interdependent that the formal function of particular passages can often be accurately described only in *expressive* terms' (1997, p. 177). The second statement seems to start by saying the same as the first but to end up saying the opposite: if you can describe a particular passage in expressive but not structural terms, or for that matter vice versa, then this seems to reinstate the dichotomy between them (an implication which becomes still clearer when the authors continue 'there is no 'strictly formal' or purely musical explanation for why our focal passage unfolds as it does in the central section of the third movement').[13] The relationship between structure and expression remains unclear.

This issue has been explicitly addressed by another musicologist, Fred Maus. In an article entitled 'Music as drama' (Maus 1988), he launches a systematic attack on the sequential, structure-to-expression approach, and then proceeds to offer an analysis of the opening of Beethoven's String Quartet, Op. 95, combining analytical and expressive

[13] Karl and Robinson make a related point in a footnote on p. 173, where they explain that 'a listener schooled in the epic symphonic tradition might expect that the tension of the third movement should be swept away at the beginning of the finale ... Upon finding this expectation frustrated, he or she may then feel tense, impatient, or bewildered ... The listener's feelings of impatience or frustration, while poorly mirroring the expressive structure of the work, may nonetheless provide the initial clues that something is amiss ... providing an impetus to interpretation'. In this way the frustration of expectation which Meyer saw as the source of affect functions as an interpretative cue: implicit in this is a distinction between the listener's emotional response and the expressive properties of the music *per se*. (This distinction bulks large in philosophical writing on the subject, particularly Kivy's, but falls outside the scope of this chapter.)

vocabulary and commenting self-consciously on his analytical strategies as he does so.[14] The conclusion that Maus draws from this analysis—as much an analysis of analysis as of Beethoven—is that music has neither structural nor emotional content. Rather it consists of a series of *events*, which we make sense of by regarding them as the *actions* of imaginary agents, so attributing intentions or motivations to them. His Beethoven analysis, Maus claims, '*explains* events by regarding them as *actions* and suggesting *motivation*, *reasons* why those actions are performed, and the reasons consist of combinations of psychological states' (1988, p. 67). It is this imagined dramatic content that both structural and expressive vocabularies seek to represent, each in their own way: as Maus (1988, p. 69) explains,

> the technical language and the dramatic language offer descriptions of *the same events*. That event at the opening of the quartet, according to the analysis, is an outburst and it is also a unison passage with an obscure relation between metrical hierarchy and pitch hierarchy. The technical vocabulary of the analysis describes the actions that make up the piece.

While referring to the same musical content, then, the two vocabularies construct it in different ways, filter it differently, and the analyst can exploit the asymmetries between them in order to gain purchase on the music. It is for this reason, presumably, that Maus observes that 'Both sorts of description—"technical" or music-theoretical, "dramatic" or anthropomorphically evocative—belong, interacting, to the analysis' (1988, p. 63), and Robert Hatten uses the same word when he writes of 'the interaction of expressively significant . . . thematic, motivic, or topical events with structurally significant voice-leading events' (Hatten 1994, p. 320, n. 8). Hatten's book is, to date, the most comprehensive attempt to incorporate expressive and structural analysis within a coherent critical practice, and it brings together many of the approaches we have described so far. As his reference to topics suggests, Hatten builds on the documentary evidence that historical listeners (his book focuses on Beethoven) not only identified topical references in the music they heard but also saw them as one of the main ways in which it conveyed emotional or other meaning; to this extent Hatten's work, like Agawu's, links with the tradition of understanding emotion as a public, rationalized state, which as we have seen goes back to the baroque affections. Unlike Agawu's work, however, Hatten's also embraces nineteenth-century conceptions of emotion as a private, subjective experience, and indeed the book is easily read as a contribution to the hermeneutic tradition (like Newcomb, Hatten claims to be reconstructing historical practices of listening, and his concept of 'expressive genre' corresponds closely to Newcomb's 'plot archetype'). More centrally, it brings together extroversive and introversive approaches within a unified theoretical framework drawn from present-day semiotic theory. The question on which we wish to focus, however, is the extent to which Hatten succeeds in theorizing the interaction between structure and expression to which he refers.

The immediate impression of Hatten's working procedure is that, once again, he starts with structural analysis, and then adds in the interpretation. The first ten pages of his analysis of the first movement of the Quartet, Op. 130, for instance, consist of structural

[14] For detailed discussion of the relationship between structural and expressive vocabularies in critical writings which draw analogies between music and narrative, see Maus (1997).

analysis, while the final page offers an expressive interpretation in terms of a quasi-Hegelian synthesis of opposed emotions (Hatten 1994, pp. 134–45). And while he does sometimes begin with a provisional and intuitive identification of the music's expressive content, following this with structural analysis and then a refinement of the expressive interpretation based on that analysis, it is significant that Hatten never goes on to the next stage (that is, returns to and refines the structural analysis on the basis of the expressive one). To this extent the relationship between structure and expression is still an unequal one: as usual in musical analysis, the cards are stacked in favour of structure. In other contexts, however, such as his account of the *Cavatina* from the same quartet, Hatten's treatment is more even-handed. He makes use of vocabulary that applies equally well to structure or expression (undercutting, irruption, or reversal, for example). He mingles structural and expressive vocabulary (1994, p. 213):

> A strong wedge motion in m. 5 expands registrally to the apex on the downbeat of m. 6, which is negated as a climax by the more intensely expressive crux created by the unexpected reversal (registral collapse) on the second beat. The 'willed' (basically stepwise) ascent takes on a hopeful character supported by the stepwise bass'.

At other times, he offers parallel structural and expressive interpretations; on p. 214 he writes of bar 12 that 'As the vi region of E♭ major, C minor would appear to be an appropriate choice in light of the harmonic emphasis it has already received in m. 6. The region could also be motivated by the expressive value of the relative minor as an emotionally troubled opposition to the serenity of the major'.

But most revealing is the way in which he stresses what, in 'purely musical' terms, might be seen as points of abnormality or incoherence, and siezes upon them as interpretative opportunities. For instance, he says of the repeated iv^7 chords on the second beats of bars 15 and 16, following anomalously on cadential six-four chords, that they support (1994, p. 215)

> a construal as 'parenthetical' or outside the normal course of time, thus akin to 'insight' in that it comes without logical necessity or sequential train of thought . . . Interactively interpreting these inflections of meaning, one might understand the resulting trope as 'tragically weighted insight or reflection, expanding an instant that seems frozen within the flow of time'.

Expanding the same principle to the scale of the movement's formal unfolding, he provides a figure showing 'unconvincing formal analyses' (1994, p. 209, Fig. 8.1): the very incoherence of the movement when understood in purely formal terms becomes a source of its overall expressive meaning, which Hatten sees as a kind of metaphorical blend of tragic insight and faith, each illuminating the other. In this way, expression is not seen as simply a gloss on structure; it works in counterpoint with it.

Writers such as Karl and Robinson, Maus, and Hatten demonstrate that it is possible to use structural and expressive vocabularies together in a way that does not simply map the one onto the other, in the manner of Kivy's 'new music criticism'. It might be going too far to say that any of them succeeds in talking in a sustained manner about both the music and the emotion (even Hatten sometimes gives the impression of lurching from one to the other). But they manage to do so in flashes, and the result is illuminating.

3.5 Conclusion: discourse and emotion in music

In the work of some writers, the distance between technical and 'anthropomorphically evocative' interpretation, to borrow Maus's phrase, becomes much greater. A good illustration is provided by a pair of curiously similar essays: by Charles Fisk on the first movement of Schubert's Sonata in B♭ major, D. 960 (Fisk 1997), and by Marion Guck on—among other things—the second movement of Mozart's G minor Symphony, K. 550 (Guck 1994). Each begins with a single, portentous moment in the piece:[15] the left hand trill in the seventh bar of Schubert's sonata, and the C♭ in bar 53 of the symphony movement. And each constructs out of this moment a similar story: that of an alien element, an 'outsider' who after a succession of vicissitudes becomes accepted within the larger context represented by the piece—is accepted, in other words, as an 'insider'. The link that each author makes between music on the one hand, and on the other the narrative of rejection and acceptance, alterity and assimilation, builds on the expressive properties of the music and at the same time brings new expressive properties, new connotations of positive or negative emotion, to bear upon it. Neither author, of course, is claiming that the original music was in any sense 'about' immigration. Like Newcomb in the case of Schumann's Second Symphony, and Karl and Robinson in the case of Shostakovitch's Tenth, Fisk invokes the circumstances of Schubert's life to add credibility to, or at least to deepen, his interpretation: maybe, he says, the (again arguably) homosexual Schubert felt himself to be an outsider in his own society and so 'took solace, at least unconsciously' from his own parable of integration (Fisk 1997, p. 200). Whereas Karl and Robinson give the impression of speaking from a position of interpretative authority, however ('Shostakovich, ever mistrustful of happy endings, undercuts its optimistic qualities' (Karl & Robinson 1997, p. 178)), Fisk claims to be doing no more than telling a story, offering 'a naively poetic description of what happens in the music' (Fisk 1997, p. 195), and the personal and provisional nature of his interpretation is highlighted in the title: 'What Schubert's last sonata might hold' (further glossed, on the final page of the article, as 'what Schubert's last sonata holds for me'). Guck similarly introduces her account as 'a story about C♭' (Guck 1994, p. 67).

Then what, you might ask, is the point of all this? Fisk tells his story in order to substantiate an argument that every listener projects his or her own emotional experiences into the music, which in turn moulds those experiences so that they become in some sense purely musical emotions (Fisk 1997, p. 182). The limitation of his approach, however, is that he begins with technical analysis, goes on to unfold his narrative (showing how it can be fitted to the framework of the analysis)—and then stops. Guck, by contrast, structures her article through a process of oscillation between technical and expressive interpretation. She begins with her perception of the C♭'s portentousness, an observation which (as she puts it) 'incorporates a conceptual structure that is covert' (Guck 1994, p. 71). The purpose of constructing the parallel narrative, she continues, is that 'the conceptual structure of the immigrant's tale is revealed in the process of its telling'; in other words, the story renders the structure explicit, and so initiates the

[15] Both authors use this word 'portent'/'portentous': Fisk (1997, p. 184) and Guck (1994, p. 63).

process of answering the analytical question '*why* is the C♭ portentous?'. But to complete the answer it is necessary to return to the text, to the plane of technical analysis, understanding and experiencing the music in light of the narrative: as Guck puts it, her story 'suggests a strategy for hearing not only the highlighted events but also the lines of development in which they participate, which is to say that it provides a means of codifying and enriching the hearing of the whole piece' (1994, p. 71). The point of the analysis, in short, is not just to describe how you experience the music, but to *change* how you experience it, both in technical terms and emotionally.

It is not only Fisk's and Guck's analyses which do this. We mentioned above that Hatten presents his work as, in essence, an exercise in the reconstruction of historical listening practices. However, this is not the only nor necessarily the most productive way of reading it, and indeed Hatten does not embark upon the systematic kind of historical reconstruction of period perception, based on contemporary documentation, that has been attempted for instance by Johnson (1995). The alternative is to read Hatten's work as a sustained argument about how we might most fruitfully hear Beethoven's music today. Understood this way, Hatten's book becomes an attack on the etiolated listening practices brought about by what he refers to as the 'errors of formalism' (Hatten 1994, p. 228); by contrast, he is offering a richer, more complex, more human way to hear the music, and one which (as a bonus) perhaps recreates something of the manner in which Beethoven's first listeners heard it. Another way to express this is that it is not simply a matter of hearing emotions out of the music—that is, hearing the meanings that were always there within it—but, so to speak, of hearing them *into* it. Understood this way, analytical and critical practices are less concerned with how the music *is* than how it might be heard to be; they aim less at proof than at persuasion (as Guck puts it, 'Truth is replaced by the plausibility of the narrative'; 1994, p. 72). This is the basis of what we term a 'performative' approach to music and expressive meaning.[16]

There is a sense in which writing about music has always been performative, and one of the most common ways of misinterpreting the documents of music history is by reading them as descriptions of actual practice rather than interventions in it. This is obvious in the case of the treatises of the baroque and classical periods, which prescribed how their readers were to compose, perform, or understand music (and in some cases the music they were to compose, perform, or understand, too).[17] Equally, musicological knowledge can shape perceptions: Spitzer (1987) has shown how divergent accounts by different critics of the same piece of music (*Sinfonia Concertante* in E♭,

[16] The concept of the performative derives from speech act theory (Austin 1962) and is particularly influential in performance and gender studies (see, respectively, Schechner 1988 and Butler 1990). Central to it is the idea that meaning is constructed through performative acts: whereas the meaning of 'the sky is blue' is referential (it refers to an external reality), when you say 'I promise' you are not referring to something but actually *doing* it by virtue of what you say. The term therefore has no direct link with performance in the musical sense (which is not to say that performative approaches do not have much to offer the study of musical performance).

[17] For an example of the role of performance pedagogy in the construction of musical experience, see Blasius (1996). Blasius argues that, along with other discursive domains, early nineteenth-century piano method is a realization of the eighteenth-century project to systematize affect and rhetoric.

attributed to Mozart) are not simply due to differences in taste, but reflect debate over the work's authenticity. (Not only do critics tend to write more positively when they think the music is by Mozart, Spitzer found, but they tend to focus on the same passages and use the same metaphors in describing them.) And one might equally claim that, to misquote Judith Butler, all the approaches to musical emotion outlined in the previous sections have helped to bring about the very responses and practices which they purport to describe.[18] Or to use the language of social constructionism, discourse about music (by which we mean principally, but certainly not exclusively, verbal discourse) actively constructs rather than simply reconstructs its expressivity. The very act of saying that a certain piece of music is expressive in a certain sort of way leads you to hear it that way, and so one can think of dominant interpretations of particular compositions (Tovey's interpretation of the first movement recapitulation of the Ninth Symphony as the embodiment of cosmic catastrophe, for instance, or for that matter McClary's interpretation of the same passage in terms of a rapist's fantasy) as exercises in the creation and not merely the reporting of expressive meaning.

There was a strong awareness of the performative value of criticism among certain writers associated with the 'new' musicology (in particular, Kramer and Abbate[19]). More generally, and reflecting parallel trends in cultural studies, the ethnomusicologist Philip Bohlman (1993) argued in his significantly named article 'Musicology as a political act' that the discipline as a whole is as much involved in the generation as the analysis of the values and meanings that are ascribed to music. Attempts to develop explicit theoretical models for the attribution of meaning to music, however, are a more recent development and arise out of a promising intersection of music theory, psychology, and cognitive science. Zbikowski (1999), for instance, has drawn on conceptual blending theory (itself representing the intersection of linguistics and literary theory) in order to analyse three separate settings of the same poem, Müller's *Trockne Blumen*. Without entering into details, the basic idea is that there are aspects of shared structure (what Zbikowski calls a 'common topography') between the words and the music, which enables us to map the one onto the other as we listen to the song.[20] The result is a blending of the attributes of each, which gives rise to emergent meaning—meaning, that is, which is not present in either words or music separately but arises out of their interac-

[18] '[Gender] identity is performatively constituted by the very 'expressions' that are said to be its results' (Butler 1990, p. 25).

[19] See, in particular, Kramer (1990) and Abbate (1991). More recently, Monson (1996) has applied the same principle to the analysis of jazz performance, arguing that 'emotion is constituted or constructed through social practices . . .. Music, it seems to me, is a particularly powerful constructor of emotion . . . a powerful activity that can produce a 'community of sentiment' binding performers and audiences into something larger than the individual' (p. 178).

[20] The analysis involves the creation of a graphic diagram or 'conceptual integration framework' (CIN) which shows four interrelated 'spaces'. These are the 'text space' and 'music space', which show the corresponding features on which the mapping is based; the 'generic space', which indicates the dimension within which it takes place; and the 'blended space', where attributes of the text and music spaces are combined to create new meaning. For further explanation of CINs, which derive from the work of Mark Turner and Gilles Fauconnier, see Zbikowski (1999, pp. 310–14).

tion. In this way the emotional associations of the words are transferred to the music: as Zbikowski says, 'We can easily imagine outward physical expressions of the miller's torment—facial contortions, hand wringing, pacing—mirroring his internal conflict' (1999, p. 309). The point is that these become as much properties of the music as of the words,[21] so that once again there is a sense in which we are talking about emotional content even as we analyse musical structure. Up to now such approaches have been principally applied to the analysis of multimedia texts (Cook 1998b builds a general theory of multimedia on a similar basis), but there is no reason why this should be the case: you can equally well use them to compare Tovey's and McClary's interpretations of the first movement recapitulation of the Ninth Symphony, demonstrating the manner in which each interpretation creates new meaning (Cook, forthcoming). Used this way, the conceptual blending approach reveals how meaning is constructed through the interaction between musical texts and the invisible web of discourse, ranging from books and CD liners to television and concert-interval chatter, that surrounds them.

Coming from a different direction but converging with the conceptual blending approach is another, drawn this time from psychology—specifically, from James Gibson's (1979) 'ecological' approach to perception (which musicologists and music theorists are only now beginning to explore). Traditional approaches to music perception see it as built up in succession from basic elements such as tones, scale patterns, chords, and so on, with expressive or social meaning representing, to repeat our earlier phrase, the icing on the cake. (This corresponds to the sequential approach we have criticized: first analysing the structure, and then interpreting the meaning.) By contrast, the ecological approach seeks to understand perception in terms of its function, that is to say the means by which any organism grasps and interacts with its environment, and from this perspective the semantic properties of any stimulus, including its emotional properties, are just as basic—just as much properties of the music—as any acoustic ones. Emotional properties, in short, are not deduced through interpretation of the music, but directly specified by it. But this does not represent a reversion to earlier ideas that meaning is 'locked into the sounds', to borrow Moore's phrase (1993, p. 157), just waiting to be unlocked by listeners, because meaning emerges from a mutual relationship between perceiver and perceived in which any number of personal, historical, or critical influences come into play. It is this mutual relationship that becomes the object of analysis. As most conspicuously represented by Clarke's (1999) study of subject position in music by Frank Zappa and P. J. Harvey, the aim is very much the same as we have described in the work of Zbikowski: to find a way of talking about music which articulates the emotional properties that keep us listening to it, while at the same time conforming to the requirements for intersubjective intelligibility in the absence of which writing about music becomes a critical free-for-all where anything goes.

New as they may be, at least to musicology, such approaches address an old problem: how to speak about music and emotional meaning at the same time, without changing the subject. In addition, they emphasize the intrinsic reflexivity of critical activity—

[21] This links with Fisk's claim, mentioned in the previous section, that listeners' emotions are so moulded by music as to become purely musical emotions.

what we say about music's meaning contributes to bringing that meaning into being. If the further development of musicological approaches to emotion depends on continued cross-fertilization with other disciplines, then (to misquote Butler again) this book may itself contribute to the very thinking we have attempted to describe.

CHAPTER 4

PSYCHOLOGICAL PERSPECTIVES ON MUSIC AND EMOTION

JOHN A. SLOBODA AND PATRIK N. JUSLIN

4.1 The psychological approach

In the context of a multidisciplinary work, it may be appropriate for us to briefly set out what we consider to be the essentials of a psychological approach, so as to show its distinct orientation, alongside the other disciplines represented here. Yet, we are also mindful of the apocryphal tale of a young colleague of William James who was asked by the master to take an introductory course in psychology while James was away, and thought he would begin by defining psychology, and was still struggling to do that when James returned 12 weeks later!

So as not to delay our treatment of emotion for too long, let alone its intersection with music, we shall confine our remarks on psychology to a set of rather dogmatic statements. We believe that in broad outline they describe what most psychologists do, although there is much dispute over the details, with differing schools and periods placing differing emphasis on the various subcomponents (Leahey 1987). More importantly for the present chapter, perhaps, these statements reflect our own perceptions of what it is to do psychology, of both music and emotion, and form some sort of underlying framework for the material we present here.

1. Psychology is concerned with the explanation of human behaviour. Behaviour includes overt action as well as 'inner' behaviour, such as thought, emotion, and other reportable mental states. It can include behaviour of which the agent is not fully or even partly aware, such as the dilation of the pupils of the eye.

A psychological approach to music and emotion therefore seeks an explanation for how and why we experience emotional reactions to music, and how and why we experience music as expressive of emotion.

2. The explanations sought by psychologists are essentially causal and organismic. They are causal in the sense that they seek both to discover antecedents to the behaviours requiring explanation and uncover or postulate mechanisms whereby the antecedents interact to bring about the observed behaviours. They are organismic in that the primary interest of psychology is in mechanisms which are internal to the organism. External causes, such as historical or social factors, are only relevant to a

psychological framework where, even if only in sketched in principle, there is a route by which these may impact on the internal mechanisms.

In the study of music and emotion, a central aim of psychology is to understand the mechanisms that intervene between music reaching a person's ears and an emotion being experienced or detected by that person as a result of hearing that music. Other important aims involve understanding the roles of emotion in composing and performing music.

3. There are different levels at which organismic explanations can operate. These include the physiological and the phenomenological. A physiological explanation attempts to describe the causal pathway in terms of mechanisms within the nervous system, the endocrine system, and other biological constellations. A phenomenological explanation, on the other hand, attempts to describe the causal pathway in terms of the intentions, meanings, and interpretations that the individual concerned places on his or her own behaviours. There is, however, an explanatory level intermediate between these extremes, which is the core concern of psychology. A term commonly used for this level of explanation is 'cognitive'. Another term is 'computational'. The concern of a cognitive explanation is more in the functional logic of the mechanism (what it does—the 'software') than the precise neural location and instantiation (how it does it—the 'hardware'). However, this is not simply a redescription of the phenomenological level, because some of the most significant advances made by the psychological approach relate to aspects of behaviour which are pre-conscious and therefore could not—even in principle—be incorporated at the phenomenological level.

We shall try to be explicit about the level of explanation that is being used at various points in the psychological arguments that we describe and critique.

4. Psychology is a materialist science. Psychology is materialist because it holds some version of reductionism (or mind-brain identity). Every event describable at a phenomenological level (e.g. an intention) is, at the same time, assumed to be describable as a set of physical events (e.g. a particular constellation of biological events). Psychology is a science because it only allows explanations to survive in the long term when they have withstood repeated, critical interactions with observed data. The organization and interpretation of such interactions are collectively known as 'the scientific method' (Neale & Liebert 1986).

Emotional responses to music are material phenomena whose components are correlated with observable phenomena in law-governed ways. We aim in this chapter to demonstrate the relationships between scientific observations and the development of theory.

5. Whilst psychology operates within a materialist framework, it is—at least tactically—not reductionist in its programme. Many psychologists believe that seeking links between biological events and behavioural or phenomenological events does not always lead to scientific progress. For instance, showing a lawful correspondence between a set of behavioural and biological events (which is rarely easy to do) does not in itself yield an explanation of how the biology and the behaviour

are causally linked. Psychological explanations have sufficient explanatory and predictive power that few psychologists currently operate on the ambition to render psychological explanations obsolete in favour of biological ones. Indeed, psychological explanations allow certain kinds of understanding that biological explanations cannot easily support (see next point).

In this chapter, we shall centre our account at the psychological level, leaving detailed treatment of other levels to other authors.

6. Psychological explanations are particularly successful at incorporating teleological or functional perspectives. Understanding a behaviour requires more than knowing how it was caused. It also requires knowing something about the ends that the behaviour serves. What, in other words, does the behaviour and the psychological mechanisms that support it allow the organism to achieve? Functional explanations may also be offered at different levels. At the most distal, functions can be considered in terms of the survival of the individual, or even of the species. However, more proximally, functions may be considered in terms of individual goals and plans, which may be very short term and malleable.

An adequate psychological theory of emotional responses to music should, therefore, explain how such emotions reflect the ways that emotions serve to fulfil psychological goals and outcomes. It is not enough to simply demonstrate law-like relationships between musical antecedents and emotional consequents.

Before considering the enduring issues of music and emotion from a psychological perspective, we briefly review emotion concepts and major approaches to emotion. This serves to anchor our subsequent discussion of music and emotion.

4.2 What is an emotion?

Emotion is one of the most pervasive aspects of human existence, related to practically every aspect of human behaviour—action, perception, memory, learning, and decision making. It is thus all the more remarkable that the study of emotion has been neglected throughout much of psychology's brief history. Although the scientific study of emotions dates back to the nineteenth century (Darwin 1872; James 1884; Wundt 1897), studies of emotion have often been eclipsed by studies concerned with the 'higher' forms of mental processes, such as reasoning, problem solving, and decision making. As noted by Lazarus (1991, p. 4), 'Failure to give emotion a central role puts theoretical and research psychology out of step with human preoccupations since the beginning of recorded time.' Almost every great philosopher has been concerned with the nature of emotions. Writers, artists, and musicians have always attempted to appeal to the emotions, to influence and move the audience through emotional communication.

What is an emotion? This question, which incidentally was the title of one of William James's (1884) most famous papers, has not yet received a definitive answer. There are many reasons for this state of affairs. One reason is that emotions are difficult to define and measure. As pointed out by Fehr and Russell (1984, p. 464), 'everyone knows what an emotion is, until asked to give a definition'. Another reason may be the 'disruptive' role ascribed to emotions as motivators of human behaviour. Although our

view of the emotions has changed considerably throughout history, one of the prevailing views has been that rationality can be hijacked by the pirates of emotion (Cacioppo & Gardner 1999). Only recently have researchers seriously reconsidered the role played by emotions in human rationality (Damasio 1994; De Souza 1987; Johnson-Laird & Oatley 1992; Simon 1967). This has reached the point where scientists today readily speak of 'emotional intelligence' (e.g. Mayer & Salovey 1993), a notion that would have been inconceivable during the heyday of behaviourism!

Emotion is both an everyday concept and a scientific construct. As such it involves both an implicit and an explicit body of knowledge (e.g. Plutchik 1980). The implicit knowledge is embodied in the so-called 'folk theories' of emotion. We all know something about emotions. We think that they are powerful forces that affect our behaviour and thoughts in powerful ways, that some emotions feel good and some bad, and that some people are more 'emotional' than others. The explicit knowledge is based on studies of problems such as how emotions develop, whether emotions are associated with physiological changes, and how well we judge emotions from facial or vocal expressions. Emotion as a scientific construct is inferred from three kinds of evidence: (a) self-reports; (b) expressive behaviour; and (c) physiological measurement.

The most common—and deceptively simple—way to measure emotional responses in human adults is by means of *self-report*: adjective checklists, rating scales, questionnaires, or free descriptions. This approach is associated with numerous problems, such as the imperfect relationship between emotions and words that denote emotions, and the problem of choosing which words to include in checklists or scales. At the same time, self-reports are probably the most direct form of evidence, and it is conceivable that certain aspects of emotional life (e.g. 'peak' experiences, see Gabrielsson, this volume) cannot be reached in any other way.

Because the use of self-reports is not always possible—or reliable, some would say—another approach has been to measure different forms of *expressive behaviour*, or products of expressive behaviour (such as drawings; see, for instance, Smith & Williams 1999). This may include facial expressions, vocalizations, and body language (e.g. gestures). The most famous example is perhaps Ekman's (1973) cross-cultural studies of facial expression of emotion. One problem with this form of evidence is that emotions are not always accompanied by expressive behaviours. Furthermore, expressive behaviours often occur in the absence of emotions, because people use such behaviours intentionally to communicate information to other individuals.

The third kind of evidence that is used to infer emotions involves various *physiological measures* of emotion. This kind partly reflects the early work of William James, who claimed that emotion was basically a perception of internal bodily changes. Since then, researchers of emotion have used a number of physiological indices to measure emotion, including heart rate, respiration, skin conductance, muscle tension, electrocadiagram (EKG), blood pressure, and electroencephalograph (EEG) (for a review, see Cacioppo *et al.* 1993). There are many problems with physiological measures, the most serious of which is probably that autonomic changes often occur even in the absence of emotions (primarily because each physiological system has many different functions within the body). Therefore, it is difficult to establish clear-cut relationships between emotional states and physiological responses.

Based on these three kinds of evidence, theorists have proposed a number of different definitions of emotion during the past 100 years. For example, Kleinginna and Kleinginna (1981) identified 92 definitions found in textbooks, articles, dictionaries, and other sources. Based upon a review of these definitions they proposed the following consensual definition (Kleinginna & Kleinginna 1981, p. 355):

> Emotion is a complex set of interactions among subjective and objective factors, mediated by neural/hormonal systems, which can (a) give rise to affective experiences such as feelings of arousal, pleasure/displeasure; (b) generate cognitive processes such as perceptually relevant effects, appraisals, labeling processes; (c) activate widespread physiological adjustments to the arousing conditions; and (d) lead to behavior that is often, but not always, expressive, goal-directed, and adaptive.

Many researchers like to think of emotion as a sequence of events: emotions are triggered by our cognitive appraisals of significant events; these appraisals evoke strong reactions of most of our bodily systems; the bodily reactions generate subjective experiences of feeling; and the subjective experiences yield action tendencies and expressive behaviour. However, researchers often disagree about the precise sequence of events, and about where such an episode begins or ends (Scherer 1993).

As even a superficial reading of the literature on emotion would show, scientists have used a number of different terms to denote the phenomena of interest in this chapter—affect, emotion, mood, feeling, arousal, etc. We think that much of the confusion and controversy in the field of music and emotion has been caused by the lack of clear definitions of these terms. Whereas most researchers of music appear to have used the terms affect, emotion, and mood interchangeably—lay people certainly do that—there is a growing consensus among emotion researchers that the three terms should be differentiated from one another. Affect is seen as a more general term than emotion or mood (Oatley & Jenkins 1996, p. 124). Affect refers to the positive or negative valence of the emotional experience. Many researchers consider affective valence as the most basic feature of emotional life, and believe that affect is phylogenetically and ontogenetically more primitive than emotion or mood (cf. Batson *et al.* 1992). Emotions are often said to differ from moods in three ways. First, emotions are said to be brief, whereas moods last much longer. Second, many researchers think that emotions usually have an identifiable stimulus event, whereas moods do not. Third, some researchers have proposed that emotions are accompanied by distinct facial expressions, whereas moods are not (Ekman & Davidson 1994, pp. 51–96).

Davidson (1994), however, suggests that it is more useful to differentiate emotion and mood in terms of their functions. He proposes that 'emotions bias action, whereas moods bias cognition' (p. 54). Emotions arise most often when adaptive action is needed. Moods, on the other hand, tend to shift the 'mode' of information processing in ways that influence memory, decision making, and evaluative judgments (see Bless & Forgas 2000). In this way moods can alter the probability that particular emotions will be triggered. Thus, emotions can be viewed as *phasic* perturbations that are superimposed on the *tonic*, affective background provided by the mood (Davidson 1994).

Arousal is often considered to be an important aspect of emotional reactions, and this term has figured prominently in many theories of emotion (e.g. Mandler 1984), and

also in many accounts of music and emotion (Berlyne 1971; Gaver & Mandler 1987; Meyer 1956; see also Simonton, this volume). Sometimes, the term is used more generally to refer to the level of emotional intensity of the response, other times it is used to refer specifically to the sympathic activation of the nervous system. The relationship between the two meanings of the term is not clear. For example, there is evidence that people can feel intense emotion, without showing autonomic arousal (Harrer & Harrer 1977).

A major element in both folk theories and scientific theories of emotion is that emotions are subjective feelings that people experience—the word 'emotion' comes from a Latin word which means 'move' or 'to stir up' (Plutchik 1994). But how many emotions are there, and how do different emotions relate to each other?

4.3 Major approaches to emotion

The ways that emotions are experienced and expressed help both scientists and lay people to conceptualize emotions and differentiate among them. In this section, we describe the most prominent approaches to conceptualizing emotion: the categorical approach, the dimensional approach, and the prototype approach. We also consider an additional class of affects—the vitality affects—which we believe could be useful in explaining listeners' responses to music.

4.3.1 The categorical approach

According the categorical approach, people experience emotions as categories that are distinct from each other. Essential to this approach is the concept of *basic emotions*; that is, the idea that there is a limited number of innate and universal emotion categories from which all other emotional states can be derived (see Ekman 1992; Izard 1977; Oatley 1992; Plutchik 1994; Power & Dalgleish 1997; Tomkins 1962). Each 'basic' emotion can be defined functionally in terms of a key appraisal of goal-relevant events that have occurred frequently during evolution (Table 4.1). Thus, basic emotions are regarded as adaptive in dealing with life emergencies without resorting to time-consuming processing: 'When no fully rational solution is available for a problem of action, a basic

Table 4.1 Key appraisals for basic emotions adapted from Oatley[1] (1992) and Lazarus[2] (1991)

Emotion	Juncture of plan[1]	Core relational theme[2]
Happiness	Subgoals being achieved	Making reasonable progress towards a goal
Anger	Active plan frustrated	A demeaning offense against me and mine
Sadness	Failure of major plan or loss of active goal	Having experienced an irrevocable loss
Fear	Self preservation goal threatened or goal conflict	Facing an immediate, concrete, or overwhelming physical danger
Disgust	Gustatory goal violated	Taking in or being close to an indigestible object or idea (metaphorically speaking)

emotion functions to prompt us in a direction that is better than a random choice' (Johnson-Laird & Oatley 1992, p. 201). Basic emotions solve problems with speed rather than precision. They may be viewed as 'fast and frugal algorithms' that cope with conditions of limited time, knowledge, or cognitive capacities (Gigerenzer & Goldstein 1996).

Some general criteria for distinguishing basic emotions from 'secondary' or 'complex' emotions have been suggested. The most important of these are that basic emotions: (a) have distinct functions that contribute to individual survival; (b) are found in all cultures; (c) are experienced as unique feeling states; (d) appear early in development; (e) are associated with distinct patterns of physiological changes; (f) can be inferred in other primates; and (g) have distinct emotional expressions. A considerable body of evidence supports the case for a concept of basic emotions as defined by these criteria (see Ekman 1992; Izard 1977; Oatley 1992; Panksepp 1992; Power & Dalgleish 1997). 'Secondary' emotions are usually believed to be founded on basic emotions, but involve 'blends' of basic emotions (Plutchik 1994), or particular cognitive evaluations that occur together with a basic emotion (Oatley 1992).

The notion of basic emotions has been criticized on a number of grounds, most notably because different researchers have come up with different sets of basic emotions (Ortony & Turner 1990). However, as noted by Oatley (1992) 'this issue is not about voting, it is about theory' (p. 104). It all depends on how we *define* emotions. Therefore, if one takes a closer look at the researchers who consider emotions in terms of their functional significance, one finds that there is reasonable agreement among researchers with regard to at least five basic emotions: happiness, sadness, anger, fear, and disgust (Kemper 1987; Plutchik 1994; Power & Dalgleish 1997). For an example of how the basic emotions approach has been applied in the case of music, see Juslin (this volume).

4.3.2 The dimensional approach

The categorical approach focuses mainly on the characteristics that distinguish emotions from one another. In contrast, the dimensional approach focuses on identifying emotions based on their placement on a small number of dimensions, such as *valence*, *activity*, and *potency*. The search for the dimensional structure of emotions dates back to Spencer (1890; cited in Izard 1977), but more influential formulations of this same notion were provided by Wundt (1897), Woodworth (1938), and Schlosberg (1941). A dimensional structure can be derived from any type of response data, although the most common sources are similarity judgments of emotion words or facial expressions that are analysed using factor analysis or multidimensional scaling.

Russell's (1980) *circumplex model* has generated the most research (Fig. 4.1). This model consists of a two-dimensional, circular structure involving the dimensions of *activation* and *valence*. Within this structure, emotions that are across the circle from one another, such as sadness and happiness, correlate inversely. The circumplex model captures two important aspects of emotions: that they vary in their degree of similarity and that certain emotions (e.g. happy, sad) are often thought of as bipolar. About the same circular structure has been found in a large number of different domains—including music (Thayer 1986)—suggesting that the circumplex model really captures something fundamental about emotional responses.

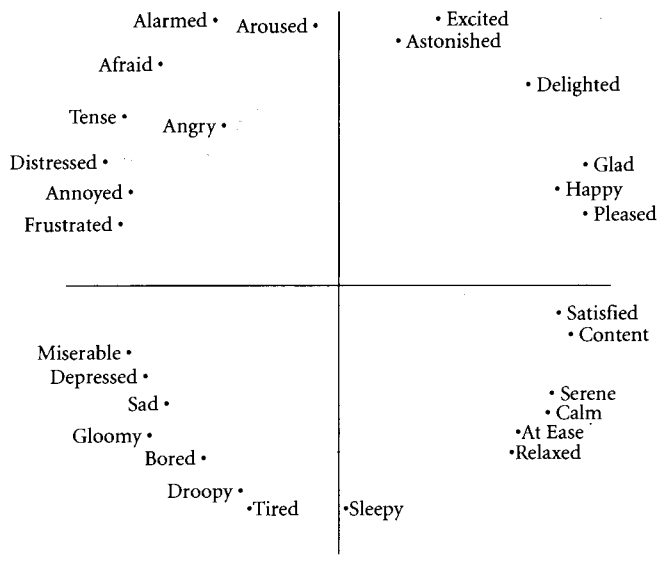

Figure 4.1 A circumplex model of emotion (from Russell 1980). (Copyright ©1980 by the American Psychological Association. Reprinted with permission.)

Among the strengths of the circumplex model is that it suggests a simple yet powerful way of organizing different emotions in terms of their affect appraisals (pleasant or unpleasant) and physiological reactions (high or low arousal). On the other hand, dimensional approaches have been criticized on the grounds that they blur important psychological distinctions and therefore obscure important aspects of the emotion process (cf. Lazarus 1991). In Russell's circumplex model, for example, emotions that are placed in the same position in the circular matrix may, in fact, be very different. Thus, anger and fear are two emotions that are highly correlated within the model, because they are both high in activity and unpleasantness. Yet, they are very different in terms of their implications for the organism (see Table 4.1).

Notably, many researchers regard categorical and dimensional approaches to emotion as complementary to each other (Nyklicek *et al.* 1997) and both receive some support from neurophysiological data (Damasio 1994). Dimensional models may be especially useful for capturing the continuous changes in emotional expression that occur during a piece of music. For examples of response methods based on the dimensional approach to emotion, see Schubert (this volume).

4.3.3 The prototype approach

The prototype approach to emotions is based on the work by Rosch (1978). Essential to this approach is the idea that language, and knowledge structures associated with language, shape how people conceptualize and categorize information. A basic principle is that membership in a particular category is determined by resemblance to prototypical exemplars. The prototype itself is an abstract image that consists of a set of weighted features that represent the exemplar of a family of instances. Thus, for example, robins

are presumably more prototypical of birds than ostriches. Similarly, some emotions (e.g. elation) are probably better exemplars of joy than others (e.g. relief), depending on related features such as elicitors, cognitive appraisals, and physiological reactions.

The prototype approach provides an interesting compromise between categorical and dimensional approaches to emotion—it addresses both the contents of individual categories and the hierarchical relationships among categories. An example of a prototype structure is shown in Fig. 4.2. The vertical dimension of the structure shows the hierarchical relationships among categories. The most general level is the *superordinate* level, which is defined by the positive or negative valence of the emotions within a particular category. The middle level represents the basic-level categories, or *prototypes*, of emotions, which anchor our mental representations of all emotions within a given category. The *subordinate* level consists of all other emotions related to a particular prototype. Finally, the horizontal dimension shows the relations among members of the same prototype category (Shaver *et al.* 1987).

Critics of the prototype approach have argued that people's accounts of emotions are insufficient for capturing the underlying structure of emotions. For instance, the prototype structure presented in Fig. 4.2 includes surprise among the prototypes, despite the fact that many researchers would not consider surprise an emotion (cf. Oatley 1992; Plutchik 1994). Critics also complain that there is disagreement about which emotions qualify as basic-level prototypes, and that emotions may cross boundaries in the prototype structures. However, supporters of the prototype approach accept that boundaries between emotion categories are sometimes 'fuzzy', and argue that emotions cannot be defined in terms of a set of necessary and sufficient conditions.

4.3.4 The vitality affects

Apart from the more traditional approaches to emotion, there is another class of qualities that, although their status as emotions may be called into question, seems to be particularly relevant in the case of music. Stern (1985) introduced the concept of *vitality affects* to describe a set of elusive qualities related to intensity, shape, contour, and movement. These characteristics are best described in dynamic terms such as crescendo, fleeting, explosive, diminuendo, etc. These qualities are not emotions, but rather abstract 'forms' of feeling that occur both together with, and in the absence of, proper emotions. The vitality affects are 'amodal' in the sense that they are common to all modes of expression. Stern (1985) suggests that the vitality affects are of a particular importance in the early communicative acts of mother and infant. Mother and infant respond to one another by constantly adapting and adjusting the intensity, timing, and contour of their expressive acts. This process of constant matching of gestural events is referred to as *attunement.* Lack of capacity to enter into such interpersonal synchrony is often regarded as symptomatic of mental illness (Bunt & Pavlicevic, this volume).

Although the notion of vitality affects is admittedly vague, it seems to capture something important about music's expressiveness. Often when researchers speak about affect in music, they seem to be thinking about something akin to the vitality affects rather than true emotions. Vitality affects, with their dynamic changes and patterns of events, are somewhat reminiscent of philosopher Susanne Langer's (1951)

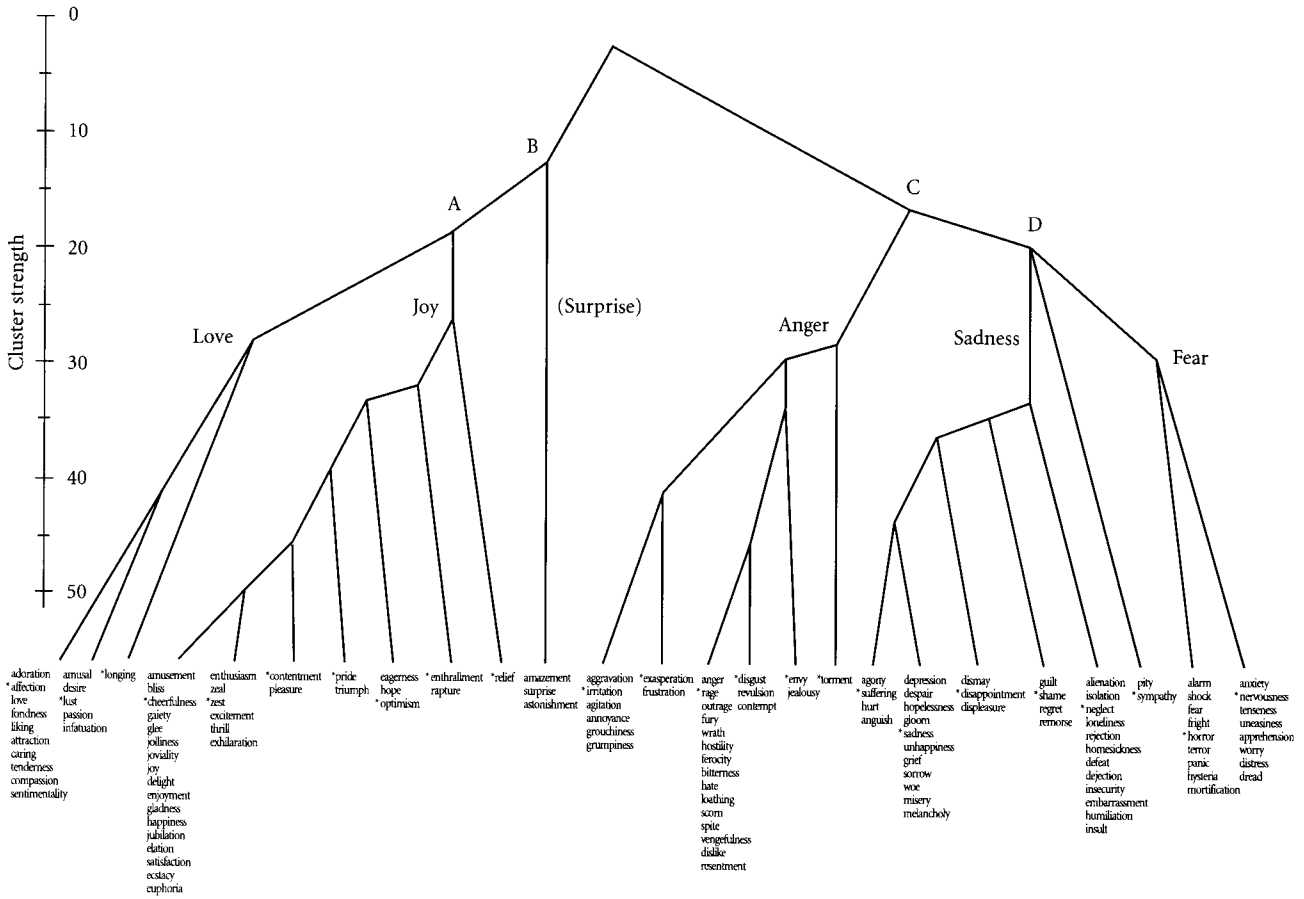

Figure 4.2 A prototype analysis of emotion words (from Shaver et al. 1987). (Copyright ©1987 by the American Psychological Association. Reprinted with permission.)

notion of music as expressive of the forms of feeling. Music, suggests Langer, represents the *dynamic form* of emotional life, not specific emotions. When Langer observes that 'some musical forms seem to bear a sad and happy interpretation equally well' (Langer 1951, p. 202), this might be because vitality affects are not emotions themselves, and because some vitality affects are common to many different emotions.

Of all art forms, no one may be better equipped to capture vitality affects than music, in particular classical music. For an example of how the notion of vitality affects can be applied to a phenomenological description of music experience, see Imberty (1997). Imberty argues that musical style is ultimately 'an architecture of vitality affects', and goes on to discuss the role of vitality affects in the protonarrative character of musical time. The notion of vitality affects is also important in accounts of emotional processes in music therapy, in which dynamic form in improvisation is used to communicate a statement of the self (Bunt & Pavlicevic, this volume).

Having briefly reviewed the major approaches to emotion, we are ready to look more closely at the relationship between music and emotion.

4.4 The study of emotion in relation to music

Although emotions have been studied scientifically for a century, treatises on emotion rarely consider emotional reactions to music (for a few notable exceptions, see Fridja 1989; Lazarus 1991; Oatley 1992; Zajonc 1994). This may reflect the assumption that emotions experienced while listening to music are in some sense different from other emotions. To be sure, there are important differences between musical emotions and other emotions, both in antecedents and consequences, although this in itself does not imply that the emotions themselves are different. Another reason for the neglect of music in the emotion literature could be that such emotions are somehow considered less important—perhaps because scientists have failed to realize that music fulfils vital functions in many people's daily lives (Sloboda & O'Neill, this volume).

Aesthetic emotions—emotional reactions to films, drama, music, or paintings—have never been in the 'mainstream' of psychology (Lazarus 1991). Although psychologists have acknowledged that art may evoke strong emotional reactions despite its illusory nature, few scientists seem to have considered this problem worthy of study. Even in contemporary music psychology, the study of emotion has occupied a peripheral existence (cf. Gabrielsson 1993). However, we sense an increased interest in music and emotion at the moment, and today it is almost fashionable among music scientists to move into the emotion field. We believe that this interest may reflect an increasing awareness that music psychology has made limited progress regarding the problem that should be closest to its heart—how people experience music.

Musical emotions are, at a first glance, of two kinds: first, there are those emotions that concern the aesthetical value of music. Psychologists have, on the whole, embarrassingly little to say about the aesthetics of music, whereas philosophers have been discussing this topic for centuries (Budd 1985). It has been suggested that an aesthetic response is an intense personal experience that provides insight into the nature of life, and that involves emotional, cognitive, and social components (Konečni 1979). In the field of 'new' empirical aesthetics, however, researchers have focused on more mundane

relations between liking, or preference, and such informational properties of the stimulus as its complexity, expectedness, or familiarity (e.g. Berlyne 1971; North & Hargreaves 1997; for a review of musical preferences, see Russell 1997).

Second, there are those emotions that are induced or expressed by the music, more or less apart from the aesthetical value of the music. These are the emotions with which we will mainly concern ourselves in this chapter. However, the two classes of emotion are not wholly independent of each other, and we believe that an understanding of psychological aspects of music and emotion requires that researchers make the connection between the two explicit.

The study of emotion in relation to music is problematic in many ways. First, emotional reactions are commonly understood in terms of their adaptive functions related to biological survival. Since emotional reactions to music are not as directly related to biological survival, they seem to be difficult to explain within existing theories of emotion (Dowling & Harwood 1986). Second, scientists who wish to study emotional reactions to music are faced with the problem that there is great variability between individuals, and across time within individuals (Sloboda 1996). Third, experiments that attempt to measure listeners' affective responses to music may impact so much on the listening process that the task destroys the very thing it is supposed to measure—the problem of *reactivity* (Neale & Liebert 1986).

On the other hand, some authors have suggested that music is an excellent medium for studying emotion. For example, Gaver and Mandler (1987) have argued that using musical stimuli to study emotion is ecologically valid, because people are used to making judgments about music and their affective responses to music. They also note that music has a structure that is rich, and yet fairly well known, and that understanding the structure of an event may help in understanding an emotional reaction to it. Yet another advantage of using music as a stimulus is that it avoids many of the ethical concerns associated with other kinds of stimuli.

A review of the literature on music and emotion reveals the atheoretical nature of much of this work. Music psychologists have been strikingly reluctant to turn to emotion psychology for theoretical guidance (Juslin 1997*a*). One reason for this could be that the field of emotion has presented such a confusing picture that many researchers have found it difficult to distil something useful from this research. Another reason may be that researchers have considered current theories of emotion inadequate for explaining emotional responses to music—a view also evident in the work of some philosophers (e.g. Kivy 1990). In our view, however, the problem does not lie in current theories of emotion, but in the fact that most researchers have not made serious attempts to apply the theories to their problems. It is significant that one of the most influential analyses of music and emotion to date, namely that of Meyer (1956), was partly based on a theory of emotion (Dewey 1894).

One of the primary questions in the field of emotion is whether there are some underlying and objectively observable characteristics that are invariably present in the class of phenomena we normally describe as emotions. In the following section, we describe typical characteristics of emotion and show how these apply in the case of music.

4.5 Typical characteristics of emotions

4.5.1 Emotions are functional despite their apparent non-instrumentality

Fridja (1986) has provided one of the most influential psychological analyses of the behavioural characteristics that lead one to impute emotion to a person. His analysis is particularly valuable because it is not circular—it does not smuggle in the very concepts it is supposed to explain. He says the following (Fridja 1986, p. 2):

> At some moments when observing behaviour, that behaviour seems to come to a stop. Effective interaction with the environment halts and is replaced by a behaviour that is centered, as it were, around the person himself, as in a fit of weeping or laughter, anger or fear. Or interaction with the environment may go on but seems peculiarly ineffective. When someone smashes the dinner plates, the broken plates would hardly seem to be the end result the person had in mind. Other behaviour that invites emotion words seems to contain a surplus that is not needed for the end result: superfluous emphasis in speed and scope of movement, or hesitation and undue toning down, or a smile that, in someone who is stroking a child, does not add to the tenderness of the touch.

To capture this aspect of emotion Frijda uses the notion of 'non-instrumentality', in that the emotional phenomena do not seem to be linked in any direct way towards the achievement of immediate goals and plans. A major purpose of emotion science is therefore to explain what functionality emotions do have. Are they useful to us, and if so how? Most researchers seem to believe they are (Keltner & Gross 1999). There is some consensus that the primary function of emotions is to guide behaviour; emotions evolved because they enabled successful interaction with the environment. But how does the idea of functionality apply in the case of music?

First, the view of emotions as functional adaptations has important implications for how we should understand and explain emotional responses to music (Juslin 1997*a*). Specifically, the functional architecture of emotions should *constrain* our responses to music, such that our responses to music can be explained by the ways that emotions have been shaped by biological evolution. Thus, for example, some of our emotional responses to music might be understood in terms of selective pressures favouring our ability to employ acoustic cues in our environment—particularly the social environment—to make useful inferences about the probable behaviours of other individuals (e.g. Juslin, 2001). Such mechanisms have presumably been favoured by biological evolution because they contribute to individual survival.

A second, and by no means less important, sense in which the functionality of emotions should be considered is the functions that music serve in everyday life, an aspect which is still obscure and poorly understood (Sloboda & O'Neill, this volume). Until we have a clear notion of what a person's involvement in music is for, then we are not going to know whether or not the emotions it evokes are or are not instrumental or functional, and in what way. It has been suggested that music may serve a mood-optimizing function in people's lives (Zillman 1988). However, the mere fact that emotional responses to music are so puzzling—even to the very people who often experience and value such emotions—suggests that musical emotions share in the apparent non-instrumentality of other emotions.

4.5.2 Emotions have behavioural, physiological, and experiential components

Although it may seem self-evident that we experience emotions to music, it is really an open question whether the conditions for ascribing emotion in music are the same as in other areas of emotional life. We noted in Section 4.2 that emotion is usually inferred from three kinds of evidence—self-reports, expressive behaviour, and physiological behaviour. It seems pertinent to ask, then, to what extent these kinds of evidence can be obtained also in connection to music.

The most basic observations arguably come from studies that use self-reports. These studies have yielded evidence that people experience emotions while listening to music, and that they perceive music as expressive of emotions. An interesting example is Pike's (1972) phenomenological analysis of music experience. Pike asked a number of musically untrained participants to listen to different pieces of music. After hearing each piece, which lasted no more than 5 minutes, the participants were asked to write down their responses. Through content analysis, the listeners' responses were reduced to a small set of common experiential factors (listed in the order of their frequency of occurrence): (a) feeling of pleasure (96 per cent); (b) perception of stable moods (86 per cent); (c) feeling of oneness with the music (83 per cent); (d) perception of spontaneous and transient emotional states (72 per cent); and (e) feeling of movement (65 per cent). This finding suggests that emotional responses to music—like emotional responses to other stimuli—include stable moods, transient emotions, and feelings of pleasure. Many other studies provide evidence from self-reports that listeners experience emotions in relation to music (e.g. Behne 1997; Gabrielsson 1991; Krumhansl 1997; Sloboda 1991, 1992; Waterman 1996).

We also have some evidence of expressive behaviour in responses to music. For example, Gabrielsson (1991), Waterman (1996), and Sloboda (1991) have shown that people really do cry when listening to some music. Furthermore, studies using facial electromyography (EMG) have suggested that people react with subliminal facial expressions towards expressive music (Witvliet & Vrana 1996). Kenealy (1988) found that a music mood-induction procedure yielded significant effects on behavioural measures, such as decision time, distance approximation, and writing speed (behaviours believed to be affected by moods). Moreover, there are many social contexts in which music provides a rich stimulus for expressive behaviours (e.g. rock concerts).

There is also evidence of physiological reactions to music (Bartlett 1996). Krumhansl (1997) has reported that the constellation of physiological responses occurring while people listen to music generally judged to be sad, fearful, or happy, under laboratory conditions (i.e. still and silent) are similar, although not always identical, to those constellations identified by other researchers as present when people experience these emotions to non-musical events—particularly in situations involving behavioural suppression (cf. Cacioppo *et al.* 1993; Gross & Levinson 1993). Nyklicek *et al.* (1997) have reported evidence of cardiorespiratory differentiation of music-induced emotions (happy, serene, sad, agitated). Finally, a few studies have explored a special kind of intense emotional responses to music called 'thrills' or 'chills', indicating that such responses to music are quite common, and are more prevalent for sad than for happy pieces of music (see Goldstein 1980; Panksepp 1995). For a review of physiological studies, see Scherer and Zentner (this volume).

Regardless of the particular method used, all these studies have provided evidence that emotional responses to music involve what Scherer (1993, p. 3) has termed the classic 'reaction triad' of subjective feeling, expressive behaviour, and physiological reaction.

4.5.3 Emotions have proximal elicitors

Frijda (1986, p. 4) again gives an influential expression to this feature: 'Emotions are elicited. The eliciting events appear to fulfill a special role: they are not just stimuli. They appear to act through their significance, their meaning, their rewarding or aversive nature.'

This characteristic of emotions seems to be necessary in order to distinguish them from other classes of affective phenomena. For instance, sadness which is pervasive and prolonged tends to be seen as a mood or a disposition rather than an emotion, according to its duration and the relative difficulty of isolating a specific proximal stimulus. However, the distinctions are necessarily imprecise. Clearly, weeping on first news of the death of a loved one is part of an emotional reaction to that event. A year later, a predominant and pervasive sense of sadness would not easily be characterized as an emotional reaction to the death, but rather a mood (although even at that distance a specific instance of weeping might well be viewed as an emotion if a proximal reminder of the loved one could be identified as a proximal elicitor).

A particularly interesting set of issues arise with respect to the assertion that eliciting stimuli should have significance or meaning to the person experiencing the emotion. Is it necessary that this person should be able to know, consciously, what meanings mediate the emotion? Is it, in other words, plausible to attribute emotion in the case that a stimulus occurs, the experience of sadness follows, the person believes that the stimulus has caused or triggered his or her response, and yet the person experiencing this response has no knowledge of why this stimulus should cause the reaction it does? This is an important issue for the application of emotion to the musical domain, because a great deal of what looks like emotional response to music is not accompanied by any strong sense of where the significance lies. A person can be reduced to tears by a particular passage of music, yet be completely unable to specify, even in outline, any objective feature of the music which would account for its grief-inducing qualities.

Fortunately, music is not unique in this respect. Research has shown that people often perceive and process emotional information in a pre-conscious or automatic manner. LeDoux (1996), for example, has recently described a neurophysiological system consisting of parallel-processing perceptual mechanisms, or modules, that react to simple stimulus features. LeDoux has found a direct neural link from auditory nuclei in the thalamus to the 'fear effector system' in the amygdala, which provides immediate information about simple features of emotionally relevant auditory stimuli. This 'quick and dirty' route of transmission bypasses the thalamocortical pathway, which gives full meaning to the stimuli. The perceptual system outlined by LeDoux (1996) provides some support for Zajonc's (1980) controversial slogan that 'affect precedes inference', and shows how emotions can be elicited outside conscious awareness.

Of particular interest is the fact that people implicitly perceive emotional expressions, which subsequently influence their behaviour (Niedenthal & Showers 1991). This means that implicit perception of the emotional expression of a piece of music may

affect us emotionally although we are not consciously aware of this process. Much has been made by some music psychologists of the resemblance of certain musical sounds to signals that human infants may be biologically 'pre-programmed' to respond emotionally to (see Juslin, this volume).

Another class of implicit stimuli are those which obtain their emotional charge through resemblance to characteristics of events which the person can no longer remember (whether through Freudian repression, or normal processes of forgetting). One of the present authors has an overwhelming fear of being submerged in water, but no memory for any event which could account, even non-rationally, for that fear. The fear survives successful contemporary non-damaging experiences of submersion. In a similar fashion, musical stimuli might arouse strong emotions through conditioned responses, the origin of which we cannot remember.

4.5.4 Emotions are intrinsically social

Although emotions can occur when a person is alone, their full manifestation very often seems to require other people. For instance, it is well known that young children (e.g. pre-verbal) will look to a nearby adult for a cue concerning how to respond to some events, such as a fall or graze. If the adult looks upset and concerned, the infant will cry. If the adult appears calm and confident, the infant is less likely to cry. This process is referred to as *social referencing* (Sorce *et al.* 1985), and illustrates that others' emotional expressions are important sources of information which may influence our behaviour.

In another well-known series of studies, Schacter and Singer (1962) placed participants whose arousal levels had been artificially elevated into different social situations, where actor confederates of the experimenter appeared to express particular strong emotions. In general, the participants experienced the emotion displayed by the confederate. All these studies indicate that we are extremely ready to 'catch' ourselves the emotions we observe in others. Emotions are 'contagious' (Hatfield *et al.* 1994).

This tendency may be internalized in the self-regulation of emotions. For instance, a person may ask him or herself 'what would X feel in this situation' and use the stored answer to such a question to influence how he or she responds. In other situations, we identify another person's emotions not so much to align our emotional state with them, but to determine how we should respond to them. If I detect another person as uncontrollably angry, I may well become afraid of what that person might do to me, and withdraw. I might become afraid of what that person might do to someone else, become apprehensive for that person's welfare, and so attempt to help her avoid hurt.

For such reasons, identification of the emotion present in other people is a key priority for us in most situations, and therefore we have very well-developed mechanisms for scanning the environment for any cues that would allow us to both attribute emotion to others and determine whether we should feel that same emotion ourselves. These cues do not necessarily come from direct observation of another person's behaviour. We may deduce something about a person's emotional state from the way that they have affected the environment, for instance, arranged the contents of a room or written a note. People in some cultures have read emotions of unseen beings (such as gods) into such natural phenomena as storms. An angry human may throw small objects around, and so when big objects (such as trees) get thrown around, it is natural to ascribe anger to a

superhuman being. It is not only facial expression, gesture, and vocalizations that suggest emotions to us, but material phenomena which may be the outcome of, or in some sense resemble, those expressions, gestures, and vocalizations.

Music, it could be argued, has many of the requisite qualities that incline us to ascribe emotions to it. There is a great deal of evidence on this point. In general, the experimental technique has been to present a participant with a musical extract and then ask him or her to select, from a smaller or larger list of emotion-related words, those words which most closely match the extract (e.g. Gabrielsson & Juslin, in press). All of these studies confirm that there are some extract-emotion combinations which generate high agreement among listeners, even when they may not have engaged explicitly in such tasks previously. Levinson (1996) has given particularly strong form to this argument through his claim that pieces of music are often construed by listeners as a 'virtual persona'.

Sloboda (2000, p. 227) has suggested that music probably creates an environment in which the distinction between attributing detected emotion to oneself as opposed to an outside source or agent is particularly fluid: 'If I detect some piece of music as containing elements appropriate to anger, then there is a sense in which I am pretty free to ascribe that anger where I will. I may ascribe it to the composer, or to the performer, to myself, to God. None of these ascriptions need to bring me up against any of the immediate constraints or contradictions provided by a real-life event in which my own interests and relationships figure.'

4.5.5 Emotions invoke action tendencies

Emotions change the probabilities associated with subsequent behaviours (Fridja *et al.* 1989). For instance, fear renders it more probable that one will avoid (or seek to avoid) the eliciting stimulus. Frijda (1986) uses the term 'action tendency' rather than 'intention' or 'plan' because the emotion does not contain within it a specific outcome, but rather directs the person experiencing it towards one category of behaviours rather than another.

So, for instance, a fearful person may simply close her eyes, so as not to see the fear-inducing stimulus, feeling that it cannot be avoided; she may run away from it (but with no specific end-location in mind); she may move towards a known place of safety; or she may develop plans to destroy or render harmless the fearful stimulus. These actions are distinct from the set of actions which might be primed by an emotion of tenderness towards the same eliciting stimulus (e.g. a mouse). In both cases, however, the precise action that occurs is not specified from within the emotion itself. This will depend on subsequent appraisals, and the intentions, skills, and knowledge of the subject.

From this analysis comes the most generally accepted theory of what emotions are for, that is why we have developed them. Frijda's (1986, pp. 77–8) formulation is, once again, seminal:

> Action tendencies ... originate in discrepancies: in mismatch or in perception of potential match. Action tendencies terminate in unresolvable mismatch or in match. Mismatch, potential match, and match must be assumed to give rise to signals indicating that action is called for, is likely to succeed, or can terminate. We may identify these signals with feelings of pain, pleasure, and desire. These are the signals that initiate, maintain, and terminate action tendency. They constitute the direct source of 'being set' for change or continuation of the given situation. At the same

time, they confer an 'aim' upon action tendency: they provide such tendency with an end point, the functional equivalent of a goal. Action tendency continues until the mismatch signals that initiate and maintain it die down; action tendency remains aligned when potential match signals resound, and terminates where match signals indicate success.

In effect, emotions are biologically embedded mechanisms that ensure that, in general, our psychological energies are directed to the meeting of primary needs, both physical and psychological. They are 'non-negotiable' and force our attention onto the eliciting stimulus until the action tendency is realized. But emotions by themselves do not guarantee effective solutions to life's challenges, particularly in the complex and rapidly changing material and social environments that human beings have constructed for themselves. Such solutions are developed by learning and the establishment of a repertoire of problem-solving strategies.

Understanding the links between one's emotions and effective behaviour has recently been described as an important aspect of 'emotional intelligence' (Mayer & Salovey 1993). The development of effective responses to emotionally challenging situations can be helped through various kinds of 'off-line' activities, such as role playing (observed as spontaneous 'pretend play' in children), and story telling. Stories present the observer with a series of situations which elicit emotions in the protagonist, and by empathy or identification, in the reader or listener. By exploring the interactions between situations, emotions, and actions in a simulated environment, we can develop and test different strategies that might be deployed in real situations, but without the potentially harmful consequences of 'getting it wrong'.

It is in the context of such considerations that emotional responses to many art forms are rendered partly explicable. Novels, plays, operas, and films can provide opportunities to feel emotions with and for the protagonists, and explore consequences of different ways of acting on these same emotions. This is true even in the Western art culture, where the passive and immobile 'respectful silence' of the audience has such paradigmatic status. There is a strange paradox in the typical public performance, where much emotion is experienced (as evidenced by self-report of audience members) but almost none is displayed.

On the other hand, many other social contexts in which music and drama has occurred through the ages has provided opportunities for, and even encouraged, action. Pop concerts, for instance, provide a typical context and stimulus for exuberant and joyful bodily and vocal expressions among audience members. Indeed, the urge to participate seems to be a natural and early occurring phenomenon. Young children seem to spontaneously break into motion when they hear certain types of music (Moog 1976). Even when suppressing an overt response to music, listeners may still be engaging in subliminal physical action (e.g. Fraisse *et al.* 1953; Harrer & Harrer 1977). There is also evidence that soothing music yields more helpful behaviour in subjects than music that is aversive in nature (Fried & Berkowitz 1979). So action tendencies are by no means absent in emotional responses to music.

Perhaps more puzzling is the question of the underlying motivation for the action tendencies. If Frijda's analysis is correct, then music-engendered emotions, just like any other emotions, should involve the awareness of match, potential match, or

mismatch between the current situation and some envisaged situation. Emotion should be initiated, maintained, or terminated by key events or actions which bring about transitions from match to mismatch or vice versa. A central problem for music psychology is to characterize and explain the various ways in which musical events can be interpreted by the human cognitive system as marking these transitions, while not directly 'telling a story'. Not only does music achieve this, but it often achieves it spectacularly well. The emotions felt by many people to music are equal in intensity to the emotions they experience to life events. And in some circumstances, people have reported that these emotions have propelled them towards significant personal change (Bunt & Pavlicevic, this volume; Gabrielsson & Lindström 1993; Sloboda 1992).

4.5.6 Emotions change during the course of human development

All researchers who study emotion seem to agree that emotions do change with development (e.g. Ekman & Davidson 1994). However, researchers differ among themselves with regard to their views on what changes occur, and why these changes occur. Although the number of proposed changes in emotions as a function of development is too large to permit a thorough overview, they include maturational changes of the nervous system, changes in the stimulus conditions eliciting emotions, changes in emotion regulation and coping skills, changes in the relationship between cognition and emotion, changes in expressive behaviour as a consequence of mothers' communication styles, and changes associated with cultural influences, including language. Theories of emotional development typically describe how emotions develop from pleasure and displeasure to successively more differentiated emotional states (Harris 1989).

To what extent does emotional development apply to the case of music? Unfortunately, individual differences in emotional responses to music within age cohorts have by and large not been systematically examined. However, there is a stream of developmental research that has concerned the development of perception of emotional expression in music (e.g. Cunningham & Sterling 1988; Dolgin & Adelson 1990; Kastner & Crowder 1990; Kratus 1993; Terwogt & van Grinsven 1988). These studies used pictures of facial expressions and asked children to select the face that matches the music's emotional tone most closely. The results indicate that even children 3 or 4 years of age can recognize certain emotions—joy, sadness, anger, and fear—in music with an accuracy better than chance. This ability seems to increase with age, however, particularly up to the age of six.

Developmental studies show that increasingly sophisticated music-emotion associations are acquired through childhood, and suggest that recognition of emotional expression in music depends on the general development of emotions (Gembris 1995). Very little is known about the development beyond childhood. However, the simple fact that listeners' preferences for music change over the life span (Russell 1997) could partly reflect the fact that certain types of music resonate better with certain phases of life in terms of the associated emotions. Rock music, for instance, with its focus on emotions like sexuality, anger, and rebellion may have a special appeal to adolescents, for which these same emotions are especially salient.

4.5.7 Emotions involve cognitive appraisals of organism-environment relationships

For an organism to be able to seek pleasure and avoid displeasure, it has to be able to evaluate its immediate environment. Thus, most theorists believe that emotions involve some kind of cognitive appraisal. However, theorists differ in their views on how much cognitive processing is minimally required for an emotion to occur (see, for example, Lazarus 1982; Zajonc 1980). Early theorists of emotion paid limited attention to the precise analyses of the elicitors of emotion, and the 'cognitions' associated with these elicitors. However, a number of recent 'appraisal theories' (Scherer 1999) hold that the precise nature of the emotional reaction is a result of appraisal processes undertaken on the elicitor of the emotion, and the way that elicitor is construed.

Ortony *et al.* (1988) have suggested a tripartite division of elicitors into events, agents, and objects. Developing one of their examples, one could consider a person's emotional reactions to a recently acquired new car which has broken down. As object, the car may elicit valenced reactions as a result of its aesthetic qualities (shape, colour, design). These would elicit liking or disliking. As event, the breakdown would elicit pleasure or displeasure as a result of its perceived consequences for self or others. Thus, for instance, I might be pleased with the breakdown if it prevented me from making an unwelcome journey. As agent, the car would be attributed with personality or intention, and so I might feel angry with the car for not working (irrational but common!).

On such a view, the basic emotional categories would be those given in Table 4.2. Note that the emotions contained there are relatively non-specific. Ortony *et al.* place other emotions in subcategories of the basic categories in respect of further more specific qualifying conditions of the appraisal. Thus, for instance, anger turns out to be one of the more complex emotions, being, at the very least, 'disapproval of the action of an agent in causing an event which has negative consequences for oneself'.

Table 4.2 Basic emotional appraisal categories (adapted from Ortony *et al.* 1988)

	Proximal elicitor construed as		
Valence	Event	Agent	Object
Positive	Pleasure	Approval	Liking
Negative	Displeasure	Disapproval	Disliking

Waterman (unpublished, reported in Sloboda 1991) derived a list of emotion words designed to exhaustively sample the emotion space proposed by Ortony *et al.*, and asked his participants to identify which of them they had ever felt to music, and if they had not felt it, how plausible it would be for a piece of music potentially to elicit it. These data suggested that music is capable of eliciting both positive and negative emotions relevant to all three types of construals—music can be appraised as event, action of agent, and object.

However, the more complex and specific the qualifying conditions, the less likely the emotion was to be experienced (or judged as possible for experiencing) to music. So, for instance, music elicits happiness quite easily, but almost never elicits gloating, although both emotions involve positively valenced reactions to something appraised as 'event'. Gloating denotes pleasure in the very specific context of the belief that someone else has

well as by belief in others, the listener's response can be seen to be consistent with the cognitive theory of the emotions.

The claim that attitudes other than belief can play the cognitively central role in emotions is not accepted by all who support the cognitive theory of the emotions. And it might be thought that it is one thing to imagine of the emotion's object that it has emotion-pertinent features that one does not believe it to have, yet quite another to make believe that the emotion's object exists when one does not believe it to do so. In addition, there is the concern mentioned earlier: that it is not clear that what is entertained is sufficiently controlled by what happens in the music to count as belonging to the world of the work.

The arousalist maintains that what makes it true that the music is sad is that it arouses sadness in the listener; the listener's response is not to some expressive property possessed independently by the music. While the arousalist might deny that the listener's responses *mirror* an expressiveness that is independent of their reaction, still he or she must hold that the response correlates with the music's expressiveness by licensing the judgment that the music is expressive of what is felt by the listener. Given this, and also the fact that the causal relation between the music and the listener's response need not be informed by cognitions beyond those involved in tracking the unfolding of the music, a problem remains for the arousalist in characterizing the listener's reaction as emotional.

In a recent defence of arousalism, Matravers (1998) acknowledges that the crucial response is a feeling, not an emotion as such, because it lacks the cognitive contents that characterize the emotions. For instance, the response feels like sadness or pity, and this makes it true that the music expresses sadness, but the response is not an object-directed, cognitively founded emotion. This explains why listeners are not strongly inclined to act on their feelings; the prime motivators for action are beliefs and desires directed to an emotional object, but these are absent in the musical case. Because only a few feelings have distinctive phenomenologies, music can arouse only rather general feelings, and thereby is capable of expressing only a limited range of emotions.

I endorse this approach, which can be disassociated from arousalism: if the listener does mirror the music's expressiveness, that response is caused by and tracks the music, but does not take the music, or any other thing, as its emotional object. This is not to agree, however, with the arousalist's claim that it is the listener's reaction that licenses the judgment that the music is sad.

My account can appeal to one resource that is not available to the arousalist. Earlier I suggested that inanimate appearances often strike us as expressive. To this it can be added that sometimes we find expressive characteristics in appearances highly evocative of responses of the mirroring kind (Davies 1994), not only in the musical case but in others (see Hatfield *et al.* 1994). Whether through empathy or sociality, we often 'catch' the mood prevailing around us. Both high spiritedness and despondency can be 'contagious'. The same applies sometimes, I claim, when we are confronted with powerfully expressive appearances that are not connected to occurrent emotions. There is no reason why appearances of sadness should make me feel gloomy if I do not think they show how anyone feels (and often they do not do so); which is to say, mere appearances of sadness are not a suitable object for sadness, since they are not thought to be

been less fortunate than oneself. It is this precise cognitive context that defines the emotion. Music seems ill-suited for carrying such specific messages.

Rather clear examples of the three major categories of construal are provided by the study of Waterman (1996). He asked participants to listen to prerecorded pieces of music in a comfortable and quiet laboratory situation. They were asked to press a button each time they 'felt something'. After the music ended, the recording was played back, and stopped at each point where they had pressed, with a request to explain what had been going through their minds when they pressed. Event-related appraisals often concerned structural awareness (e.g. 'I knew the end was coming'). Action-of-agent appraisals often related to the performer or composer (e.g. 'her technique fascinated me'). Object-related appraisals included evaluations of the piece as a whole (e.g. 'I liked it') or of specific aspects of it (e.g. 'I didn't like the singer's voice'). What is particularly interesting about Waterman's study is that, although different listeners tended to press the 'felt something' button at the same point in the music, their stated reasons for pressing were very different from one another. This suggests that in music there may be a partial decoupling between the mechanisms that determine intensity of affect and those that determine emotional content, the former being predominantly determined by structural characteristics of the music (*intrinsic emotion*), the latter being determined more strongly by contextual factors, including the memories, associations, and priorities of the person hearing the music (*extrinsic emotion*).

Having established that responses to music involves true instances of emotion, we move on to consider the sources of emotion in more detail.

4.6 Sources of emotion in music

4.6.1 Intrinsic emotion

There is now an accumulating body of knowledge that shows that there is a lawful relation between the intensity of emotional qualities experienced in music and the specific structural characteristics of the music at a particular point in time. The intensity of emotional response to a piece of music often rises and falls as the music unfolds. Musical discourse, both formal and informal, talks of climaxes and points of repose, tension, and relaxation. In other words, there are peaks, where intense emotions (or other affective sensations) are prone to be experienced, and troughs, where the intensity is weak.

Sloboda (1991, 1992) has identified a set of structural characteristics that are associated with the elicitation of bodily and behavioural manifestations of emotion, such as weeping or piloerection ('thrills' or 'shivers') (Goldstein 1980; Panksepp 1995). These characteristics include syncopations, enharmonic changes, melodic appoggiaturas, and other music-theoretical constructs, which have in common their intimate relationship to the creation, maintenance, confirmation, or disruption of musical expectations. The positing of a central role for such constructs in generating emotional responses to music has characterized the accounts of a number of influential musicological theorists (e.g. Meyer 1956; Narmour 1991; see also Meyer, this volume). It is only in the last decade, however, that their intuitions have been substantiated by scientific data.

The term 'intrinsic' seems appropriate because it is only with reference to other musical events and structures that particular events become more or less expected. These expectations may reflect learning, or may operate at the level of primitive perceptual processes, such as the 'gestalt laws' of perception, where, for instance, movement in a particular direction creates expectation for further movement in that direction (law of good continuation) (Meyer 1956). Narmour (1990) provides a particularly detailed theoretical working out of these ideas in the context of melodic perception and expectancy. Other expectations may arise as a function of exposure to a large body of music sharing a set of structural regularities. Some expectations relate to the entire body of, for instance, tonal music; others may relate to specific styles or genres (e.g. AABA song form, sonata form).

Sloboda (2000) has discussed some of the issues that need to be resolved before strong predictions can be made about the intensity of emotional responses on the basis of structural analysis. Thus, for example, almost every note in a piece of music confirms or violates *some* expectancy. Therefore, in order to predict actual emotional responses, further parameters must be added to the basic model. These may include density of eliciting events, positioning within the compositional architecture, and what Sloboda has called 'asynchrony of levels'—an event which simultaneously confirms an expectation on one level while violating it on another. None of these factors has yet been the subject of scientific investigation. However, some preliminary models of musical expectancy have recently been tested (Eerola & North 2000).

If musical expectation is really the key to emotional intensity, how is it that we can feel emotions to music we are highly familiar with? First, many of the violations of expectations may occur on a subconscious level, involving modules for music processing that are denied conscious access (cf. Fodor 1983). Second, even when the musical 'narrative' is familiar to us, we may still be able to enjoy it. Much like when re-watching a great movie, we can appreciate the twists and turns of a good story in music, even though we already know how the story is going to end. Third, iconic and associative sources of emotion, such as emotional contagion and memories, may remain much the same throughout repeated listening to the same piece of music (many of our emotional responses to music may simply reflect the fact that we find the music beautiful, and this beauty may be perceived each time we listen to the piece). Fourth, a basic principle says that familiarity with an object itself mght increase our liking of that object up to a certain point (Gaver & Mandler 1987). Finally, it is possible that some effects of music processing are executed by a processor, whose responses are 'hard-wired' in regard to certain perceptual primitives. If this processor is 'sealed' from other more labile parts of the system, then it may be possible that however well one knows the piece, expectation, suspense, and surprise can still occur within the processor, because the processor is always hearing the piece 'for the first time' (Jackendoff 1992).

A theory of emotional responses to music in terms of 'musical expectations' has clear explanatory value in relation to Frijda's (1986) notion of emotions as a function of monitoring match and mismatch. Most compositional systems, such as the tonal system, provide a set of dimensions that establish psychological distance from a 'home' or 'stability point'. Proximity or approach to this resting point involves reduction of tension; distance or departure involves increase of tension. Distance can be measured on a number of dimensions, including rhythm and metre (strong beats are stable, weak beats

and syncopations are unstable), and tonality (the tonic is stable, non-diatonic notes are unstable). There is now much experimental evidence that the human listener is sensitive to such features, and represents music in relation to them (e.g. Bharucha 1994; Krumhansl 1990). These features provide reference points against which the emotional system can plausibly compute match or mismatch in terms of envisaged end-points.

One problem with this approach is that it cannot without some difficulty explain why people experience different emotions in relation to pieces of music. The interplay of tension, release, surprise, and confirmation does not amount yet to a full-blown emotion. It is better characterized as 'proto-emotion', because it has a strong tendency to grow into emotions through the addition of further mental content (e.g. appraisal, valence). For instance, if the surprise is appraised as pleasurable, then an emotion of joy or elation may emerge (a similar point has been made by Ortony *et al.* 1988). What is needed to turn the structure-induced proto-emotions into full-blown emotions is semantic content. They need to be about something. Theory and evidence suggest two sources of content—iconic and associational. Because they both refer outside the music, we call these sources extrinsic.

4.6.2 Extrinsic emotion

Iconic sources of emotion

Iconic relationships come about through some formal resemblance between a musical structure and some event or agent carrying emotional 'tone' (e.g. Dowling & Harwood 1986). So, for instance, loud and fast music shares features with events of high energy and so suggests a high energy emotion such as excitement.

Iconic relationships are closely associated with the abundant literature on expression in music. Throughout history, there has been a number of different views on what music is able—or unable—to express. Music has, for example, been regarded as expressive of: (a) emotion; (b) motion; (c) beauty; (d) Christian faith; (e) tension and release; (f) things and events; (g) human character; and (h) political and social conditions. Empirical research has touched on only a few of these aspects. At some level, the common denominator for all these aspects may be human feeling, of one kind or another. Thus, it is perhaps not so surprising that psychological research has focused mainly on iconic relationships between musical features and particular emotions (for an extensive review, see Gabrielsson & Juslin, in press).

Empirical studies have shown that iconic relationships may specify particular emotions, and that they thus supply emotional content to the non-specific sensations of surprise, tension, and arousal engendered by the listener's engagement at the purely structural level of the music. Examples of studies of such iconic correspondences between musical variables and emotions are seen in Bruner (1990), Hevner (1935), Juslin (1997*b*), Rigg (1964), Scherer and Oshinsky (1977), and Wedin (1972). One recent strand in this work has been the suggestion that certain musical devices directly suggest gestural and other expressions of emotions by the human body (e.g. Clynes 1977; Scherer 1995). Another development has been studies of how performers communicate emotions to listeners through their performance of a piece of music (Gabrielsson & Juslin 1996; Juslin 1997*a*, 2000).

Unfortunately, most of these studies have measured only a few musical parameters and their main effects, whereas intercorrelations and possible interaction effects have been largely unexplored. Generally, the amount of study carried out on a particular musical parameter is inversely related to the difficulty of quantifying it. Therefore, most studies have not taken into consideration the dynamic changes in emotional expression that take place during a piece of music. Only recently have music researchers devised new techniques to capture the moment-to-moment changes in emotional expression (for a review, see Schubert, this volume). For a review of associations between composed structure and emotional expression, see Gabrielsson and Lindström (this volume). For a review of associations between performance features and emotional expression, see Juslin (this volume).

Study of emotional expression in music is probably the most common of all approaches to music and emotion in psychology—perhaps because of the relative ease with which such studies are carried out. A number of generalizations have emerged from this research. First, listeners seem to find it natural to attach emotion labels to pieces of music. Second, listeners are often consistent in their judgments and agree about the emotional expression of the music. Third, the veridicality of the judgments is rarely studied due to a lack of sufficient criteria of composers' intentions. Fourth, iconic representation of emotions in music seems to operate on a broad level of emotion categories, perhaps corresponding to the 'basic' emotion categories (cf. Dowling & Harwood 1986; Juslin 1997*c*; Krumhansl 1997). Fifth, listeners' judgments of emotion are influenced by such musical parameters as tempo, dynamics, rhythm, timbre, articulation, pitch, mode, tone attacks, and harmony.

The term 'iconic' seems particularly appropriate for this set of relationships, because the resemblances between a musical event and its non-musical referent is, in some sense, obvious to anyone who is familiar with the non-musical referent. Therefore, as a number of studies have shown (e.g. Juslin 1997*a*), recognition of iconic emotional meaning does not seem to require specific musical training. Non-musicians access iconic meanings just as easily as do musicians.

A second feature of iconic relationships is that, like the intrinsic relationships described in the previous section, they are non-arbitrarily embedded in specific structural characteristics of the music. If you change the structures then, perforce, the iconic meanings change. This means that iconic sources mediate moment-to-moment changes in emotional experience as a piece of music unfolds. Iconic relationships contribute to the ebb and flow of music-entrained emotion.

Associative sources of emotion

Associative sources of emotion are those that are premised on arbitrary and contingent relationships between the music being experienced and a range of non-musical factors which also carry emotional messages of their own. A memorable formulation of a key exemplar of associative sources is that of Davies (1978) who identifies associative theories as 'Darling, they're playing our tune' theories.

There are certain types of stimuli (e.g. music, smells, and tastes) which seem to become associated in human memory with particular contexts or events in earlier life, and provide a trigger to the recall of these events. This seems particularly so when the

earlier events were, in themselves, occasions of strong emotion (Dutta & Kanungo 1975). Many investigators (e.g. Gabrielsson 1991; Sloboda 1991) have found examples of specific pieces of music that trigger strong emotion in this way. Such emotions tend to lead attention away from the present music onto the remembered past event.

Waterman (1996) has demonstrated that even when music does not directly trigger past experiences, many of the emotional processes are self-referring in some way (e.g. 'I should have recognized that', 'this is not my type of music'). Because these feelings are linked to the life histories of individuals they are often completely idiosyncratic. However, common cultural experiences can sometimes lead to shared emotions which still are fundamentally extrinsic, for example, the extreme negative emotions felt by many Jews after the Second World War on hearing the music of Richard Wagner; the strong emotional identification of generational cohorts with the popular music prevalent in their teenage years (e.g. Holbrook & Schindler 1989); and the cultural associations formed by film-music pairings, such as Johann Strauss' 'Blue Danube' waltz, with the spaceship docking sequence in Stanley Kubrick's film *2001: A Space Oddesey.*

Unlike the intrinsic and iconic sources of emotion, associative sources are often bound non-specifically to entire pieces or passages, and do not require any particular feature of the music for their binding (i.e. other than some means of identifying the music in question as the relevant music rather than a different piece or genre). Although associative sources of emotion are obvious and pervasive, there is little scientific research into them. This may be because the intrinsic idiosyncrasy of these associations renders control and generalizability problematic.

4.6.3 Interactions between different sources of emotion

In the foregoing, we noted that emotional responses to music reflect both intrinsic emotion that is locally focused, and extrinsic emotion that is more globally context-dependent. Furthermore, music both induces emotions in listeners and is perceived by listeners as expressive of emotion. This means that emotional responses to music may come about in a large number of different ways, and failure to recognize this fact may account for some of the past disagreements in the field. In each listening situation, (a) all, (b) only some, or (c) none of the different sources of emotion may be present. Much of the richness of emotional responses to music comes from this multitude of sources of emotion. Moreover, different sources of emotion may interact in interesting ways. For example, the mood of a particular piece of music (iconic signification) may evoke mood-congruent memories (associative signification) through so-called 'spread of activation' in neural networks associated with emotional reactions (Bower 1981). Similarly, the manner in which a particular section of a piece of music builds up tension through musical expectations (intrinsic affect) may remind us of the patterns of tension and release in a certain extramusical context (extrinsic affect). Furthermore, different sources of emotion may support or contradict one another, thus creating either clarity or ambiguity in the emotional impact of the music. The emotional ambiguity of certain pieces of music is, of course, reminiscent of the mixed emotions we often experience in many other domains of life (Oatley & Duncan 1994).

Music (instrumental music, at least) often suggest emotions in a vague fashion. Sloboda (2000, p. 226) notes that music:

can suggest or resemble certain types of human gestures and actions. Given shared experience and understandings, it is easy to see how a group of people might be able to extrapolate specific emotions from such cues. It is equally easy to see how there is room for ambiguity and imprecision. Very often we feel that there is an emotion present, we know it is of one general type rather than that of another, but we cannot quite tie it down. In such a state of ambiguity and cue-impoverishment we may well expect the profound and semi-mystical experiences that music seems to engender. Our own subconscious desires, memories, and preoccupations rise to the flesh of the emotional contours that the music suggests. The so-called 'power' of music may very well be in its emotional cue-impoverishment. It is a kind of emotional Rorschach blot.

4.7 Implications and future directions

This chapter has suggested a multitude of ways in which emotional processes may occur in relation to music. Yet, this chapter has provided only a small glimpse of all the work that has been carried out within the psychological approach to music and emotion. One implication of the foregoing overview is that emotional responses to music have very much in common with emotional responses to other stimuli. However, in the case of a non-musical stimulus, emotion is usually generated via appraisal of the capacity of the stimulus to affect the interests, values, and goals of the perceiver. Because music has no direct capacity to further or block such goals, a challenge for theorists of music and emotion has been to provide an alternative but plausible account of the casual path between musical features and experienced emotion, for instance in terms of musical expectations or various extramusical associations.

Given the emphasis on emotional responses to music in this chapter, we should perhaps note that music does not always arouse emotional responses in listeners. Often, we may listen to a piece of music without feeling anything in particular. In fact, some people claim that they rarely, if ever, experience emotional reactions to music. Unfortunately, there is little research so far on the *epidemiological* aspects of musical emotions; in other words, how often people experience emotions to music under various circumstances. This represents a crucial area for future research. We should attempt to delineate the conditions (including the music, person, and situation) under which a listener is most likely to react emotionally to music. This might involve the kind of diary approach that have been used in earlier research on epidemiological aspects of emotions (Oatley & Duncan 1994).

Psychological studies of music and emotion have largely ignored the interaction among three factors: the listener, the music, and the context (cf. Gabrielsson, this volume). Previous research has focused mainly on factors in the music. We know quite a lot about the ways that factors in the music can induce and represent emotions. However, the fact that different styles of music may yield very different emotional responses in listeners has received little attention. Therefore, it should be acknowledged that theoretical explanations of emotional responses relevant to one particular style of music (e.g. classical music) may not apply equally well to a different style (e.g. blues).

A fair amount of research has focused on factors in the individual that might influence emotional responses to music. Listeners' affective responses to music are likely to depend to some extent on their age, gender, personality, training, current mood, and so

forth (Abeles & Chung 1996). Interactions between music and listener may involve the listener's familiarity with the music (North & Hargreaves 1997) and his or her musical preferences (Holbrook & Schindler 1989; Russell 1997).

The factor that has been mostly ignored in previous research is the context—including everything from the concrete situation in which the musical activity takes place, to the wider social and cultural context. Konečni (1982) has strongly criticized previous empirical studies for having treated aesthetical responses as if they occur in a social, emotional, and cognitive 'vacuum'. Emotional responses to music are likely to depend on what the music is used for. To understand emotional responses to music, we should consider the social functions of the music in its particular context. Hargreaves and North (1999) have suggested that the social functions of music manifest themselves in three main ways: (a) the formulation and expression of self-identity (our responses to some musical styles may partly reflect what they stand for in the larger social context); (b) the establishment and maintenance of personal relationships (e.g. prestige effects and conformity); and (c) mood management (music tastes reflect situationally determined goals of 'mood optimization'). Studies of music and emotion have recently begun to address these issues (e.g. DeNora 2000, this volume; North & Hargreaves 1997; Sloboda & O'Neill, this volume).

One example of the strong social influence is the kind of emotion that arises from what one has been told, and therefore may come to believe, about the music in question. A seminal study by Weick *et al.* (1973) manipulated the reputation of the composer of a jazz orchestra piece by telling some players it was by an established jazz composer and others that it was by a dance band arranger (not exactly a high prestige genre for jazz players). This manipulation clearly affected emotional and motivational involvement with the piece. Players who thought the piece was by an established composer both liked the piece more and devoted more effort to learning it. As suggested by this study, almost every piece of music is given a cultural value by members of the community within which it is experienced, produced, and discussed. Therefore, there is little music that we come to 'blind'. Our hearing of a Beethoven Symphony cannot now be dissociated from the ubiquitous discourse (available on programme notes, CD cases, radio stations, etc.) that assigns him a pre-eminent position of 'greatness' in the canon of masterworks. Because greatness has been ascribed to Beethoven, our emotional response to hearing a famous Beethoven work is conditioned by cultural attitudes appropriate to 'greatness' (e.g. reverence). We may rebel against these tendencies, but we cannot ignore them.

Such considerations lead us into the heart of contemporary debates in musicology (see Cook 1998). Traditional musicology has become increasingly under fire for being unreflexive about the cultural and social sources of its own attitude toward the music it was studying, an attitude which could lead to the assumption that Beethoven's greatness was 'for all times and all places' and had nothing to do with the particularities of nineteeth- and twentieth-century European societies into which his music has been received and championed. The increasing self-critical reflexivity of the musicological community augurs well for developments in psychology. Many psychologists have been 'victims' of the same cultural unawareness that dominated mid twentieth-century musicology, and this may be one reason why this area has not

been well researched. Psychologists have not really grasped the nature of the problem. To put the problem is its most acute form, one of the most prevalent cultural discourses about music concerns its emotional power. This discourse surrounds all of us from our earliest years. We, therefore, approach any new music already expecting (even willing) it to have an emotional content. One answer to the question 'why is music so emotionally powerful' is that we have decided to construe it thus. At one very important level of analysis, music is not inherently emotional. It is the way we hear it that makes it so (see Becker, this volume).

Because the concept of emotion itself relies on research from such diverse domains as philosophy, psychology, sociology, biology, anthropology, and physiology, we believe that interdisciplinary collaborations provide the royal road to progress in this field. Juslin (1997*c*, pp. 15–16) notes that music researchers have approached questions of music and emotion with empirical rigor but that:

> this has unfortunately not been matched by an equal sophistication concerning conceptual problems. There are often vague references to the 'musical emotions', without further clarification of the meaning of this concept. Philosophers may, of course, contribute to these conceptual problems through thoughtful analyses, but too often they are not familiar with the latest developments in emotion psychology, which means that their ground premises may be wrong. In the end, it may turn out that we can make progress in this area only through the combined efforts of different disciplines.

We believe that psychologists must learn to draw from the knowledge currently available in related disciplines—philosophy, sociology, anthropology, biology, and musicology.

Given the problems of the study of music and emotion, we think it is also desirable for music researchers to follow closely the developments in the emotion domain more generally. Recent debates in emotion psychology have involved: (a) the role and limits of self-reports in the study of emotion; (b) cross-cultural agreement in emotion judgments; (c) the nature and existence of basic emotions; (d) individual differences in emotion disposition; (e) the tracking of phasic aspects of emotion; (f) linguistic analyses of emotion; and (g) relationships between emotion and cognition (Cacioppo & Gardner 1999), all of which have a direct bearing on the study of emotion in music. The implication is that music researchers cannot escape from the theoretical and methodological problems confronted by other researchers who study emotion. Studies of music and emotion that measure emotions in multiple channels simultaneously (self-report, physiology, expressive behaviour), and over time, is clearly an important goal for future research. Such an endeavour may have to involve a switch from the traditional agrarian-based inferential statistics to non-linear, dynamic models that are better suited to the time-dependent nature of emotional responses to music.[1]

[1] We thank Carol Krumhansl and Klaus Scherer for useful comments on a preliminary version of this chapter.

CHAPTER 5

LISTEN TO THE BRAIN: A BIOLOGICAL PERSPECTIVE ON MUSICAL EMOTIONS

ISABELLE PERETZ

The functioning of the brain is fascinating. It fascinates for the obvious reason that the brain is the commander of all our actions, thoughts, and motivations. By studying its functioning, the hope is to obtain crucial information about the biological determinants of human cognition and emotion. Neuropsychology is the discipline concerned with these questions. As its name indicates, neuropsychology aims to relate neural mechanisms to mental functions. It is an old discipline, dating back to the discovery that speech was related to the functioning of a small region of the left brain by Broca in 1861. Following this discovery, the neural correlates of musical abilities were similarly scrutinized (for a recent review, see Marin & Perry 1999). Although the neuropsychological approach to music is a century old, progress has been slow. However, the recent advances made in brain-imaging techniques, as well as the current trend of viewing most human activities from a biological perspective, has intensified research activities in the field.

As a result of this biological trend, neuropsychology has been recently renamed 'cognitive neuroscience'. This change in terminology reflects the intention to include neuropsychology within the vast domain of neuroscience. Since neuroscience covers a large spectrum of disciplines, going from the physiological study of single neurons in the turtle retina (Sernagor & Grzywacz 1996) to the brain organization subserving the sense of humour in humans (Shammi & Stuss 1999), 'cognitive' has qualified the 'neuroscience' term. The qualifier is unfortunate because 'cognitive' usually excludes emotion. Cognition is often seen as antagonistic to emotion. For example, Kivy (1990) in his influential essay on the meaning of music coined the term 'cognitivist' to refer to the position that holds that music simply expresses emotions without inducing them. The opposite position, called 'emotivist', holds that music elicits emotional responses in listeners.

The antagonism between 'cognitivists' and 'emotivists' is not limited to music psychology. It has a long history starting with Descartes' early separation of emotion and reason. Still, today, the majority of experimental psychologists and neuropsychologists are 'cognitivists' by default. They have simply ignored emotions. This neglect partly reflects the information-processing approach that started in the early 1960s (e.g. Neisser 1967) and that used the computer as a metaphor for mental functions. Following this approach, the brain is a machine, devoid of emotions.

Recently, neuropsychologists have become more concerned with emotions. Although neuropsychologists do distinguish between emotional and cognitive processes, they no longer reject the emotional part as being too obscure or subjective to be scientifically studied. On the contrary, emotions are now studied for their own sake. In their two popular books published in 1994 and 1996, respectively, Damasio and LeDoux have greatly contributed to the *rapprochement* between cognition and emotion in neuropsychology. Reason is no longer seen as the human-specific activity that controls emotional irrationality. As Damasio (1994) has shown, emotional processes are an integral part of decision making and are no longer confined to subcortical brain structures that are shared with other animals. Emotions recruit portions of the frontal lobes, which are the largest and latest brain structures to develop in the human brain. Thus, neuropsychologists are currently studying emotions in the same way as any other mental function worthy of enquiry.

The objective of this chapter is to present current knowledge about musical emotions from a biological perspective. I will introduce this topic by first covering neuropsychological data accumulated on facial expressions of emotions. This area of investigation has made remarkable progress recently. An outline of the major findings will allow me to illustrate a number of principles that characterize the field of neuropsychology in general. After this excursion into the facial processing domain, I will cover what is currently known about the neural correlates of musical emotions. Then, I will address the possibility that musical emotions follow similar paths to vocal emotions (the emotional expressions produced by non-verbal inflections of the human voice) by reviewing the relevant literature. Although the neuropsychological study of musical emotions lags behind, drawing parallels across domains should benefit the musical endeavour and, hopefully, promote cross-fertilization.

5.1 An illustration of the rise of affective neuroscience: facial expressions

Emotions have generally been considered too personal, elusive, and variable to be studied scientifically. *A fortiori*, emotions could hardly be conceived as subserved by a neuroanatomical arrangement that can be shared by all members of the same species. The work of Paul Ekman on human facial expressions has contributed to convince the scientific community that the above view is inadequate. In what follows, I will summarize his work and the subsequent research done on the neural substrates of human facial expressions, because it has spurred my own interest in studying the neural basis of musical emotions. Above all, it will allow me to introduce basic concepts about the neuroanatomical substrates of emotions and the major technologies by way of an example rather than as a disembodied general model associated with a series of techniques without objects.

5.1.1 Facial expressions: universality and innateness

Like music, facial expressions are non-verbal communicative displays, which can be very subtle but none the less quickly and easily appreciated by humans. Infants show a precocious ability to respond to different facial expressions of emotions (Field *et al.*

1982). Darwin (1872) was the first to hypothesize the innateness and universality of facial expressions of emotions, but his proposal received little attention. It was only in the late 1960s, with the work of Ekman (Ekman 1994; Ekman *et al.* 1969) and Izard (1971), that Darwin's position regained credibility. At the time Ekman and Izard began their studies, it was thought that facial expressions of emotions are socially learned and therefore variable from culture to culture. Ekman and his collaborators dismissed the idea that facial expressions are pure social constructs, in showing that a variety of emotions are expressed cross-culturally by the same facial movements (even though there might be culture-specific variations as captured by Ekman's concept of 'display rules').

For example, Ekman and collaborators (1987) reported a study in which facial expressions were examined in Japanese and Americans while they watched stress-inducing films (e.g. body mutilations) and neutral films (nature scenes). When the subjects in each culture watched the films alone, unaware of a hidden camera, the same negative facial responses were emitted regardless of culture. However, when a scientist was present while they watched the films, the Japanese more than the Americans masked their expressions with smiles. This study illustrates how universal expressions of disgust on faces can manifest themselves, beyond cultural differences, in their display. In other studies, the same group of researchers has convincingly demonstrated that facial expressions of 'basic' emotions (for a further explanation of this concept, see Sloboda & Juslin, this volume), such as happiness, sadness, anger, and fear, are easy to recognize by members of widely different and isolated cultures. The general rules and processes subserving facial expressions appear universal.

The universality of emotion expressions is necessary but not sufficient for considering them to be innate or biologically determined, as initially posited by Darwin (1872). Universality can arise as common learning experiences because all infants are exposed to the same situations, such as pain, being left alone, or reassured, across cultures. However, as summarized by Oster and Ekman (1978), even premature newborns are capable of producing all the discrete facial muscle movements involved in the expressions of basic emotions such as disgust, endogenous smiling, and sadness. Children born deaf and blind show similar facial expressions to those of hearing and seeing children (e.g. Eibl-Eibesfeldt 1973). Before 1 year of age, infants demonstrate meaningful relations between events and expressions of joy, sadness, fear, disgust, and anger. It is unlikely that young infants could have learned all these complex muscular patterns of facial expressions so quickly. The notion that facial expressions are learned lacks plausibility. Rather, facial expressions appear constrained by innate mechanisms. Thus, the innateness and universality of facial expressions appears sufficiently robust to consider Darwin's hypothesis established.

5.1.2 Facial expressions: brain specialization

The fact that facial expressions of emotion exhibit universality and innateness is important from a neuropsychological perspective. More specifically, brain organization is expected to differ for functions that respond to cultural pressure and for functions that meet biological requirements. Functions resulting from social conventions might be implemented in neural networks that vary across individuals. Depending on the quality and quantity of familiarization with a skill, various brain regions might be mobilized to

different degrees in individuals. Driving a car, an obvious cultural and recent acquisition in the human behavioural repertoire, would be expected to be subserved by variable, not specialized, neural networks. In order to drive a car, a person would be expected to borrow functional principles and neural resources from other skills, such as navigating, and to adjust them to their processing needs. In contrast, biologically important functions are likely to be subserved by a fixed and specialized neural architecture. This is probably the case for both expression and recognition of emotions in faces, since they exhibit universality and precociousness. Hence, the neural basis of facial expressions is expected to exhibit the same functional and neuroanatomical specialization across human brains. Accordingly, specification of the functional neuroanatomy underlying facial expressions should be relatively easy.

The first neural property that facial expressions should possess is brain specialization. That is, recognition of emotional expressions should be isolable in the brain. This property is indeed verified. Selective losses in the ability to recognize emotions from faces have been reported after focal brain damage (e.g. Calder *et al.* 1996; Etcoff 1984; Parry *et al.* 1991; Sprengelmeyer *et al.* 1996; Young *et al.* 1993). Such patients can recognize all known faces and infer the age of unknown faces, but are unable to see variations in emotional expressions. Conversely, other patients remain capable of discriminating and identifying various facial expressions, while being entirely unable to recover the identities of familiar faces of relatives and even of themselves (e.g. Tranel *et al.* 1988).

The study of the effects of brain lesions on a particular mental function is the oldest method used in neuropsychology. The observed disorders reveal both how the function under study is organized functionally and what part of the brain is *necessarily* involved in its processing. The idea is that the disorder is not arbitrary, but rather reveals the organization of the brain prior to the accident. Assumptions and methods have become extremely sophisticated over the past 20 years, so the patient-based approach remains one of the major sources of information in cognitive neuroscience (see Rapp 2001, for a new textbook devoted to just this: what deficits reveal about the human mind). One of the landmarks of this approach is its power to reveal functional and neural specificity, often referred to as 'modularity'. It is this phenomenon of functional specificity that is illustrated here in the recognition of facial expressions of emotion relative to the recognition of the identity of the face.

The neural segregation of facial emotion and facial identity that emerges from lesion studies has been confirmed by functional brain imaging. For example, Sergent and collaborators (1994) have shown that different brain regions are involved in the analysis of identity and expression by measuring variations of regional cerebral blood flow in normal brains with the positron emission tomography (PET) technique.

The PET technique and the functional magnetic resonance imaging (fMRI) technique are two recent tools that are most often used today for studying the functioning of *normal* brains. PET is more invasive than fMRI because it involves the injection of radioactive substance. However, PET scanning is less noisy, and hence more appropriate for studying music perception. Fortunately, new means have been developed to facilitate auditory testing in the MRI machine. One such means consists in clustering volume acquisition (and hence noise) by acquiring all images of the brain in rapid succession for about 1 second, every 10 seconds, and so providing a period of quiet during which the stimuli may be presented uninterrupted and uncontaminated

by cortical responses to the noise (e.g. Edmister *et al.* 1999). Both PET and fMRI are valuable neuropsychological tools because they allow the measurement of variations of cerebral blood flow in three dimensions in the brain of a participant who is performing a task. Local variations in blood flow, or oxygen consumption, respond to different needs at any given time during the performance. However, measurements of cerebral blood flow changes are slow relative to the speed of information processing—requiring 2–3 minutes or 4–5 seconds with PET and fMRI scanning methods, respectively. All measures are taken after transformation of the magnetic resonance images of each individual into a standardized stereotaxic space. This manipulation eliminates any differences attributable to global differences in overall brain size or shape.

Using the PET technique with visual presentations of faces, Sergent and her co-workers were able to show that the processing of facial identity is associated with the ventromesial region of the right hemisphere (i.e. the fusiform gyrus and the lingual gyrus) and the parahippocampal gyrus, whereas facial emotion (covering happiness, sadness, fear, disgust) mostly engages the lateral part of the right occipital cortex and the cingulate gyrus (located in the limbic system). The regions are indicated in Fig. 5.1. Similarly, in the monkey, cells selective for facial identity and expression are found in different brain areas; cells which respond to face identity tend to be located in the inferior temporal gyrus, whereas cells whose responses are modulated preferentially by expression are located within the monkey's superior temporal sulcus (e.g. Hasselmo *et al.* 1989).

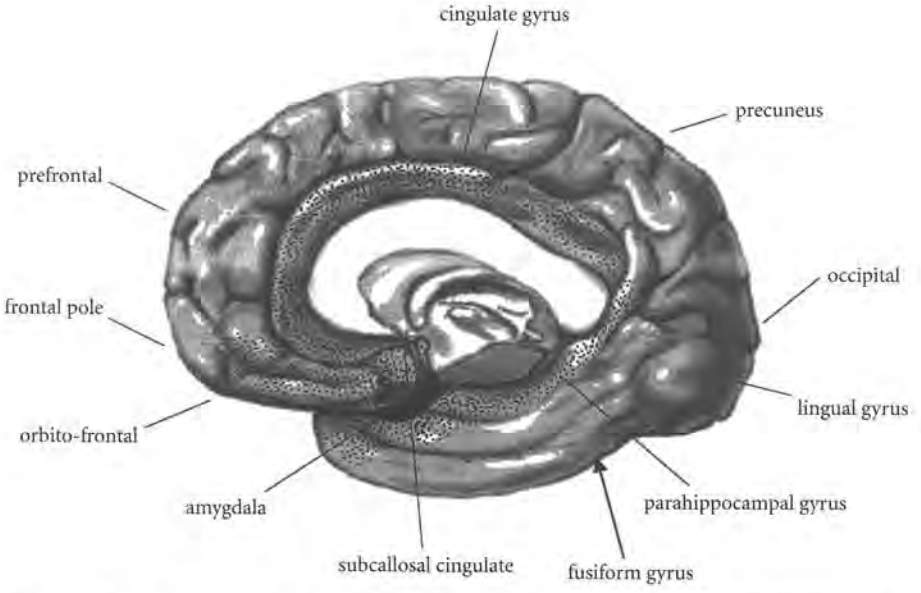

Figure 5.1 A medial inside view of the brain. The stippled area is the classic limbic system. The fusiform gyrus is hidden inside the temporal lobe. The amygdala, represented in black, is found deep inside the medial part of the temporal lobe.

5.1.3 Facial emotions: the role of the amygdala

We have seen that the processing of facial emotions is isolable in the brain. This does not mean facial emotions are subserved by a unique neural pathway. Rather, neural systems appear specialized for the recognition of specific emotions. The clearest evidence comes from studies of patients with damage to the amygdala, a brain structure long thought to play an important role in emotion. The amygdala is located in the limbic system (see Fig. 5.1). This system, named 'le grand lobe limbique' by Broca (1878), corresponds to subcortical structures that appeared early in evolution and remained relatively stable across species. The limbic system was designated as the substrate of emotions by Broca over a century ago, and later also by Papez (1937). Since then, the concept has gradually developed to include many more regions, both cortical and subcortical (Damasio 1994; LeDoux 1996). Emotions are no longer confined to the functioning of the limbic system, although the latter retains its fundamental role in emotion.

In the limbic system, the amygdala has been identified as the brain structure most implicated in fear. Bilateral amygdala damage impairs the recognition of unpleasant emotions, especially fear, in facial expressions (Adolphs *et al.* 1994, 1995; Broks *et al.* 1998; Calder *et al.*, 1996; Young *et al.* 1995); but not always (see Hamann *et al.* 1996). Such patients can see happiness and sadness in faces, but have severe problems with fearful expressions.

Additional support for the selective involvement of the amygdala in perceiving fear in facial expressions has been gathered in recent functional imaging studies of normal brains. Increased neural activity has been observed within the amygdala when subjects are viewing facial expressions of fear as opposed to happiness (Breiter *et al.* 1996; Morris *et al.* 1996; Whalen *et al.* 1998), disgust (Phillips *et al.* 1997), and anger (Blair *et al.* 1999).

The involvement of the amygdala is not limited to facial expressions of fear. The amygdala also plays a key role in conditioned fear in both humans and rats (Bechara *et al.* 1995; LeDoux 1996), as well as in fear-related behaviours such as uncontrollable rage reactions (Davis 1992). Moreover, direct stimulation of the human amygdala with in-depth electrodes evokes similar reactions (Halgren *et al.* 1978), further suggesting that the amygdala is critical to the processing of a class of emotions, namely those related to threat and danger.

The amygdala is strongly connected to the autonomic nervous system, which induces changes in physiological measures such as heart rate, blood flow, and respiration. This connectivity, coupled with the selectivity, of the emotional response, suggests that the amygdala is appropriately located in the brain to enable reactions to threat and danger, without the necessity of higher-level processing. The idea is that an expression of fear on the face of a conspecific may trigger an automatic and quick response to potential danger via the amygdala.

The role of the amygdala is highly selective. It does not participate in the evaluation of all negative emotions expressed by faces. For instance, the amygdala is not as actively engaged in perceiving disgust. Disgust rather involves the basal ganglia and the anterior insula. Increased activation of the insula has been observed in a functional brain-imagery study (Phillips *et al.* 1997), while impairments in disgust have been reported in patients with Huntington's disease, which is a neurological disorder that initially affects the basal ganglia (Gray *et al.* 1997; Sprengelmeyer *et al.* 1996). Disgust is another distinct

facial expression that has clear survival value, as does fear. Recognition of disgust allows avoiding contamination by offensive stimuli, and, in particular, the avoidance of ingestion of potentially harmful food. The neural response to facial expressions of disgust appears closely related to another, but related, sensory organ, namely taste. In humans, the anterior insula is particularly activated by aversive tasting (e.g. Zald *et al.* 1998). Altogether, the localization of the neural structures involved in disgust confirms common sense—that disgust is closely related to the perception of unpleasant tastes and smells.

The major implication of the relative engagement of the amygdala in perceiving fear relative to disgust in facial expressions is that it raises the possibility that different basic emotions have different underlying neural substrates. Basic emotions serve important and distinct functions, and the brain appears to be organized so as to respond to these distinct functions with distinct neural systems.

5.1.4 Facial expressions: the contribution of the cortical systems

The cortical systems are the neural structures that are evolutionarily more recent, and are particularly developed in the human brain. These cortical systems involve the occipital, temporal, parietal, and frontal cortex (Fig. 5.2). Another characteristic of these cortical structures is that they exhibit functional specialization within and across the two cerebral hemispheres. For example, it is well established that regions of the left hemisphere of the brain are much more essential for speech comprehension and expression than the right side of the brain.

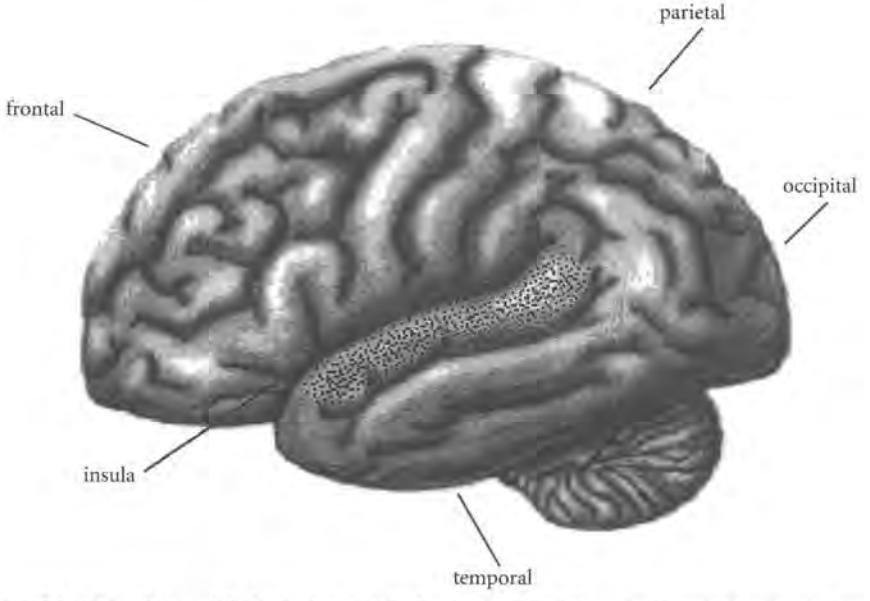

Figure 5.2 A lateral view of the brain showing the four lobes of the left cerebral hemisphere in which several structures of interest are indicated. The stippled area corresponds to the superior temporal gyrus (see text for explanation).

With respect to emotions, there is currently a debate involving two alternative views. One view is that the right hemisphere is specialized for processing *all* emotions, by containing all 'modules' for non-verbal affect computation (e.g. Bowers *et al.* 1993). This position is known as the 'right hemisphere hypothesis'. The opposing view is the 'valence hypothesis' according to which the right hemisphere is more involved in negative emotions and the left hemisphere more engaged in positive emotions (e.g. Davidson 1992). Both hypotheses have been discussed with regard to the expression and recognition of emotion, as well as the experience of emotion.

The first observations related to the emotional competence of each cerebral hemisphere go back to Jackson (1878), who noticed that emotional language is often preserved in aphasic patients. He attributed the source of the preserved affective utterances to the contribution of the right hemisphere. This dissociation between propositional and affective language has often been reported since. However, it is difficult to reconcile with another classic pattern in clinical neurology that identifies each hemisphere with a distinct affective style. A lesion in the right hemisphere often produces indifference (anosognosia) and a tendency to joke. In contrast, an injury in the left hemisphere often leads to depressive–catastrophic states. The former is obviously less comprehensible than the latter as a reaction to the brain accident. The two emotional modes of responding have been associated with differences in 'affective styles' of the cerebral hemispheres. The left and right frontal cortex would be mediating approach and avoidance, respectively (for a recent review, see Davidson & Irwin 1999).

The valence hypothesis accounts more convincingly for expression and experience of emotions than for perception of emotions. For the latter, the bulk of the evidence seems to favour the right hemisphere hypothesis. In the study of normal adults' perceptual asymmetries, a left visual field (i.e. right hemisphere) superiority is typically found for both positive and negative expressions (see Best *et al.* 1994, for a recent review and additional data on adults' perception of infants' emotional expressions).

Perceptual asymmetries can be easily measured in normal right-handed subjects, in all modalities. In the visual modality, which is used for face presentation, facial expressions are typically and quickly presented to the left or to the right of a central fixation point. A left visual field advantage is inferred if the subjects process more accurately or more quickly the facial expressions presented on the left side of the screen than the expressions presented on the right side. Since the left visual field is directly projected to the right cerebral hemisphere, the advantage is taken to reflect a right hemispheric superiority for the task under study. The same logic applies to the auditory modality with which we will be concerned in the next section. This technique, often referred to as *dichotic listening*, consists of presenting different auditory stimuli in each ear, simultaneously. A right ear advantage is interpreted as a left hemispheric superiority, because it is well established that the information that enters in one ear reaches mostly the primary auditory cortex of the opposite hemisphere. It should be noted that although laterality measures are convenient and non-invasive tools for testing hemispheric specialization, they are less used nowadays because they have low sensitivity and low reliability, particularly in the auditory modality.

Lesion studies are compatible with both the right hemisphere hypothesis and the valence hypothesis. In a recent study involving a large sample of brain-damaged patients, Adolphs and his collaborators (1996) found that lesions of the right hemisphere led to impairments in recognizing negative emotions, such as fear and sadness, but spared

recognition of happy expressions. However, there are fewer positive than negative emotions regarded as basic emotions. Positive emotions, such as happiness, may simply be easier to distinguish from negative expressions than are negative emotions from each other. For example, a single prototypical feature (smile) distinguishes happiness from all other emotions.

Although the nature of each hemispheric contribution to the perception of facial expression remains to be determined, the presence of hemispheric advantages highlights the contribution of non-limbic cortical structures. It is plausible that the cortical contribution is related to both the demands of the perceptual analysis of the input (e.g. detailed facial features) and the contribution of memory, such as factual knowledge about emotions.

5.1.5 Facial expressions: a lesson and challenge

We have seen that recognition of facial expressions is the result of an adapted behavioural system that is implemented in a distributed neural network involving the limbic system, the amygdala in particular, but that it is not limited to this system. Recent research suggests additional and differential implication of the left and right prefrontal cortex, the anterior cingulate (see Fig. 5.1), and the insular cortex (see Fig. 5.2). Each of these regions appears to play a distinct function in emotional appraisal, with different distributed networks underlying different emotions such as fear and disgust.

Just as cognitive neuroscience has demonstrated the necessity to fractionate global functions, such as face processing or music recognition (Rapp 2001), into more elementary constituents whose neural substrates can be identified, so too modern research in the neuroscience of emotions suggests fractionation of affective processes. This conclusion highlights what is often not obvious to psychologists. It shows why the study of neural correlates in general, and brain localization in particular, is of importance. Examination of brain correlates can shed light on more general assumptions, by requiring that complex brain functions be decomposed into simpler processes so that simple components can be localized anatomically and studied in relative isolation. This fractionation into elementary localized mechanisms can then serve to test current models of emotional functioning or contribute to the building of new models.

5.2 Neural correlates of musical emotions

We have seen how facial emotions have become a tractable problem in the neurosciences. The central question is now to examine whether the neuropsychological study of musical emotions will hold similar promises.

5.2.1 Which musical emotions and what for?

Like facial expressions, certain musical emotions can be categorized as happiness, sadness, anger, and fear. The happy and sad emotional tones tend to be among the easiest ones to communicate in music (e.g. Gabrielsson & Juslin 1996; Krumhansl 1997). Like facial expressions, these emotions might be expressed by similar structural

features across musical styles and cultures. But the claim cannot be made forcefully, since the search of universals in the expression of musical emotions has just begun (Balkwill & Thompson 1999; but see also Juslin, this volume). In contrast, there is increasing evidence that musical emotions are quickly and easily perceived by members of the same culture. For example, ordinary adult listeners need less than a quarter of a second of music (e.g. one chord or a few notes) to reliably distinguish the tone of the whole musical excerpt as happy or sad (Peretz *et al.* 1998a). Moreover, and more generally, we were struck by the systematicity and reliability of the judgment data collected with ordinary listeners. Emotional judgments exhibit a high degree of consistency, suggesting that perception of emotions in music is natural and effortless for the large majority of listeners.

Developmental perspectives

Perception of emotion in music is also a skill that appears early in life. Recent empirical research suggests that music plays an important role in emotion regulation and emotional communication between care-givers and infants (e.g. Trehub & Trainor 1999). From birth, care-givers around the world sing to their infants, with the intuition (or instinct?) that music has the power to regulate the infant's state (e.g. comforting) or the quality of interaction (e.g. attention getting). The care-givers nicely mirror infants' perceptual abilities by singing more slowly, at higher pitch, with exaggerated rhythm, and in a more loving or emotionally engaging manner than when singing alone (e.g. Trainor *et al.* 1997). Responsiveness to such infant-directed singing appears inborn. Two-day-old hearing infants, born from congenitally deaf parents (who sign and do not sing or speak), prefer infant-directed singing to adult-directed singing (Masataka 1999).

Care-givers also speak to infants in a special, singing manner, so-called 'baby talk' or 'motherese' (see Bunt & Pavlicevic, this volume). Nevertheless, infants seem to discriminate between infant-directed speech and infant-directed music. Trehub (2001) reports a study in which 6-month-old infants viewed videotaped performances of their own mothers (recorded while singing or speaking to their infants). The infants showed more sustained attention to their mothers' singing episodes than to their speaking episodes. Infants were 'hypnotized' by these sung performances, remaining 'glued' to the monitor for extended periods. Mothers' speaking was not as engaging as their singing. The fact that infants are particularly responsive to the emotional messages of music directed toward them suggests an adaptive value of maternal singing. Mother–infant emotional communication is crucial to survival.

It is also remarkable how skilled the young children are in emotional perception. From the age of 3 years, they show the ability to recognize happiness in elaborate, art music of their culture, and by the age of 6 years they show adult-like abilities to identify sadness, fear, and anger in music (Cunningham & Sterling 1988; Terwogt & van Grinsven 1988, 1991; but for later emergence, see Dolgin & Adelson 1990). Furthermore, the child competence can be related to abstraction of specific musical features. At 5 years of age, children are able to discriminate between happy and sad excerpts by relying on tempo differences (fast vs. slow). At 6, children show evidence of using both tempo and mode (major vs. minor) like adults do. Although the results suggest that sensitivity

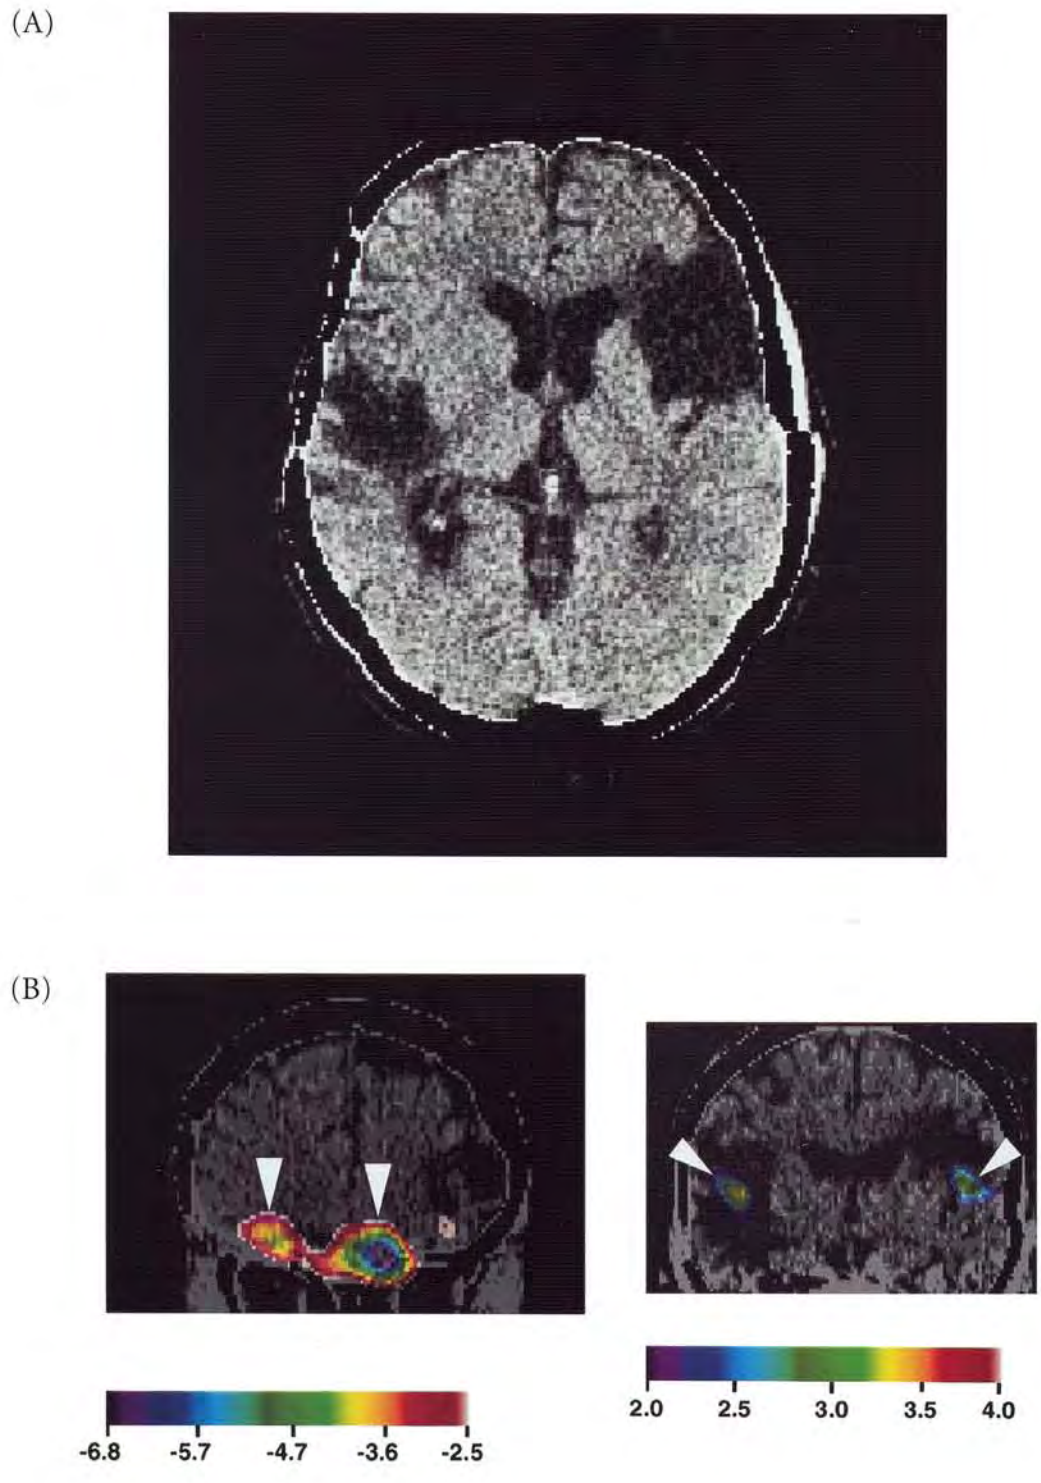
to tempo precedes sensitivity to mode, it is remarkable that by the age of 6 years, children show full knowledge of the rules that govern the happy–sad character of surrounding music. This ability seems to remain generally unchanged over a lifetime (Dalla Bella *et al.* 2001; Gerardi & Gerken 1995; Gregory *et al.* 1996; Kastner & Crowder 1990; Kratus 1993). Therefore, with consistency and precociousness, musical emotions resemble facial emotions.

Evolutionary perspectives

Musical emotions also seem to respond to important needs of the organism, even though considerable controversy surrounds the questions of the origin, biological significance, and function of music (e.g. Pinker 1997). In other words, music may have adaptive significance. Two main evolutionary explanations have been offered. The initial account was provided by Darwin himself (1871), who proposed that music serves to attract sexual partners. This view has been recently revived by Miller (2000), who reminds us that music making is still a young male trait. However, the dominant view of the adaptive value of music lies at the group level rather than at the individual level, with music helping to promote group cohesion. The initial step for this bonding effect of music could be the mother–infant interactive pattern created through maternal singing. The individual- and group-level roles attributed to music do not need to be mutually exclusive. As pointed out by Kogan (1994), individuals taking the lead in gatherings by virtue of their musical and dance prowess can achieve leadership status in the group, a factor that contributes to reproductive success (for other formulations of these evolutionary issues, see Wallin *et al.* 2000).

In support of the contention that music has an adaptive value, particularly for the group, is the fact that music possesses two design features that reflect an intrinsic role in communion (as opposed to communication, which is the key function of speech). Pitch intervals allow harmonious voice blending when sounding together, and temporal regularity facilitates motor synchronicity. These two musical features are highly effective in promoting simultaneous singing and dancing (Brown 2000). The design is specific to music; it is certainly not shared with speech, which requires individuality for its intelligibility. These special features fit with the important criterion, discussed by Buss and collaborators (1998), that for a system to qualify as 'adaptive' it must offer effective solutions to a problem. The system must have a 'special design'. The bonding problem in the case of music is to override 'selfish genes' for the benefit of the group.

For neuropsychologists, this evolutionary perspective on music is essential. As mentioned earlier, the fact that musical emotions are viewed as adaptive responses that can be aroused similarly in every human being is best conceived as the product of neural structures that are specialized for their computation. Furthermore, if biologically important, these emotions can even be seen as *reflexes* in their operation. That is, musical emotions would occur with rapid onset, through automatic appraisal, and with involuntary changes in physiological and behavioural responses. This conception would correspond to the fact that 'we often experience emotions as happening to us, not as chosen by us. We do not simply decide when to have or not have a particular emotion' (Ekman 1994, p. 17).



5.2.2 Musical emotions: brain specialization

Support for the existence of specialized neural networks for music processing is presently compelling (for reviews, see Peretz 2001*a*, 2001*b*). However, the evidence relies on the detailed study of music perception and memory, that is on the processing of music as a special auditory structure, not as an emotional medium. Emotional appreciation of music is a new research avenue in neuropsychology. Hence, the data are scarce, albeit consistent and promising.

First of all, musical emotions appear isolable in the human brain. By isolable, I mean that musical emotions can be selectively either lost or spared, usually as a consequence of a brain accident occurring at an adult age. There are a number of case reports that describe musicians who retained their musical skills, but who complained that they lost interest in music because it sounded 'flat' or without emotion (Mazzoni *et al.* 1993; Mazzuchi *et al.* 1982). Unfortunately, the reports are anecdotal. No attention was paid to the emotional complaints of the two patients because of 'the highly subjective nature of the symptom concerned' (Mazzuchi *et al.* 1982, p. 646) or because 'disturbances of this type are, unfortunately, difficult to view objectively because of their highly subjective nature' (Mazzoni *et al.* 1993, p. 322).

However, recent progress made in affective neuroscience in general, and in the study of facial expressions in particular, has encouraged us to go beyond anecdotal reports and study emotional responses in the laboratory. In doing so, we have been able to discover mirror cases, that is, patients who manifest selective sparing of musical emotions. The case of one patient, IR, who suffers from longstanding bilateral brain damage to the auditory cortex (see panel A in Fig. 5.3) is given here. The case is remarkable in that 15 years after the brain damage, IR still experiences severe difficulties with music while her language abilities and her general intellectual and memory abilities are normal (Peretz *et al.* 1997; Peretz & Gagnon 1999). Despite her severe musical deficits, she reports that she still enjoys music, listening regularly to prerecorded music in the car. This possible preservation of emotions for music appeared to us as paradoxical, given the severity of IR's perceptual disorders with music. Therefore, we decided to study her emotional judgments in detail. Three independent studies have been completed with her that will be summarized here.

The goal of the first study (Peretz & Gagnon 1999) was to verify experimentally IR's insights. To do so, IR was presented with popular melodies, half of which are familiar in Québec where the study was conducted. IR performed two judgments: in the emotional judgments, she classified the melodies as 'happy' or 'sad'. In the non-emotional 'control' task, she performed a 'familiar–unfamiliar' classification task. The results confirm her report. She is able to classify melodies as 'happy' and 'sad' as normal controls do, while she fails to reach normal performance in classifying these same melodies for familiarity. For example, when presented with the melody of 'Happy Birthday' without its lyrics, IR would say 'I don't know that tune but it sounds happy'. Similarly, CN, another patient with severe recognition problems for melodies that were once highly familiar to her (Peretz 1996), had an interesting reaction. When listening to the famous adagio of Albinoni taken from her own record collection, CN first said that she had never heard that piece before. Suddenly, she said: 'it makes me feel sad . . . the feeling makes me think of Albinoni's adagio' (R. Kolinsky, personal communication). CN, who was totally

CT scan of I.R.'s brain, transformed into the standardized stereotaxic space. For a more detailed caption see Fig. 5.3 on p.117.

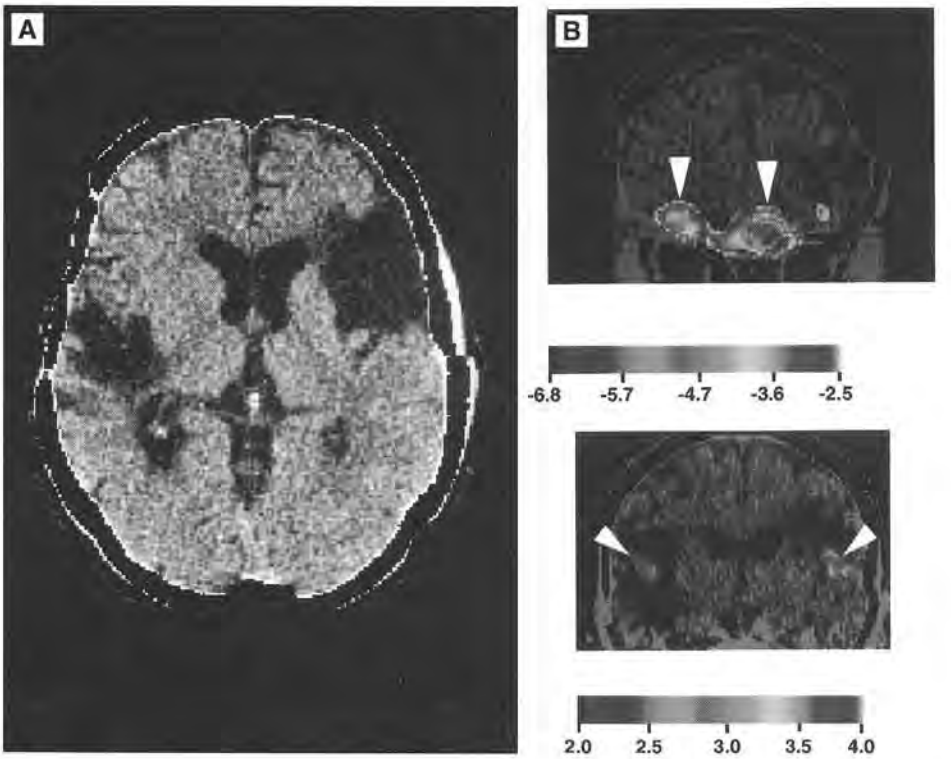


Figure 5.3 CT scan of IR's brain, transformed into standardized stereotaxic space. The right side of the scan corresponds to the right side of the brain. (A) Horizontal slice showing the differing locations of temporal and frontal lobe damage (i.e. darker areas correspond to damaged tissue) in the left and right hemispheres, and (B) coronal slices showing PET data from a group of normal non-musicians (Blood *et al.* 1999*a*) superimposed on the CT scan of IR's brain. The top panel shows areas whose cerebral blood flow (CBF) changes are related to pleasantness judgments; the arrowheads show the subcallosal area and the left orbitofrontal areas. None of the paralimbic or neocortical regions recruited by the dissonance manipulation in normals overlapped with the lesions in IR's brain. The panel below illustrates areas of significant CBF increase in the subtraction of a highly consonant stimulus condition with a matched noise baseline condition. This illustrates the areas of activity within the superior temporal gyri bilaterally (indicated by arrowheads). Note that these regions overlapped significantly with the lesions in IR's brain. The *t*-statistic ranges are coded by the colour scale below the corresponding panel. (Adapted from Peretz *et al.* 2001.) (See also colour section).

unable to recognize melodies that were highly familiar to her before the brain accident, was able to do so via her emotional responses. This is probably not an isolated finding. However, we did not pursue our work in that direction. Rather, we wished to establish more firmly the dissociation observed in IR between emotion and perception.

In a follow-up study of IR (Peretz *et al.* 1998a), we were interested in explaining how she could derive the emotional tone from melodies, while her ability to recognize and discriminate melodies is so limited. One intriguing possibility, derived from the animal

work of LeDoux (1996) and from the theoretical position of Zajonc (1984), is that emotions need no cortical mediation. That is, basic emotional responses might function like subcortical reflexes. These emotional responses would be immediate but superficial. They would not require the additional time taken by elaborate processing of the signal in cortical structures. Since IR's lesions are vast, but limited to cortical structures, perhaps her intact limbic system is responsible for her spared ability to distinguish happy from sad music.

To assess the nature of this spared emotional pathway in IR, and to further assess its independence from the rest of her processing system for music, we tested her in a series of experiments employing the same set of excerpts taken from the classical repertoire (e.g. Albinoni's adagio). These were selected to unambiguously convey a 'happy' or 'sad' tone, and were presented under various transformations and with different task demands. At first sight, IR's results seemed to conform to the separate pathways view. As with normals, IR was able to use both the mode and the tempo characteristics to derive the 'happy' or 'sad' tone of the music. Moreover, as with normals, IR's judgments were immediate. In contrast with the relatively sophisticated emotional processing of the musical excerpts, IR showed impaired performance in her non-emotional assessment. Specifically, she performed well below normal controls in the discrimination of these musical excerpts in a 'same–different' classification task that was very easy for controls. Likewise, she failed to detect most errors purposely inserted on either the pitch or time dimension of the musical excerpts, although these mistakes were obvious to control subjects. Thus, IR's pattern of results suggests that perceptual analysis of the musical input is intact for emotional purposes and defective for non-emotional ones.

The relative independence of the emotional pathway from non-emotional processing of music is consistent with previous data of ours that were obtained with neurologically intact students. We showed in a series of experiments that exposure effects differed for recognition and liking judgments (Peretz *et al.* 1998b). Similarly, we showed that IR can process melodies for emotion recognition, but not for identity recognition (Peretz & Gagnon 1999) or discrimination (Peretz *et al.* 1998a). However, IR's spared emotional processing cannot be easily accommodated with the isolated functioning of a subcortical pathway. IR is able to use a change of mode, from major to minor and vice versa, in elaborate musical structures. This ability can hardly be conceived as the result of the operation of a primitive subcortical system. Furthermore, as we will see later, there is presently little support for the involvement of a subcortical 'short cut' in emotional processing of music. Rather, musical emotions seem to require cortical mediation. Therefore, all we can conclude from these studies with IR and CN is that severe deficits in perceptual processing and memorization of music can leave emotional judgments of music unimpaired. Such a spectacular isolation of emotional judgments of music suggests the presence of a specialized cortical arrangement for it.

5.2.3 Musical emotions: hemispheric specialization

As mentioned above, there are indications that emotional judgments require cortical mediation. The participation of cortical structures seems to depend on the cerebral hemisphere concerned, as observed for facial expressions. Likewise, the available data are divided between the two current hypotheses regarding the nature of this specialization.

Support for the valence hypothesis has been obtained in two recent studies measuring brain electrical activity—the electroencephalogram (EEG)—from scalp electrodes in normal listeners (Schmidt & Trainor 2001; Tsang *et al.* 2001).

EEG methods are non-invasive measurements of the ongoing electrical activity that can be captured by electrodes located on the scalp of the listener. Various measurements are made possible with the recent increases in computer power. The EEG method used in the studies by Schmidt and Tsang that are cited here consists of recording the EEG variations over extended periods of time, in the order of 60 seconds, while the subject is listening to a piece of music. The EEG signal is then decomposed into particular frequency bands, such as the alpha bands taken to reflect variations in activation. Another EEG method that is increasingly exploited in neuropsychology is the evoked response potential (ERP) (for a review of its use with regard to music, see Besson 1997). This method consists of averaging EEG signals time-locked to a particular category of events. The advantage of the ERP is that it is an on-line measure of processing that has a high temporal resolution window, of the order of a few milliseconds. By increasing the number of electrodes over the scalp, and by exploiting sophisticated algorithms to locate the neural source responsible for the observed response, it is now possible to obtain information about brain localization.

Asymmetrical frontal EEG activity has been found to distinguish the valence of musical excerpts taken from the classical repertoire. Subjects exhibit greater relative left frontal activity to music expressing joy and happiness and greater relative right frontal EEG activity to music expressing fear and sadness (Schmidt & Trainor 2001). Subsequently, the same group of researchers (Tsang *et al.* 2001), using the same EEG technique, were able to replicate and relate the EEG findings to musical structure, using our set of musical excerpts used with IR (Peretz *et al.* 1998a). They observed that changes in both tempo and mode in the happier direction resulted in greater relative left frontal activation, whereas changes in both tempo and mode in the sadder direction resulted in greater relative right frontal activation.

In a similar vein, Gagnon and Peretz (2000) have observed ear asymmetries in normal listeners that are compatible with the notion that the left hemisphere contributes more to the perception of positive emotions and the right hemisphere more to negative emotions in listeners. Non-musicians were required to classify tonal and atonal melodies as pleasant and unpleasant in one condition. In a non-affective 'control' condition, the same subjects were required to judge if the melodies sounded correct or not. Listeners exhibited a left-ear superiority effect, taken to reflect the predominance of the right hemisphere, when judging atonal melodies as unpleasant while they displayed a tendency towards the right ear when judging tonal melodies as pleasant. This pattern of ear asymmetries was specific to emotional judgments since a different pattern was obtained when the same melodies had to be classified for 'correctness'.

However, the valence account of cerebral asymmetries is not systematically observed. Two studies are more supportive of the right hemisphere hypothesis. The first one measured ear asymmetries in normal subjects who were judging minor and major melodies as eliciting positive or negative emotions (Bryden *et al.* 1982). In that study, an overall left ear (i.e. right hemisphere) advantage was observed across positive and negative emotional judgments. The second study measured changes in regional cerebral blood flow

with the PET technique as a function of pleasantness judgments for chord sequences varying in degree of dissonance (Blood *et al.* 1999*a*). In that study, the activated neural structures by pleasantness judgments were found primarily in the right hemisphere. Moreover, reciprocal activation was found between particular neural structures and the valence of the musical stimulus. However, these reciprocal activations did not occur between hemispheres but rather between the parahippocampal and frontal regions.

5.2.4 Musical emotions: contribution of distributed neural structures

Up to now, we have reviewed data suggesting that emotional appreciation of music is subserved by a distinct neural pathway that probably requires cortical mediation. Cortical mediation appears to involve primarily the right hemispheric structures, with a possible contribution of the left frontal regions, depending on the valence of the perceived emotion. More specific localization suggestions have been made by Blood and collaborators (1999*a*), using dissonance as the emotion-eliciting stimulus and PET scanning as the brain-recording measure.

In that PET study, regional cerebral blood flow changes were obtained in several distinct paralimbic and neocortical regions of the brain. Most activated areas depend on the valence of emotion. Activity in the right parahippocampal gyrus and precuneus regions is associated with increasing dissonance, whereas activity in the bilateral orbitofrontal, medial subcallosal cingulate, and right frontal polar cortex correlates with decreasing dissonance (or increasing consonance). In contrast, activity in the superior temporal cortices is observed bilaterally, independently of dissonance level. All implicated regions are indicated in Fig. 5.1.

One powerful means to determine which neural region is essential in a given function is to compare brain-imaging data with brain-lesion data. To this aim, we tested IR, our case with bilateral lesions to the auditory temporal cortex, with consonant and dissonant music (Peretz *et al.* 2001). In fact, IR is unable to distinguish consonant from dissonant versions of the same musical excerpts in pleasantness judgments, although she is able to judge the 'happy–sad' character of the music. This is a striking disorder. Preference of consonant over dissonant music is widely shared by ordinary listeners, beginning with 4-month-old infants (see, for example, Trainor & Heinmiller 1998; Zentner & Kagan 1996). IR has lost this ability. Localization of the responsible damage cannot be easily determined in her brain. As can be seen in Fig. 5.3, IR's lesions are extensive and asymmetrically localized in her cerebral hemispheres. Therefore, it is not clear which of these damaged areas can be taken as responsible for the observed deficit in responding to dissonance. By combining information about IR's lesion localization with normal cerebral regions that are implicated in judging dissonance, we might be able to isolate the critical neural regions.

Therefore, we co-registered images of IR's brain with the activated brain regions found in normal brains. We found that the complex network involving paralimbic and neocortical regions associated with the affective evaluation of dissonance did not overlap with IR's lesions (see top panel B in Fig. 5.3). In contrast, significant overlap was found between IR's lesions and the pattern of activity elicited by all musical stimuli, irrespective of dissonance level (see bottom panel B in Fig. 5.3). The damaged areas in IR's brain coincided with the regions located in the superior temporal gyri that were

involved in the perceptual analysis, including those related to dissonance, of the chord sequences in normal brains. Therefore, we can infer that the critical networks for dissonance appraisal are located bilaterally in the superior temporal gyri. Furthermore, we can ascribe IR's indifference to dissonance to a perceptual defect.

That IR's problem with dissonance lies at the perceptual level is consistent with a number of independent observations. First, in general, IR's emotional processes appear fairly normal. Second, the neural network specifically associated with emotional evaluation of dissonance, which involves the subcortical–frontal areas, seems largely spared in IR's brain. Third, IR was unable to discriminate the different versions of the same musical sequence that only differed in degrees of dissonance. Therefore, a plausible account of IR's lack of responsiveness to dissonance is simply that she does not perceive it. Had she perceived it correctly, she would have judged its emotional valence accordingly. If this interpretation is correct, affective responses to dissonance are mediated via an obligatory cortical perceptual relay.

In summary, the present findings suggest a particular functional architecture underlying emotional interpretation of music. Taken together, the results suggest that the musical input first reaches the superior temporal gyri, where perceptual organization is taking place. The perceptual output is then relayed to emotional systems in the paralimbic structures or more frontal areas, depending on its valence. This two-stage model suggests that emotion and perception are not taking place along two parallel and independent pathways as some models (LeDoux 2000; Zajonc 1984) posit. However, caution is required because this model only derives from the study of a single emotional dimension, relating dissonance to unpleasant judgments.

5.3 Fractionation of musical emotions

As seen with facial expressions, neuropsychological methods are most productive for dissecting emotions and their neural substrates into elementary components. Unfortunately, research has just begun with musical emotions. Hence, the power of the methods cannot be fully appreciated in the musical domain. In what follows, I will raise a few questions that, I believe, are important to address using neuropsychological methods. Since these questions do not have an answer yet, their outlining should be regarded as guidelines for future research.

5.3.1 Single or multiple emotional systems for music?

In theory, lesion studies and functional brain imagery should provide evidence regarding the possibility that there is not a single but multiple emotional systems that can be aroused by music, depending on its content. Although parsimonious, the notion of a single emotional system is difficult to hold given the diversity of emotions and their differential functionality for the organism. This was illustrated earlier with the neuropsychological separation of fear from disgust with regard to facial expressions. The problem with musical emotions is that their functionality is not settled, and *a fortiori* the principles along which musical emotions may fractionate remain open. But neuropsychology may, in principle, provide relevant cues.

For example, there are indications that musical emotions can be studied in relative isolation from each other. The 'happy–sad' character of music can be studied independently from a valence ('pleasant–unpleasant') dimension. As shown in the study of IR, discrimination of happiness and sadness in music can be preserved in the presence of a lost sensitivity to dissonance. Although this dissociation has a perceptual rather than an emotional origin, it highlights one clear advantage of studying musical emotions over other domains, such as facial and vocal expressions. In music, it is easier to manipulate structural characteristics systematically so that the same music can express different emotions gradually. For example, tempo increase and decrease are easy to apply without altering other aspects of the musical structure (e.g. Gagnon & Peretz 2001, within certain limits). We can also manipulate two emotional dimensions orthogonally, as previously done with the same set of stimuli, by modifying mode (from major to minor and vice versa) and dissonance, independently (Peretz *et al.* 2001). There is such a close relationship between structural characteristics and certain emotional expressions in music that the domain lends itself to experimentation. This is hardly a new finding (see Gabrielsson & Lindström, this volume; Juslin, this volume). Yet, it is often overlooked in the literature.

Finally, musical emotions present interesting peculiarities. Sadness in music is a good example. It is pleasurable in music while perceived as unpleasant in most other channels. By studying the neural correlates of certain musical emotions, like sadness, the generalization and neuropsychological validity of various taxonomies of emotions can be advantageously tested. It may turn out that some musical emotions are unlike any other type of emotion. If that is the case, the evidence will in all likelihood come from neuropsychology, since the discipline is perfectly suited to reveal functional specificity.

5.3.2 Are emotional systems domain-specific?

As indirectly suggested, musical emotions might differ from other emotions in numerous aspects. However, there is as yet no theoretical or empirical reason for assuming such specificity. Inversely, musical emotions are frequently compared to vocal expressions (Juslin, this volume), with the idea that the two expressive channels may derive ontogenetically and phylogenetically from a unique and common mode of communication. In this context, it may seem curious that up to now I have only considered the advances made in the domain of facial expressions. The reason is simply that progress has been much slower in the domain of vocal expressions of emotions.

Perhaps vocal expressions of emotions have not yet received sufficient theoretical attention (but see Johnstone & Scherer 2000, for a recent summary of promising findings). Despite the obvious biological significance of vocal emotions, there is no consensus over an evolutionary-based theory of it. This lack of theoretical development, compared to, say, the domain of facial expressions, might in turn explain why the topic of vocal expressions has had a limited impact in the recent shaping of the neuropsychology of emotions. This is certainly not due to lack of interest. The literature is abundant, as summarized below.

Vocal emotions: neural correlates

Just as musical expressions of emotions can be conveyed by variations in pitch and articulation, emotions can be expressed by modulations of the tone of the voice.

Emotion expressions through vocal sounds can take two different forms in humans. It can be conveyed by the tone of voice in speaking or by non-verbal expressions such as in laughing, crying, and screaming. There has been a greater interest in the first category of vocal expressions, and it is usually referred to as *affective prosody*. However, there is as yet no empirical or theoretical basis for distinguishing these two classes of vocal expressions of emotions, and thus they will not be treated separately in what follows.

The most remarkable neuropsychological property of the system underlying both kinds of vocal expressions of emotions is its specificity. The neural system appears highly specialized, both functionally and neuroanatomically. Firstly, despite the obvious link between facial and vocal expression of emotions, emotional evaluation of the tone of voices is dissociable from the emotional evaluation of faces. Some patients can infer the emotional tone of vocal expressions but not of facial expressions, whereas others show the opposite pattern (e.g. Hornak *et al.* 1996). This dissociation is not due to differences related to the modality of input, because the patient's ability to process other aspects of faces and voices is spared. The separability of vocal from facial emotions is impressive, given that they typically signal emotions in a consistent manner at any given time. Yet, the two modes of expressions seem to be captured by independent neural systems.[1]

Secondly, within the speech signal, the recognition of vocal cues that are emotionally meaningful is clearly dissociable from the recognition of vocal cues that are semantically informative. As mentioned previously, Jackson (1878) was the first to notice the separability of affective prosody from propositional speech. The distinction has been made several times in perception as well. For example, in dichotic listening studies with normal adults, Ley and Bryden (1982) have found a left ear (right hemisphere) advantage for the perception of the emotional tone of voice, and a right ear (left hemisphere) superiority for the recognition of the actual content of the words from the same set of sentences. Similarly, patients who can no longer understand speech, but who are still able to infer the emotion conveyed by vocal cues, have been reported (e.g. Barrett *et al.* 1999). These findings show that emotional processing of speech signals can take different routes, one determined by semantic content and one determined by vocal form.

Finally, the tone of the voice is not analysed just for affective purposes. Prosodic cues can provide important person-specific information (e.g. identity, age, and sex) and linguistic, non-semantic information (i.e. differentiating a question from a statement). Once again, the use of these non-affective cues can dissociate from their emotional use. Brain lesions can interfere with the identification of vocal emotions of happiness, sadness, and fear and spare the identification of prosodic differences marking questions, exclamations, and assertions in spoken sentences (e.g. Heilman *et al.* 1984). Similarly, functional imaging of neurologically intact brains points to the involvement of distinct neural regions in the recognition of emotions and of the speaker's identity in spoken sentences (Imaizumi *et al.* 1997). Together, these findings highlight the fine tuning and specialization of the neural system underlying the emotional interpretation of vocal sounds.

[1] This conclusion requires more systematic work, realized in more comparable testing situations. Computer facilities allow the testing of participants with dynamic events where facial expressions and vocal emissions can be studied jointly. To my knowledge, such testing situations have not yet been exploited with brain-damaged patients or with functional brain imaging.

This highly specific system mostly recruits cortical structures of the right hemisphere. Right hemispheric lateralization has been frequently reported after the seminal work of Heilman and collaborators (1975) in brain-damaged patients (for a review, see Etcoff 1989). It has been observed in normal listeners tested either with laterality paradigms (e.g. Ley & Bryden 1982), as described above, or with functional brain-imaging techniques (e.g. George *et al.* 1996; but see Morris *et al.* 1999, for negative findings relative to hemispheric asymmetry). Within the right hemisphere, and at times in the left hemisphere as well, various cortical and subcortical structures have been identified as contributing to the emotional evaluation of vocal sounds. These structures are the temporal cortex, the insula, the basal ganglia, the caudate nucleus, and the ventral prefrontal cortex (for example, for recent brain-imaging data, see Morris *et al.* 1999, and for recent lesion data, see Hornak *et al.* 1996). Thus, the neural basis of vocal emotions appears rather distributed and complex. Specification of the role of each contributing structure remains a task for the future.

Nevertheless, it is worth noting that attempts to find evidence for the involvement of the amygdala have been negative (Adolphs & Tranel 1999; Anderson & Phelps 1998; but see also Scott *et al.* 1997). Patients with selective bilateral damage to the amygdala, who show evidence of impaired recognition of fear in faces, show preserved recognition of fearful voices. This lack of convergence in recruiting the amygdala across non-verbal communication channels in response to danger is consistent with the general conclusion that the vocal emotional system is subserved by distinct neural structures.

Are vocal emotions separable from musical emotions?

Because the neural organization underlying the recognition of vocal expression of emotions appears highly specialized, I find it difficult to conceive how it might also serve musical emotions. However, this is a highly speculative and controversial issue. Juslin (this volume) argues that if the neural circuitry used in the recognition of emotion in vocal expression is used also in music, it can be only for those aspects of music's expressiveness that are common to speech and musical performance, that is, cues like speed, intensity, and timbre. However, music's expressiveness does not derive solely from such cues, but also from intrinsic sources of emotion (cf. Sloboda & Juslin, this volume) having to do with the internal structure (e.g. harmonic progression), and so it would not be surprising to find that perception of musical emotions involves neural substrates over and above those involved in the perception of vocal expressions. Panksepp (1995) sees similarities in the emotional 'chills' evoked by sad music and those engendered by 'distress calls' of young children and animals. Yet, Blood and collaborators (1999*b*) suggested the implication of the septum, a region typically associated with pleasure, in emotional 'chills' for self-selected music. In any case, neuropsychological methods are ideally suited for comparing vocal and musical emotions. As a result of advances in neuroscientific procedures and improved digital-processing techniques, findings obtained in the coming years should prove especially informative for our understanding of emotional processing through the vocal and musical channel.

5.3.4 Is emotion recognition dissociable from emotion experience?

A crucial question that I have left for the end is to what extent all the evidence reviewed in prior sections is related to emotional experience. What was said above mainly derived from tasks requiring emotion recognition, rather than emotion experience. Thus, results may just reflect emotional knowledge, not felt emotions. In theory, all emotions, including fear, may be perceived, recognized, known, described, and mimicked, without being felt. I can see fear in the face displayed on the screen, I can recognize that the Albinoni's adagio expresses sadness in an exquisite manner. Yet, it may leave me cold, particularly in impoverished experimental settings that are of typical use in current research. In this perspective, the study of emotions remains 'cognitivist', contributing little to the building of affective neuroscience as a new discipline.

The debate around the separability of emotion recognition from emotion experience has a long history in the musical domain (cf. Cook & Dibben, this volume). Although the problem seems easy to conceptualize, it is difficult to solve empirically. One solution is to exploit more 'objective' or 'direct' measures of emotions. By objective measures, it is generally meant those measures that cannot be under the voluntary control of the subject. The measures typically pertain to the domain of psychophysiology. In fact, it is well established that emotions are accompanied by physiological changes that occur automatically without voluntary control. It takes talent or intensive training to control physiological expressions of emotions. Musical emotion is no exception. Music may be particularly powerful in eliciting such changes, particularly 'chills' or 'shivers' (e.g. Goldstein 1980). More commonly, music can elicit changes in heart beat, electrodermal responses, respiration, skin temperature, etc. (e.g. Krumhansl 1997). A review of physiological changes is provided by Scherer and Zentner (this volume; see also Bartlett 1999).

Physiological measures do not solve all problems, however. They have their own limitations. First, their 'objectivity' should not be equated with 'specificity'. Just because physiological changes occur without voluntary control this does not mean that they reveal emotions unequivocally. Physiological measures are notorious for their lack of selectivity in addition to their limited sensitivity (e.g. it is common to reject half the subjects because they are 'non-responders'). Physiological changes do not easily discriminate among emotions. For instance, different types of music (happy, sad, fearful) may all produce physiological changes, but the changes may be in the same direction compared with baseline (Krumhansl 1997; but see Nyklicek *et al.* 1997, for a recent example where physiological measures did discriminate among emotions). Nevertheless, physiological changes represent an interesting complement to other brain-related measurements of emotion. Convergence of measurements is highly desirable, probably more in the emotional domain than in any other field.

Does this mean that if we combine behavioural judgments with physiological measurements and both converge, we can safely conclude that the emotion under study was not only recognized but also experienced? Probably. However, the setting is costly in terms of sample size and of technological sophistication. Fortunately, there are other solutions worthy of investigation. One promising alternative is to study emotions *indirectly* or implicitly.

Musical emotions have been typically studied in a direct and explicit way, by asking listeners to judge, label, or categorize music in emotional terms, or by inviting performers to interpret a musical piece with a particular emotion. The impact of musical emotions is rarely assessed indirectly by the way it affects other tasks or behaviours, without awareness. There are different means to probe emotional judgments indirectly. One procedure that has been successfully used with facial expressions was to require a gender decision (e.g. 'Is this a face of a woman or of a man?', which can be difficult to answer when hair and accessories are removed from the picture). The key variable was that some of the faces displayed an emotion, such as fear or disgust, with various degrees of intensity. The indirect influence of the facial expression can then be measured in a graded fashion on both the timing of the gender decision and the resulting changes in cerebral blood flow as measured by functional brain imagery (for a review of their work done with this procedure, see Dolan & Morris 2000).

The advantage of indirect measurement is that emotional responding is studied as a spontaneous, automatic response of the organism. This is what emotions are: spontaneous responses that are difficult to disguise and that may occur without awareness. However, the question is to what extent these spontaneous responses arise from the operation of the same mechanisms as those implicated in emotional judgments or rather reflect the functioning of different systems. Curiously, this question of consciousness, which has been addressed in various domains such as memory and face recognition, has as yet attracted little attention in affective neuroscience.

My intuition, and experience as illustrated below, is that musical emotions typically occur without consciousness or willingness. For example, a few years ago, I felt obliged to accompany a friend to a Broadway show, featuring 'Mrs Butterfly'. I do not like those shows; I find them boring and caricatural. Yet, at the end of the show, I found myself in tears. The show was not of any better quality than any other one, I found. However, my disliking was probably a cultural response, whereas my emotional reaction was a biological reflex.

To summarize, it is possible, at least in theory, that emotions can be recognized without being experienced. To bypass this problem, one can take different routes. These include brain-related and physiological measurements but also consideration of *indirect* measures. There is an obvious need to go beyond conventional means of studying emotions.

5.4 Other issues related to musical emotions

There are a number of issues related to the neural correlates of musical emotions that have not been addressed in this chapter because of insufficient relevant data. One of these issues is the possible exploitation of *neurochemical correlates* of musical emotions. Neurochemicals are neurotransmitters and hormones that alter the response properties of sets of neurons. Music is apparently effective in eliciting such responses, as suggested by the action of the antagonists of endorphins (Goldstein 1980) and cortisol measures (Trehub 2001). The study of these neurochemicals would provide yet another neuropsychological avenue to better understanding of the nature and brain organization of musical emotions (for reviews, see Buck 1999; Panksepp 1998).

A completely different neurological condition that can help in understanding the nature of musical emotions is the study of individuals suffering from *autism* and *Williams' syndrome*. Both disorders are usually associated with intellectual deficiency and a relatively high level of musical proficiency (Don *et al.* 1999; Levitin & Bellugi 1998; Miller 1989). However, the two disorders diverge in several ways. The most apparent distinctive feature concerns sociability. Autistic individuals are socially handicapped, avoiding contacts and interactions with others. In contrast, individuals with Williams' syndrome are very friendly and avid of social exchanges. Since both forms of neurological disorders spare musical skills to a large extent, it would be interesting to compare the consequences of the two disorders for the ability to recognize and express musical emotions.

My prediction is that only individuals with Williams' syndrome, not autistic individuals who are matched for cognitive and musical skills, will be able to interpret music emotionally. Specifically, music is above all seen as a function serving social ends. Because autistic individuals are handicapped at this level,[2] it seems reasonable to expect them to have failed to develop an emotionally responsive system for music. Music would have a different meaning for autistic individuals. Although music performance by 'musical savants' has been qualified at times as 'mechanical' (Mottron *et al.* 1999; Sloboda *et al.* 1985), it has never been experimentally assessed. The only empirical study that has been undertaken in relation to musical emotions in autism has reported negative results (Heaton *et al.* 1999). That is, autistic children were found to be able to distinguish musical excerpts as 'happy' or 'sad'. However, performance was generally poor in that study and measured in a single test. Further investigation is worth undertaking, preferably by coupling different types of measurements, as advocated earlier.

5.5 Conclusion

The neuropsychology of musical emotions is in its infancy. One of the most vexing issues in this respect is the lack of consensus of what music is for (see, for example, Sloboda & O'Neill, this volume). Knowing better the functionality of music would certainly help neuroscientists to identify the musical emotions that are most probably hard-wired in the brain. Nevertheless, this lack of knowledge has not prevented researchers from making progress in understanding what are the neural bases underlying both our intuitions of what emotions are and what music appreciation might be.

The current evidence is pointing to the existence of a specific neural arrangement for certain musical emotions, such as happiness and sadness. It is also apparent that there is not a single, unitary emotional system underlying all emotional responses to music. For instance, most of the neural pathway underlying pleasantness judgments as related to consonance has been delineated, and involves a complex and distributed system in the brain. Yet, this pleasant-consonant pathway is distinguishable from the happy–sad

[2] One collorary assumption is that music deprivation should lead to social deficiencies. This prediction might be difficult to test since music deprivation almost never occurs. Even deaf individuals manage to dance based on what they can perceive as musical.

neural system. Finally, both forms of emotional judgments require cortical mediation and confirm recent conceptualization of emotions as being subserved by evolved brain structures.

Important advances are to be expected in the near future. This progress will be mostly due to the flourishing of new brain-imaging techniques, but will also reflect the new interest in the domain of emotions in neuroscience. The motivation for understanding the biological foundations of music is also currently high in the scientific community (see, for instance, the two target articles bearing on the biology of music in *Science*, 5 January 2001). There is increasing awareness of the social value of music, particularly with respect to its effectiveness in communicating emotions. Nowadays, music plays an even more powerful and unique role in human life than ever, with wide-ranging effects on many aspects of functioning besides its obvious social function. Music has become such a key element in the human behavioural repertoire that it might be considered as a defining human attribute. In fact, music is so highly valued that very few people are willing to acknowledge a lack of emotional responsiveness to music.[3]

CHAPTER 6

ANTHROPOLOGICAL PERSPECTIVES ON MUSIC AND EMOTION

JUDITH BECKER

The study of anthropology is the study of the modes of being human, while the study of ethnomusicology is the study of the modes of music making as a means of cultural expression and as sources of meaning. Both are concerned with human behaviour and the cultural ideologies that inform behaviour; both tend to rely upon ethnographic research and techniques of participant observation, with the results later written and published as a monograph. Within each discipline there are 'universalists' who tend to look for commonalities of behaviour and beliefs, and 'particularists' who are more interested in how we differ one from another, one group from another group.

Whatever the difference of perspective, nearly all anthropologists and ethnomusicologists subscribe to the dictum that one must attempt to understand behaviours and belief systems from within, that is, the necessity for making the effort to understand other musics and other styles of emotional expression from the perspective of their owners. This is related to, but not the same thing as, what is called 'cultural relativism,' which is taken to mean a refusal to make value judgments about beliefs and practices of peoples outside one's own group. A commitment to trying to comprehend the motivations and underlying paradigms of another's actions certainly delays or impedes a 'rush to judgment'. In the case of music and emotion, the ethnographic approach involves both looking closely at the cultural construction of emotion and at the cross-cultural differences in the uses, purposes, and meanings of musical expression.

In this chapter, I will present a theoretical frame for the cross-cultural exploration of music and emotion, provide specific examples, and conclude with a section on the possibility of conjoining humanistic and scientific approaches.

6.1 Culturally inflected listening

Studies on music and emotion conducted by Western scholars and scientists nearly always presume a particular image of musical listeners: silent, still listeners, paying close attention to a piece of music about which they communicate the type of emotion evoked by the piece to an attendant researcher. Communication of the emotion may be immediate in a laboratory setting, or retrospective, recalling the emotion after the musical event.

What is wrong with this image?

Nothing, if the intent is to describe the emotional responses to decontextualized performances by middle-class American or European listeners to music while seated quietly, in the second half of the twentieth century or the early twenty-first century. The laboratory situation may reflect the habit of many current Western listeners, possibly even more so now than in the past as so much musical listening takes place attached to headphones, rather than at live performances. Silent, still, focused listening is also the habit in some other musical traditions, notably the north Indian Hindustani 'classical' tradition, where one sits quietly, introspectively listening to the gradually developing filigree of the musical structure of a *raga*, played, perhaps, on a sitar. Thoughts and feelings are turned inward. The setting is intimate, conducive to introspection, and a distancing from one's fellow listeners.

But if the intent is to delineate something more general about the relationships between musical event and musical affect, the image of an inwardly focused, isolated listener is inadequate. This portrayal of listener and listening presents a set of unexamined ideologies and presuppositions that would not apply for most of the world. The unasked questions include: What constitutes 'listening' to music? What are the appropriate kinds of emotions to feel? What kind of subjectivity is assumed? Who is it that is 'having' the emotions? How is the event framed?

Anthropology and ethnomusicology have contributed to the study of music and emotion an expanded notion of the possibilities that constitute the relationship between the musical event and the listener, and the degree to which emotional response to musical events is culturally inflected. Musical performances and listeners find themselves in a relationship in which they define each other through continuous, interactive, ever-evolving musical structures and listener responses. Meaning resides in the mutual relationship established at any given moment in time between particular listeners and musical events. A group of listeners develops a 'community of interpretation' (Fish 1980), not necessarily uniform, but overlapping in some salient features. This community of listening means that when presented with a musical event, this community will approach the music with a pre-given set of expectations, a 'forestructure of understandings' (Gergen 1991, p. 104). Every hearer occupies a position in a cultural field not of his or her own making: every hearing is situated.

We accumulate our listening habits and expectations largely unawares; only when confronted with an alternate kind of listening are we likely to reflect upon our own conventionalized mode. Listeners can shift modes in different contexts, such as the ways in which one listens to music at a chamber music recital, or at a rock concert, or a jazz club, or a cinema, or at a salsa club (Becker 1983). Cross-culturally, modes of listening may add features not shared by us, or may not involve features that we take for granted. What is appropriate to say about musical affect, what one does *not* say, what one feels, and what one does *not* feel may reveal underlying assumptions surrounding musical listening. What is *not* assumed in one mode (such as bodily movement in Western classical listening) may become central in another mode (such as dancing while listening to a salsa band). To sit quietly focused on musical structure at a salsa concert is as inappropriate as swing dancing to a Schubert quintet.

We need a term to express the temporal and spacial situatedness of the hearer which is the aural equivalent of the visual term for modes of seeing; that is, *the gaze*. Frequently a feminist challenge to the dominance of *the male gaze* in literature (Kern 1996), film (Zizek 1991, p. 88), painting (Hebdige 1995), photography (Slater 1995), television (Morley 1995), psychoanalysis (Zizek 1996, p. 90), medicine (O'Neill 1995), and advertising (Barnard 1995), the term *gaze* is now used in a wide variety of contexts to exemplify the situatedness of looking, the historical and psychological specificity of any one visual approach, and the complex imbrication of modes of seeing with rhetorical and institutional structures and beliefs (Brennan & Jay 1996; Gamman & Marshment 1988; Jenks 1995).

Modes of *looking* imply habits of seeing that change not only across space (Mitchell 1986), but also at different historical periods within a single culture (Baxandall 1974; Goldhill 1996). Similarly, modes of *listening* vary according to the kind of music being played, the expectations of the musical situation, and the kind of subjectivity that a particular culture has fostered in relation to musical events (Johnson 1995). Even more than modes of looking, modes of listening implicate not only structures of knowledge and beliefs, but intimate notions of personhood and identity. Listening addresses interiors; listening provides access to what is hidden from sight.

Styles of audition, of aural perception, of aural awareness, of *listening* in response to musical events directly impinge upon studies of music and emotion. A given community will foster a particular comportment to listening; a comportment not only of attitude, affect, and expectation, but also bodily gesture. Emotional responses to music do not occur spontaneously, nor 'naturally', but rather, take place within complex systems of thought and behaviour concerning what music means, what it is for, how it is to be perceived, and what might be appropriate kinds of expressive responses. We need a word like Bourdieu's (1977) *habitus*, coined as an alternative to terms such as 'culture' which seemed too static, and sometimes seemed to imply a rigidity, an all-inclusiveness that obscured individual, idiosyncratic, or innovative modes of thought and behaviour. Still left with the need to refer to the ways in which beliefs and behaviours seem relatively stereotypical within a given society, Bourdieu (1977, p. 72) proposed the term habitus to do the theoretical work formerly carried by the word 'culture':

> The structures constitutive of a particular type of environment (e.g. the material conditions of existence characteristic of a class condition) produce *habitus*, systems of durable, transposable *dispositions* . . . that is, as principles of the generation and structuring of practices and representations which can be objectively 'regulated' and 'regular' without in any way being the product of obedience to rules, objectively adapted to their goals without presupposing a conscious aiming at ends or an express mastery of the operations necessary to attain them and, being all this, collectively orchestrated without being the product of the orchestrating action of a conductor.

Bourdieu (1977, p. 214, f. 1) goes on to define what he means by *dispositions*:

> The word *disposition* seems particularly suited to express what is covered by the concept of habitus defined as a system of dispositions. It expresses first the *result of an organizing action*, with a meaning close to that of words such as structure; it also designates a *way of being, a habitual state* (especially of the body and, in particular, a *predisposition, tendency, propensity*, or *inclination*.

Habitus is an embodied pattern of action and reaction, in which we are not fully conscious of why we do what we do; not totally determined, but a *tendency* to behave in a certain way. Our habitus of listening is tacit, unexamined, seemingly completely 'natural'. We listen in a *particular* way without thinking about it, and without realizing that it even is a particular way of listening. Most of our styles of listening have been learned through unconscious imitation of those who surround us and with whom we continually interact. A habitus of listening suggests, not a necessity or a rule, but an inclination, a disposition to listen with a particular kind of focus, to expect to experience particular kinds of emotion, to move with certain stylized gestures, and to interpret the meaning of the sounds and one's emotional responses to the musical event in somewhat (never totally) predictable ways. Scholars working within the disciplines of anthropology or ethnomusicology typically assume that the stance of the listener is not a given, not *natural*, but necessarily influenced by place, time, the shared context of culture, and the intricate and unreproduceable details of one's personal biography.

The term I have adapted from Bourdieu, habitus of listening, underlines the interrelatedness of the perception of musical emotion and learned interactions with our surroundings. Our perceptions operate within a set of habits gradually established throughout our lives and developed through our continual interaction with the world beyond our bodies, the evolving situation of *being in the world.*

6.2 Emotion as a cultural construct

> But recognition of the fact that thought is always culturally patterned and infused with feelings, which themselves reflect a culturally ordered past, suggests that just as thought does not exist in isolation from affective life, so affect is culturally ordered and does not exist apart from thought. (Rosaldo 1984, p. 137)

This view, while in the ascendancy among cultural anthropologists and ethnomusicologists, has not gone unchallenged within the discipline of anthropology:

> I can make no sense of a line of thought which claims that 'passions' are culturally defined. From my prejudiced position as a social anthropologist this passage reveals with startling clarity the ultimately radical weakness of the basic assumption of cultural anthropology, namely, that not only are cultural systems infinitely variable, but that human individuals are products of their culture rather than of their genetic predisposition. (Leach 1981, p. 16)

These two quotations, starkly put and differentiated by nationality, gender, and perspective—the American, female, cultural anthropologist and the British, male, social anthropologist—state baldly the issue at hand: the cultural relativism of emotion and thought, or the universality of emotion and thought. (Leach was not a racist, but rather a believer in the commonality of mankind. See also Brown 1991; Goodenough 1970, p. 122; Levi-Strauss 1962, p. 161; Spiro 1984; Turner 1983). These contesting views have elicited penetrating dialogues on both sides of the divide and continue to evoke considerable emotion in their defenders. There are good reasons for these passions: much is at stake.

Informing our beliefs about the universality or, conversely, the culturally conditioned aspects of music and emotion, the path of Western intellectual history leads in both

directions; one direction taken by the sciences that stresses general laws and instances, the other taken by the humanities and cultural anthropology that stresses cases and interpretations (Geertz 1983*a*).

One way to understand the divide between the scientific and the cultural approach is to look at its development from the eighteenth-century Enlightenment onwards. One of the great contributions of the Enlightenment was the propagation of the idea (already taught by religion, but little observed by society) that humankind shared a basic natural state, independent of geography, chronology, or personality ('We hold these truths to be self evident: that all men are created equal'; Jefferson 1994). In its day, this doctrine was dazzlingly liberal and liberating. It led, in spite of all the detours to the contrary, to the end (almost) of institutionalized slavery in the Western world. A sentence from a history book of the eighteenth-century vividly presents a theatrical metaphor for the belief in the commonality of human life and human nature.

> The stage-setting [in different periods of history] is, indeed, altered, the actors change their garb and their appearance; but their inward motions arise from the same desires and passions of men, and produce their effects in the vicissitudes of kingdoms and peoples. (J. J. Mascou, *Geschichte der Teutschen*, quoted in Lovejoy 1948, p. 173)

While elegantly simple, and a vast improvement over earlier views concerning 'The Great Chain of Being' (Lovejoy 1964), this view, in practice, led to the assumption that all peoples everywhere thought and felt like educated, male, Europeans and Americans. Post-colonial studies (Appadurai 1996; Spivak 1988) and gender studies (McClary 1991; Solie 1993) have brought home the bias in such views. We have come to appreciate the nuanced differences of emotion with different stage settings, garbs, and appearances. The 'desires and passions of men' have come to be seen as *not* producing identical 'inward motions'. Partly through the cumulative effects of works by cultural anthropologists writing in the 1970s (Geertz 1973, p. 36; Myers 1979), the 1980s (Levy 1984; Lutz 1986, 1988; Rosaldo 1984; Shweder & Bourne 1984), and the 1990s (Irvine 1990; Lutz & Abu-Lughod 1990), scholars who have championed the concept of the cultural construction of emotion, social scientists and psychologists are increasingly sensitive to the cultural component in the categorizing of, the interpretation of, and the expression of emotion (Davidson 1992; Ekman 1980, p. 90; Ortony *et al.* 1988, p. 26; Russell 1991*a*, 1991*b*).

If we accept Leach's version of the uniformity of human passions, we condone the silences imposed upon subalterns of all times and places whose feelings were assumed to be isomorphic with those of the persons who controlled the writing of history, and we ignore the developing body of data supporting the cultural inflection of the emotions. If we accept the idea of the social construction of knowledge, of morality, and emotion, we seem to be abandoning the idea of a *human* nature, a bond of mind, emotion, and meaning that enfolds us all, and binds us to one another. We may also be in danger of losing sight of the individual as he or she slips into the constructed conventionality of cultural appearance, behaviour, beliefs, and desires and disappears altogether. Persons may become exemplars, instances of this or that cultural model.

I would like to propose that both approaches have incontrovertible empirical support, and that rather than choose sides, we need to accept the paradox that, in fact, we

cannot do without either perspective (Needham 1981; Nettl 1983, p. 36; Shweder 1985; Solomon 1984). Cultural difference in the expression of, the motivation for, and the interpretation of emotion in relation to musical events has been persuasively demonstrated over and over again; for example in music from South Africa (Blacking 1973, p. 68), Liberia (Stone 1982, p. 79), Brazil (Seeger 1987, p. 129), New Guinea (Feld 1982, p. 32), Peru (Turino 1993, p. 82), South India (Viswanathan & Cormack 1998, p. 225), Java (Benamou 1998), and Arabic music (Racy 1998, p. 99). Likewise, the fact that most of us can, with experience and empathy, come to understand differing expressive reactions to different kinds of music as reasonable and coherent demonstrates some level of commonality and universality in relation to both music and emotion. It may be that we come into the world with the full range of human emotional expression available to us (Geertz 1974, p. 249). Through continual patterns of interaction with (primarily) close family members in the early years, we develop particular patterns of emotional feelings and expressions in relation to the events of our lives. For the most part, habituated responses and actions delimit the range and type of any one person's emotional responses. Yet, it would appear that we can imaginatively enter into a much wider palette of human emotional possibilities. We need to make a Hegelian move and transcend the dichotomy between scientific universalism and humanistic particularity and embrace both as necessary to the study of music and emotion.

6.3 Person as a cultural construct

> The 'subjectivity' we are discussing here is the capacity of the speaker to posit himself as 'subject'. It is defined not by the feeling which everyone experiences of being himself (this feeling, to the degree that it can be taken note of, is only a reflection) but as the psychic unity that transcends the totality of the actual experiences it assembles and that makes the permanence of the consciousness. (Benveniste 1971, p. 224)

Benveniste has argued that the sense of person is a product of 'languaging', as have many others, most notably, Buddhist philosophers. (The gerund 'languaging' is a form favoured by scholars who wish to differentiate language activity from the structure of language, see Becker 1995, p. 9; Maturana & Varela 1987, p. 234; Smith & Ferstman 1996, p. 52). While the sense of personhood seems inextricably tied to the development of language, one's sense of bodily boundaries—our sense of what (somatically) belongs to us and where our bodies end—seems to escape the linguistic formation of person and takes shape in areas of the brain not directly involved with languaging (Damasio 1999, p. 108; Melzack 1992). The literature on subjectivity is vast and cannot be dealt with here. None the less, an important aspect of any particular habitus of listening is the way in which the listener thinks of him or herself as a person, how he or she establishes identity in relation to other persons and the phenomenal world.

A classic definition of Western identity is that formulated by Clifford Geertz (1983*b*, p. 59):

> The Western conception of the person as a bounded, unique, more or less integrated motivational cognitive universe, a dynamic center of awareness, emotion, judgment, and action organized into a distinctive whole and set contrastively both against other such wholes and against its social

and natural background, is, however incorrigible it may seem to us, a rather peculiar idea within the context of the world's cultures.

Among others, the philosopher Charles Taylor (1989) has written about the development of this style of personhood in the West, from Plato to the present day (see also Gergen 1991, p. 18):

> Our modern notion of the self is related to, one might say constituted by, a certain sense (or perhaps a family of senses) of inwardness . . . The unconscious is for us within, and we think of the depths of the unsaid, the unsayable, the powerful inchoate feelings and affinities and fears which dispute with us the control of our lives, as inner . . . But as strong as this partitioning of the world appears to us, as solid as this localization may seem, and anchored in the very nature of the human agent, it is in large part a feature of our world, the world of modern, Western people. The localization is not a universal one, which human beings recognize as a matter of course, as they do for instance that their heads are above their torsos. Rather it is a function of a historically limited mode of self-interpretation, one which has become dominant in the modern West and which may indeed spread thence to other parts of the globe, but which had a beginning in time and space and may have an end. (Taylor 1989, p. 111)

It is almost a truism of contemporary cultural anthropology that the nature of subjectivity, of the sense of self, varies cross-culturally. This is a profoundly anti-intuitive notion, and one that has strong objectors in philosophy from St Augustine (von Campenhausen 1964, pp. 226–7) to Bertrand Russell (Seckel 1986, p. 96). As with the issue of 'emotion', to say that subjectivity is culturally constructed seems to deny the basic humanity of mankind. Yet, differences seem to remain in how persons think of themselves in relation to other persons, and these differences are often markedly cultural (Shweder & Bourne 1984, p. 191).

6.4 Person and emotion in the habitus of listening

The particular subjectivity of the listeners described in psychological studies, the prototypical Western, middle-class listener to music is likely to be some variant of the following: an individual with a strong sense of separateness, of uniqueness from all other persons, an individual whose emotions and feelings are felt to be known in their entirety and complexity only to him or herself, whose physical and psychic privacy is treasured, and whose emotional responses to a given piece of music are not felt to be in relation to anything outside of his or her own particular self-history and personality: The emotion, for us, belongs to the individual, not to the situation or to relationships. Emotion is the authentic expression of one's being, and is, in some sense, natural and spontaneous. The emotion is interior, may or may not be shared with anyone else, and may be a guide to one's inner essence. Leo Treitler (1993, p. 48) has written about one way in which this style of subjectivity can relate to listening to music:

> It is that interaction of the selves of the listener with those in the music—no, better put: the awareness of the self (selves) in the music through its (their) interaction with the listener's self—that interests me here; musical communication as a function of the interaction of identities.

The differing identities of the listening subject, and those projected by the music become the focus of interest for Treitler. One common variant of this Western kind of subjectivity while listening to music is to identify with the different identity projected by the music. Listening to music offers the opportunity to temporarily be another kind of person than one's ordinary, everyday self. This interpretation segues into theories concerning one's fantasy life and seems to be a fruitful approach to the kind of emotion associated with music that one finds, for example, among adolescents (Frith 1987, p. 143; Shepherd & Giles-David 1991), and may help to explain their profound identification with the popular music of their times. Musical listening may offer the opportunity of experiencing relief from one's own presentation of everyday self (Goffman 1959) by trying on another self-presentation (see also DeNora, this volume).

6.4.1 Being a griot

How different is the subjectivity, the habitus of listening of the Western listeners to the Wolof griots of Senegal as described by Judith Irvine (1990). Among the Wolof, the musical expression of emotion is dialogical and situational, not personal and interior. Griots, low-caste individuals, are believed to be highly expressive, highly excitable, 'volatile and theatrical'. The nobles are believed to be the opposite: composed, 'cool', detached, and somewhat bland in affect. It is the duty of the griots to stimulate the nobles to action, nobles who might otherwise be given over to lethargy. The highly expressive, emotional performances of the griots are intended, in part, to provide the energy to the nobles that they might carry out their governing duties. Irvine relates that a frequent image in Wolof oral poetry and epic narratives involves the playing of an ensemble of drums and iron clappers to awaken the king 'lest his royal duties go unfulfilled' (Irvine 1990, p. 134). The emotion of the musicians and dancers is contrasted to the lack of emotion of their primary audience, the nobles. Both the emotion of the griots and its absence in the nobles are public, dialogical, and situational; not private and hidden. One of the primary manifestations of subjectivity among Europeans and Americans, emotions are not personal attributes for the Wolof griots and nobles in the same way. For us, emotional responses to music are not considered to be assigned by virtue of one's class and profession, but to be an inalienable characteristic of a bounded, inviolate individual. This is not at all to say that Wolof nobles do not feel strong personal emotions, or that a griot is necessarily always highly extroverted and volatile. It is only to say that these are the *dispositions*, the *inclinations* that are likely to be fulfilled more often than not. The key participants in these musical events exhibit a habitus of listening and a type of subjectivity that largely conforms to Wolof cultural expectations.

6.4.2 The habitus of listening to the sitar, tambura, and tabla

Earlier, mention was made of the similarity of the habitus of listening of the listener of Hindustani 'classical' music and the Western middle-class listener in terms of physical stillness, focused attention, and inner withdrawal. Furthermore, both traditions would claim that music can *represent* emotion. In his autobiography, Ravi Shankar (1968, pp. 23, 27) describes his own subjectivity as a musician, a style of personhood that seems concordant with what I or most readers of this essay might feel as performing musicians:

A *raga* is an aesthetic projection of the artist's inner spirit; it is a representation of his most profound sentiments and sensibilities, set forth through tones and melodies . . . I may play *Raga Malkauns*, whose principal mood [*rasa*] is *veera* [heroic], but I could begin by expressing *shanta* [serenity] and *karuna* [compassion] in the *alap* and develop into *veera* and *adbhuta* [astonishment] or even *raudra* [anger] in playing the *jor* or *jhala*.

The inner spirit of the artist, functioning within culturally constructed categories of emotion, is made manifest in the outward expressions of his musical presentation. Bringing yet another dimension of similarity to the two listening situations is the fact that emotion (*rasa*) experienced in listening to Hindustani classical music is distanced and impersonal. One can feel the emotion without the troublesome immediacy and consequences of an emotion that compels action (Abhinavagupta in Gnoli 1968, pp. 82–5; Masson & Patwardhan 1969, p. 46). June McDaniel (1995, p. 48), writing of *rasa* in the Indian province of Bengal, uses the metaphor of the glass window separating the experiencer from the emotion while still allowing a clear view:

Bhava is a personal emotion; *rasa* is an impersonal or depersonalized emotion, in which the participant is distanced as an observer. Why is a depersonalized emotion considered superior to a personal one? Because the aesthete can experience a wide range of emotions yet be protected from their painful aspects. Emotion is appreciated through a glass window, which keeps out unpleasantness. Though the glass is clear, thus allowing a union of sorts with the observed object, the window is always present, thus maintaining the dualism.

The following description is a Western mirror-image of the way to experience *rasa*:

When people listen, say, to 'Questi i campi di Tracia' from Monteverdi's *Orfeo* . . . they do not directly perceive the anguish and guilt of the twice-widowed singer. Listeners only hear a *representation* [italics mine] of the way his voice moves under the influence of his emotions. Nevertheless, this can give listeners important insights into a type of emotional response. Monteverdi skillfully displays the contortions through which Orpheus's voice goes. When listeners know how a voice moves under the influence of an affect, they are given (if they are familiar with the conventions of the music, and otherwise qualified) an immediate demonstration of something about the affect. A good performance of this aria immediately demonstrates to a sensitive audience something about what it is like to feel guilt, remorse, and despair. (Young 1999, p. 48)

In both the Hindustani and the Western classical listener, an emotion evoked by listening to music can be contemplated with a certain deliberation and calmness. But at some point the congruencies between the habitus of listening of each breaks down. The Western observer may well, as Treitler suggests, be involved with comparing identities, or with constructing a more glamorous self in relation to the music heard, or with contemplating 'what it is like to feel guilt, remorse, and despair'. The Indian, however, may be performing a very different act, a somewhat strenuous religious exercise, a kind of refining of emotional essence, a distillation of his or her emotion that will lead to a transformation of consciousness to a higher level of spirituality. Listening to music for the Hindustani classical music devotee should not be, according to canon, a passive act, but requires the active will and mind of the listener to carry consciousness to a higher plane, closer to the divine (Coomaraswamy 1957, p. 39). Western references to *inspiration* or *genius*, which at one time perhaps indicated a holy possession, have become

largely metaphoric rather than literal expressions of sacred connections between musical performance and musical listening. In Indian classical traditions, the pursuit of emotion, of *rasa*, in relation to listening to music, may be a path to greater awareness, leading one to cosmic insight. Dance can share as well in this configuration of emotion as a stepping stone to a higher gnosis. One of India's most revered Bharata Natyam dancers has written the following:

> It is here that Bharata Natyam, the ancient and holy art of Indian dance, cuts deeply into the conscious and subconscious levels and revealingly brings to the forefront the fact that it is ultimately and intimately oriented to the nucleus, *atman* [the universal self]. It is a revelation not only to the performing artist, but in an equal measure to the audience as well . . . By the inexplicable power born of the union of melody, lyric, rhythm and gesture, the emotions are released from their limited secular locus and are expanded to universal proportions where there is only pure spirit with nothing of the sensual. (Balasaraswati 1985, pp. 2–3)

According to the Bengali version of the theory of *rasa*, intense emotions, not milder 'aesthetic emotions', are the appropriate vehicle to lead one to mystical knowledge of life's meaning and purpose. Emotions are compared to water that can best be understood by immersion in an ocean rather than by the delicate feel of a raindrop (McDaniel 1995, p. 51). What we might call emotional excesses become pregnant possibilities for greater spiritual attainment for an Indian music listener. While the quiet stance and introverted demeanor of the listener in the prototypical Western case and the Hindustani classical listener is similar, the understanding and interpretation of what is supposed to happen in each case differs. In one case, the listener may be exploring the emotional nuances of his or her inner self or identifying with the emotional interiors presented by the music: In the other, the listener is trying to bring about a kind of 'sea' change, a different self altogether, one that comes closer to divinity.

6.5 Arousal: a human universal

Particularities relating to the cultural construction of personhood and of emotion may obscure certain physiological constants that are the correlates of listening to music. Arousal, defined in its most narrow sense as stimulation of the autonomic nervous system (ANS), is one of the most important aspects of musical performance and plays into nearly all studies of music and emotion (see Meyer, this volume; Scherer & Zentner, this volume; Sloboda & Juslin, this volume). The heart beats faster, the pulse rises, breathing becomes shallower, the skin temperature rises, and the pattern of brain waves becomes less regular. All these changes have been observed without any necessary reference to the affective, interpretive component of arousal. They may occur in relation to sexual activity, to exercise, or as a result of drugs or alcohol, as well as to musical listening.

In his famous and controversial theory of the emotions, William James claimed that the physiological component of arousal is primary and precedes the interpretation of the subsequent emotion (James 1950, pp. 442–85). The 'feeling' of anger is the feeling that results from an angry facial expression, bodily stance, shallow breathing, etc. Anger, the emotion, *is*, according to James, what one *feels* when enacting this display. Following

James, but with much more knowledge of the neurophysiology of emotion, Damasio (1999, p. 79) claims that the term 'emotion' should be applied to ANS arousal, and that 'feeling' which follows 'emotion' should be applied to the complex cognitive, culturally inflected interpretation of 'emotion'. Both the Polish Grotowski school of acting (Grotowski 1968) and the Indian Kathakali theatre tradition (Schechner 1988, p. 270) seem to support the theories of James and Damasio. Training a Kathakali actor, or a Western actor of the Grotowski tradition, begins with *mimesis*, recreating the bodily gestures of an emotion, not with delving into one's memories to recreate a 'feeling', as in Stanislavsky's school of 'method' acting (Stanislavsky 1958, p. 1977).

In any case, it is useful analytically to separate physiological arousal ('emotion' for James and Damasio) from the more cognitive concept of 'feeling'. Unlike feelings that directly relate to judgments and beliefs learned within a cultural context and rely upon linguistic categories which are often incommensurable across languages, arousal is more clearly a universal response to musical listening. Combined with a concentrated religious focus, musical arousal can contribute to extreme states of emotion.

Happiness is the emotion most frequently associated with musical listening and may constitute one of the 'universals' of cross-cultural studies of music and emotion. From the 'polka happiness' of the Polish-American parties of Chicago (Keil 1987, p. 276), to the !Kung of the Kalahari desert: 'Being at a dance makes our hearts happy' (Katz 1982, p. 348), to the Basongye of the Congo who 'make music in order to be happy' (Merriam 1964, p. 82), to the extroverted joy of a Pentecostal musical service, music has the ability to make people feel good (cf. Gabrielsson, this volume; Sloboda & O'Neill, this volume). The happiness of listening to music, however one construes 'happiness', is in part the simple result of musical arousal. We tend to feel better when we are musically aroused and excited. The emotion may be attributed to some other aspect of the event, such as the text or our own dancing; none the less, the musical stimulation should not be minimized. Music can be a catalyst for a changing state of consciousness (cf. Persson, this volume).

The following section includes three examples of extreme emotion contextually situated within a religious ceremony in which music is an essential element; all three are sites of the author's fieldwork.

6.5.1 Music and ecstasy: the Sufis

The strongest version of happiness in relation to musical listening and an example of extreme arousal is ecstasy. (See Rouget 1985 for descriptions of music and trancing in many time periods and geographical locations.) Usually associated with religious rituals, ecstasy, as extreme joy, almost by definition involves a sense of the sacred (although musical ecstasy can justly be claimed by some attendees at secular musical events such as rock concerts). The degree to which Muslim Sufi orders have formalized and institutionalized musical ecstasy has seldom been exceeded. The works of the eleventh-century Persian Sufi mystic al Ghazzali about music and ecstasy are still basic pedagogical texts for contemporary Sufis in Iran, Afghanistan, Pakistan, and north India.

> The heart of man has been so constituted by the Almighty that, like a flint, it contains a hidden fire which is evoked by music and harmony, and renders man beside himself with ecstasy. These

harmonies are echoes of that higher world of beauty which we call the world of spirits, they remind man of his relationship to that world, and produce in him an emotion so deep and strange that he himself is powerless to explain it. (Ghazzali 1991, p. 57)

Sufi musicians, called *qawwal* in Pakistan and north India, play for religious ceremonies in which the devotees may reach toward a pinnacle of ecstasy that will bring them into close communion with Allah. The *qawwals* move from song to song, eliciting reactions from the devotees such as moaning, sighing, swaying, even rising up and turning in place as a certain text line speaks directly to the spiritual condition of a particular devotee (Qureshi 1986, p. 119). For a devout Sufi, his ecstasy is a preview, a foretasting of his ultimate union: and though he may weep, he weeps from excess of joy.

Sufi doctrine interprets the music as supportive, as secondary to the all important text, the religious poetry (Qureshi 1986, p. 83). Yet the question remains: to what degree is the arousal stimulated by the sensual overload of intensifying rhythms and soaring phrases sung over and over again at the top of the *qawwal's* range? (For examples, listen to any of the many CDs of Nusrat Fateh Ali Khan.)

A Sufi habitus of listening at a musical religious ceremony involves a sequence of feeling and action that could be called a 'script' (Russell 1991*a*, 1991*b*). Initially, while sitting quietly and reverently, the listener may hope that he or she will be touched by a particular line of text that seems directly applicable to his or her personal situation. If the lead *qawwal* catches the subtle indications of arousal in a listener, he will begin repeating the verse over and over again. The Sufi script then calls for swaying, weeping, rising up, moving to the centre of the room, and slowly turning in place (Fig. 6.1). The emotion of the script, when fully acted out, is the ultimate joy of a direct and personal knowledge of Allah. Musical emotion in the listener changes both its form and its intensity as the script progresses.

6.5.2 Music and rage: Balinese bebuten trancing

In Bali, an exorcist ceremony is performed when misfortune befalls a village in which the negative powers of the divine witch Rangda must be neutralized for the well-being of the community. The elaborate mask of the witch Rangda will be brought from its storage place in the temple, blessed and infused with spirit in a potent ceremony conducted by a priest. An exceptionally tall and spiritually strong man will be chosen to undergo the trance of *becoming* the witch. A number of men will volunteer to undergo another kind of trance called *bebuten*, from the root *buta*, which means a creature of base instincts, low on the ladder of sentient beings, often translated as *demon*. These men will confront the witch and ultimately neutralize her power with the help of a magical beast called Barong. *Bebuten* trance is not ecstasy. It is a feeling of rage directed toward the witch Rangda, and may leave the trancer feeling embarrassed later by his behaviour during the trance and with an exhaustion that may last for several days (Eiseman 1989, p. 153). Yet, the trancing is a social obligation which he fulfills voluntarily, surrendering his own comfort for the betterment of his community. He experiences a kind of homicidal rage (or, rather, 'theo-cidal' rage). One experienced trancer (I Wayan Dibia) passionately described his feelings while listening to the music of the gamelan (Fig. 6.2) upon encountering the witch:

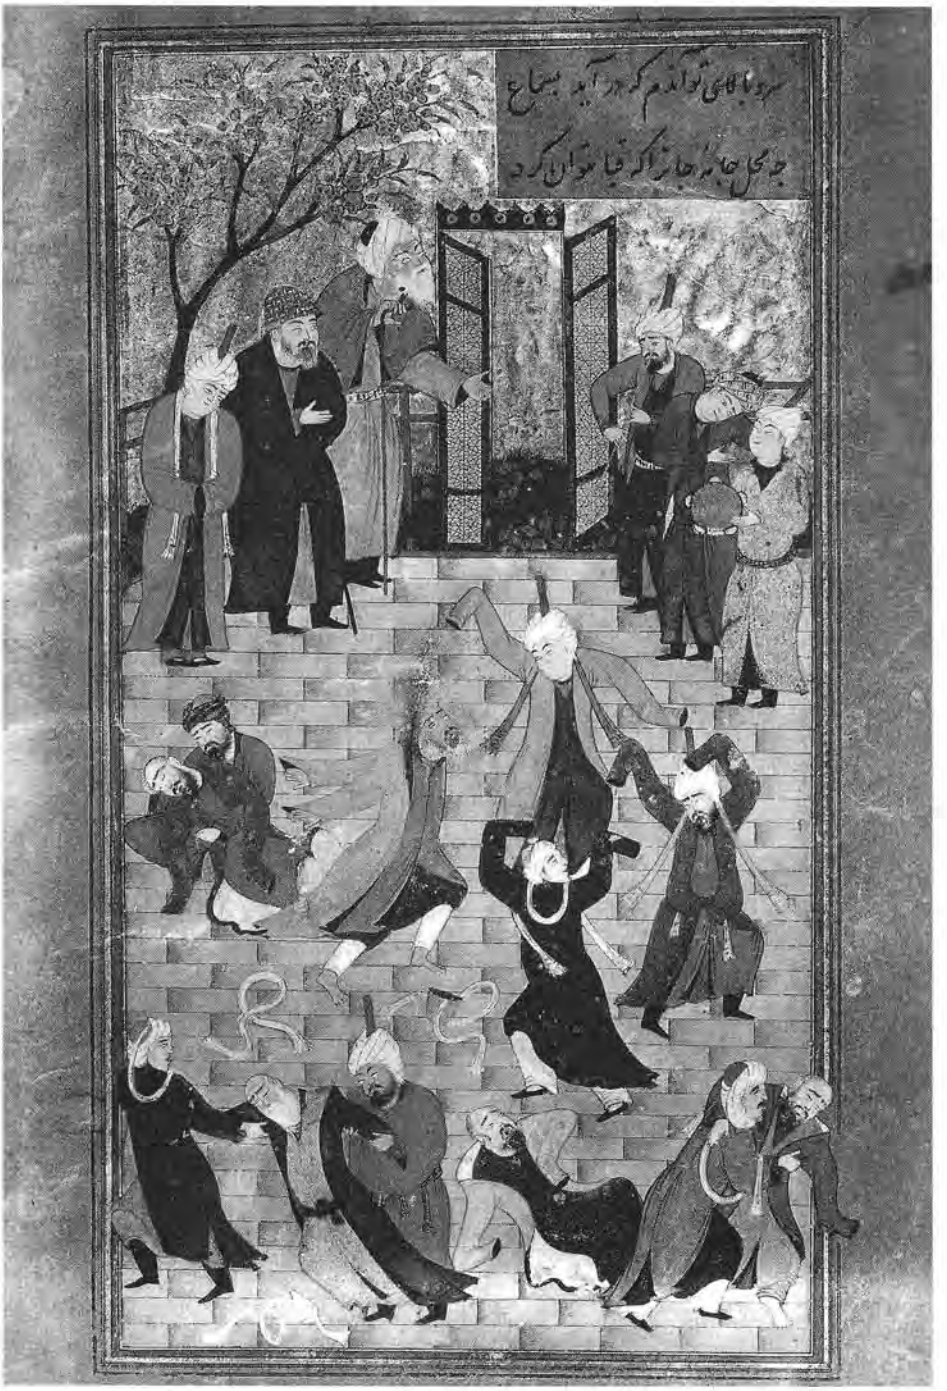

Figure 6.1 Dancing Sufis From the Divan (Book of poems) of Hafiz (Walters Art Gallery, Baltimore).

When I come up to that tower, when the curtain opens like that, as soon as I step up to approach Rangda, I see a strong fire coming from her eyes! I just—Oh! [slaps his hands together]—I do this! I just jump! I feel myself floating—because of the excitement! . . . Whenever they pick up the music [sings 'jangga jangga jangga'], whenever you sing that song [sings a bit of the gamelan piece that accompanies the trance] people just go crazy! I want to attack Rangda!!!' (I Wayan Dibia, interview, 1996)

Figure 6.2 Gamelan musicians accompanying a Rangda/Barong ritual (photo by Judith Becker).

Neither the trance, nor the ceremony, nor the pacification of the witch can happen without the gamelan music (Fig 6.3). The habitus of listening of I Wayan Dibia upon encountering Rangda would have to include a description of not only the gamelan music and the presence of the witch, but a complex of beliefs about the negative forces of the universe, their effects upon human communities, the embodiment of these forces in the divine witch Rangda, and the methods by which she may be contained and controlled. His own emotion, culturally constituted but felt interiorly, is a necessary component of the maintenance of community well-being. His murderous passion has little to do with an interiorized self, with the identity of I Wayan Dibia. His rage, in part musically induced, is in the service of his community. Like the Wolof griots, musical emotion for the trancer in a Balinese Rangda exorcism is public, situational, predictable, and culturally sanctioned.

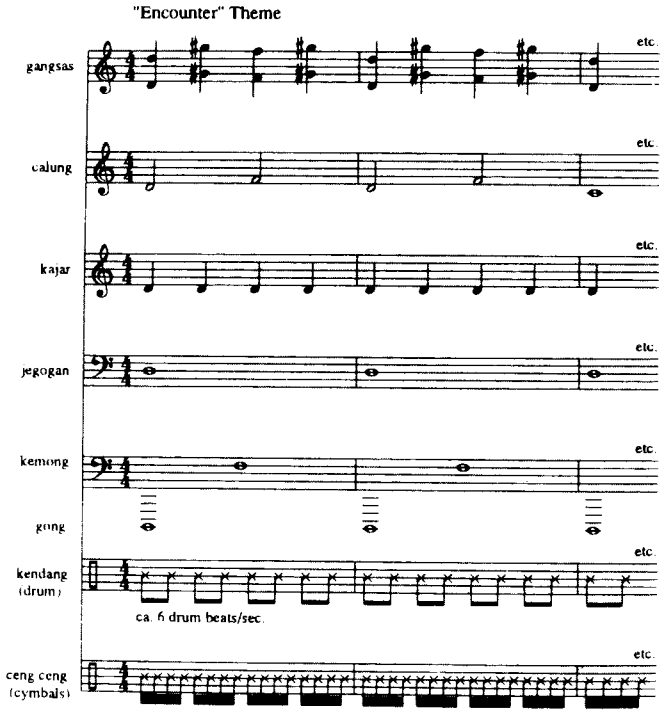

Figure 6.3 Musical transcription of the 'encounter' theme from a Rangda/Barong ritual.

6.5.3 Pentecostal arousal: 'music brought me to Jesus' (Cox 1995, p. 139)

Pentecostal religions were formally constituted at the beginning of the twentieth century, and are now rivalled only by Islam in their spread to all parts of the globe (Cox 1995, p. 15). Pentecostalism constitutes a faith that is dependent upon music to structure its religious services and to validate its system of beliefs by provoking intense emotional reactions within its most devote practitioners, leading them to 'testify'. To dance in The Spirit, to be possessed by the Holy Ghost, is demonstration that one is accepted into the congregation of those who will experience the final act of history, the reappearance of Jesus Christ and the establishment of the Kingdom of God on earth (Abell 1982). Music is the driving force for this emotional apotheosis. From softly played passages underlining a sermon or a prayer, to swinging, driving choruses sustaining a wave of religious emotionalism, music is rarely absent from the hours-long services. Pentecostal musical offerings shape a musical/emotional/religious arc that carries the congregation along with it. A service will begin with quiet, slow, soothing music: 'Music gets people in the attitude of worship. It helps them to forget outside influences and to focus on the Lord' (Interview with Jerry Trent, Church of God, Willow Run, Michigan, 1996).

Pentecostal churches may use a wide variety of musical instruments, often including piano, electric organ, synthesizer, guitars, and drumset to back up their driving, repetitive gospel hymns. As the music becomes louder, more rhythmic, and more repetitive, its driving quality supports, propels, and sustains the hand-waving, hand-clapping, foot-stomping choruses of 'Amen!' as the emotional temperature of the congregation gradually rises. High on the trajectory of the musical arc, worshippers may come forward to the altar to pray, and some may dance or trance. As in the Sufi services, the musical support will continue at a high intensity until all worshippers have worked through their transport and regained their normal composure. Religious ecstasy is always accompanied by great joy as it is a confirmation of the salvation of the worshipper. He or she has become a part of the historical narrative of millenarial Christianity and will join fellow believers and Jesus at the last day. The music never flags as some members are moved to tears, to dance, to quiver and jerk in the uncoordinated gestures of some religious trances. As religious passions subside, so does the music, until every last ecstatic has become quiet—exhausted and joyful. 'And it was terrific', exclaimed one worshipper at a service marked by intense, sustained, high-energy music, dancing, and trancing, 'and we really *got down* here. I mean we really *had church*' (Cox 1995, p. 268).

The musical listener at a Pentecostal service is expectant, alert, and waiting for the song leader, the musicians, the singing congregation, and the pastor to transport him or her to the point of experiencing the Holy Spirit in his or her own body. The attitude is one of surrender and openness. No critical irony, no mental busyness, or aesthetic evaluation can be allowed to interfere with a process of holy possession called 'Slain in the Spirit'.

Similar to the Sufi listener and the Balinese *bebuten* trancer, for a Pentecostal listener, the habitus of listening involves a scripted sequence of actions, emotions, and interpretations. Within each of these three scripts, musical, behavioural, and emotional events will occur within a certain predictable frame. Simultaneously, each individual event will be unique and non-repeatable. The listeners to a Wolof griot, an Indian sitar player, a group of *qawwali* singers, a Balinese *bebuten* trancer, or a Pentecostal worshipper have all developed habits of mind and body in response to specific musical events. These habits are acquired throughout their life experiences of interaction with others in similar situations. The emotions are private *and* public, interior *and* exterior, individual *and* communal.

6.6 Music, emotion, and 'being': conjoining anthropology, ethnomusicology, psychology, and neurophysiology

It seems clear to this author that a common ground needs to be explored between the more humanistic, cultural anthropological approach and the more scientific, cognitive psychological approach. I see the bringing together of the scientific and cultural approaches to the study of music and emotion as one of the great challenges of our fields. While the styles of argument and the criteria for evidence may remain distinct, the conclusions need to be comparable and not incommensurable. Both disciplinary areas may have to give up some of their established scholarly practices.

6.6.1 Single brain/body approaches

For those approaching the study of the emotional effect of musical listening on the brain, the unit of analysis is usually the brain or body of a single listener. From the early studies of music and the brain, such as Neher's early work in the 1960s (Neher 1961, 1962) analysing the brain rhythms of subjects listening to drum beats in a laboratory, to the more recent works of Clynes (1986), Wallin (1991), Peretz (this volume), and many others, musical scholars have adopted the scientific model and studied single brains or bodies in isolation. Studies in music cognition have largely followed the empirical models of cognitive studies in general in their efforts to model the algorithms of single brains processing music (Lerdahl & Jackendoff 1983; Raffman 1993). Neurophysiologists and psychologists of consciousness likewise follow the dictates of their scientific training, isolating and narrowing the problem as much as possible in order to have some control over the variables. In fact, some of the most exciting advances in the understanding of the mind are coming from scientists and philosophers who have focused on single minds/brains (Churchland 1986; Dennett 1991; Edelman 1992). The development of technologies such as magnetic resonance imaging (MRI) and positron emission tomography (PET) scanning have reinforced the practice of the study of single minds in the attempt to unravel the mysteries of conscious experience (see Peretz, this volume). The choice of a single human brain as the unit of analysis has larger implications as well. The emphasis upon the primacy of the self-contained individual has been a treasured credo of Western intellectual pursuits in all fields for many centuries. Contemporary examples include the cognitive sciences, Piaget's genetic epistemology, and Freudian psychoanalysis.

Without intending to denigrate any of these fields, and while fully acknowledging their enormous contributions, I am suggesting that the scripts of music and emotion, the habitus of listening, can be helpfully understood as a process which is supra-individual (Nunez 1997), in which the relationship between music and emotion needs to be understood as extending beyond the minds and bodies of single musicians and listeners, that is as a contextually situated social practice. Emotions relating to music are culturally embedded and socially constructed and can usefully be viewed as being about an individual within a community, rather than being exclusively about internal states. First-person descriptions of music and emotion are rife with tropes of interiority, yet the understanding of how music affects interiors takes place within consensual, shared views of what makes up 'reality'. Musical events set up an aural domain of coordination that envelops all those present.

6.6.2 Rhythmic entrainment

A familiar example of a changed interior, personal consciousness in a musical domain of coordination is the phenomenon of *rhythmic entrainment* (Chapple 1970, p. 38; Condon 1986; Hall 1977, p. 61; McNeill 1995, p. 6; Neher 1961, 1962; Rider & Eagle 1986; Vaughn 1990; Walter & Walter 1949). Bodies and brains synchronize gestures, muscle actions, breathing, and brain waves while enveloped in musicking. (The gerund 'musicking' is preferred for the same reasons as 'languaging'. The activity, the

process, the experiencing of music is foregrounded; see Small 1998.) Many persons, bound together by common aims, may experience revitalization and general good feeling. The situation is communal and individual, the music descends upon all alike, while each person's joy is his or her own.

> . . . it is no wonder that our words fumble when seeking to describe what happens within us when we dance or march. The initial seat of excitement is far removed from our verbal capabilities. It centers instead in those parts of the nervous system that function subconsciously, maintaining rhythmic heartbeat, digestive peristalsis, and breathing, as well as all the other chemical and physiological balances required for the maintenance of ordinary bodily functions. (McNeill 1995, p. 6)

6.6.3 Habitus of listening: culture and biology

An enactive approach to meaning and cognition based in biology has recently been proposed by Maturana and Varela (1987), Varela *et al.* (1991), Nunez (1997), and Foley (1997)—a group including biologists, linguists, and psychologists. While Bourdieu (and others) developed the analytical tool of habitus from an anthropological and sociological perspective, these scholars are reaching toward phenomenology to develop a comparable biological model which transcends the division between the cultural and the biological; between phenomenology and scientific materialism. The two approaches (Bourdieu and this group) are strikingly similar. While wishing to examine the relationships between music and emotion as supra-individual, one may still view the scripts associated with the habitus of listening as a biological process.

A biological process is a process that has an autopoietic organization (i.e. it is self-producing), a process that has boundaries between itself and the enveloping environment, the components of which (people) are dynamically related in a network of ongoing interactions that change the structure of the individuals as well as the structure of their interactions. Further criteria for biological processes are that they are autonomous, that is, that they can specify their own laws, and that they only allow changes to occur dependent upon maintaining the viability of their own structures (Maturana & Varela 1987, pp. 47–52). Groups of people who are focused on a common event and who share a common history of that event act, react, and to some extent think in concert, without sacrificing their bounded personal identities.

Viewing music and emotions as scripts that involve supra-individual biological processes, one can describe the changes that occur in these time sequences as having evolved over time through a historical process called 'structural coupling' (Maturana & Varela 1987, pp. 75–80). 'Structural coupling' describes the internal, structural changes that occur within an organism as a result of interaction with other organisms and with a world; changes of one's being or one's ontology. These changes become new domains of knowledge, knowledge gained through interactive behaviours, through doing. Music listeners as well as musicians undergo a learning process in which they imitate physical and mental gestures that ultimately transform both their inner structures as well as their relations to everything beyond the boundaries of their skins. Music and emotion are part of a larger processual event that includes many other people doing many other things while the whole event unfolds as a unity that

has been organized and reorganized over time by small structural changes within the participants.

We are accustomed to thinking of biological processes as extending from a single cell, to multicellular organisms such as a tree, to animals, and to a single human being. When groups of people are acting in some kind of accord, we tend to say that the phenomenon is social, or psychological, or political, but not biological. If we think of music making and music listening within a process that may also include quiet introspection or, conversely, include preaching, glossolalia, and dancing, or the murmuring of mantras, as all part of a biological process that has had a long history of structural coupling, or continual self-recreation, we can begin to think of the music, the emotion, and every other aspect of the process as contributing to bringing forth the activities of each other, as bringing forth a world or a reality in which certain emotions and actions are expected and appropriate, and in which the reality brought forth by all is enacted by all (Dreyfus 1991). A musical event is not just in the minds of the participants, it is in their bodies; like a vocal accent in speaking, emotion in relation to musical listening is personally manifested, but exists supra-individually. Each person, both musicians and listeners, seem to be acting as self-contained, bounded individuals, and indeed they experience whatever they experience as deeply personal and emotional, but the event as a whole plays itself out in a supra-individual domain.

> This embodied understanding, including dispositions in the habitus, is tacit knowledge and hence one can only be subsidiarily aware of it; this accounts for why so much of the habitus is preconscious and unable to be reflected on or modified. This conservatism leads to the practices generated by the dispositions of the habitus being transmitted from generation to generation, in other words they are potentially *cultural practices*. Culture in this view is that transgenerational domain of practices through which human organisms in a social system communicate with each other. These practices may be verbal or non-verbal, but they must be communicative in the sense that they occur as part of ongoing histories of social structural coupling and contribute to the viability of continued coupling . . . Culture, then, consists of the things people do to communicate in ongoing transgenerational histories of social interaction. (Foley 1997, p. 14)

Emotion is an enactment, not a representation in the mind. It is a way of *being-in-the-world*, not a way of thinking about the world.

> The experience of anything out there is validated in a special way by the human structure, which makes possible 'the thing' that arises in the description. This circularity, this connection between action and experience, this inseparability between a particular way of being and how the world appears to us, tells us that *every act of knowing brings forth a world* . . . All this can be summed up in the aphorism *All doing is knowing, and all knowing is doing.* (Maturana & Varela 1987, p. 26)

Language, music, and dance become one system of ontogenic coordination of actions. Together, they bring about changes in being and changes in the music event involved. While it is the individual who experiences the emotion, it is the group and its domain of coordinations that triggers the emotion. The changes in the neurophysiology of the listener are not attributable simply to the brain/body of a self-contained

individual. They occur through the group processes of recurrent interactions between co-defined individuals in a rhythmic domain of music.

Thinking of the relationship of music and emotion as a biological process with a co-defined, historically enacted ontology, as a group creation in which self-contained individuals have undergone structural changes through their interaction with other self-contained individuals helps to provide an embodied analysis of the relationship of music and emotion and the mysteries of musical affect. The domain of musicking and emotion is intrinsically social, visibly embodied, profoundly cognitive, and biologically consistent with the created domains of many other kinds of living creatures.

This type of analysis is aided by technologies such as film and video. One needs to be able to see everything at once, and to have the opportunity to replay the event. Qureshi's skilful score-like transcriptions of the multiple events at a Sufi religious ceremony demonstrate one method of researching music and emotion that does not focus on individual emotions, but on individual emotions within the context of many other individual emotions (Qureshi 1986, pp. 143–16). One can study her scores and literally *see* how the musicians interact with the congregants, and one can imagine how the emotions of one listener may have stimulated the emotions of another, leading to the ultimate reaction, an enactment of trancing (Fig 6.4).

6.6.4 What is gained by claiming that these processes are biological?

We may claim that special modes of conscious experience such as emotional responses to music listening, a habitus of listening, emerges as a phenotypic feature of humankind, as a biological development in the evolution of the species, emerging from both genetic and environmental influences. Music and emotion, viewed as evolving together in the interaction of each individual with performances throughout his or her life, dissolves intractable dichotomies concerning nature versus culture, and scientific universalism versus cultural particularism.

Furthermore, for those of us who want to use the word 'culture' but are inhibited by all the recent attacks upon the term relating to essentialism, historical stasis, and reified, abstracted psychology, culture can be restored as a more precise, more useful term. Culture (redefined) can be understood as a supra-individual biological phenomenon—a transgenerational history of social interactions that become embodied in the individual and transmitted through future actions.

No habitus of listening is entirely stable nor entirely fluid. As interactions change, so do the interiors of those who are interacting. We may have developed a habitus of listening that inclines us to introspectively contemplate the colourful fluidity of changing emotional states in response to Bach's *Musical Offering*, but if it would not disturb the viability of our own structures, we could learn to dance ecstatically in The Spirit with the Pentecostals.

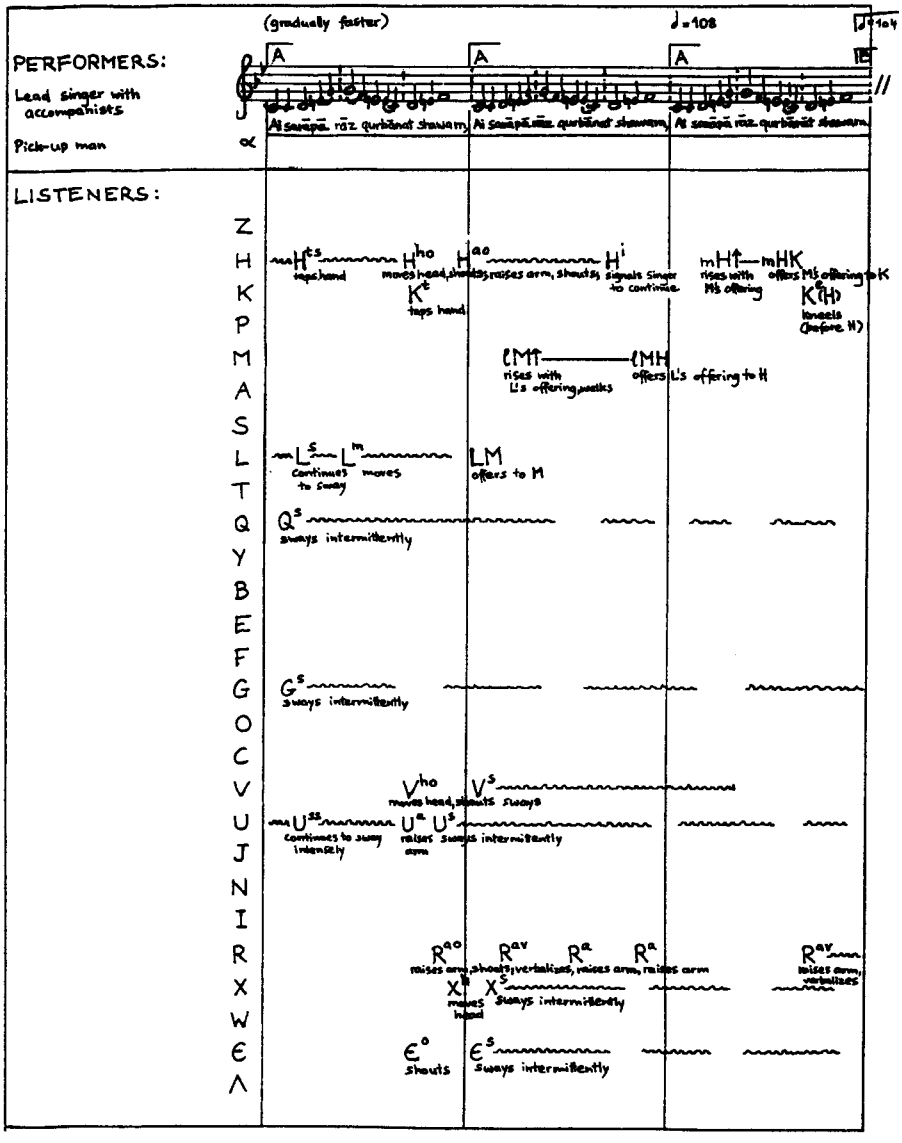

Figure 6.4 Transcription (excerpt) of music/participant interactions in a north Indian Sufi ritual (from Qureshi 1986, p. 171).
