OPENSTAX

OpenStax provides free, peer-reviewed, openly licensed textbooks for introductory college and Advanced Placement® courses and low-cost, personalized courseware that helps students learn. A nonprofit ed tech initiative based at Rice University, we're committed to helping students access the tools they need to complete their courses and meet their educational goals.

RICE UNIVERSITY

OpenStax is an initiative of Rice University. As a leading research university with a distinctive commitment to undergraduate education, Rice University aspires to path-breaking research, unsurpassed teaching, and contributions to the betterment of our world. It seeks to fulfill this mission by cultivating a diverse community of learning and discovery that produces leaders across the spectrum of human endeavor.

PHILANTHROPIC SUPPORT

OpenStax is grateful for the generous philanthropic partners who advance our mission to improve educational access and learning for everyone. To see the impact of our supporter community and our most updated list of partners, please visit openstax.org/impact.

KINETIC

The science behind the science

OpenStax Kinetic provides personalized learning feedback to you as you deepen your knowledge of science.

You can participate in a range of free research studies on Kinetic to deepen your understanding of who you are as a science learner, including:

- **Foundational lab and chemistry knowledge**
- **Early science and math experiences**
- **STEM interests and matching careers**

You can even become better at time management, goal setting, and reducing procrastination! Whatever your learning goals may be, Kinetic has a study to help you uncover more.

**Learn while you earn
with OpenStax Kinetic!**

We take the privacy and security of our users' data seriously. Our full privacy notice is available at openstax.org/privacy.

CONTENTS

Dedication and Preface 1

CHAPTER 1

Structure and Bonding 7

Why This Chapter? 7

1.1 Atomic Structure: The Nucleus 9

1.2 Atomic Structure: Orbitals 9

1.3 Atomic Structure: Electron Configurations 11

1.4 Development of Chemical Bonding Theory 12

1.5 Describing Chemical Bonds: Valence Bond Theory 15

1.6 sp^3 Hybrid Orbitals and the Structure of Methane 17

1.7 sp^3 Hybrid Orbitals and the Structure of Ethane 18

1.8 sp^2 Hybrid Orbitals and the Structure of Ethylene 19

1.9 sp Hybrid Orbitals and the Structure of Acetylene 21

1.10 Hybridization of Nitrogen, Oxygen, Phosphorus, and Sulfur 22

1.11 Describing Chemical Bonds: Molecular Orbital Theory 24

1.12 Drawing Chemical Structures 25

Chemistry Matters—Organic Foods: Risk versus Benefit 28

Key Terms 29

Summary 29

Additional Problems 30

CHAPTER 2

Polar Covalent Bonds; Acids and Bases 37

Why This Chapter? 37

2.1 Polar Covalent Bonds and Electronegativity 38

2.2 Polar Covalent Bonds and Dipole Moments 40

2.3 Formal Charges 42

2.4 Resonance 44

2.5 Rules for Resonance Forms 45

2.6 Drawing Resonance Forms 46

2.7 Acids and Bases: The Brønsted–Lowry Definition 48

2.8 Acid and Base Strength 50

2.9 Predicting Acid–Base Reactions from pK_a Values 51

2.10 Organic Acids and Organic Bases 53

2.11 Acids and Bases: The Lewis Definition 55

2.12 Noncovalent Interactions between Molecules 58

Chemistry Matters—Alkaloids: From Cocaine to Dental Anesthetics 61

Key Terms 62

Summary 62

Additional Problems 63

CHAPTER 3

Organic Compounds: Alkanes and Their Stereochemistry 71

Why This Chapter? 71

3.1 Functional Groups 72

3.2 Alkanes and Alkane Isomers	78
3.3 Alkyl Groups	81
3.4 Naming Alkanes	84
3.5 Properties of Alkanes	89
3.6 Conformations of Ethane	90
3.7 Conformations of Other Alkanes	92
Chemistry Matters—Gasoline	97
Key Terms	98
Summary	98
Additional Problems	99

CHAPTER 4

Organic Compounds: Cycloalkanes and Their Stereochemistry

105

Why This Chapter?	105
4.1 Naming Cycloalkanes	106
4.2 Cis–Trans Isomerism in Cycloalkanes	108
4.3 Stability of Cycloalkanes: Ring Strain	110
4.4 Conformations of Cycloalkanes	112
4.5 Conformations of Cyclohexane	113
4.6 Axial and Equatorial Bonds in Cyclohexane	115
4.7 Conformations of Monosubstituted Cyclohexanes	118
4.8 Conformations of Disubstituted Cyclohexanes	120
4.9 Conformations of Polycyclic Molecules	123
Chemistry Matters—Molecular Mechanics	126
Key Terms	127
Summary	127
Additional Problems	128

CHAPTER 5

Stereochemistry at Tetrahedral Centers

135

Why This Chapter?	135
5.1 Enantiomers and the Tetrahedral Carbon	136
5.2 The Reason for Handedness in Molecules: Chirality	137
5.3 Optical Activity	140
5.4 Pasteur's Discovery of Enantiomers	142
5.5 Sequence Rules for Specifying Configuration	143
5.6 Diastereomers	147
5.7 Meso Compounds	150
5.8 Racemic Mixtures and the Resolution of Enantiomers	152
5.9 A Review of Isomerism	154
5.10 Chirality at Nitrogen, Phosphorus, and Sulfur	155
5.11 Prochirality	156
5.12 Chirality in Nature and Chiral Environments	159
Chemistry Matters—Chiral Drugs	161
Key Terms	162
Summary	162
Additional Problems	163

CHAPTER 6

An Overview of Organic Reactions 171

Why This Chapter?	171
6.1 Kinds of Organic Reactions	172
6.2 How Organic Reactions Occur: Mechanisms	173
6.3 Polar Reactions	173
6.4 An Example of a Polar Reaction: Addition of HBr to Ethylene	178
6.5 Using Curved Arrows in Polar Reaction Mechanisms	181
6.6 Radical Reactions	183
6.7 Describing a Reaction: Equilibria, Rates, and Energy Changes	185
6.8 Describing a Reaction: Bond Dissociation Energies	187
6.9 Describing a Reaction: Energy Diagrams and Transition States	189
6.10 Describing a Reaction: Intermediates	192
6.11 A Comparison Between Biological Reactions and Laboratory Reactions	194
Chemistry Matters—Where Do Drugs Come From?	197
Key Terms	198
Summary	198
Additional Problems	199

CHAPTER 7

Alkenes: Structure and Reactivity 207

Why This Chapter?	207
7.1 Industrial Preparation and Use of Alkenes	208
7.2 Calculating the Degree of Unsaturation	209
7.3 Naming Alkenes	211
7.4 Cis–Trans Isomerism in Alkenes	213
7.5 Alkene Stereochemistry and the <i>E,Z</i> Designation	214
7.6 Stability of Alkenes	217
7.7 Electrophilic Addition Reactions of Alkenes	219
7.8 Orientation of Electrophilic Additions: Markovnikov's Rule	222
7.9 Carbocation Structure and Stability	226
7.10 The Hammond Postulate	228
7.11 Evidence for the Mechanism of Electrophilic Additions: Carbocation Rearrangements	230
Chemistry Matters—Bioprospecting: Hunting for Natural Products	233
Key Terms	234
Summary	234
Additional Problems	235

CHAPTER 8

Alkenes: Reactions and Synthesis 243

Why This Chapter?	243
8.1 Preparing Alkenes: A Preview of Elimination Reactions	244
8.2 Halogenation of Alkenes: Addition of X ₂	245
8.3 Halohydrins from Alkenes: Addition of HO-X	247
8.4 Hydration of Alkenes: Addition of H ₂ O by Oxymercuration	249
8.5 Hydration of Alkenes: Addition of H ₂ O by Hydroboration	252
8.6 Reduction of Alkenes: Hydrogenation	255
8.7 Oxidation of Alkenes: Epoxidation and Hydroxylation	259
8.8 Oxidation of Alkenes: Cleavage to Carbonyl Compounds	261
8.9 Addition of Carbenes to Alkenes: Cyclopropane Synthesis	263

8.10 Radical Additions to Alkenes: Chain-Growth Polymers	265
8.11 Biological Additions of Radicals to Alkenes	269
8.12 Reaction Stereochemistry: Addition of H ₂ O to an Achiral Alkene	270
8.13 Reaction Stereochemistry: Addition of H ₂ O to a Chiral Alkene	272
Chemistry Matters—Terpenes: Naturally Occurring Alkenes	273
Key Terms	274
Summary	275
Summary of Reactions	275
Additional Problems	277

CHAPTER 9

Alkynes: An Introduction to Organic Synthesis 287

Why This Chapter?	287
9.1 Naming Alkynes	288
9.2 Preparation of Alkynes: Elimination Reactions of Dihalides	288
9.3 Reactions of Alkynes: Addition of HX and X ₂	289
9.4 Hydration of Alkynes	291
9.5 Reduction of Alkynes	294
9.6 Oxidative Cleavage of Alkynes	296
9.7 Alkyne Acidity: Formation of Acetylide Anions	297
9.8 Alkylation of Acetylide Anions	298
9.9 An Introduction to Organic Synthesis	300
Chemistry Matters—The Art of Organic Synthesis	304
Key Terms	305
Summary	305
Summary of Reactions	306
Additional Problems	307

CHAPTER 10

Organohalides 315

Why This Chapter?	315
10.1 Names and Structures of Alkyl Halides	316
10.2 Preparing Alkyl Halides from Alkanes: Radical Halogenation	318
10.3 Preparing Alkyl Halides from Alkenes: Allylic Bromination	320
10.4 Stability of the Allyl Radical: Resonance Revisited	321
10.5 Preparing Alkyl Halides from Alcohols	323
10.6 Reactions of Alkyl Halides: Grignard Reagents	325
10.7 Organometallic Coupling Reactions	326
10.8 Oxidation and Reduction in Organic Chemistry	328
Chemistry Matters—Naturally Occurring Organohalides	331
Key Terms	332
Summary	332
Summary of Reactions	332
Additional Problems	333

CHAPTER 11

Reactions of Alkyl Halides: Nucleophilic Substitutions and Eliminations 339

Why This Chapter?	339
11.1 The Discovery of Nucleophilic Substitution Reactions	340
11.2 The S _N 2 Reaction	342

11.3 Characteristics of the S _N 2 Reaction	344
11.4 The S _N 1 Reaction	350
11.5 Characteristics of the S _N 1 Reaction	354
11.6 Biological Substitution Reactions	358
11.7 Elimination Reactions: Zaitsev's Rule	360
11.8 The E2 Reaction and the Deuterium Isotope Effect	362
11.9 The E2 Reaction and Cyclohexane Conformation	365
11.10 The E1 and E1cB Reactions	367
11.11 Biological Elimination Reactions	368
11.12 A Summary of Reactivity: S _N 1, S _N 2, E1, E1cB, and E2	369
Chemistry Matters—Green Chemistry	371
Key Terms	372
Summary	372
Summary of Reactions	373
Additional Problems	373

CHAPTER 12

Structure Determination: Mass Spectrometry and Infrared Spectroscopy 383

Why This Chapter?	383
12.1 Mass Spectrometry of Small Molecules: Magnetic-Sector Instruments	384
12.2 Interpreting Mass Spectra	386
12.3 Mass Spectrometry of Some Common Functional Groups	389
12.4 Mass Spectrometry in Biological Chemistry: Time-of-Flight (TOF) Instruments	394
12.5 Spectroscopy and the Electromagnetic Spectrum	395
12.6 Infrared Spectroscopy	397
12.7 Interpreting Infrared Spectra	398
12.8 Infrared Spectra of Some Common Functional Groups	402
Chemistry Matters—X-Ray Crystallography	408
Key Terms	409
Summary	409
Additional Problems	409

CHAPTER 13

Structure Determination: Nuclear Magnetic Resonance Spectroscopy 417

Why This Chapter?	417
13.1 Nuclear Magnetic Resonance Spectroscopy	418
13.2 The Nature of NMR Absorptions	420
13.3 Chemical Shifts	422
13.4 Chemical Shifts in ¹ H NMR Spectroscopy	423
13.5 Integration of ¹ H NMR Absorptions: Proton Counting	425
13.6 Spin–Spin Splitting in ¹ H NMR Spectra	426
13.7 ¹ H NMR Spectroscopy and Proton Equivalence	430
13.8 More Complex Spin–Spin Splitting Patterns	432
13.9 Uses of ¹ H NMR Spectroscopy	433
13.10 ¹³ C NMR Spectroscopy: Signal Averaging and FT–NMR	434
13.11 Characteristics of ¹³ C NMR Spectroscopy	436
13.12 DEPT ¹³ C NMR Spectroscopy	438
13.13 Uses of ¹³ C NMR Spectroscopy	441

Chemistry Matters—Magnetic Resonance Imaging (MRI)	442
Key Terms	443
Summary	443
Additional Problems	443

CHAPTER 14

Conjugated Compounds and Ultraviolet Spectroscopy 455

Why This Chapter?	455
14.1 Stability of Conjugated Dienes: Molecular Orbital Theory	456
14.2 Electrophilic Additions to Conjugated Dienes: Allylic Carbocations	459
14.3 Kinetic versus Thermodynamic Control of Reactions	462
14.4 The Diels–Alder Cycloaddition Reaction	464
14.5 Characteristics of the Diels–Alder Reaction	465
14.6 Diene Polymers: Natural and Synthetic Rubbers	469
14.7 Ultraviolet Spectroscopy	471
14.8 Interpreting Ultraviolet Spectra: The Effect of Conjugation	473
14.9 Conjugation, Color, and the Chemistry of Vision	474
Chemistry Matters—Photolithography	477
Key Terms	478
Summary	478
Summary of Reactions	479
Additional Problems	479

CHAPTER 15

Benzene and Aromaticity 489

Why This Chapter?	489
15.1 Naming Aromatic Compounds	490
15.2 Structure and Stability of Benzene	493
15.3 Aromaticity and the Hückel $4n + 2$ Rule	495
15.4 Aromatic Ions	497
15.5 Aromatic Heterocycles: Pyridine and Pyrrole	499
15.6 Polycyclic Aromatic Compounds	502
15.7 Spectroscopy of Aromatic Compounds	503
Chemistry Matters—Aspirin, NSAIDs, and COX-2 Inhibitors	508
Key Terms	509
Summary	509
Additional Problems	510

CHAPTER 16

Chemistry of Benzene: Electrophilic Aromatic Substitution 521

Why This Chapter?	521
16.1 Electrophilic Aromatic Substitution Reactions: Bromination	522
16.2 Other Aromatic Substitutions	525
16.3 Alkylation and Acylation of Aromatic Rings: The Friedel–Crafts Reaction	530
16.4 Substituent Effects in Electrophilic Substitutions	534
16.5 Trisubstituted Benzenes: Additivity of Effects	544
16.6 Nucleophilic Aromatic Substitution	545
16.7 Benzyne	548
16.8 Oxidation of Aromatic Compounds	550
16.9 Reduction of Aromatic Compounds	552
16.10 Synthesis of Polysubstituted Benzenes	553

Chemistry Matters—Combinatorial Chemistry	558
Key Terms	559
Summary	559
Summary of Reactions	560
Additional Problems	561

CHAPTER 17

Alcohols and Phenols 571

Why This Chapter?	571
17.1 Naming Alcohols and Phenols	572
17.2 Properties of Alcohols and Phenols	574
17.3 Preparation of Alcohols: A Review	578
17.4 Alcohols from Carbonyl Compounds: Reduction	579
17.5 Alcohols from Carbonyl Compounds: Grignard Reaction	583
17.6 Reactions of Alcohols	587
17.7 Oxidation of Alcohols	592
17.8 Protection of Alcohols	594
17.9 Phenols and Their Uses	596
17.10 Reactions of Phenols	598
17.11 Spectroscopy of Alcohols and Phenols	599
Chemistry Matters—Ethanol: Chemical, Drug, and Poison	603
Key Terms	604
Summary	604
Summary of Reactions	604
Additional Problems	606

CHAPTER 18

Ethers and Epoxides; Thiols and Sulfides 619

Why This Chapter?	619
18.1 Names and Properties of Ethers	620
18.2 Preparing Ethers	621
18.3 Reactions of Ethers: Acidic Cleavage	624
18.4 Cyclic Ethers: Epoxides	625
18.5 Reactions of Epoxides: Ring-Opening	626
18.6 Crown Ethers	630
18.7 Thiols and Sulfides	631
18.8 Spectroscopy of Ethers	634
Chemistry Matters—Epoxy Resins and Adhesives	637
Key Terms	638
Summary	638
Summary of Reactions	638
Additional Problems	639
Preview of Carbonyl Chemistry	649

CHAPTER 19

Aldehydes and Ketones: Nucleophilic Addition Reactions 659

Why This Chapter?	659
19.1 Naming Aldehydes and Ketones	660
19.2 Preparing Aldehydes and Ketones	662
19.3 Oxidation of Aldehydes and Ketones	663
19.4 Nucleophilic Addition Reactions of Aldehydes and Ketones	664

19.5 Nucleophilic Addition of H ₂ O: Hydration	667
19.6 Nucleophilic Addition of HCN: Cyanohydrin Formation	670
19.7 Nucleophilic Addition of Hydride and Grignard Reagents: Alcohol Formation	670
19.8 Nucleophilic Addition of Amines: Imine and Enamine Formation	672
19.9 Nucleophilic Addition of Hydrazine: The Wolff–Kishner Reaction	677
19.10 Nucleophilic Addition of Alcohols: Acetal Formation	679
19.11 Nucleophilic Addition of Phosphorus Ylides: The Wittig Reaction	682
19.12 Biological Reductions	685
19.13 Conjugate Nucleophilic Addition to α,β -Unsaturated Aldehydes and Ketones	686
19.14 Spectroscopy of Aldehydes and Ketones	690
Chemistry Matters—Enantioselective Synthesis	695
Key Terms	696
Summary	696
Summary of Reactions	697
Additional Problems	698

CHAPTER 20

Carboxylic Acids and Nitriles 713

Why This Chapter?	713
20.1 Naming Carboxylic Acids and Nitriles	714
20.2 Structure and Properties of Carboxylic Acids	717
20.3 Biological Acids and the Henderson–Hasselbalch Equation	719
20.4 Substituent Effects on Acidity	720
20.5 Preparing Carboxylic Acids	723
20.6 Reactions of Carboxylic Acids: An Overview	724
20.7 Chemistry of Nitriles	725
20.8 Spectroscopy of Carboxylic Acids and Nitriles	730
Chemistry Matters—Vitamin C	732
Key Terms	733
Summary	733
Summary of Reactions	734
Additional Problems	735

CHAPTER 21

Carboxylic Acid Derivatives: Nucleophilic Acyl Substitution Reactions 745

Why This Chapter?	745
21.1 Naming Carboxylic Acid Derivatives	746
21.2 Nucleophilic Acyl Substitution Reactions	749
21.3 Reactions of Carboxylic Acids	753
21.4 Chemistry of Acid Halides	761
21.5 Chemistry of Acid Anhydrides	765
21.6 Chemistry of Esters	766
21.7 Chemistry of Amides	771
21.8 Chemistry of Thioesters and Acyl Phosphates: Biological Carboxylic Acid Derivatives	774
21.9 Polyamides and Polyesters: Step-Growth Polymers	776
21.10 Spectroscopy of Carboxylic Acid Derivatives	779
Chemistry Matters— β -Lactam Antibiotics	781
Key Terms	782
Summary	782

Summary of Reactions	783
Additional Problems	784

CHAPTER 22

Carbonyl Alpha-Substitution Reactions 797

Why This Chapter?	797
22.1 Keto–Enol Tautomerism	798
22.2 Reactivity of Enols: α -Substitution Reactions	800
22.3 Alpha Halogenation of Aldehydes and Ketones	801
22.4 Alpha Bromination of Carboxylic Acids	803
22.5 Acidity of Alpha Hydrogen Atoms: Enolate Ion Formation	804
22.6 Reactivity of Enolate Ions	807
22.7 Alkylation of Enolate Ions	808
Chemistry Matters—Barbiturates	816
Key Terms	817
Summary	817
Summary of Reactions	818
Additional Problems	819

CHAPTER 23

Carbonyl Condensation Reactions 827

Why This Chapter?	827
23.1 Carbonyl Condensations: The Aldol Reaction	828
23.2 Carbonyl Condensations versus Alpha Substitutions	830
23.3 Dehydration of Aldol Products: Synthesis of Enones	831
23.4 Using Aldol Reactions in Synthesis	833
23.5 Mixed Aldol Reactions	834
23.6 Intramolecular Aldol Reactions	835
23.7 The Claisen Condensation Reaction	837
23.8 Mixed Claisen Condensations	839
23.9 Intramolecular Claisen Condensations: The Dieckmann Cyclization	840
23.10 Conjugate Carbonyl Additions: The Michael Reaction	842
23.11 Carbonyl Condensations with Enamines: The Stork Enamine Reaction	845
23.12 The Robinson Annulation Reaction	847
23.13 Some Biological Carbonyl Condensation Reactions	848
Chemistry Matters—A Prologue to Metabolism	851
Key Terms	852
Summary	852
Summary of Reactions	853
Additional Problems	854

CHAPTER 24

Amines and Heterocycles 863

Why This Chapter?	863
24.1 Naming Amines	864
24.2 Structure and Properties of Amines	866
24.3 Basicity of Amines	867
24.4 Basicity of Arylamines	870
24.5 Biological Amines and the Henderson–Hasselbalch Equation	872
24.6 Synthesis of Amines	873
24.7 Reactions of Amines	881

24.8 Reactions of Arylamines	883
24.9 Heterocyclic Amines	889
24.10 Spectroscopy of Amines	894
Chemistry Matters—Green Chemistry II: Ionic Liquids	898
Key Terms	899
Summary	899
Summary of Reactions	900
Additional Problems	902

CHAPTER 25

Biomolecules: Carbohydrates 913

Why This Chapter?	913
25.1 Classification of Carbohydrates	914
25.2 Representing Carbohydrate Stereochemistry: Fischer Projections	915
25.3 D,L Sugars	918
25.4 Configurations of the Aldoses	919
25.5 Cyclic Structures of Monosaccharides: Anomers	923
25.6 Reactions of Monosaccharides	927
25.7 The Eight Essential Monosaccharides	933
25.8 Disaccharides	935
25.9 Polysaccharides and Their Synthesis	937
25.10 Some Other Important Carbohydrates	940
Chemistry Matters—Sweetness	941
Key Terms	942
Summary	943
Summary of Reactions	943
Additional Problems	944

CHAPTER 26

Biomolecules: Amino Acids, Peptides, and Proteins 951

Why This Chapter?	951
26.1 Structures of Amino Acids	952
26.2 Amino Acids and the Henderson–Hasselbalch Equation: Isoelectric Points	957
26.3 Synthesis of Amino Acids	959
26.4 Peptides and Proteins	961
26.5 Amino Acid Analysis of Peptides	963
26.6 Peptide Sequencing: The Edman Degradation	964
26.7 Peptide Synthesis	966
26.8 Automated Peptide Synthesis: The Merrifield Solid-Phase Method	969
26.9 Protein Structure	971
26.10 Enzymes and Coenzymes	973
26.11 How Do Enzymes Work? Citrate Synthase	975
Chemistry Matters—The Protein Data Bank	981
Key Terms	982
Summary	982
Summary of Reactions	983
Additional Problems	984

CHAPTER 27

Biomolecules: Lipids 991

Why This Chapter?	991
-------------------	-----

27.1 Waxes, Fats, and Oils	992
27.2 Soap	995
27.3 Phospholipids	996
27.4 Prostaglandins and Other Eicosanoids	997
27.5 Terpenoids	1000
27.6 Steroids	1009
27.7 Biosynthesis of Steroids	1012
Chemistry Matters—Saturated Fats, Cholesterol, and Heart Disease	1019
Key Terms	1020
Summary	1020
Additional Problems	1021

CHAPTER 28

Biomolecules: Nucleic Acids 1027

Why This Chapter?	1027
28.1 Nucleotides and Nucleic Acids	1028
28.2 Base Pairing in DNA	1030
28.3 Replication of DNA	1032
28.4 Transcription of DNA	1034
28.5 Translation of RNA: Protein Biosynthesis	1035
28.6 DNA Sequencing	1038
28.7 DNA Synthesis	1039
28.8 The Polymerase Chain Reaction	1042
Chemistry Matters—DNA Fingerprinting	1044
Key Terms	1044

CHAPTER 29

The Organic Chemistry of Metabolic Pathways 1051

Why This Chapter?	1051
29.1 An Overview of Metabolism and Biochemical Energy	1052
29.2 Catabolism of Triacylglycerols: The Fate of Glycerol	1055
29.3 Catabolism of Triacylglycerols: β -Oxidation	1058
29.4 Biosynthesis of Fatty Acids	1063
29.5 Catabolism of Carbohydrates: Glycolysis	1068
29.6 Conversion of Pyruvate to Acetyl CoA	1075
29.7 The Citric Acid Cycle	1079
29.8 Carbohydrate Biosynthesis: Gluconeogenesis	1083
29.9 Catabolism of Proteins: Deamination	1089
29.10 Some Conclusions about Biological Chemistry	1094
Chemistry Matters—Statin Drugs	1095
Key Terms	1096
Summary	1096
Additional Problems	1097

CHAPTER 30

Orbitals and Organic Chemistry: Pericyclic Reactions 1105

Why This Chapter?	1105
30.1 Molecular Orbitals of Conjugated π Systems	1106
30.2 Electrocyclic Reactions	1107

30.3 Stereochemistry of Thermal Electrocyclic Reactions	1110
30.4 Photochemical Electrocyclic Reactions	1111
30.5 Cycloaddition Reactions	1112
30.6 Stereochemistry of Cycloadditions	1113
30.7 Sigmatropic Rearrangements	1115
30.8 Some Examples of Sigmatropic Rearrangements	1117
30.9 A Summary of Rules for Pericyclic Reactions	1121
Chemistry Matters—Vitamin D, the Sunshine Vitamin	1122
Key Terms	1123
Summary	1123
Additional Problems	1123

CHAPTER 31

Synthetic Polymers 1131

Why This Chapter?	1131
31.1 Chain-Growth Polymers	1132
31.2 Stereochemistry of Polymerization: Ziegler–Natta Catalysts	1133
31.3 Copolymers	1135
31.4 Step-Growth Polymers	1137
31.5 Olefin Metathesis Polymerization	1138
31.6 Intramolecular Olefin Metathesis	1140
31.7 Polymer Structure and Physical Properties	1140
Chemistry Matters—Degradable Polymers	1144
Key Terms	1145
Summary	1145
Additional Problems	1146

Appendix A Nomenclature of Polyfunctional Organic Compounds 1151

Appendix B Acidity Constants for Some Organic Compounds 1157

Appendix C Glossary 1165

Appendix D Periodic Table 1185

Answer Key 1187

Index 1227

DEDICATION AND PREFACE

This 10th edition of *Organic Chemistry* is dedicated to the memory of my son, Peter McMurry, who passed away in 2019 after a lifelong struggle with Cystic Fibrosis (CF). He was brilliant, strong, and truly the kindest person I have ever known.

Peter McMurry

12/10/1968 – 12/12/2019

Just about every first-year medical student at New York Presbyterian Hospital/Columbia Medical Center knew and admired Peter, who was asked every year to meet and speak with incoming students about his experiences as a patient. He always enjoyed talking to the students, kidding them about their having had to take organic chemistry in college, and asking them if anyone recognized his last name from their O-Chem textbook.

If Peter were still alive, I have no doubt that he would want me to work on this 10th edition with a publisher that would give the book away free to students rather than with one that would charge a large amount. So that is what I have done. To make this possible, I am not receiving any payment for this book, and generous supporters have not only covered the production costs but have also made a donation to the Cystic Fibrosis Foundation to help find a cure for this terrible disease. Anything that readers of this book might donate in Peter's memory to the **Cystic Fibrosis Foundation** (<https://openstax.org/r/22cystfibrofoun>) would also be much appreciated.

John McMurry

Welcome to *Organic Chemistry: A Tenth Edition*, an OpenStax resource. This textbook was written to increase student access to high-quality learning materials, maintaining highest standards of academic rigor at little to no cost.

About OpenStax

OpenStax is part of Rice University, which is a 501(c)(3) nonprofit charitable corporation. As an educational initiative, it's our mission to improve educational access and learning for everyone. Through our partnerships with philanthropic organizations and our alliance with other educational resource companies, we're breaking down the most common barriers to learning. Because we believe that everyone should and can have access to knowledge.

About OpenStax resources

Customization

Organic Chemistry: A Tenth Edition is licensed under a Creative Commons Attribution-NonCommercial-ShareAlike 4.0 (CC BY NC-SA) license, which means that you can non-commercially distribute, remix, and build upon the content, as long as you provide attribution to OpenStax and its content contributors, under the same license.

Because our books are openly licensed, you are free to use the entire book or pick and choose the sections that are most relevant to the needs of your course. Feel free to remix the content by assigning your students certain chapters and sections in your syllabus, in the order that you prefer. You can even provide a direct link in your syllabus to the sections in the web view of your book.

Instructors also have the option of creating a customized version of their OpenStax book. The custom version can be made available to students in low-cost print or digital form through their campus bookstore. Visit the Instructor Resources section of your book page on OpenStax.org for more information.

Art attribution

In *Organic Chemistry: A Tenth Edition*, photos contain attribution to their creator, rights holder, host platform, and/or license within the caption. Photos may be reused for non-commercial purposes and with the same attribution to their original source. To maximize readability and content flow, illustrations do not include attribution in the text. When re-using or redistributing illustrations, please use the following attribution: Copyright Rice University, OpenStax, under CC BY-NC-SA 4.0 license.

Errata

All OpenStax textbooks undergo a rigorous review process. However, like any professional-grade textbook, errors sometimes occur. Since our books are web based, we can make updates periodically when deemed pedagogically necessary. If you have a correction to suggest, submit it through the link on your book page on OpenStax.org. Subject matter experts review all errata suggestions. OpenStax is committed to remaining transparent about all updates, so you will also find a list of past and pending errata changes on your book page on OpenStax.org.

Format

You can access this textbook for free in web view or PDF through OpenStax.org, and for a low cost in print. The web view is the recommended format because it is the most accessible – including being WCAG 2.0 AA compliant – and most current. Print versions are available for individual purchase, or they may be ordered through your campus bookstore.

From the author—About *Organic Chemistry: A Tenth Edition*

Organic Chemistry: A Tenth Edition, like previous editions, is intended for a two-semester introductory organic chemistry course. I recognize that many students in this course are biology or pre-med majors so, when appropriate, I bring in biological examples. Color is used consistently through the texts and illustrations. Problems are categorized (see below) and vary in level. My goal is to be as economical as possible with changes so that the overall length of *Organic Chemistry* does not increase.

Changes to the tenth edition

I continue to review every word and every explanation, updating many small details and improving problems where needed. My aim is always to refine the features that made earlier editions so successful, while adding new ones. Reviewer comments are also extensively considered during the reviewer process. All the problems in every chapter are also reviewed for clarity. The detailed list of changes will be available upon publication at the OpenStax website. However, the following is a list of the major changes made to the tenth edition.

Chapter 6

- Polar Reactions are now covered before Radical Reactions

Chapter 17

- Section 17.5: Added newly discovered reaction of Grignard reagents with carboxylic acids to prepare ketones

Chapter 18

- Section 18.7: Added coverage of ionophores

Chapter 19

- Section 19.5: Added coverage of alpha-keto acid hydrates

Chapter 21

- Section 21.3: Added synthesis of amides by reaction of carboxylic acids and amines using (1-Ethyl-3-(3-dimethylaminopropyl)carbodiimide (EDEC)

Chapter 26

- Section 26.7: Added synthesis of amides by reaction of carboxylic acids and amines using (1-Ethyl-3-(3-dimethylaminopropyl)carbodiimide (EDEC)
- Section 26.8: Updated details for solid phase peptide synthesis

Chapter 30

- Section 30.8: Increased coverage of Cope rearrangement
- Section 30.8: New coverage of Oxy Cope reaction

Chapter 31

- Section 31.6: Discuss intramolecular olefin metathesis use in ring-closing
- *Chemistry Matters*: Discuss intramolecular olefin metathesis use in ring-closing

Coverage and scope

Organic Chemistry: A Tenth Edition, like previous editions, is intended for a two-semester introductory organic chemistry course. The tenth edition retains the functional group approach of prior editions and the table of contents is retained.

Pedagogical foundation and features

- **“Why This Chapter?”** is a brief section that appears before the introduction to every chapter and tells students why the material about to be covered is important.
- **Worked Examples** includes a strategy and a detailed solution and is followed by problems for students to try on their own. The tenth edition has more than 1800 in-text and end-of-chapter problems.
- **Visualizing Chemistry Problems** occur at the end of each chapter. The problems offer students an opportunity to see chemistry in a different way by visualizing molecules rather than by simply interpreting structural formulas.
- **Mechanism Problems** are grouped together at the end of each chapter.
- **Summaries and Key Terms** lists help students by outlining the key concepts of each chapter.
- **Summaries of Reactions** at the ends of appropriate chapters bring together the key reactions from the chapter in one complete list.

Comprehensive art program

The art program is designed to enhance students' understanding of concepts through clear, effective illustrations, diagrams, and photographs.

About the author

John E. McMurry

John E. McMurry is a Professor Emeritus in the Department of Chemistry and Chemical Biology at Cornell University. He holds an A.B. degree from Harvard University and a Ph.D. from Columbia University. McMurry has authored over 100 research papers and is well-known for his contributions to the field of chemistry, particularly the development of the McMurry reaction. This reaction involves the coupling of two molecules of ketone or aldehyde to produce an alkene when treated with titanium(III) chloride and a reducing agent like Zn(Cu). The McMurry reaction has found extensive use in the laboratory synthesis of complex organic molecules and in the commercial synthesis of various drugs by the pharmaceutical industry.

McMurry was elected a Fellow of the American Association for the Advancement of Science in 1985 and received a Max Planck Society Research Award in 1991. Apart from his scientific contributions, McMurry is also a prolific author in the field of chemistry education. He has written 45 undergraduate chemistry textbooks, which have been translated into 12 languages and used worldwide. Among his notable works, *Organic Chemistry*, first published in 1984, stands as his most popular textbook.

Additional resources

Diversity and Inclusion Modules

Developed independently of this textbook by Dr. Rhett Smith (Clemson University), this resource is a unique website linked to *Organic Chemistry: A Tenth Edition*. This resource is free for instructors and students to use if they so choose. The website is mapped to *Organic Chemistry: A Tenth Edition* to provide a more complete, diverse, and inclusive picture of the development and current state of organic chemistry research. The figures whose work is highlighted in this online resource include historical figures from the developmental years of chemistry as well as researchers still active in the community. Each lesson currently consists of a brief introduction followed by a one-page description of the highlighted researcher and their work as it relates to relevant course topics. This is then followed by links to additional readings or videos about the life and research of the highlighted individual as well as quiz questions. The site also integrates into your learning management system (LMS).

Study Guide and Student Solutions Manual

Authored by Susan McMurry, the Student Study Guide and Student Solutions Manual are now separate items. Both the Study Guide and Student Solutions Manual, for the first time, will also be openly licensed and free for students in digital formats. Both resources have been updated to reflect the changes in the text and revised to meet accessibility standards.

Additional resources can be found by going to the instructors resource page for this text (<https://openstax.org/details/books/organic-chemistry?Instructor%20resources>).

Academic integrity

Academic integrity builds trust, understanding, equity, and genuine learning. While students may encounter significant challenges in their courses and their lives, doing their own work and maintaining a high degree of authenticity will result in meaningful outcomes that will extend far beyond their college career. Faculty, administrators, resource providers, and students should work together to maintain a fair and positive experience.

We realize that students benefit when academic integrity ground rules are established early in the course. To that end, OpenStax has created an interactive to aid with academic integrity discussions in your course.

Visit our **academic integrity slider** (<https://www.openstax.org/r/academic-integrity-slider>). Click and drag icons along the continuum to align these practices with your institution and course policies. You may then include the graphic on your syllabus, present it in your first course meeting, or create a handout for students.

At OpenStax we are also developing resources supporting authentic learning experiences and assessment. Please visit this book's page for updates. For an in-depth review of academic integrity strategies, we highly recommend visiting the International Center of Academic Integrity (ICAI) website at <https://academicintegrity.org/> (<https://academicintegrity.org>).

Community Hubs

OpenStax partners with the Institute for the Study of Knowledge Management in Education (ISKME) to offer Community Hubs on OER Commons—a platform for instructors to share community-created resources that support OpenStax books, free of charge. Through our Community Hubs, instructors can upload their own materials or download resources to use in their own courses, including additional ancillaries, teaching material, multimedia, and relevant course content. We encourage instructors to join the hubs for the subjects most relevant to your teaching and research as an opportunity both to enrich your courses and to engage with other faculty. To reach the Community Hubs, visit www.oercommons.org/hubs/openstax.

Technology partners

As allies in making high-quality learning materials accessible, our technology partners offer optional low-cost tools that are integrated with OpenStax books. To access the technology options for your text, visit your book page on OpenStax.org.

CHAPTER 1

Structure and Bonding

FIGURE 1.1 The enzyme HMG–CoA reductase, shown here as a so-called ribbon model, catalyzes a crucial step in the body’s synthesis of cholesterol. Understanding how this enzyme functions has led to the development of drugs credited with saving millions of lives. (credit: image from the RCSB PDB (rcsb.org) of PDB ID 1HW9 (E.S. Istvan, J. Deisenhofer) (2001) Structural mechanism for statin inhibition of HMG-CoA reductase *Science* 292: 1160–1164/RCSB PDB, CC BY 1.0)

- 1.1 Atomic Structure: The Nucleus
- 1.2 Atomic Structure: Orbitals
- 1.3 Atomic Structure: Electron Configurations
- 1.4 Development of Chemical Bonding Theory
- 1.5 Describing Chemical Bonds: Valence Bond Theory
- 1.6 sp^3 Hybrid Orbitals and the Structure of Methane
- 1.7 sp^3 Hybrid Orbitals and the Structure of Ethane
- 1.8 sp^2 Hybrid Orbitals and the Structure of Ethylene
- 1.9 sp Hybrid Orbitals and the Structure of Acetylene
- 1.10 Hybridization of Nitrogen, Oxygen, Phosphorus, and Sulfur
- 1.11 Describing Chemical Bonds: Molecular Orbital Theory
- 1.12 Drawing Chemical Structures

WHY THIS CHAPTER? We’ll ease into the study of organic chemistry by first reviewing some ideas about atoms, bonds, and molecular geometry that you may recall from your general chemistry course. Much of the material in this chapter and the next is likely to be familiar to you, but it’s nevertheless a good idea to make sure you understand it before moving on.

What is organic chemistry, and why should you study it? The answers to these questions are all around you.

Every living organism is made of organic chemicals. The proteins that make up your hair, skin, and muscles; the DNA that controls your genetic heritage; the foods that nourish you; and the medicines that heal you are all organic chemicals. Anyone with a curiosity about life and living things, and anyone who wants to be a part of the remarkable advances taking place in medicine and the biological sciences, must first understand organic chemistry. Look at the following drawings for instance, which show the chemical structures of some molecules whose names might be familiar to you. Although the drawings may appear unintelligible at this point, don't worry. They'll make perfectly good sense before long, and you'll soon be drawing similar structures for any substance you're interested in.

Historically, the term *organic chemistry* dates to the mid-1700s, when it was used to mean the chemistry of substances found in living organisms. Little was known about chemistry at that time, and the behavior of the “organic” substances isolated from plants and animals seemed different from that of the “inorganic” substances found in minerals. Organic compounds were generally low-melting solids and were usually more difficult to isolate, purify, and work with than high-melting inorganic compounds.

By the mid-1800s, however, it was clear that there was no fundamental difference between organic and inorganic compounds. The only distinguishing characteristic of organic compounds is that all contain the element carbon.

Organic chemistry, then, is the study of carbon compounds. But why is carbon special? Why, of the more than 197 million presently known chemical compounds, do almost all of them contain carbon? The answers to these questions come from carbon's electronic structure and its consequent position in the periodic table (**FIGURE 1.2**). As a group 4A element, carbon can share four valence electrons and form four strong covalent bonds. Furthermore, carbon atoms can bond to one another, forming long chains and rings. Carbon, alone of all elements, is able to form an immense diversity of compounds, from the simple methane, with one carbon atom, to the staggering complex DNA, which can have more than *100 million* carbons.

Group 1A												Group 8A					
1A	2A											3A	4A	5A	6A	7A	8A
H	Li											B	C	N	O	F	He
Na	Be											Al	Si	P	S	Cl	Ar
K	Ca	Sc	Ti	V	Cr	Mn	Fe	Co	Ni	Cu	Zn	Ga	Ge	As	Se	Br	Kr
Rb	Sr	Y	Zr	Nb	Mo	Tc	Ru	Rh	Pd	Ag	Cd	In	Sn	Sb	Te	I	Xe
Cs	Ba	La	Hf	Ta	W	Re	Os	Ir	Pt	Au	Hg	Tl	Pb	Bi	Po	At	Rn
Fr	Ra	Ac															

FIGURE 1.2 Carbon, hydrogen, and other elements commonly found in organic compounds are shown in the colors typically used to represent them.

Not all carbon compounds are derived from living organisms, however. Modern chemists have developed a remarkably sophisticated ability to design and synthesize new organic compounds in the laboratory—medicines, dyes, polymers, and a host of other substances. Organic chemistry touches the lives of

everyone. Its study can be a fascinating undertaking.

1.1 Atomic Structure: The Nucleus

As you might remember from your general chemistry course, an atom consists of a dense, positively charged nucleus surrounded at a relatively large distance by negatively charged electrons (**FIGURE 1.3**). The nucleus consists of subatomic particles called *neutrons*, which are electrically neutral, and *protons*, which are positively charged. Because an atom is neutral overall, the number of positive protons in the nucleus and the number of negative electrons surrounding the nucleus are the same.

FIGURE 1.3 A schematic view of an atom. The dense, positively charged nucleus contains most of the atom's mass and is surrounded by negatively charged electrons. The three-dimensional view on the right shows calculated electron-density surfaces. Electron density increases steadily toward the nucleus and is 40 times greater at the **blue solid surface** than at the **gray mesh surface**.

Although extremely small—about 10^{-14} to 10^{-15} meter (m) in diameter—the nucleus nevertheless contains essentially all the mass of the atom. Electrons have negligible mass and circulate around the nucleus at a distance of approximately 10^{-10} m. Thus, the diameter of a typical atom is about 2×10^{-10} m, or 200 picometers (pm), where $1 \text{ pm} = 10^{-12}$ m. To give you an idea of how small this is, a thin pencil line is about 3 million carbon atoms wide. Although most chemists throughout the world use the International System (SI) of units and describe small distances in picometers, many organic chemists and biochemists in the United States still use the unit angstrom (Å) to express atomic distances, where $1 \text{ Å} = 100 \text{ pm} = 10^{-10}$ m. As you probably did in your general chemistry course, however, we'll stay with SI units in this book.

A specific atom is described by its **atomic number (Z)**, which gives the number of protons (or electrons) it contains, and its **mass number (A)**, which gives the total number of protons and neutrons in its nucleus. All the atoms of a given element have the same atomic number: 1 for hydrogen, 6 for carbon, 15 for phosphorus, and so on; but they can have different mass numbers depending on how many neutrons they contain. Atoms with the same atomic number but different mass numbers are called **isotopes**. The element carbon, for instance, has three isotopes that occur naturally, with mass numbers of 12, 13, and 14. Carbon-12 has a natural abundance of 98.89%, carbon-13 has a natural abundance of 1.11%, and carbon-14 has only a negligible natural abundance.

The weighted-average of an element's naturally occurring isotopes is called **atomic weight** and is given in unified atomic mass units (u) or daltons (Da) where 1 u or 1 Da is defined as one twelfth the mass of one atom of carbon-12. Thus, the atomic weight is 1.008 u for hydrogen, 12.011 u for carbon, 30.974 u for phosphorus, and so on. Atomic weights of all elements are given in the periodic table in **Appendix D**.

1.2 Atomic Structure: Orbitals

How are the electrons distributed in an atom? You might recall from your general chemistry course that, according to the *quantum mechanical model*, the behavior of a specific electron in an atom can be described by a mathematical expression called a *wave equation*—the same type of expression used to describe the motion of waves in a fluid. The solution to a wave equation is called a *wave function*, or **orbital**, and is denoted by the lowercase Greek letter psi (ψ).

When the square of the wave function, ψ^2 , is plotted in three-dimensional space, an orbital describes the volume of space around a nucleus that an electron is most likely to occupy. You might therefore think of an orbital as looking like a photograph of the electron taken at a slow shutter speed. In such a photo, the orbital would appear as a blurry cloud, indicating the region of space where the electron has been. This electron cloud doesn't have a sharp boundary, but for practical purposes we can set the limits by saying that an orbital represents the space where an electron spends 90% to 95% of its time.

What do orbitals look like? There are four different kinds of orbitals, denoted *s*, *p*, *d*, and *f*, each with a different shape. Of the four, we'll be concerned primarily with *s* and *p* orbitals because these are the most common in

organic and biological chemistry. An s orbital has a spherical shape, with the nucleus at its center; a p orbital has a dumbbell shape with two parts, or *lobes*; and four of the five d orbitals have a cloverleaf shape with four lobes, as shown in **FIGURE 1.4**. The fifth d orbital is shaped like an elongated dumbbell with a doughnut around its middle.

FIGURE 1.4 Representations of s , p , and d orbitals. An s orbital is spherical, a p orbital is dumbbell-shaped, and four of the five d orbitals are cloverleaf-shaped. Different lobes of p orbitals are often drawn for convenience as teardrops, but their actual shape is more like that of a doorknob, as indicated.

The orbitals in an atom are organized into different layers around the nucleus called **electron shells**, which are centered around the nucleus and have successively larger size and energy. Different shells contain different numbers and kinds of orbitals, and each orbital within a shell can be occupied by two electrons. The first shell contains only a single s orbital, denoted $1s$, and thus holds only 2 electrons. The second shell contains one $2s$ orbital and three $2p$ orbitals and thus holds a total of 8 electrons. The third shell contains a $3s$ orbital, three $3p$ orbitals, and five $3d$ orbitals, for a total capacity of 18 electrons. These orbital groupings and their energy levels are shown in **FIGURE 1.5**.

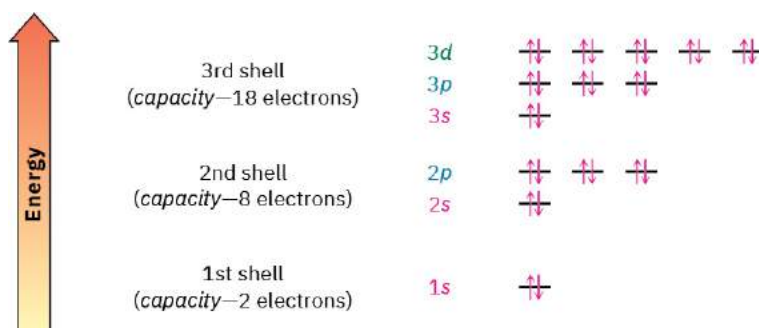

FIGURE 1.5 Energy levels of electrons in an atom. The first shell holds a maximum of 2 electrons in one $1s$ orbital; the second shell holds a maximum of 8 electrons in one $2s$ and three $2p$ orbitals; the third shell holds a maximum of 18 electrons in one $3s$, three $3p$, and $3d$ orbitals; and so on. The two electrons in each orbital are represented by five up and down arrows, $\uparrow\downarrow$. Although not shown, the energy level of the $4s$ orbital falls between $3p$ and $3d$.

The three different p orbitals within a given shell are oriented in space along mutually perpendicular directions, denoted p_x , p_y , and p_z . As shown in **FIGURE 1.6**, the two lobes of each p orbital are separated by a region of zero electron density called a **node**. Furthermore, the two orbital regions separated by the node have different algebraic signs, + and –, in the wave function, as represented by the different colors in **FIGURE 1.4** and **FIGURE 1.6**. As we'll see in **Section 1.11**, these algebraic signs for different orbital lobes have important consequences with respect to chemical bonding and chemical reactivity.

FIGURE 1.6 Shapes of the $2p$ orbitals. Each of the three mutually perpendicular, dumbbell-shaped orbitals has two lobes separated by a node. The **two lobes** have different algebraic signs in the corresponding wave function, as indicated by the different colors.

1.3 Atomic Structure: Electron Configurations

The lowest-energy arrangement, or **ground-state electron configuration**, of an atom is a list of the orbitals occupied by its electrons. We can predict this arrangement by following three rules.

RULE 1

The lowest-energy orbitals fill up first, $1s \rightarrow 2s \rightarrow 2p \rightarrow 3s \rightarrow 3p \rightarrow 4s \rightarrow 3d$, according to the following graphic, a statement called the **Aufbau principle**. Note that the $4s$ orbital lies between the $3p$ and $3d$ orbitals in energy.

RULE 2

Electrons act in some ways as if they were spinning around an axis, somewhat as the earth spins. This spin can have two orientations, denoted as up (\uparrow) and down (\downarrow). Only two electrons can occupy an orbital, and they must have opposite spins, a statement called the **Pauli exclusion principle**.

RULE 3

If two or more empty orbitals of equal energy are available, one electron occupies each with spins parallel until all orbitals are half-full, a statement called **Hund's rule**.

Some examples of how these rules apply are shown in **TABLE 1.1**. Hydrogen, for instance, has only one electron, which must occupy the lowest-energy orbital. Thus, hydrogen has a $1s$ ground-state configuration. Carbon has six electrons and the ground-state configuration $1s^2 2s^2 2p_x^1 2p_y^1$, and so forth. Note that a superscript is used to represent the number of electrons in a particular orbital.

TABLE 1.1 Ground-State Electron Configurations of Some Elements

Element	Atomic number	Configuration
Hydrogen	1	1s ↑
Carbon	6	2p ↑ ↑ — 2s ↑↓ 1s ↑↓
Phosphorus	15	3p ↑ ↑ ↑ 3s ↑↓ 2p ↑↓ ↑↓ ↑↓ 2s ↑↓ 1s ↑↓

PROBLEM What is the ground-state electron configuration of each of the following elements:

1-1 (a) Oxygen **(b)** Nitrogen **(c)** Sulfur

PROBLEM How many electrons does each of the following biological trace elements have in its outermost **1-2** electron shell?

(a) Magnesium **(b)** Cobalt **(c)** Selenium

1.4 Development of Chemical Bonding Theory

By the mid-1800s, the new science of chemistry was developing rapidly, especially in Europe, and chemists had begun to probe the forces holding compounds together. In 1858, the German chemist August Kekulé and the Scottish chemist Archibald Couper independently proposed that, in all organic compounds, carbon is *tetravalent*—it always forms four bonds when it joins other elements to form stable compounds. Furthermore, said Kekulé, carbon atoms can bond to one another to form extended chains of linked atoms. In 1865, Kekulé provided another major advance when he suggested that carbon chains can double back on themselves to form *rings* of atoms.

Although Kekulé and Couper were correct in describing the tetravalent nature of carbon, chemistry was still viewed in a two-dimensional way until 1874. In that year, the Dutch chemist Jacobus van't Hoff and French chemist Joseph Le Bel added a third dimension to our ideas about organic compounds when they proposed that the four bonds of carbon are not oriented randomly but have specific spatial directions. Van't Hoff went even further and suggested that the four atoms to which carbon is bonded sit at the corners of a regular tetrahedron, with carbon in the center.

A representation of a tetrahedral carbon atom is shown in **FIGURE 1.7**. Note the conventions used to show three-dimensionality: solid lines represent bonds in the plane of the page, the heavy wedged line represents a bond coming out of the page toward the viewer, and the dashed line represents a bond receding back behind the page, away from the viewer. Get used to them; these representations will be used throughout the text.

FIGURE 1.7 A representation of van't Hoff's tetrahedral carbon atom. The solid lines represent bonds in the plane of the paper, the heavy wedged line represents a bond coming out of the plane of the page toward the viewer, and the dashed line represents a bond going back behind the plane of the page away from the viewer.

Why, though, do atoms bond together, and how can chemical bonds be described electronically? The *why* question is relatively easy to answer: atoms bond together because the compound that results is more stable and lower in energy than the separate atoms. Energy—usually as heat—is always released and flows out of the chemical system when a bond forms. Conversely, energy is added to the chemical system when a bond breaks. Making bonds always releases energy, and breaking bonds always absorbs energy. The *how* question is more difficult. To answer it, we need to know more about the electronic properties of atoms.

We know through observation that eight electrons (an electron *octet*) in an atom's outermost shell, or **valence shell**, impart special stability to the noble-gas elements in group 8A of the periodic table: Ne ($2 + 8$); Ar ($2 + 8 + 8$); Kr ($2 + 8 + 18 + 8$). We also know that the chemistry of the main-group elements on the left and right sides of the periodic table is governed by their tendency to take on the electron configuration of the nearest noble gas. The alkali metals such as sodium in group 1A, for example, achieve a noble-gas configuration by losing the single *s* electron from their valence shell to form a cation, while the halogens such as chlorine in group 7A achieve a noble-gas configuration by gaining a *p* electron to fill their valence shell and form an anion. The resultant ions are held together in compounds like $\text{Na}^+ \text{Cl}^-$ by the electrical attraction of unlike charges that we call an **ionic bond**.

But how do elements closer to the middle of the periodic table form bonds? Look at methane, CH_4 , the main constituent of natural gas, for example. The bonding in methane is not ionic because it would take too much energy for carbon ($1s^2 2s^2 2p^2$) either to gain or lose four electrons to achieve a noble-gas configuration. Instead, carbon bonds to other atoms, not by gaining or losing electrons, but by *sharing* them. Such a shared-electron bond, first proposed in 1916 by the American chemist G. N. Lewis, is called a **covalent bond**. The neutral collection of atoms held together by covalent bonds is called a **molecule**. Ionic compounds such as sodium chloride, however, are not called molecules.

A simple way of indicating the covalent bonds in molecules is to use what are called **Lewis structures**, or **electron-dot structures**, in which the valence-shell electrons of an atom are represented as dots. Thus, hydrogen has one dot representing its $1s$ electron, carbon has four dots ($2s^2 2p^2$), oxygen has six dots ($2s^2 2p^4$), and so on. A stable molecule results whenever a noble-gas configuration of eight dots (an octet) is achieved for all main-group atoms or two dots for hydrogen. Even simpler than Lewis structures is the use of **Kekulé structures**, or **line-bond structures**, in which the two-electron covalent bonds are indicated as lines drawn between atoms.

The number of covalent bonds an atom forms depends on how many additional valence electrons it needs to reach a noble-gas configuration. Hydrogen has one valence electron ($1s$) and needs only one more to reach the helium configuration ($1s^2$), so it forms one bond. Carbon has four valence electrons ($2s^2 2p^2$) and needs four more to reach the neon configuration ($2s^2 2p^6$), so it forms four bonds. Nitrogen has five valence electrons ($2s^2 2p^3$), needs three more, and forms three bonds; oxygen has six valence electrons ($2s^2 2p^4$), needs two more, and forms two bonds; and the halogens have seven valence electrons, need one more, and form one bond.

Valence electrons that are not used for bonding remain as dots in structures and are called **lone-pair electrons**, or **nonbonding electrons**. The nitrogen atom in ammonia, NH_3 , for instance, shares six valence electrons in three covalent bonds and has its remaining two valence electrons as two dots in a nonbonding lone pair. As a time-saving shorthand, nonbonding electrons are often omitted when drawing line-bond structures, but you still have to keep them in mind since they're often crucial in chemical reactions.

WORKED EXAMPLE 1.1

Predicting the Number of Bonds Formed by Atoms in Molecules

How many hydrogen atoms does phosphorus bond to in forming phosphine, PH_3 ?

Strategy

Identify the periodic group of phosphorus, and find from that how many electrons (bonds) are needed to make an octet.

Solution

Phosphorus is in group 5A of the periodic table and has five valence electrons. It thus needs to share three more electrons to make an octet and therefore bonds to three hydrogen atoms, giving PH_3 .

WORKED EXAMPLE 1.2

Drawing Electron-Dot and Line-Bond Structures

Draw both electron-dot and line-bond structures for chloromethane, CH_3Cl .

Strategy

Remember that a covalent bond—that is, a pair of shared electrons—is represented as a line between atoms.

Solution

Hydrogen has one valence electron, carbon has four valence electrons, and chlorine has seven valence electrons. Thus, chloromethane is represented as

PROBLEM Draw a molecule of chloroform, CHCl_3 , using solid, wedged, and dashed lines to show its tetrahedral geometry.
1-3

PROBLEM Convert the following representation of ethane, C_2H_6 , into a conventional drawing that uses solid, wedged, and dashed lines to indicate tetrahedral geometry around each carbon (black = C, gray = H).
1-4

1.5 Describing Chemical Bonds: Valence Bond Theory

How does electron sharing lead to bonding between atoms? Two models have been developed to describe covalent bonding: *valence bond theory* and *molecular orbital theory*. Each model has its strengths and weaknesses, and chemists tend to use them interchangeably depending on the circumstances. Valence bond theory is the more easily visualized of the two, so most of the descriptions we'll use in this book derive from that approach.

According to **valence bond (VB) theory**, a covalent bond forms when two atoms approach each other closely and a singly occupied orbital on one atom *overlaps* a singly occupied orbital on the other atom. The electrons are now paired in the overlapping orbitals and are attracted to the nuclei of both atoms, thus bonding the atoms together. In the H_2 molecule, for instance, the H–H bond results from the overlap of two singly occupied hydrogen $1s$ orbitals.

The overlapping orbitals in the H_2 molecule have the elongated egg shape we might get by pressing two spheres together. If a plane were to pass through the middle of the bond, the intersection of the plane and the overlapping orbitals would be a circle. In other words, the H–H bond is cylindrically symmetrical, as shown in **FIGURE 1.8**. Such bonds, which are formed by the head-on overlap of two atomic orbitals along a line drawn between the nuclei, are called **sigma (σ) bonds**.

FIGURE 1.8 The cylindrical symmetry of the H–H σ bond in an H_2 molecule. The intersection of a plane cutting through the σ bond is a circle.

During the bond-forming reaction $2\text{H}\cdot \rightarrow \text{H}_2$, 436 kJ/mol (104 kcal/mol) of energy is released. Because the product H_2 molecule has 436 kJ/mol less energy than the starting 2 $\text{H}\cdot$ atoms, the product is more stable than the reactant and we say that the H–H bond has a **bond strength** of 436 kJ/mol. In other words, we would have to put 436 kJ/mol of energy into the H–H bond to break the H_2 molecule apart into two H atoms (**FIGURE 1.9**). For convenience, we'll generally give energies in both kilocalories (kcal) and the SI unit kilojoules (kJ): 1 kJ = 0.2390 kcal; 1 kcal = 4.184 kJ.

FIGURE 1.9 Relative energy levels of two H atoms and the H_2 molecule. The H_2 molecule has 436 kJ/mol (104 kcal/mol) less energy than the two separate H atoms, so 436 kJ/mol of energy is **released when the H–H bond forms**. Conversely, 436 kJ/mol is **absorbed when the H–H bond breaks**.

How close are the two nuclei in the H_2 molecule? If they are too close, they will repel each other because both are positively charged. Yet if they're too far apart, they won't be able to share the bonding electrons. Thus, there is an optimum distance between nuclei that leads to maximum stability (**FIGURE 1.10**). Called the **bond length**, this distance is 74 pm in the H–H molecule. Every covalent bond has both a characteristic bond strength and bond length.

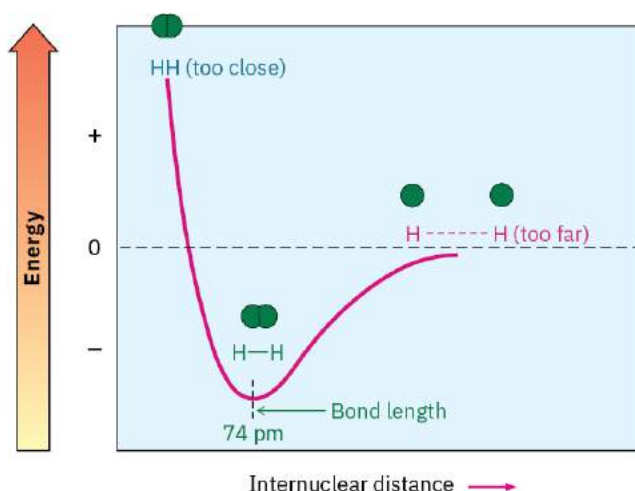

FIGURE 1.10 A plot of energy versus internuclear distance for two hydrogen atoms. The distance between nuclei at the minimum energy point is the **bond length**.

1.6 sp^3 Hybrid Orbitals and the Structure of Methane

The bonding in the hydrogen molecule is fairly straightforward, but the situation is more complicated in organic molecules with tetravalent carbon atoms. Take methane, CH_4 , for instance. As we've seen, carbon has four valence electrons ($2s^2 2p^2$) and forms four bonds. Because carbon uses two kinds of orbitals for bonding, $2s$ and $2p$, we might expect methane to have two kinds of C–H bonds. In fact, though, all four C–H bonds in methane are identical and are spatially oriented toward the corners of a regular tetrahedron, as shown previously in **FIGURE 1.7**. How can we explain this?

An answer was provided in 1931 by Linus Pauling, who showed mathematically how an s orbital and three p orbitals on an atom can combine, or *hybridize*, to form four equivalent atomic orbitals with tetrahedral orientation. Shown in **FIGURE 1.11**, these tetrahedrally oriented orbitals are called **sp^3 hybrid orbitals**. Note that the superscript 3 in the name sp^3 tells how many of each type of atomic orbital combine to form the hybrid, not how many electrons occupy it.

FIGURE 1.11 Four sp^3 hybrid orbitals, oriented toward the corners of a regular tetrahedron, are formed by the combination of an s orbital and three p orbitals (red/blue). The sp^3 hybrids have two lobes and are unsymmetrical about the nucleus, giving them a directionality and allowing them to form strong bonds to other atoms.

The concept of hybridization explains how carbon forms four equivalent tetrahedral bonds but not why it does so. The shape of the hybrid orbital suggests the answer to why. When an s orbital hybridizes with three p orbitals, the resultant sp^3 hybrid orbitals are unsymmetrical about the nucleus. One of the two lobes is larger than the other and can therefore overlap more effectively with an orbital from another atom to form a bond. As a result,

sp^3 hybrid orbitals form stronger bonds than do unhybridized s or p orbitals.

The asymmetry of sp^3 orbitals arises because, as noted previously, the two lobes of a p orbital have different algebraic signs, + and -, in the wave function. Thus, when a p orbital hybridizes with an s orbital, the positive p lobe adds to the s orbital but the negative p lobe subtracts from the s orbital. The resultant hybrid orbital is therefore unsymmetrical about the nucleus and is strongly oriented in one direction.

When each of the four identical sp^3 hybrid orbitals of a carbon atom overlaps with the $1s$ orbital of a hydrogen atom, four identical C–H bonds are formed and methane results. Each C–H bond in methane has a strength of 439 kJ/mol (105 kcal/mol) and a length of 109 pm. Because the four bonds have a specific geometry, we also can define a property called the **bond angle**. The angle formed by each H–C–H is 109.5° , the so-called tetrahedral angle. Methane thus has the structure shown in **FIGURE 1.12**.

FIGURE 1.12 The structure of methane, showing its 109.5° bond angles.

1.7 sp^3 Hybrid Orbitals and the Structure of Ethane

The same kind of orbital hybridization that accounts for the methane structure also accounts for the bonding together of carbon atoms into chains and rings to make possible many millions of organic compounds. Ethane, C_2H_6 , is the simplest molecule containing a carbon–carbon bond.

We can picture the ethane molecule by imagining that the two carbon atoms bond to each other by head-on sigma (σ) overlap of an sp^3 hybrid orbital from each (**FIGURE 1.13**). The remaining three sp^3 hybrid orbitals on each carbon overlap with the $1s$ orbitals of three hydrogens to form the six C–H bonds. The C–H bonds in ethane are similar to those in methane, although a bit weaker: 421 kJ/mol (101 kcal/mol) for ethane versus 439 kJ/mol for methane. The C–C bond is 153 pm in length and has a strength of 377 kJ/mol (90 kcal/mol). All the bond angles of ethane are near, although not exactly at, the tetrahedral value of 109.5° .

FIGURE 1.13 The structure of ethane. The carbon–carbon bond is formed by σ overlap of two sp^3 hybrid orbitals. For clarity, the smaller

lobes of the sp^3 hybrid orbitals are not shown.

PROBLEM Draw a line-bond structure for propane, $\text{CH}_3\text{CH}_2\text{CH}_3$. Predict the value of each bond angle, and **1-8** indicate the overall shape of the molecule.

PROBLEM Convert the following molecular model of hexane, a component of gasoline, into a line-bond **1-9** structure (black = C, gray = H).

Hexane

1.8 sp^2 Hybrid Orbitals and the Structure of Ethylene

The bonds we've seen in methane and ethane are called *single bonds* because they result from the sharing of one electron pair between bonded atoms. It was recognized nearly 150 years ago, however, that carbon atoms can also form *double bonds* by sharing two electron pairs between atoms or *triple bonds* by sharing three electron pairs. Ethylene, for instance, has the structure $\text{H}_2\text{C}=\text{CH}_2$ and contains a carbon-carbon double bond, while acetylene has the structure $\text{HC}\equiv\text{CH}$ and contains a carbon-carbon triple bond.

How are multiple bonds described by valence bond theory? When we discussed sp^3 hybrid orbitals in **Section 1.6**, we said that the four valence-shell atomic orbitals of carbon combine to form four equivalent sp^3 hybrids. Imagine instead that the $2s$ orbital combines with only *two* of the three available $2p$ orbitals. Three **sp^2 hybrid orbitals** result, and one $2p$ orbital remains unchanged. Like sp^3 hybrids, sp^2 hybrid orbitals are unsymmetrical about the nucleus and are strongly oriented in a specific direction so they can form strong bonds. The three sp^2 orbitals lie in a plane at angles of 120° to one another, with the remaining p orbital perpendicular to the sp^2 plane, as shown in **FIGURE 1.14**.

FIGURE 1.14 sp^2 Hybridization. The three equivalent sp^2 hybrid orbitals lie in a plane at angles of 120° to one another, and a single unhybridized p orbital (red/blue) is perpendicular to the sp^2 plane.

When two carbons with sp^2 hybridization approach each other, they form a strong σ bond by sp^2 - sp^2 head-on overlap. At the same time, the unhybridized p orbitals interact by sideways overlap to form what is called a **pi (π) bond**. The combination of an sp^2 - sp^2 σ bond and a $2p$ - $2p$ π bond results in the sharing of four electrons and the formation of a carbon-carbon double bond (**FIGURE 1.15**). Note that the electrons in the σ bond occupy the region centered between nuclei, while the electrons in the π bond occupy regions above and below a line drawn between nuclei.

To complete the structure of ethylene, four hydrogen atoms form σ bonds with the remaining four sp^2 orbitals. Ethylene thus has a planar structure, with H-C-H and H-C-C bond angles of approximately 120° . (The actual values are 117.4° for the H-C-H bond angle and 121.3° for the H-C-C bond angle.) Each C-H bond has a length of 108.7 pm and a strength of 464 kJ/mol (111 kcal/mol).

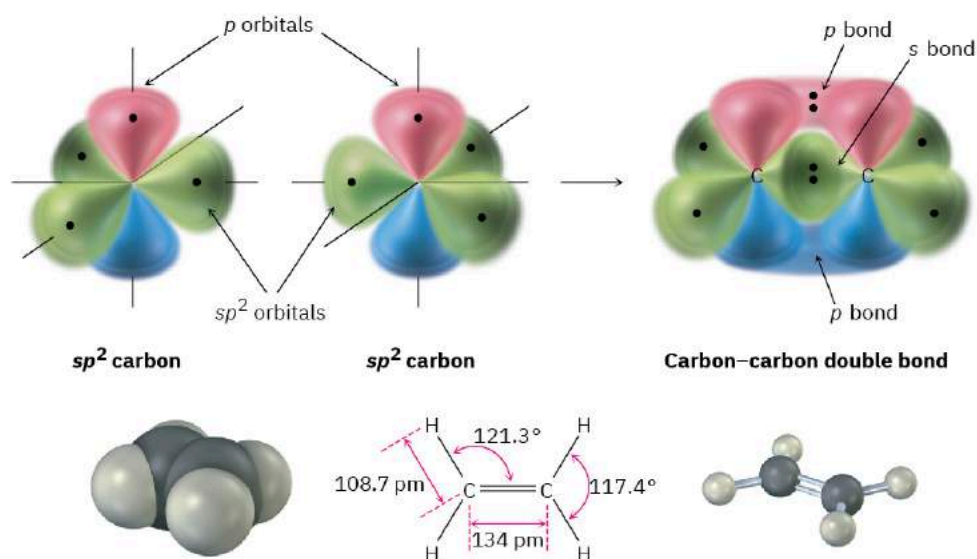

FIGURE 1.15 The structure of ethylene. One part of the double bond in ethylene results from σ (head-on) overlap of sp^2 hybrid orbitals, and the other part results from π (sideways) overlap of unhybridized p orbitals (red/blue). The π bond has regions of electron density above and below a line drawn between nuclei.

As you might expect, the carbon–carbon double bond in ethylene is both shorter and stronger than the single bond in ethane because it has four electrons bonding the nuclei together rather than two. Ethylene has a C=C bond length of 134 pm and a strength of 728 kJ/mol (174 kcal/mol) versus a C–C length of 153 pm and a strength of 377 kJ/mol for ethane. The carbon–carbon double bond is less than twice as strong as a single bond because the sideways overlap in the π part of the double bond is not as great as the head-on overlap in the σ part.

WORKED EXAMPLE 1.3

Drawing Electron-Dot and Line-Bond Structures

Commonly used in biology as a tissue preservative, formaldehyde, CH_2O , contains a carbon–oxygen double bond. Draw electron-dot and line-bond structures of formaldehyde, and indicate the hybridization of the carbon orbitals.

Strategy

We know that hydrogen forms one covalent bond, carbon forms four, and oxygen forms two. Trial and error, combined with intuition, is needed to fit the atoms together.

Solution

There is only one way that two hydrogens, one carbon, and one oxygen can combine:

Like the carbon atoms in ethylene, the carbon atom in formaldehyde is in a double bond and its orbitals are therefore sp^2 -hybridized.

PROBLEM 1-10 Draw a line-bond structure for propene, $\text{CH}_3\text{CH}=\text{CH}_2$. Indicate the hybridization of the orbitals on each carbon, and predict the value of each bond angle.

PROBLEM 1-11 Draw a line-bond structure for 1,3-butadiene, $\text{H}_2\text{C}=\text{CH}-\text{CH}=\text{CH}_2$. Indicate the hybridization of the orbitals on each carbon, and predict the value of each bond angle.

PROBLEM A molecular model of aspirin (acetylsalicylic acid) is shown. Identify the hybridization of the orbitals on each carbon atom in aspirin, and tell which atoms have lone pairs of electrons (black = C, red = O, gray = H).

1-12

1.9 *sp* Hybrid Orbitals and the Structure of Acetylene

In addition to forming single and double bonds by sharing two and four electrons, respectively, carbon can also form a *triple bond* by sharing six electrons. To account for the triple bond in a molecule such as acetylene, $\text{H}-\text{C}\equiv\text{C}-\text{H}$, we need a third kind of hybrid orbital, an ***sp* hybrid**. Imagine that, instead of combining with two or three *p* orbitals, a carbon *2s* orbital hybridizes with only a single *p* orbital. Two *sp* hybrid orbitals result, and two *p* orbitals remain unchanged. The two *sp* orbitals are oriented 180° apart on the right-left (*x*) axis, while the *p* orbitals are perpendicular on the up-down (*y*) axis and the in-out (*z*) axis, as shown in **FIGURE 1.16**.

FIGURE 1.16 *sp* Hybridization. The two ***sp* hybrid orbitals** are oriented 180° away from each other, perpendicular to the two remaining ***p* orbitals** (red/blue).

When two *sp*-hybridized carbon atoms approach each other, *sp* hybrid orbitals on each carbon overlap head-on to form a strong *sp-sp* σ bond. At the same time, the p_z orbitals from each carbon form a p_z-p_z π bond by sideways overlap, and the p_y orbitals overlap similarly to form a p_y-p_y π bond. The net effect is the sharing of six electrons and formation of a carbon-carbon triple bond. Each of the two remaining *sp* hybrid orbitals forms a σ bond with hydrogen to complete the acetylene molecule (**FIGURE 1.17**).

FIGURE 1.17 The structure of acetylene. The two carbon atoms are joined by one sp - sp σ bond and two p - p π bonds.

As suggested by sp hybridization, acetylene is a linear molecule with H-C-C bond angles of 180° . The C-H bonds have a length of 106 pm and a strength of 558 kJ/mol (133 kcal/mol). The C-C bond length in acetylene is 120 pm, and its strength is about 965 kJ/mol (231 kcal/mol), making it the shortest and strongest of any carbon-carbon bond. A comparison of sp , sp^2 , and sp^3 hybridization is given in [TABLE 1.2](#).

TABLE 1.2 Comparison of C-C and C-H Bonds in Methane, Ethane, Ethylene, and Acetylene

Molecule	Bond	Bond strength		Bond length (pm)
		(kJ/mol)	(kcal/mol)	
Methane, CH ₄	(sp^3) C-H	439	105	109
Ethane, CH ₃ CH ₃	(sp^3) C-C (sp^3)	377	90	153
	(sp^3) C-H	421	101	109
Ethylene, H ₂ C=CH ₂	(sp^2) C=C (sp^2)	728	174	134
	(sp^2) C-H	464	111	109
Acetylene, HC≡CH	(sp) C≡C (sp)	965	231	120
	(sp) C-H	558	133	106

PROBLEM Draw a line-bond structure for propyne, CH₃C≡CH. Indicate the hybridization of the orbitals on **1-13** each carbon, and predict a value for each bond angle.

1.10 Hybridization of Nitrogen, Oxygen, Phosphorus, and Sulfur

The valence-bond concept of orbital hybridization described in the previous four sections is not limited to carbon. Covalent bonds formed by other elements can also be described using hybrid orbitals. Look, for instance, at the nitrogen atom in methylamine (CH₃NH₂), an organic derivative of ammonia (NH₃) and the substance responsible for the odor of rotting fish.

The experimentally measured H-N-H bond angle in methylamine is 107.1° , and the C-N-H bond angle is

110.3°, both of which are close to the 109.5° tetrahedral angle found in methane. We therefore assume that nitrogen forms four sp^3 -hybridized orbitals, just as carbon does. One of the four sp^3 orbitals is occupied by two nonbonding electrons (a lone pair), and the other three hybrid orbitals have one electron each. Overlap of these three half-filled nitrogen orbitals with half-filled orbitals from other atoms (C or H) gives methylamine. Note that the unshared lone pair of electrons in the fourth sp^3 hybrid orbital of nitrogen occupies as much space as an N–H bond does and is very important to the chemistry of methylamine and other nitrogen-containing organic molecules.

Methylamine

Like the carbon atom in methane and the nitrogen atom in methylamine, the oxygen atom in methanol (methyl alcohol) and many other organic molecules can be described as sp^3 -hybridized. The C–O–H bond angle in methanol is 108.5°, very close to the 109.5° tetrahedral angle. Two of the four sp^3 hybrid orbitals on oxygen are occupied by nonbonding electron lone pairs, and two are used to form bonds.

**Methanol
(methyl alcohol)**

In the periodic table, phosphorus and sulfur are the third-row analogs of nitrogen and oxygen, and the bonding in both can be described using hybrid orbitals. Because of their positions in the third row, however, both phosphorus and sulfur can expand their outer-shell octets and form more than the typical number of covalent bonds. Phosphorus, for instance, often forms five covalent bonds, and sulfur often forms four.

Phosphorus is most commonly encountered in biological molecules in compounds called *organophosphates*, which contain a phosphorus atom bonded to four oxygens, with one of the oxygens also bonded to carbon. Methyl phosphate, $\text{CH}_3\text{OPO}_3^{2-}$, is the simplest example. The O–P–O bond angle in such compounds is typically in the range 110° to 112°, implying sp^3 hybridization for phosphorus orbitals.

**Methyl phosphate
(an organophosphate)**

Sulfur is most commonly encountered in biological molecules either in compounds called *thiols*, which have a sulfur atom bonded to one hydrogen and one carbon, C–S–H or in *sulfides*, which have a sulfur atom bonded to two carbons, C–S–C. Produced by some bacteria, methanethiol (CH_3SH) is the simplest example of a thiol, and dimethyl sulfide, $\text{H}_3\text{C–S–CH}_3$, is the simplest example of a sulfide. Both can be described by approximate sp^3 hybridization around sulfur, although both have significant deviation from the 109.5° tetrahedral angle.

PROBLEM 1-14 Identify all nonbonding lone pairs of electrons in the following molecules, and tell what geometry you expect for each of the indicated atoms.

- (a) The oxygen atom in dimethyl ether, $\text{CH}_3\text{-O-CH}_3$ (b) The nitrogen atom in trimethylamine,

- (c) The phosphorus atom in phosphine, PH_3
 (d) The sulfur atom in the amino acid methionine,

1.11 Describing Chemical Bonds: Molecular Orbital Theory

We said in [Section 1.5](#) that chemists use two models for describing covalent bonds: valence bond theory and molecular orbital theory. Having now seen the valence bond approach, which uses hybrid atomic orbitals to account for geometry and assumes the overlap of atomic orbitals to account for electron sharing, let's look briefly at the molecular orbital approach to bonding. We'll return to this topic in Chapters 14, 15, and 30 for a more in-depth discussion.

Molecular orbital (MO) theory describes covalent bond formation as arising from a mathematical combination of atomic orbitals (wave functions) on different atoms to form *molecular orbitals*, so called because they belong to the entire molecule rather than to an individual atom. Just as an *atomic* orbital, whether unhybridized or hybridized, describes a region of space around an *atom* where an electron is likely to be found, so a *molecular* orbital describes a region of space in a *molecule* where electrons are most likely to be found.

Like an atomic orbital, a molecular orbital has a specific size, shape, and energy. In the H_2 molecule, for example, two singly occupied $1s$ atomic orbitals combine to form two molecular orbitals. There are two ways for the orbital combination to occur—an additive way and a subtractive way. The additive combination leads to formation of a molecular orbital that is lower in energy and roughly egg-shaped, while the subtractive combination leads to a molecular orbital that is higher in energy and has a node between nuclei ([FIGURE 1.18](#)). Note that the additive combination is a single, egg-shaped, molecular orbital; it is not the same as the two overlapping $1s$ atomic orbitals of the valence bond description. Similarly, the subtractive combination is a single molecular orbital with the shape of an elongated dumbbell.

FIGURE 1.18 Molecular orbitals of H₂. Combination of two hydrogen 1s atomic orbitals leads to two H₂ molecular orbitals. The lower-energy, **bonding MO** is filled, and the higher-energy, **antibonding MO** is unfilled.

The additive combination is lower in energy than the two hydrogen 1s atomic orbitals and is called a **bonding MO** because electrons in this MO spend most of their time in the region between the two nuclei, thereby bonding the atoms together. The subtractive combination is higher in energy than the two hydrogen 1s orbitals and is called an **antibonding MO** because any electrons it contains *can't* occupy the central region between the nuclei, where there is a node, and thus can't contribute to bonding. The two nuclei therefore repel each other.

Just as bonding and antibonding σ molecular orbitals result from the head-on combination of two s atomic orbitals in H₂, so bonding and antibonding π molecular orbitals result from the sideways combination of two p atomic orbitals in ethylene. As shown in **FIGURE 1.19**, the lower-energy, π bonding MO has no node between nuclei and results from the combination of p orbital lobes with the same algebraic sign. The higher-energy, π antibonding MO has a node between nuclei and results from the combination of lobes with opposite algebraic signs. Only the bonding MO is occupied; the higher-energy, antibonding MO is vacant. We'll see in Chapters 14, 15, and 30 that molecular orbital theory is particularly useful for describing π bonds in compounds that have more than one double bond.

FIGURE 1.19 A molecular orbital description of the C–C π bond in ethylene. The lower-energy, **π bonding MO** results from an additive combination of p orbital lobes with the same algebraic sign and is filled. The higher-energy, **π antibonding MO** results from a subtractive combination of p orbital lobes with opposite algebraic signs and is unfilled.

1.12 Drawing Chemical Structures

Let's cover just one more point before ending this introductory chapter. In the structures we've been drawing until now, a line between atoms has represented the two electrons in a covalent bond. Drawing every bond and every atom is tedious, however, so chemists have devised several shorthand ways for writing structures. In **condensed structures**, carbon–hydrogen and carbon–carbon single bonds aren't shown; instead, they're understood. If a carbon has three hydrogens bonded to it, we write CH₃; if a carbon has two hydrogens bonded to it, we write CH₂; and so on. The compound called 2-methylbutane, for example, is written as follows:

2-Methylbutane

Note that the horizontal bonds between carbons aren't shown in condensed structures—the CH_3 , CH_2 , and CH units are simply placed next to each other—but vertical carbon-carbon bonds like that of the first of the condensed structures drawn above is shown for clarity. Notice also in the second of the condensed structures that the two CH_3 units attached to the CH carbon are grouped together as $(\text{CH}_3)_2$.

Even simpler than condensed structures are **skeletal structures** such as those shown in [TABLE 1.3](#). The rules for drawing skeletal structures are straightforward.

RULE 1

Carbon atoms aren't usually shown. Instead, a carbon atom is assumed to be at each intersection of two lines (bonds) and at the end of each line. Occasionally, a carbon atom might be indicated for emphasis or clarity.

RULE 2

Hydrogen atoms bonded to carbon aren't shown. Because carbon always has a valence of 4, we mentally supply the correct number of hydrogen atoms for each carbon.

RULE 3

Atoms other than carbon and hydrogen *are* shown.

One further comment: Although such groupings as $-\text{CH}_3$, $-\text{OH}$, and $-\text{NH}_2$ are usually written with the C, O, or N atom first and the H atom second, the order of writing is sometimes inverted to $\text{H}_3\text{C}-$, $\text{HO}-$, and $\text{H}_2\text{N}-$ if needed to make the bonding connections clearer. Larger units such as $-\text{CH}_2\text{CH}_3$ are not inverted, though; we don't write $\text{H}_3\text{CH}_2\text{C}-$ because it would be confusing. There are, however, no well-defined rules that cover all cases; it's largely a matter of preference.

TABLE 1.3 Line-bond and Skeletal Structures for Some Compounds

Compound	Line-bond structure	Skeletal structure
Isoprene, C_5H_8		
Methylcyclohexane, C_7H_{14}		
Phenol, $\text{C}_6\text{H}_6\text{O}$		

WORKED EXAMPLE 1.4

Interpreting a Line-Bond Structure

Carvone, a substance responsible for the odor of spearmint, has the following structure. Tell how many hydrogens are bonded to each carbon, and give the molecular formula of carvone.

Strategy

The end of a line represents a carbon atom with 3 hydrogens, CH₃; a two-way intersection is a carbon atom with 2 hydrogens, CH₂; a three-way intersection is a carbon atom with 1 hydrogen, CH; and a four-way intersection is a carbon atom with no attached hydrogens.

Solution

PROBLEM 1-15 How many hydrogens are bonded to each carbon in the following compounds, and what is the molecular formula of each substance?

Adrenaline

Estrone (a hormone)

PROBLEM 1-16 Propose skeletal structures for compounds that satisfy the following molecular formulas: There is more than one possibility in each case.

(a) C₅H₁₂ (b) C₂H₇N (c) C₃H₆O (d) C₄H₉Cl

PROBLEM 1-17 The following molecular model is a representation of *para*-aminobenzoic acid (PABA), the active ingredient in many sunscreens. Indicate the positions of the multiple bonds, and draw a skeletal structure (black = C, red = O, blue = N, gray = H).

CHEMISTRY MATTERS

Organic Foods: Risk versus Benefit

Contrary to what you may hear in supermarkets or on television, all foods are organic—that is, complex mixtures of organic molecules. Even so, when applied to food, the word *organic* has come to mean an absence of synthetic chemicals, typically pesticides, antibiotics, and preservatives. How concerned should we be about traces of pesticides in the food we eat? Or toxins in the water we drink? Or pollutants in the air we breathe?

Life is not risk-free—we all take many risks each day without even thinking about it. We decide to ride a bike rather than drive, even though there is a ten times greater likelihood per mile of dying in a bicycling accident than in a car. We decide to walk down stairs rather than take an elevator, even though 32,000 people die from falls each year in the United States. Some of us decide to smoke cigarettes, even though it increases our chance of getting cancer by 50%. But what about risks from chemicals like pesticides?

FIGURE 1.20 How dangerous is the pesticide being sprayed on this crop? (credit: “NRCSAR83001(265)” by USDA Natural Resources Conservation Service/Wikimedia Commons, Public Domain)

One thing is certain: without pesticides, whether they target weeds (herbicides), insects (insecticides), or molds and fungi (fungicides), crop production would drop significantly, food prices would increase, and famines would occur in less developed parts of the world. Take the herbicide atrazine, for instance. In the United States alone, approximately 100 million pounds of atrazine are used each year to kill weeds in corn, sorghum, and sugarcane fields, greatly improving the yields of these crops. Nevertheless, the use of atrazine continues to be a concern because traces persist in the environment. Indeed, heavy atrazine exposure *can* pose health risks to humans and some animals. Because of these risks, the United States Environmental Protection Agency (EPA) has decided not to ban its use because doing so would result in lower crop yields and increased food costs, and because there is no suitable alternative herbicide available.

Atrazine

How can the potential hazards from a chemical like atrazine be determined? Risk evaluation of chemicals is carried out by exposing test animals, usually mice or rats, to the chemical and then monitoring the animals for signs of harm. To limit the expense and time needed, the amounts administered are typically hundreds or thousands of times greater than those a person might normally encounter. The results obtained in animal tests are then distilled into a single number called an LD₅₀, the amount of substance per kilogram of body weight that

is a lethal dose for 50% of the test animals. For atrazine, the LD₅₀ value is between 1 and 4 g/kg depending on the animal species. Aspirin, for comparison, has an LD₅₀ of 1.1 g/kg, and ethanol (ethyl alcohol) has an LD₅₀ of 10.6 g/kg.

TABLE 1.4 lists the LD₅₀ for some other familiar substances. The lower the value, the more toxic the substance. Note, though, that LD₅₀ values only pertain to the effects of heavy exposure for a relatively short time. They say nothing about the risks of long-term exposure, such as whether the substance can cause cancer or interfere with development in the unborn.

TABLE 1.4 Some LD₅₀ Values

Substance	LD ₅₀ (g/kg)	Substance	LD ₅₀ (g/kg)
Strychnine	0.005	Chloroform	1.2
Arsenic trioxide	0.015	Iron(II) sulfate	1.5
DDT	0.115	Ethyl alcohol	10.6
Aspirin	1.1	Sodium cyclamate	17

So, should we still use atrazine? All decisions involve tradeoffs, and the answer is rarely obvious. Does the benefit of increased food production outweigh possible health risks of a pesticide? Do the beneficial effects of a new drug outweigh a potentially dangerous side effect in a small number of users? Different people will have different opinions, but an honest evaluation of facts is surely the best way to start. As of June 2022, atrazine was still approved for continued use in the United States because the EPA believes that the benefits of increased food production outweigh possible health risks. At the same time, atrazine is little used, though not banned, in the European Union.

Key Terms

- antibonding MO
- atomic number (*Z*)
- Aufbau principle
- bond angle
- bond length
- bond strength
- bonding MO
- condensed structure
- covalent bond
- electron shell

- molecular orbital (MO) theory
- molecule
- node
- nonbonding electron
- orbital
- organic chemistry
- Pauli exclusion principle
- pi (π) bond
- sigma (σ) bond
- skeletal structure
- *sp* hybrid orbital
- *sp*² hybrid orbital
- *sp*³ hybrid orbital
- valence bond (VB) theory
- valence shell

Summary

The purpose of this chapter has been to get you up to speed—to review some ideas about atoms, bonds, and molecular geometry. As we've seen, **organic chemistry** is the study of carbon compounds. Although a division into organic and inorganic chemistry occurred historically, there is no scientific reason for the division.

An atom consists of a positively charged nucleus surrounded by one or more negatively charged electrons. The electronic structure of an atom can be described by a quantum mechanical wave equation, in which electrons are considered to occupy **orbitals** around the nucleus. Different orbitals have different energy levels and different shapes. For example, *s* orbitals are spherical and *p* orbitals are dumbbell-shaped. The **ground-state electron configuration** of an atom can be found by assigning electrons to the proper orbitals, beginning with the lowest-energy ones.

A **covalent bond** is formed when an electron pair is shared between atoms. According to **valence bond (VB) theory**, electron sharing occurs by the overlap of two atomic orbitals. According to **molecular orbital (MO) theory**, bonds result from the mathematical combination of atomic orbitals to give molecular orbitals, which belong to the entire molecule. Bonds that have a circular cross-section and are formed by head-on interaction are called **sigma (σ) bonds**; bonds formed by sideways interaction of *p* orbitals are called **pi (π) bonds**.

In the valence bond description, carbon uses hybrid orbitals to form bonds in organic molecules. When forming only single bonds with tetrahedral geometry, carbon uses four equivalent **sp^3 hybrid orbitals**. When forming a double bond with planar geometry, carbon uses three equivalent **sp^2 hybrid orbitals** and one unhybridized *p* orbital. When forming a triple bond with linear geometry, carbon uses two equivalent **sp hybrid orbitals** and two unhybridized *p* orbitals. Other atoms such as nitrogen, phosphorus, oxygen, and sulfur also use hybrid orbitals to form strong, oriented bonds.

Organic molecules are usually drawn using either condensed structures or skeletal structures. In **condensed structures**, carbon-carbon and carbon-hydrogen bonds aren't shown. In **skeletal structures**, only the bonds and not the atoms are shown. A carbon atom is assumed to be at the ends and at the junctions of lines (bonds), and the correct number of hydrogens is supplied mentally.

WHY YOU SHOULD WORK PROBLEMS

There's no surer way to learn organic chemistry than by working problems. Although careful reading and rereading of this text are important, reading alone isn't enough. You must also be able to use the information you've read and be able to apply your knowledge in new situations. Working problems gives you practice at doing this.

Each chapter in this book provides many problems of different sorts. The in-chapter problems are placed for immediate reinforcement of ideas just learned, while end-of-chapter problems provide additional practice and come in several forms. They often begin with a short section called "Visualizing Chemistry," which helps you see the microscopic world of molecules and provides practice for working in three dimensions. After the visualizations are many further problems, which are organized by topic. Early problems are primarily of the drill type, providing an opportunity for you to practice your command of the fundamentals. Later problems tend to be more thought-provoking, and some are real challenges.

As you study organic chemistry, take the time to work the problems. Do the ones you can, and ask for help on the ones you can't. If you're stumped by a particular problem, check the accompanying *Study Guide* and *Student Solutions Manual* for an explanation that should help clarify the difficulty. Working problems takes effort, but the payoff in knowledge and understanding is immense.

Additional Problems

Visualizing Chemistry

PROBLEM Convert each of the following molecular models into a skeletal structure, and give the formula of **1-18** each. Only the connections between atoms are shown; multiple bonds are not indicated (black = C, red = O, blue = N, gray = H).

PROBLEM 1-19 The following model is a representation of citric acid, the key substance in the so-called citric acid cycle, by which food molecules are metabolized in the body. Only the connections between atoms are shown; multiple bonds are not indicated. Complete the structure by indicating the positions of multiple bonds and lone-pair electrons (black = C, red = O, gray = H).

PROBLEM 1-20 The following model is a representation of acetaminophen, a pain reliever sold in drugstores under a variety of names, including Tylenol. Identify the hybridization of each carbon atom in acetaminophen, and tell which atoms have lone pairs of electrons (black = C, red = O, blue = N, gray = H).

PROBLEM 1-21 The following model is a representation of aspartame, $C_{14}H_{18}N_2O_5$, known commercially under many names, including NutraSweet. Only the connections between atoms are shown; multiple bonds are not indicated. Complete the structure for aspartame, and indicate the positions of multiple bonds (black = C, red = O, blue = N, gray = H).

Electron Configurations

PROBLEM How many valence electrons does each of the following dietary trace elements have?

1-22 (a) Zinc **(b)** Iodine **(c)** Silicon **(d)** Iron

PROBLEM Give the ground-state electron configuration for each of the following elements:

1-23 (a) Potassium **(b)** Arsenic **(c)** Aluminum **(d)** Germanium

Electron-Dot and Line-Bond Structures

PROBLEM What are likely formulas for the following molecules?

1-24 (a) $\text{NH}_? \text{OH}$ **(b)** $\text{AlCl}_?$ **(c)** $\text{CF}_2 \text{Cl}_?$ **(d)** $\text{CH}_? \text{O}$

PROBLEM Why can't molecules with the following formulas exist?

1-25 (a) CH_5 **(b)** $\text{C}_2\text{H}_6\text{N}$ **(c)** $\text{C}_3\text{H}_5\text{Br}_2$

PROBLEM Draw an electron-dot structure for acetonitrile, $\text{C}_2\text{H}_3\text{N}$, which contains a carbon–nitrogen triple

1-26 bond. How many electrons does the nitrogen atom have in its outer shell? How many are bonding, and how many are nonbonding?

PROBLEM Draw a line-bond structure for vinyl chloride, $\text{C}_2\text{H}_3\text{Cl}$, the starting material from which PVC

1-27 poly(vinyl chloride) plastic is made.

PROBLEM Fill in any nonbonding valence electrons that are missing from the following structures:

1-28

Dimethyl disulfide

Acetamide

Acetate ion

PROBLEM Convert the following line-bond structures into molecular formulas:

1-29

Aspirin
(acetylsalicylic acid)

Vitamin C
(ascorbic acid)

Nicotine

Glucose

PROBLEM Convert the following molecular formulas into line-bond structures that are consistent with valence rules:

1-30 (a) C_3H_8 **(b)** CH_5N **(c)** $\text{C}_2\text{H}_6\text{O}$ (2 possibilities) **(d)** $\text{C}_3\text{H}_7\text{Br}$ (2 possibilities)
(e) $\text{C}_2\text{H}_4\text{O}$ (3 possibilities) **(f)** $\text{C}_3\text{H}_9\text{N}$ (4 possibilities)

PROBLEM Draw a three-dimensional representation of the oxygen-bearing carbon atom in ethanol,

1-31 $\text{CH}_3\text{CH}_2\text{OH}$, using the standard convention of solid, wedged, and dashed lines.

PROBLEM Oxaloacetic acid, an important intermediate in food metabolism, has the formula $C_4H_4O_5$ and contains three $C=O$ bonds and two $O-H$ bonds. Propose two possible structures.

1-32

PROBLEM Draw structures for the following molecules, showing lone pairs:

- 1-33** (a) Acrylonitrile, C_3H_3N , which contains a carbon-carbon double bond and a carbon-nitrogen triple bond
 (b) Ethyl methyl ether, C_3H_8O , which contains an oxygen atom bonded to two carbons
 (c) Butane, C_4H_{10} , which contains a chain of four carbon atoms
 (d) Cyclohexene, C_6H_{10} , which contains a ring of six carbon atoms and one carbon-carbon double bond

Hybridization

PROBLEM What is the hybridization of each carbon atom in acetonitrile (Problem 1-26)?

1-34

PROBLEM What kind of hybridization do you expect for each carbon atom in the following molecules?

1-35

- (a) Propane, $CH_3CH_2CH_3$ (b) 2-Methylpropene, $\begin{array}{c} CH_3 \\ | \\ CH_3C=CH_2 \end{array}$ (c) But-1-en-3-yne, $H_2C=CH-C\equiv CH$
 (d) Acetic acid, $\begin{array}{c} O \\ || \\ CH_3COH \end{array}$

PROBLEM What is the shape of benzene, and what hybridization do you expect for each carbon?

1-36

PROBLEM What bond angle do you expect for each of the indicated atoms, and what kind of hybridization do you expect for the central atom in each molecule?

1-37

PROBLEM Propose structures for molecules that meet the following descriptions:

- 1-38** (a) Contains two sp^2 -hybridized carbons and two sp^3 -hybridized carbons
 (b) Contains only four carbons, all of which are sp^2 -hybridized
 (c) Contains two sp -hybridized carbons and two sp^2 -hybridized carbons

PROBLEM What kind of hybridization do you expect for each carbon atom in the following molecules:

1-39

PROBLEM 1-40 Pyridoxal phosphate, a close relative of vitamin B₆, is involved in a large number of metabolic reactions. What is the hybridization and the bond angle for each nonterminal atom?

Skeletal Structures

PROBLEM 1-41 Convert the following structures into skeletal drawings:

1-41

PROBLEM 1-42 How many hydrogens are bonded to each carbon atom in the following substances, and what is the molecular formula of each?

PROBLEM 1-43 Quetiapine, marketed as Seroquel, is a heavily prescribed antipsychotic drug used in the treatment of schizophrenia and bipolar disorder. Convert the following representation into a skeletal structure, and give the molecular formula of quetiapine.

PROBLEM 1-44 How many hydrogens are bonded to each carbon atom in (a) the antiinfluenza agent oseltamivir, marketed as Tamiflu, and (b) the platelet aggregation inhibitor clopidogrel, marketed as Plavix? Give the molecular formula of each.

General Problems

PROBLEM 1-45 Why do you suppose no one has ever been able to make cyclopentyne as a stable molecule?

PROBLEM 1-46 Allene, $\text{H}_2\text{C}=\text{C}=\text{CH}_2$, has two adjacent double bonds. Draw a picture showing the orbitals involved in the σ and π bonds of allene. Is the central carbon atom sp^2 - or sp -hybridized? What about the hybridization of the terminal carbons? What shape do you predict for allene?

PROBLEM 1-47 Allene (see Problem 1-46) is structurally related to carbon dioxide, CO_2 . Draw a picture showing the orbitals involved in the σ and π bonds of CO_2 , and identify the likely hybridization of carbon.

PROBLEM 1-48 Complete the electron-dot structure of caffeine, showing all lone-pair electrons, and identify the hybridization of the indicated atoms.

PROBLEM 1-49 Most stable organic species have tetravalent carbon atoms, but species with trivalent carbon atoms also exist. Carbocations are one such class of compounds.

(a) How many valence electrons does the positively charged carbon atom have?

- (b) What hybridization do you expect this carbon atom to have?
 (c) What geometry is the carbocation likely to have?

PROBLEM A *carbanion* is a species that contains a negatively charged, trivalent carbon.

1-50

- (a) What is the electronic relationship between a carbanion and a trivalent nitrogen compound such as NH_3 ?
 (b) How many valence electrons does the negatively charged carbon atom have?
 (c) What hybridization do you expect this carbon atom to have?
 (d) What geometry is the carbanion likely to have?

PROBLEM Divalent carbon species called *carbenes* are capable of fleeting existence. For example, methylene,

1-51 $:\text{CH}_2$, is the simplest carbene. The two unshared electrons in methylene can be either paired in a single orbital or unpaired in different orbitals. Predict the type of hybridization you expect carbon to adopt in singlet (spin-paired) methylene and triplet (spin-unpaired) methylene. Draw a picture of each, and identify the valence orbitals on carbon.

PROBLEM Two different substances have the formula C_4H_{10} . Draw both, and tell how they differ.

1-52

PROBLEM Two different substances have the formula C_3H_6 . Draw both, and tell how they differ.

1-53

PROBLEM Two different substances have the formula $\text{C}_2\text{H}_6\text{O}$. Draw both, and tell how they differ.

1-54

PROBLEM Three different substances contain a carbon–carbon double bond and have the formula C_4H_8 . Draw them, and tell how they differ.

1-55

PROBLEM Among the most common over-the-counter drugs you might find in a medicine cabinet are mild pain relievers such ibuprofen (Advil, Motrin), naproxen (Aleve), and acetaminophen (Tylenol).

1-56

Ibuprofen

Naproxen

Acetaminophen

- (a) How many sp^3 -hybridized carbons does each molecule have?
 (b) How many sp^2 -hybridized carbons does each molecule have?
 (c) What similarities can you see in their structures?

CHAPTER 2

Polar Covalent Bonds; Acids and Bases

2.10 Organic Acids and Organic Bases

2.11 Acids and Bases: The Lewis Definition

2.12 Noncovalent Interactions between Molecules

WHY THIS CHAPTER? Understanding organic chemistry means knowing not just what happens but also why and how it happens at the molecular level. In this chapter, we’ll look at some of the ways that chemists describe and account for chemical reactivity, thereby providing a foundation to understand the specific reactions discussed in subsequent chapters. Topics such as bond polarity, the acid–base behavior of molecules, and hydrogen-bonding are a particularly important part of that foundation.

We saw in the previous chapter how covalent bonds between atoms are described, and we looked at the valence

electronegative elements are polarized so that carbon bears a partial negative charge and the other atom bears a partial positive charge. An example is the C–Li bond in methyllithium, CH_3Li (FIGURE 2.4b).

FIGURE 2.4 Polar covalent bonds. (a) Methanol, CH_3OH , has a polar covalent C–O bond, and (b) methyllithium, CH_3Li , has a polar covalent C–Li bond. The computer-generated representations, called electrostatic potential maps, use color to show calculated charge distributions, ranging from red (electron-rich; δ^-) to blue (electron-poor; δ^+).

Note in the representations of methanol and methyllithium in FIGURE 2.4 that a crossed arrow $\text{+} \rightarrow$ is used to indicate the direction of bond polarity. By convention, electrons are displaced in the direction of the arrow. The tail of the arrow (which looks like a plus sign) is electron-poor (δ^+), and the head of the arrow is electron-rich (δ^-).

Note also in FIGURE 2.4 that calculated charge distributions in molecules can be displayed visually with what are called **electrostatic potential maps**, which use color to indicate electron-rich (red; δ^-) and electron-poor (blue; δ^+) regions. In methanol, oxygen carries a partial negative charge and is colored red, while the carbon and hydrogen atoms carry partial positive charges and are colored blue-green. In methyllithium, lithium carries a partial positive charge (blue), while carbon and the hydrogen atoms carry partial negative charges (red). Electrostatic potential maps are useful because they show at a glance the electron-rich and electron-poor atoms in molecules. We'll make frequent use of these maps throughout the text and will see many examples of how electronic structure correlates with chemical reactivity.

When speaking of an atom's ability to polarize a bond, we often use the term *inductive effect*. An **inductive effect** is simply the shifting of electrons in a σ bond in response to the electronegativity of nearby atoms. Metals, such as lithium and magnesium, inductively donate electrons, whereas reactive nonmetals, such as oxygen and nitrogen, inductively withdraw electrons. Inductive effects play a major role in understanding chemical reactivity, and we'll use them many times throughout this text to explain a variety of chemical observations.

PROBLEM Which element in each of the following pairs is more electronegative?

2-1 (a) Li or H (b) B or Br (c) Cl or I (d) C or H

PROBLEM Use the δ^+/δ^- convention to indicate the direction of expected polarity for each of the bonds indicated.

2-2 (a) $\text{H}_3\text{C}-\text{Cl}$ (b) $\text{H}_3\text{C}-\text{NH}_2$ (c) $\text{H}_2\text{N}-\text{H}$ (d) $\text{H}_3\text{C}-\text{SH}$ (e) $\text{H}_3\text{C}-\text{MgBr}$ (f) $\text{H}_3\text{C}-\text{F}$

PROBLEM Use the electronegativity values shown in Figure 2.3 to rank the following bonds from least polar to most polar: $\text{H}_3\text{C}-\text{Li}$, $\text{H}_3\text{C}-\text{K}$, $\text{H}_3\text{C}-\text{F}$, $\text{H}_3\text{C}-\text{MgBr}$, $\text{H}_3\text{C}-\text{OH}$

2-3

PROBLEM Look at the following electrostatic potential map of methylamine, a substance responsible for the odor of rotting fish, and tell the direction of polarization of the C–N bond:

2-4

Methylamine

2.2 Polar Covalent Bonds and Dipole Moments

Just as individual bonds are often polar, molecules as a whole are often polar as well. Molecular polarity results from the vector summation of all individual bond polarities and lone-pair contributions in the molecule. As a practical matter, strongly polar substances are often soluble in polar solvents like water, whereas less polar substances are insoluble in water.

Net polarity is measured by a quantity called the *dipole moment* and can be thought of in the following way: assume that there is a center of mass of all positive charges (nuclei) in a molecule and a center of mass of all negative charges (electrons). If these two centers don't coincide, then the molecule has a net polarity.

The **dipole moment**, μ (lowercase Greek letter mu), is defined as the magnitude of the charge Q at either end of the molecular dipole times the distance r between the charges, $\mu = Q \times r$. Dipole moments are expressed in *debyes* (D), where $1 \text{ D} = 3.336 \times 10^{-30}$ coulomb meters ($\text{C} \cdot \text{m}$) in SI units. For example, the unit charge on an electron is $1.60 \times 10^{-19} \text{ C}$. Thus, if one positive charge and one negative charge are separated by 100 pm (a bit less than the length of a typical covalent bond), the dipole moment is $1.60 \times 10^{-29} \text{ C} \cdot \text{m}$, or 4.80 D.

$$\mu = Q \times r$$

$$\mu = (1.60 \times 10^{-19} \text{ C})(100 \times 10^{-12} \text{ m}) \left(\frac{1 \text{ D}}{3.336 \times 10^{-30} \text{ C} \cdot \text{m}} \right) = 4.80 \text{ D}$$

Dipole moments for some common substances are given in [TABLE 2.1](#). Of the compounds shown in the table, sodium chloride has the largest dipole moment (9.00 D) because it is ionic. Even small molecules like water ($\mu = 1.85 \text{ D}$), methanol (CH_3OH ; $\mu = 1.70 \text{ D}$), and ammonia ($\mu = 1.47 \text{ D}$), have substantial dipole moments, however, both because they contain strongly electronegative atoms (oxygen and nitrogen) and because all three molecules have lone-pair electrons. The lone-pair electrons on oxygen and nitrogen stick out into space away from the positively charged nuclei, giving rise to a considerable charge separation and making a large contribution to the dipole moment.

TABLE 2.1 Dipole Moments of Some Compounds

Compound	Dipole moment (D)	Compound	Dipole moment (D)
NaCl	9.00	NH ₃	1.47
CH ₂ O	2.33	CH ₃ NH ₂	1.31
CH ₃ Cl	1.87	CO ₂	0
H ₂ O	1.85	CH ₄	0
CH ₃ OH	1.70	CH ₃ CH ₃	0

TABLE 2.1 Dipole Moments of Some Compounds

Compound	Dipole moment (D)	Compound	Dipole moment (D)
CH ₃ CO ₂ H	1.70	 Benzene	0
CH ₃ SH	1.52		

Water
($\mu = 1.85$ D)

Methanol
($\mu = 1.70$ D)

Ammonia
($\mu = 1.47$ D)

In contrast with water, methanol, and ammonia, molecules such as carbon dioxide, methane, ethane, and benzene have zero dipole moments. Because of the symmetrical structures of these molecules, the individual bond polarities and lone-pair contributions exactly cancel.

WORKED EXAMPLE 2.1

Predicting the Direction of a Dipole Moment

Make a three-dimensional drawing of methylamine, CH₃NH₂, and show the direction of its dipole moment ($\mu = 1.31$).

Strategy

Look for any lone-pair electrons, and identify any atom with an electronegativity substantially different from that of carbon. (Usually, this means O, N, F, Cl, or Br.) Electron density will be displaced in the general direction of the electronegative atoms and the lone pairs.

Solution

Methylamine contains an electronegative nitrogen atom with a lone pair of electrons. The dipole moment thus points generally from $-CH_3$ toward the lone pair.

Methylamine
($\mu = 1.31$)

PROBLEM 2-5 Ethylene glycol, HOCH₂CH₂OH, may look nonpolar when drawn, but an internal hydrogen bond between the two –OH groups results in a dipole moment. Explain.

PROBLEM 2-6 Make three-dimensional drawings of the following molecules, and predict whether each has a dipole moment. If you expect a dipole moment, show its direction.

- (a) H₂C=CH₂ (b) CHCl₃ (c) CH₂Cl₂ (d) H₂C=CCl₂

2.3 Formal Charges

Closely related to the ideas of bond polarity and dipole moment is the assignment of *formal charges* to specific atoms within a molecule, particularly atoms that have an apparently “abnormal” number of bonds. Look at dimethyl sulfoxide (CH₃SOCH₃), for instance, a solvent commonly used for preserving biological cell lines at low temperature. The sulfur atom in dimethyl sulfoxide has three bonds rather than the usual two and has a formal positive charge. The oxygen atom, by contrast, has one bond rather than the usual two and has a formal negative charge. Note that an electrostatic potential map of dimethyl sulfoxide shows the oxygen as negative (red) and the sulfur as relatively positive (blue), in accordance with the formal charges.

Formal charges, as the name suggests, are a formalism and don't imply the presence of actual ionic charges in a molecule. Instead, they're a device for electron “bookkeeping” and can be thought of in the following way: A typical covalent bond is formed when each atom donates one electron. Although the bonding electrons are shared by both atoms, each atom can still be considered to “own” one electron for bookkeeping purposes. In methane, for instance, the carbon atom owns one electron in each of the four C–H bonds. Because a neutral, isolated carbon atom has four valence electrons, and because the carbon atom in methane still owns four, the methane carbon atom is neutral and has no formal charge.

The same is true for the nitrogen atom in ammonia, which has three covalent N–H bonds and two nonbonding electrons (a lone pair). Atomic nitrogen has five valence electrons, and the ammonia nitrogen also has five—one in each of three shared N–H bonds plus two in the lone pair. Thus, the nitrogen atom in ammonia has no formal charge.

The situation is different in dimethyl sulfoxide. Atomic sulfur has six valence electrons, but the dimethyl sulfoxide sulfur owns only five—one in each of the two S–C single bonds, one in the S–O single bond, and two in a lone pair. Thus, the sulfur atom has formally lost an electron and therefore has a positive formal charge. A similar calculation for the oxygen atom shows that it has formally gained an electron and has a negative charge. Atomic oxygen has six valence electrons, but the oxygen in dimethyl sulfoxide has seven—one in the O–S bond and two in each of three lone pairs. Thus, the oxygen has formally gained an electron and has a negative formal charge.

**For sulfur:**

$$\begin{aligned} \text{Sulfur valence electrons} &= 6 \\ \text{Sulfur bonding electrons} &= 6 \\ \text{Sulfur nonbonding electrons} &= 2 \\ \text{Formal charge} &= 6 - 6/2 - 2 = +1 \end{aligned}$$

For oxygen:

$$\begin{aligned} \text{Oxygen valence electrons} &= 6 \\ \text{Oxygen bonding electrons} &= 2 \\ \text{Oxygen nonbonding electrons} &= 6 \\ \text{Formal charge} &= 6 - 2/2 - 6 = -1 \end{aligned}$$

To express the calculations in a general way, the **formal charge** on an atom is equal to the number of valence electrons in a neutral, isolated atom minus the number of electrons owned by that bonded atom in a molecule. The number of electrons in the bonded atom, in turn, is equal to half the number of bonding electrons plus the nonbonding, lone-pair electrons.

$$\begin{aligned} \text{Formal charge} &= \left(\begin{array}{c} \text{Number of} \\ \text{valence electrons} \\ \text{in free atom} \end{array} \right) - \left(\begin{array}{c} \text{Number of} \\ \text{valence electrons} \\ \text{in bonded atom} \end{array} \right) \\ &= \left(\begin{array}{c} \text{Number of} \\ \text{valence electrons} \\ \text{in free atom} \end{array} \right) - \left(\frac{\text{Number of} \\ \text{bonding electrons}}{2} + \begin{array}{c} \text{Number of} \\ \text{nonbonding} \\ \text{electrons} \end{array} \right) \end{aligned}$$

A summary of commonly encountered formal charges and the bonding situations in which they occur is given in **TABLE 2.2**. Although only a bookkeeping device, formal charges often give clues about chemical reactivity, so it's helpful to be able to identify and calculate them correctly.

TABLE 2.2 A Summary of Common Formal Charges

Atom	C			N		O		S		P
Structure										
Valence electrons	4	4	4	5	5	6	6	6	6	5
Number of bonds	3	3	3	4	2	3	1	3	1	4
Number of nonbonding electrons	1	0	2	0	4	2	6	2	6	0
Formal charge	0	+1	-1	+1	-1	+1	-1	+1	-1	+1

PROBLEM Calculate formal charges for the nonhydrogen atoms in the following molecules:

PROBLEM Organic phosphate groups occur commonly in biological molecules. Calculate formal charges on

2-8

the four O atoms in the methyl phosphate dianion.

2.4 Resonance

Most substances can be represented unambiguously by the Kekulé line-bond structures we've been using up to this point, but an interesting problem sometimes arises. Look at the acetate ion, for instance. When we draw a line-bond structure for acetate, we need to show a double bond to one oxygen and a single bond to the other. But which oxygen is which? Should we draw a double bond to the “top” oxygen and a single bond to the “bottom” oxygen, or vice versa?

Although the two oxygen atoms in the acetate ion appear different in line-bond structures, experiments show that they are equivalent. Both carbon–oxygen bonds, for instance, are 127 pm in length, midway between the length of a typical C–O single bond (135 pm) and a typical C=O double bond (120 pm). In other words, neither of the two structures for acetate is correct by itself. The true structure is intermediate between the two, and an electrostatic potential map shows that both oxygen atoms share the negative charge and have equal electron densities (red).

The two individual line-bond structures for acetate ion are called **resonance forms**, and their special resonance relationship is indicated by the double-headed arrow between them. The only difference between the two resonance forms is the placement of the π and nonbonding valence electrons. The atoms themselves occupy exactly the same place in both resonance forms, the connections between atoms are the same, and the three-dimensional shapes of the resonance forms are the same.

A good way to think about resonance forms is to realize that a substance like the acetate ion is the same as any other. Acetate doesn't jump back and forth between two resonance forms, spending part of the time looking like one and part of the time looking like the other. Rather, acetate has a single unchanging structure that we say is a **resonance hybrid** of the two individual forms and has characteristics of both. The only “problem” with acetate is that we can't draw it accurately using a familiar line-bond structure—line-bond structures just don't work for resonance hybrids. The difficulty, however, is with the *representation* of acetate on paper, not with acetate itself.

Resonance is a very useful concept that we'll return to on numerous occasions throughout the rest of this book. We'll see in Chapter 15, for instance, that the six carbon–carbon bonds in aromatic compounds, such as benzene, are equivalent and that benzene is best represented as a hybrid of two resonance forms. Although each individual resonance form seems to imply that benzene has alternating single and double bonds, neither form is correct by itself. The true benzene structure is a hybrid of the two individual forms, and all six carbon–carbon bonds are equivalent. This symmetrical distribution of electrons around the molecule is evident in an

electrostatic potential map.

2.5 Rules for Resonance Forms

When first dealing with resonance forms, it's useful to have a set of guidelines that describe how to draw and interpret them. The following rules should be helpful:

RULE 1

Individual resonance forms are imaginary, not real. The real structure is a composite, or resonance hybrid, of the different forms. Species such as the acetate ion and benzene are no different from any other. They have single, unchanging structures, and they don't switch back and forth between resonance forms. The only difference between these and other substances is in the way they are represented in drawings.

RULE 2

Resonance forms differ only in the placement of their π or nonbonding electrons. Neither the position nor the hybridization of any atom changes from one resonance form to another. In the acetate ion, for instance, the carbon atom is sp^2 -hybridized and the oxygen atoms remain in exactly the same place in both resonance forms. Only the positions of the π electrons in the C=O bond and the lone-pair electrons on oxygen differ from one form to another. This movement of electrons from one resonance structure to another can be indicated with curved arrows. *A curved arrow always indicates the movement of electrons, not the movement of atoms.* An arrow shows that a pair of electrons moves *from* the atom or bond at the tail of the arrow *to* the atom or bond at the head of the arrow.

The red curved arrow indicates that a lone pair of electrons moves from the top oxygen atom to become part of a C=O bond.

The new resonance form has a double bond here...

Simultaneously, two electrons from the C=O bond move onto the bottom oxygen atom to become a lone pair.

and has a lone pair of electrons here.

The situation with benzene is similar to that with acetate. The π electrons in the double bonds move, as shown with curved arrows, but the carbon and hydrogen atoms remain in place.

RULE 3

Different resonance forms of a substance don't have to be equivalent. As an example, we'll see in Chapter 22 that a compound such as acetone, which contains a C=O bond, can be converted into its anion by reaction with a strong base. The resultant anion has two resonance forms. One form contains a carbon-oxygen double bond and has a negative charge on *carbon*; the other contains a carbon-carbon double bond and has a negative charge on *oxygen*. Even though the two resonance forms aren't equivalent, both contribute to the overall

resonance hybrid.

When two resonance forms are nonequivalent, the actual structure of the resonance hybrid resembles the more stable form. Thus, we might expect the true structure of the acetone anion to be more like that of the form that places the negative charge on the electronegative oxygen atom rather than on the carbon.

RULE 4

Resonance forms obey normal rules of valency. A resonance form is like any other structure: the octet rule still applies to second-row, main-group atoms. For example, one of the following structures for the acetate ion is not a valid resonance form because the carbon atom has five bonds and ten valence electrons:

RULE 5

The resonance hybrid is more stable than any individual resonance form. In other words, resonance leads to stability. Generally speaking, the larger the number of resonance forms a substance has, the more stable the substance is, because its electrons are spread out over a larger part of the molecule and are closer to more nuclei. We'll see in Chapter 15, for instance, that a benzene ring is more stable because of resonance than might otherwise be expected.

2.6 Drawing Resonance Forms

Look back at the resonance forms of the acetate ion and the acetone anion shown in the previous section. The pattern seen there is a common one that leads to a useful technique for drawing resonance forms. In general, any three-atom grouping with a *p* orbital on each atom has two resonance forms:

The atoms X, Y, and Z in the general structure might be C, N, O, P, S, or others, and the asterisk (*) might mean that the *p* orbital on atom Z is vacant, that it contains a single electron, or that it contains a lone pair of electrons. The two resonance forms differ simply by an exchange in position of the multiple bond and the asterisk from one end of the three-atom grouping to the other.

By learning to recognize such three-atom groupings within larger structures, resonance forms can be systematically generated. Look, for instance, at the anion produced when H^+ is removed from 2,4-pentanedione by reaction with a base. How many resonance structures does the resultant anion have?

2,4-Pentanedione

The 2,4-pentanedione anion has a lone pair of electrons and a formal negative charge on the central carbon atom, next to a C=O bond on the left. The O=C-C:⁻ grouping is a typical one for which two resonance structures can be drawn.

Just as there is a C=O bond to the left of the lone pair, there is a second C=O bond to the right. Thus, we can draw a total of three resonance structures for the 2,4-pentanedione anion.

WORKED EXAMPLE 2.2

Drawing Resonance Forms for an Anion

Draw three resonance structures for the carbonate ion, CO₃²⁻.

Strategy

Look for three-atom groupings that contain a multiple bond next to an atom with a *p* orbital. Then exchange the positions of the multiple bond and the electrons in the *p* orbital. In the carbonate ion, each singly bonded oxygen atom with three lone pairs and a negative charge is adjacent to the C=O double bond, giving the grouping $\ddot{\text{O}}=\text{C}-\ddot{\text{O}}:^-$.

Solution

Exchanging the position of the double bond and an electron lone pair in each grouping generates three resonance structures.

WORKED EXAMPLE 2.3

Drawing Resonance Forms for a Radical

Draw three resonance forms for the pentadienyl radical, where a **radical** is a substance that contains a single, unpaired electron in one of its orbitals, denoted by a dot (•).

**Strategy**

Find the three-atom groupings that contain a multiple bond next to an atom with a p orbital.

Solution

The unpaired electron is on a carbon atom next to a $C=C$ bond, giving a typical three-atom grouping that has two resonance forms.

In the second resonance form, the unpaired electron is next to another double bond, giving another three-atom grouping and leading to another resonance form.

Thus, the three resonance forms for the pentadienyl radical are:

PROBLEM Which of the following pairs of structures represent resonance forms, and which do not? Explain.

2-9

PROBLEM Draw the indicated number of resonance forms for each of the following substances:

2-10 (a) The methyl phosphate anion, $\text{CH}_3\text{OPO}_3^{2-}$ (3)(b) The nitrate anion, NO_3^- (3)(c) The allyl cation, $\text{H}_2\text{C}=\text{CH}-\text{CH}_2^+$ (2)

(d) The benzoate anion (2)

2.7 Acids and Bases: The Brønsted–Lowry Definition

Perhaps the most important of all concepts related to electronegativity and polarity is that of *acidity* and

basicity. We'll soon see, in fact, that the acid–base behavior of organic molecules explains much of their chemistry. You may recall from a course in general chemistry that two definitions of acidity are frequently used: the *Brønsted–Lowry definition* and the *Lewis definition*. We'll look at the Brønsted–Lowry definition in this and the following three sections and then discuss the Lewis definition in **Section 2.11**.

A **Brønsted–Lowry acid** is a substance that donates a hydrogen ion, H^+ , and a **Brønsted–Lowry base** is a substance that accepts a hydrogen ion. (The name *proton* is often used as a synonym for H^+ because loss of the valence electron from a neutral hydrogen atom leaves only the hydrogen nucleus—a proton.) When gaseous hydrogen chloride dissolves in water, for example, a polar HCl molecule acts as an acid and donates a proton, while a water molecule acts as a base and accepts the proton, yielding chloride anion (Cl^-) and hydronium cation (H_3O^+). This and other acid–base reactions are reversible, so we'll write them with double, forward-and-backward arrows.

Chloride ion, the product that results when the acid HCl loses a proton, is called the **conjugate base** of the acid, and hydronium ion, the product that results when the base H_2O gains a proton, is called the **conjugate acid** of the base. Other common mineral acids such as H_2SO_4 and HNO_3 behave similarly, as do organic acids such as acetic acid, $\text{CH}_3\text{CO}_2\text{H}$.

In a general sense,

For example:

Notice that water can act either as an acid or as a base, depending on the circumstances. In its reaction with HCl , water is a base that accepts a proton to give the hydronium ion, H_3O^+ . In its reaction with ammonia (NH_3), however, water is an acid that donates a proton to give ammonium ion (NH_4^+) and hydroxide ion, HO^- .

PROBLEM 2-11 Nitric acid (HNO_3) reacts with ammonia (NH_3) to yield ammonium nitrate. Write the reaction, and identify the acid, the base, the conjugate acid product, and the conjugate base product.

2.8 Acid and Base Strength

Different acids differ in their ability to donate H^+ . Stronger acids, such as HCl, react almost completely with water, whereas weaker acids, such as acetic acid (CH_3CO_2H), react only slightly. The exact strength of a given acid HA in water solution is described using the **acidity constant (K_a)** for the acid-dissociation equilibrium. Recall from general chemistry that the concentration of solvent is ignored in the equilibrium expression and that brackets [] around a substance refer to the concentration of the enclosed species in moles per liter.

Stronger acids have their equilibria toward the right and thus have larger acidity constants, whereas weaker acids have their equilibria toward the left and have smaller acidity constants. The range of K_a values for different acids is enormous, running from about 10^{15} for the strongest acids to about 10^{-60} for the weakest. Common inorganic acids such as H_2SO_4 , HNO_3 , and HCl have K_a 's in the range of 10^2 to 10^9 , while organic acids generally have K_a 's in the range of 10^{-5} to 10^{-15} . As you gain experience, you'll develop a rough feeling for which acids are "strong" and which are "weak" (always remembering that the terms are relative, not absolute).

Acid strengths are normally expressed using pK_a values rather than K_a values, where the **pK_a** is the negative common logarithm of the K_a :

$$pK_a = -\log K_a$$

A stronger acid (larger K_a) has a smaller pK_a , and a weaker acid (smaller K_a) has a larger pK_a . **TABLE 2.3** lists the pK_a 's of some common acids in order of their strength, and a more comprehensive table is given in **Appendix B**.

Notice that the pK_a value shown in **TABLE 2.3** for water is 15.74, which results from the following calculation. Because water is both the acid and the solvent, the equilibrium expression is

$$\begin{array}{c}
 H_2O + H_2O \rightleftharpoons OH^- + H_3O^+ \\
 \text{(acid) (solvent)}
 \end{array}$$

$$K_a = \frac{[H_3O^+][A^-]}{[HA]} = \frac{[H_3O^+][OH^-]}{[H_2O]} = \frac{[1.0 \times 10^{-7}][1.0 \times 10^{-7}]}{[55.4]} = 1.8 \times 10^{-16}$$

$$pK_a = 15.74$$

The numerator in this expression is the so-called ion-product constant for water, $K_w = [H_3O^+][OH^-] = 1.00 \times 10^{-14}$, and the denominator is the molar concentration of pure water, $[H_2O] = 55.4$ M at 25 °C. The calculation is artificial in that the concentration of "solvent" water is ignored while the concentration of "acid" water is not, but it is nevertheless useful for making a comparison of water with other weak acids on a similar footing.

Notice also in **TABLE 2.3** that there is an inverse relationship between the acid strength of an acid and the base strength of its conjugate base. A strong acid has a weak conjugate base, and a weak acid has a strong conjugate base. To understand this inverse relationship, think about what is happening to the acidic hydrogen in an acid–base reaction. A strong acid is one that loses H^+ easily, meaning that its conjugate base holds the H^+ weakly and is therefore a weak base. A weak acid is one that loses H^+ with difficulty, meaning that its conjugate base holds the proton tightly and is therefore a strong base. The fact that HCl is a strong acid, for example, means that Cl^- does not hold H^+ tightly and is thus a weak base. Water, on the other hand, is a weak acid, meaning that OH^- holds H^+ tightly and is a strong base.

TABLE 2.3 Relative Strengths of Some Common Acids and Their Conjugate Bases

	Acid	Name	pK_a	Conjugate base	Name	
	$\text{CH}_3\text{CH}_2\text{OH}$	Ethanol	16.00	$\text{CH}_3\text{CH}_2\text{O}^-$	Ethoxide ion	
	H_2O	Water	15.74	HO^-	Hydroxide ion	
	HCN	Hydrocyanic acid	9.31	CN^-	Cyanide ion	
	H_2PO_4^-	Dihydrogen phosphate ion	7.21	HPO_4^{2-}	Hydrogen phosphate ion	
	$\text{CH}_3\text{CO}_2\text{H}$	Acetic acid	4.76	CH_3CO_2^-	Acetate ion	
	H_3PO_4	Phosphoric acid	2.16	H_2PO_4^-	Dihydrogen phosphate ion	
	HNO_3	Nitric acid	-1.3	NO_3^-	Nitrate ion	
	HCl	Hydrochloric acid	-7.0	Cl^-	Chloride ion	

PROBLEM 2-12 The amino acid phenylalanine has $pK_a = 1.83$, and tryptophan has $pK_a = 2.83$. Which is the stronger acid?

PROBLEM 2-13 Amide ion, H_2N^- , is a much stronger base than hydroxide ion, HO^- . Which is the stronger acid, NH_3 or H_2O ? Explain.

2.9 Predicting Acid–Base Reactions from pK_a Values

Compilations of pK_a values like those in TABLE 2.3 and Appendix B are useful for predicting whether a given acid–base reaction will take place, because H^+ will always go *from* the stronger acid *to* the stronger base. That is, an acid will donate a proton to the conjugate base of a weaker acid, and the conjugate base of a weaker acid will remove a proton from a stronger acid. Since water ($pK_a = 15.74$) is a weaker acid than acetic acid ($pK_a = 4.76$), for example, hydroxide ion holds a proton more tightly than acetate ion does. Hydroxide ion will therefore react to a large extent with acetic acid, $\text{CH}_3\text{CO}_2\text{H}$, to yield acetate ion and H_2O .

Another way to predict acid–base reactivity is to remember that the product conjugate acid in an acid–base reaction must be weaker and less reactive than the starting acid and the product conjugate base must be weaker and less reactive than the starting base. In the reaction of acetic acid with hydroxide ion, for example, the product conjugate acid (H_2O) is weaker than the starting acid ($\text{CH}_3\text{CO}_2\text{H}$), and the product conjugate base (CH_3CO_2^-) is weaker than the starting base (OH^-).

WORKED EXAMPLE 2.4

Predicting Acid Strengths from pK_a Values

Water has $pK_a = 15.74$, and acetylene has $pK_a = 25$. Which is the stronger acid? Does hydroxide ion react to a significant extent with acetylene?

Strategy

In comparing two acids, the one with the lower pK_a is stronger. Thus, water is a stronger acid than acetylene and gives up H^+ more easily.

Solution

Because water is a stronger acid and gives up H^+ more easily than acetylene, the HO^- ion must have less affinity for H^+ than the $\text{HC}\equiv\text{C}^-$ ion. In other words, the anion of acetylene is a stronger base than hydroxide ion, and the reaction will not proceed significantly as written.

WORKED EXAMPLE 2.5

Calculating K_a from pK_a

According to the data in TABLE 2.3, acetic acid has $pK_a = 4.76$. What is its K_a ?

Strategy

Since pK_a is the negative logarithm of K_a , it's necessary to use a calculator with an ANTILOG or INV LOG function. Enter the value of the pK_a (4.76), change the sign (-4.76), and then find the antilog (1.74×10^{-5}).

Solution

$$K_a = 1.74 \times 10^{-5}$$

PROBLEM 2-14 Will either of the following reactions take place to a significant extent as written, according to the data in Table 2.3?

PROBLEM 2-15 Ammonia, NH_3 , has $\text{p}K_a \approx 36$, and acetone has $\text{p}K_a \approx 19$. Will the following reaction take place to a significant extent?

PROBLEM 2-16 What is the K_a of HCN if its $\text{p}K_a = 9.31$?

2.10 Organic Acids and Organic Bases

Many of the reactions we'll be seeing in future chapters, including practically all biological reactions, involve organic acids and organic bases. Although it's too early to go into the details of these processes now, you might keep the following generalities in mind:

Organic Acids

Organic acids are characterized by the presence of a positively polarized hydrogen atom (blue in electrostatic potential maps) and are of two main kinds: acids such as methanol and acetic acid that contain a hydrogen atom bonded to an electronegative oxygen atom (O–H) and those such as acetone (Section 2.5) that contain a hydrogen atom bonded to a carbon atom next to a C=O bond (O=C–C–H).

Methanol contains an O–H bond and is a weak acid, while acetic acid also contains an O–H bond and is a somewhat stronger acid. In both cases, acidity is due to the fact that the conjugate base resulting from loss of H^+ is stabilized by having its negative charge on a strongly electronegative oxygen atom. In addition, the conjugate base of acetic acid is stabilized by resonance (Section 2.4 and Section 2.5).

The acidity of acetone and other compounds with C=O bonds is due to the fact that the conjugate base resulting from loss of H⁺ is stabilized by resonance. In addition, one of the resonance forms stabilizes the negative charge by placing it on an electronegative oxygen atom.

Electrostatic potential maps of the conjugate bases from methanol, acetic acid, and acetone are shown in **FIGURE 2.5**. As you might expect, all three show a substantial amount of negative charge (red) on oxygen.

FIGURE 2.5 Electrostatic potential maps of the conjugate bases of (a) methanol, (b) acetic acid, and (c) acetone. The electronegative oxygen atoms stabilize the negative charge in all three.

Compounds called *carboxylic acids*, which contain the -CO₂H grouping, occur abundantly in all living organisms and are involved in almost all metabolic pathways. Acetic acid, pyruvic acid, and citric acid are examples. You might note that at the typical pH of 7.3 found within cells, carboxylic acids are usually dissociated and exist as their carboxylate anions, -CO₂⁻.

Organic Bases

Organic bases are characterized by the presence of an atom (reddish in electrostatic potential maps) with a lone pair of electrons that can bond to H⁺. Nitrogen-containing compounds such as methylamine are the most common organic bases and are involved in almost all metabolic pathways, but oxygen-containing compounds can also act as bases when reacting with a sufficiently strong acid. Note that some oxygen-containing compounds can act both as acids and as bases depending on the circumstances, just as water can. Methanol and acetone, for instance, act as acids when they donate a proton but as bases when their oxygen atom accepts a proton.

We'll see in Chapter 26 that substances called amino acids, so-named because they are both amines ($-\text{NH}_2$) and carboxylic acids ($-\text{CO}_2\text{H}$), are the building blocks from which the proteins in all living organisms are made. Twenty different amino acids go into making up proteins—alanine is an example. Interestingly, alanine and other amino acids exist primarily in a doubly charged form called a *zwitterion* rather than in the uncharged form. The zwitterion form arises because amino acids have both acidic and basic sites within the same molecule and therefore undergo an internal acid–base reaction.

2.11 Acids and Bases: The Lewis Definition

The Lewis definition of acids and bases is more encompassing than the Brønsted–Lowry definition because it's not limited to substances that donate or accept just protons. A **Lewis acid** is a substance that accepts an electron pair, and a **Lewis base** is a substance that donates an electron pair. The donated electron pair is shared between the acid and the base in a covalent bond.

Lewis Acids and the Curved Arrow Formalism

The fact that a Lewis acid is able to accept an electron pair means that it must have either a vacant, low-energy orbital or a polar bond to hydrogen so that it can donate H^+ (which has an empty $1s$ orbital). Thus, the Lewis definition of acidity includes many species in addition to H^+ . For example, various metal cations, such as Mg^{2+} , are Lewis acids because they accept a pair of electrons when they form a bond to a base. We'll also see in later chapters that certain metabolic reactions begin with an acid–base reaction between Mg^{2+} as a Lewis acid and an organic diphosphate or triphosphate ion as the Lewis base.

In the same way, compounds of group 3A elements, such as BF_3 and AlCl_3 , are Lewis acids because they have

unfilled valence orbitals and can accept electron pairs from Lewis bases, as shown in **FIGURE 2.6**. Similarly, many transition-metal compounds, such as TiCl_4 , FeCl_3 , ZnCl_2 , and SnCl_4 , are Lewis acids.

FIGURE 2.6 The reaction of boron trifluoride, a Lewis acid, with dimethyl ether, a Lewis base. The Lewis acid accepts a pair of electrons, and the Lewis base donates a pair of nonbonding electrons. Note how the movement of electrons from the Lewis base to the Lewis acid is indicated by a curved arrow. Note also how, in electrostatic potential maps, **the boron becomes more negative (red)** after reaction because it has gained electrons and **the oxygen atom becomes more positive (blue)** because it has donated electrons.

Look closely at the acid–base reaction in **FIGURE 2.6**, and notice how it's shown. Dimethyl ether, the Lewis base, donates an electron pair to a vacant valence orbital of the boron atom in BF_3 , a Lewis acid. The direction of electron-pair flow from base to acid is shown using a curved arrow, just as the direction of electron flow from one resonance structure to another was shown using curved arrows in **Section 2.5**. We'll use this curved-arrow notation throughout the remainder of this text to indicate electron flow during reactions, so get used to seeing it.

Some further examples of Lewis acids follow:

Lewis Bases

The Lewis definition of a base—a compound with a pair of nonbonding electrons that it can use to bond to a Lewis acid—is similar to the Brønsted–Lowry definition. Thus, H_2O , with its two pairs of nonbonding electrons

on oxygen, acts as a Lewis base by donating an electron pair to an H^+ in forming the hydronium ion, H_3O^+ .

In a more general sense, most oxygen- and nitrogen-containing organic compounds can act as Lewis bases because they have lone pairs of electrons. A divalent oxygen compound has two lone pairs of electrons, and a trivalent nitrogen compound has one lone pair. Note in the following examples that some compounds can act as both acids and bases, just as water can. Alcohols and carboxylic acids, for instance, act as acids when they donate an H^+ but as bases when their oxygen atom accepts an H^+ .

Note also that some Lewis bases, such as carboxylic acids, esters, and amides, have more than one atom with a lone pair of electrons and can therefore react at more than one site. Acetic acid, for example, can be protonated either on the doubly bonded oxygen atom or on the singly bonded oxygen atom. Reaction normally occurs only once in such instances, and the more stable of the two possible protonation products is formed. For acetic acid, protonation by reaction with sulfuric acid occurs on the doubly bonded oxygen because that product is stabilized by two resonance forms.

WORKED EXAMPLE 2.6

Using Curved Arrows to Show Electron Flow

Using curved arrows, show how acetaldehyde, CH_3CHO , can act as a Lewis base.

Strategy

A Lewis base donates an electron pair to a Lewis acid. We therefore need to locate the electron lone pairs on acetaldehyde and use a curved arrow to show the movement of a pair toward the H atom of the acid.

Solution

PROBLEM 2-17 Using curved arrows, show how the species in part (a) can act as Lewis bases in their reactions with HCl, and show how the species in part (b) can act as Lewis acids in their reaction with OH⁻.

PROBLEM 2-18 Imidazole, which forms part of amino acid histidine, can act as both an acid and a base.

- (a) Look at the electrostatic potential map of imidazole, and identify the most acidic hydrogen atom and the most basic nitrogen atom.
- (b) Draw structures for the resonance forms of the products that result when imidazole is protonated by an acid and deprotonated by a base.

2.12 Noncovalent Interactions between Molecules

When thinking about chemical reactivity, chemists usually focus their attention on bonds, the covalent interactions between atoms within molecules. Also important, however, particularly in large biomolecules like proteins and nucleic acids, are a variety of interactions *between* molecules that strongly affect molecular properties. Collectively called either **intermolecular forces**, **van der Waals forces**, or **noncovalent interactions**, they are of several different types: dipole–dipole forces, dispersion forces, and hydrogen bonds.

Dipole–dipole forces occur between polar molecules as a result of electrostatic interactions among dipoles. The forces can be either attractive or repulsive depending on the orientation of the molecules—attractive when unlike charges are together and repulsive when like charges are together. The attractive geometry is lower in energy and therefore predominates (**FIGURE 2.7**).

FIGURE 2.7 Dipole–dipole forces cause polar molecules (a) to attract one another when they orient with unlike charges together, but (b) to repel one another when they orient with like charges together.

Dispersion forces occur between all neighboring molecules and arise because the electron distribution within molecules is constantly changing. Although uniform on a time-averaged basis, the electron distribution even in nonpolar molecules is likely to be nonuniform at any given instant. One side of a molecule may, by chance, have a slight excess of electrons relative to the opposite side, giving the molecule a temporary dipole. This temporary dipole in one molecule causes a nearby molecule to adopt a temporarily opposite dipole, resulting in a tiny attraction between the two (**FIGURE 2.8**). Temporary molecular dipoles have only a fleeting existence and are constantly changing, but their cumulative effect is often strong enough to hold molecules close together so that a substance is a liquid or solid rather than a gas.

FIGURE 2.8 Attractive dispersion forces in nonpolar molecules are caused by temporary dipoles, as shown in these models of pentane, C_5H_{12} .

Perhaps the most important noncovalent interaction in biological molecules is the **hydrogen bond**, an attractive interaction between a hydrogen atom bonded to an electronegative O or N atom and an unshared electron pair on another O or N atom. In essence, a hydrogen bond is a very strong dipole–dipole interaction involving polarized O–H or N–H bonds. Electrostatic potential maps of water and ammonia clearly show the positively polarized hydrogens (blue) and the negatively polarized oxygens and nitrogens (red).

Hydrogen bonding has enormous consequences for living organisms. Hydrogen bonds cause water to be a liquid rather than a gas at ordinary temperatures, they hold enzymes in the shapes necessary for catalyzing biological reactions, and they cause strands of deoxyribonucleic acid (DNA) to pair up and coil into the double helix that stores genetic information.

A deoxyribonucleic acid segment

One further point before leaving the subject of noncovalent interactions: biochemists frequently use the term **hydrophilic**, meaning “water-loving,” to describe a substance that is attracted to water and the term **hydrophobic**, meaning “water-fearing,” to describe a substance that is not strongly attracted to water.

Hydrophilic substances, such as table sugar, often have a number of $-OH$ groups in their structure so they can form hydrogen bonds and dissolve in water, whereas hydrophobic substances, such as vegetable oil, do not have groups that form hydrogen bonds and do not dissolve in water.

Sucrose
(a disaccharide)

Animal fat—a triester
(R, R', R'' = C_{11} – C_{19} chains)

PROBLEM 2-19 Of the two vitamins A and C, one is hydrophilic and water-soluble while the other is hydrophobic and fat-soluble. Which is which?

Vitamin A
(retinol)

Vitamin C
(ascorbic acid)

CHEMISTRY MATTERS

Alkaloids: From Cocaine to Dental Anesthetics

Just as ammonia (NH_3) is a weak base, there are a large number of nitrogen-containing organic compounds called amines that are also weak bases. In the early days of organic chemistry, basic amines derived from natural sources were known as vegetable alkali, but they are now called **alkaloids**. More than 20,000 alkaloids are known. Their study provided much of the impetus for the growth of organic chemistry in the nineteenth century and remains today an active and fascinating area of research.

FIGURE 2.9 The coca bush *Erythroxylon coca*, native to upland rain forest areas of Colombia, Ecuador, Peru, Bolivia, and western Brazil, is the source of the alkaloid cocaine. (credit: "Erythroxylum coca" by Danna Guevara/Wikimedia Commons, CC BY 4.0)

Many alkaloids have pronounced biological properties, and approximately 50% of pharmaceutical agents used today are derived from naturally occurring amines. As just three examples, morphine, an analgesic agent (painkiller), is obtained from the opium poppy *Papaver somniferum*. Ephedrine, a bronchodilator, decongestant, and appetite suppressant, is obtained from *Ephedra sinica*, an evergreen shrub native to Mongolia and northeastern China. Cocaine, both an anesthetic and a stimulant, is obtained from the coca bush *Erythroxylon coca*, endemic to the upland rain forest areas of central South America. (And yes, there really was a small amount of cocaine in the original Coca-Cola recipe, although it was removed in 1906.)

Cocaine itself is rarely used medically because it is too addictive, but its anesthetic properties provoked a long search for related but nonaddictive compounds. This search ultimately resulted in the synthesis of the “caine” anesthetics that are commonly used today in dental and surgical anesthesia. Procaine, the first such compound, was synthesized in 1898 and marketed under the name Novocain. It was rapidly adopted and remains in use today as a topical anesthetic. Other related compounds with different activity profiles followed: Lidocaine, marketed as Xylocaine, was introduced in 1943, and mepivacaine (Carbocaine) in the early 1960s. More recently, bupivacaine (Marcaine) and prilocaine (Citanest) have gained popularity. Both are quick-acting, but the effects of bupivacaine last for 3 to 6 hours while those of prilocaine fade after 45 minutes. Notice some structural similarity of all the caines to cocaine itself.

An estimate from the U.S. National Academy of Sciences is that less than 1% of all living species have been characterized. Thus, alkaloid chemistry remains an active area of research, and innumerable substances with potentially useful properties have yet to be discovered. Undoubtedly even the caine anesthetics will become obsolete at some point, perhaps supplanted by newly discovered alkaloids.

Key Terms

- acidity constant (K_a)

- inductive effect
- intermolecular force
- Lewis acid
- Lewis base
- noncovalent interaction
- pK_a
- polar covalent bond
- resonance form
- resonance hybrid
- van der Waals force

Summary

Understanding organic chemistry means knowing not just what happens but also why and how it happens at the molecular level. In this chapter, we've reviewed some of the ways that chemists describe and account for chemical reactivity, thereby providing a foundation for understanding the specific reactions that will be discussed in subsequent chapters.

Organic molecules often have **polar covalent bonds** as a result of unsymmetrical electron sharing caused by differences in the **electronegativity** of atoms. A carbon–oxygen bond is polar, for example, because oxygen attracts the shared electrons more strongly than carbon does. Carbon–hydrogen bonds are relatively nonpolar. Many molecules as a whole are also polar, owing to the presence of individual polar bonds and electron lone pairs. The polarity of a molecule is measured by its **dipole moment, μ** .

Plus (+) and minus (–) signs are often used to indicate the presence of **formal charges** on atoms in molecules. Assigning formal charges to specific atoms is a bookkeeping technique that makes it possible to keep track of the valence electrons around an atom and offers some clues about chemical reactivity.

Some substances, such as acetate ion and benzene, can't be represented by a single line-bond structure and must be considered as a **resonance hybrid** of two or more structures, none of which would be correct by themselves. The only difference between two **resonance forms** is in the location of their π and nonbonding electrons. The nuclei remain in the same places in both structures, and the hybridization of the atoms remains

the same.

Acidity and basicity are closely related to the ideas of polarity and electronegativity. A **Brønsted–Lowry acid** is a compound that can donate a proton (hydrogen ion, H^+), and a **Brønsted–Lowry base** is a compound that can accept a proton. The strength of a Brønsted–Lowry acid or base is expressed by its **acidity constant, K_a** , or by the negative logarithm of the acidity constant, **pK_a** . The larger the pK_a , the weaker the acid. More useful is the Lewis definition of acids and bases. A **Lewis acid** is a compound that has a low-energy empty orbital that can accept an electron pair; Mg^{2+} , BF_3 , $AlCl_3$, and H^+ are examples. A **Lewis base** is a compound that can donate an unshared electron pair; NH_3 and H_2O are examples. Most organic molecules that contain oxygen and nitrogen can act as Lewis bases toward sufficiently strong acids.

A variety of **noncovalent interactions** have a significant effect on the properties of large biomolecules. **Hydrogen bonding**—the attractive interaction between a positively polarized hydrogen atom bonded to an oxygen or nitrogen atom with an unshared electron pair on another O or N atom, is particularly important in giving proteins and nucleic acids their shapes.

Additional Problems

Visualizing Chemistry

PROBLEM Fill in the multiple bonds in the following model of naphthalene, $C_{10}H_8$ (black = C, gray = H). How
2-20 many resonance structures does naphthalene have? Draw them.

PROBLEM The following model is a representation of ibuprofen, a common over-the-counter pain reliever.
2-21 Indicate the positions of the multiple bonds, and draw a skeletal structure (black = C, red = O, gray = H).

PROBLEM *cis*-1,2-Dichloroethylene and *trans*-1,2-dichloroethylene are *isomers*, compounds with the same
2-22 formula but different chemical structures. Look at the following electrostatic potential maps, and tell whether either compound has a dipole moment.

PROBLEM 2-23 The following molecular models are representations of **(a)** adenine and **(b)** cytosine, constituents of DNA (deoxyribonucleic acid). Indicate the positions of multiple bonds and lone pairs for both, and draw skeletal structures (black = C, red = O, blue = N, gray = H).

Mechanism Problems

PROBLEM 2-24 Predict the product(s) of the following acid/base reactions. Draw curved arrows to show the formation and breaking of bonds.

PROBLEM 2-25 Use curved arrows to draw the protonated form of the following Lewis bases.

PROBLEM 2-26 Use the curved-arrow formalism to show how the electrons flow in the resonance form on the left to give the one on the right.

PROBLEM 2-27 Double bonds can also act like Lewis bases, sharing their electrons with Lewis acids. Use curved arrows to show how each of the following double bonds will react with HCl and draw the resulting

carbocation.

Electronegativity and Dipole Moments

PROBLEM Identify the most electronegative element in each of the following molecules:

PROBLEM Use the electronegativity table given in Figure 2.3 to predict which bond in each of the following pairs is more polar, and indicate the direction of bond polarity for each compound.

PROBLEM Which of the following molecules has a dipole moment? Indicate the expected direction of each.

PROBLEM (a) The $\text{H}-\text{Cl}$ bond length is 136 pm. What would the dipole moment of HCl be if the molecule were 100% ionic, $\text{H}^+ \text{Cl}^-$?

2-31

(b) The actual dipole moment of HCl is 1.08 D. What is the percent ionic character of the $\text{H}-\text{Cl}$ bond?

PROBLEM Phosgene, $\text{Cl}_2\text{C}=\text{O}$, has a smaller dipole moment than formaldehyde, $\text{H}_2\text{C}=\text{O}$, even though it contains electronegative chlorine atoms in place of hydrogen. Explain.

2-32

PROBLEM Fluoromethane (CH_3F , $\mu = 1.81$ D) has a smaller dipole moment than chloromethane (CH_3Cl , $\mu = 1.87$ D) even though fluorine is more electronegative than chlorine. Explain.

2-33

PROBLEM Methanethiol, CH_3SH , has a substantial dipole moment ($\mu = 1.52$) even though carbon and sulfur have identical electronegativities. Explain.

2-34

Formal Charges

PROBLEM Calculate the formal charges on the atoms shown in red.

PROBLEM Assign formal charges to the atoms in each of the following molecules:

Resonance

PROBLEM Which of the following pairs of structures represent resonance forms?

PROBLEM Draw as many resonance structures as you can for the following species:

PROBLEM 1,3-Cyclobutadiene is a rectangular molecule with two shorter double bonds and two longer single bonds.

2-39 Why do the following structures not represent resonance forms?

Acids and Bases

PROBLEM Alcohols can act either as weak acids or as weak bases, just as water can. Show the reaction of

2-40 methanol, CH_3OH , with a strong acid such as HCl and with a strong base such as $\text{Na}^+ \text{NH}_2^-$

PROBLEM The O–H hydrogen in acetic acid is more acidic than any of the C–H hydrogens. Explain this result

2-41 using resonance structures.

PROBLEM Draw electron-dot structures for the following molecules, indicating any unshared electron pairs.

2-42 Which of the compounds are likely to act as Lewis acids and which as Lewis bases?

PROBLEM Write the products of the following acid–base reactions:

PROBLEM Rank the following substances in order of increasing acidity:

PROBLEM Which, if any, of the substances in Problem 2-44 is a strong enough acid to react almost completely

2-45 with NaOH ? (The $\text{p}K_a$ of H_2O is 15.74.)

PROBLEM The ammonium ion (NH_4^+ , $\text{p}K_a = 9.25$) has a lower $\text{p}K_a$ than the methylammonium ion (CH_3NH_3^+ ,

2-46 $\text{p}K_a = 10.66$). Which is the stronger base, ammonia (NH_3) or methylamine (CH_3NH_2)? Explain.

PROBLEM Is *tert*-butoxide anion a strong enough base to react significantly with water? In other words,

2-47 can a solution of potassium *tert*-butoxide be prepared in water? The $\text{p}K_a$ of *tert*-butyl alcohol is approximately 18.

PROBLEM 2-48 Predict the structure of the product formed in the reaction of the organic base pyridine with the organic acid acetic acid, and use curved arrows to indicate the direction of electron flow.

PROBLEM Calculate K_a values from the following $\text{p}K_a$'s:

2-49 (a) Acetone, $\text{p}K_a = 19.3$ **(b)** Formic acid, $\text{p}K_a = 3.75$

PROBLEM Calculate $\text{p}K_a$ values from the following K_a 's:

2-50 (a) Nitromethane, $K_a = 5.0 \times 10^{-11}$ **(b)** Acrylic acid, $K_a = 5.6 \times 10^{-5}$

PROBLEM What is the pH of a 0.050 M solution of formic acid, $\text{p}K_a = 3.75$?

2-51

PROBLEM 2-52 Sodium bicarbonate, NaHCO_3 , is the sodium salt of carbonic acid (H_2CO_3), $\text{p}K_a = 6.37$. Which of the substances shown in Problem 2-44 will react significantly with sodium bicarbonate?

General Problems

PROBLEM 2-53 Maleic acid has a dipole moment, but the closely related fumaric acid, a substance involved in the citric acid cycle by which food molecules are metabolized, does not. Explain.

PROBLEM 2-54 Assume that you have two unlabeled bottles, one of which contains phenol ($\text{p}K_a = 9.9$) and one of which contains acetic acid ($\text{p}K_a = 4.76$). In light of your answer to Problem 2-52, suggest a simple way to determine what is in each bottle.

PROBLEM 2-55 Identify the acids and bases in the following reactions:

PROBLEM Which of the following pairs represent resonance structures?

2-56

PROBLEM Draw as many resonance structures as you can for the following species, adding appropriate formal charges to each:

2-57

PROBLEM Carbocations, which contain a trivalent, positively charged carbon atom, react with water to give

2-58 alcohols:

How can you account for the fact that the following carbocation gives a mixture of *two* alcohols on reaction with water?

PROBLEM We'll see in the next chapter that organic molecules can be classified according to the functional

2-59 groups they contain, where a functional group is a collection of atoms with a characteristic chemical reactivity. Use the electronegativity values given in Figure 2.3 to predict the direction of polarization of the following functional groups.

PROBLEM The *azide* functional group, which occurs in azidobenzene, contains three adjacent nitrogen atoms.

2-60 One resonance structure for azidobenzene is shown. Draw three additional resonance structures, and assign appropriate formal charges to the atoms in all four.

PROBLEM Phenol, $\text{C}_6\text{H}_5\text{OH}$, is a stronger acid than methanol, CH_3OH , even though both contain an O–H bond.

2-61 Draw the structures of the anions resulting from loss of H^+ from phenol and methanol, and use resonance structures to explain the difference in acidity.

Phenol ($pK_a = 9.89$)Methanol ($pK_a = 15.54$)

PROBLEM 2-62 Thiamin diphosphate (TPP), a derivative of vitamin B₁ required for glucose metabolism, is a weak acid that can be deprotonated by a base. Assign formal charges to the appropriate atoms in both TPP and its deprotonation product.

PROBLEM 2-63 Which of the following compounds or ions have a dipole moment?

- (a) Carbonate ion (CO_3^{2-}) (b) (c)

PROBLEM 2-64 Use the pK_a table in Appendix B to determine in which direction the equilibrium is favored.

- (a)
- (b) $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH} + \text{NH}_2^- \rightleftharpoons \text{CH}_3\text{CH}_2\text{CH}_2\text{O}^- + \text{NH}_3$
- (c) $\text{CH}_3^- + \text{CH}_3\text{NO}_2 \rightleftharpoons \text{CH}_4 + \text{CH}_2\text{NO}_2^-$

PROBLEM 2-65 Which intermolecular force is predominantly responsible for each observation below?

- (a) $\text{CH}_3(\text{CH}_2)_{29}\text{CH}_3$, a component found in paraffin wax, is a solid at room temperature while $\text{CH}_3(\text{CH}_2)_6\text{CH}_3$ is a liquid.
- (b) $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$ has a higher boiling point than CH_4 .
- (c) $\text{CH}_3\text{CO}_2\text{H}$, which is found in vinegar, will dissolve in water but not in oil. Assume that oil is $\text{CH}_3(\text{CH}_2)_4\text{CH}_3$.

CHAPTER 3

Organic Compounds: Alkanes and Their Stereochemistry

FIGURE 3.1 The bristlecone pine is the oldest living organism on Earth. The waxy coating on its needles contains a mixture of organic compounds called alkanes, the subject of this chapter. (credit: modification of work “Gnarly Bristlecone Pine” by Rick Goldwaser/Flickr, CC BY 2.0)

CHAPTER CONTENTS

3.1 Functional Groups

3.2 Alkanes and Alkane Isomers

3.3 Alkyl Groups

3.4 Naming Alkanes

3.5 Properties of Alkanes

3.6 Conformations of Ethane

3.7 Conformations of Other Alkanes

WHY THIS CHAPTER? The group of organic compounds called *alkanes* are simple and relatively unreactive, but they nevertheless provide a useful vehicle for introducing some important general ideas. In this chapter, we'll use alkanes to introduce the basic approach to naming organic compounds and to take an initial look at some of the three-dimensional aspects of molecules, a topic of particular importance in understanding biological organic chemistry.

According to *Chemical Abstracts*, the publication that abstracts and indexes the chemical literature, there are more than 195 million known organic compounds. Each of these compounds has its own physical properties, such as melting point and boiling point, and each has its own chemical reactivity.

Chemists have learned through years of experience that organic compounds can be classified into families according to their structural features and that the members of a given family have similar chemical behavior. Instead of 195 million compounds with random reactivity, there are a few dozen families of organic compounds whose chemistry is reasonably predictable. We'll study the chemistry of specific families throughout much of this book, beginning in this chapter with a look at the simplest family, the *alkanes*.

3.1 Functional Groups

The structural features that make it possible to classify compounds into families are called *functional groups*. A **functional group** is a group of atoms within a molecule that has a characteristic chemical behavior. Chemically, a given functional group behaves in nearly the same way in every molecule it's a part of. For example, compare ethylene, a plant hormone that causes fruit to ripen, with menthene, a much more complicated molecule found in peppermint oil. Both substances contain a carbon–carbon double-bond functional group, and both therefore react with Br_2 in the same way to give a product in which a Br atom has added to each of the double-bond carbons (**FIGURE 3.2**). This example is typical: *the chemistry of every organic molecule, regardless of size and complexity, is determined by the functional groups it contains.*

FIGURE 3.2 The reactions of ethylene and menthene with bromine. In both molecules, the carbon–carbon double-bond functional group has a similar polarity pattern, so both molecules react with Br_2 in the same way. The size and complexity of the molecules are not important.

Look at **TABLE 3.1**, which lists many of the common functional groups and gives simple examples of their occurrence. Some functional groups have only carbon–carbon double or triple bonds; others have halogen atoms; and still others contain oxygen, nitrogen, or sulfur. Much of the chemistry you'll be studying is the chemistry of these functional groups.

Functional Groups with Carbon–Carbon Multiple Bonds

Alkenes, alkynes, and arenes (aromatic compounds) all contain carbon–carbon multiple bonds. *Alkenes* have a double bond, *alkynes* have a triple bond, and *arenes* have alternating double and single bonds in a six-membered ring of carbon atoms. They look different, but because of their structural similarities, they also have chemical similarities.

**TABLE 3.1** Structures of Some Common Functional Groups

Name	Structure*	Name ending	Example
Alkene (double bond)		-ene	$\text{H}_2\text{C}=\text{CH}_2$ Ethene
Alkyne (triple bond)	$\text{—C}\equiv\text{C—}$	-yne	$\text{HC}\equiv\text{CH}$ Ethyne
Arene (aromatic ring)		None	 Benzene
Halide	 (X=F, Cl, Br, I)	None	CH_3Cl Chloromethane
Alcohol		-ol	CH_3OH Methanol
Ether		ether	CH_3OCH_3 Dimethyl ether
Monophosphate		phosphate	$\text{CH}_3\text{OPO}_3^{2-}$ Methyl phosphate
Diphosphate		diphosphate	$\text{CH}_3\text{OP}_2\text{O}_6^{3-}$ Methyl diphosphate

TABLE 3.1 Structures of Some Common Functional Groups

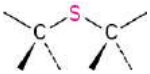

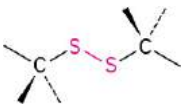

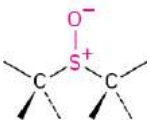

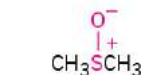

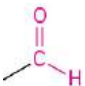

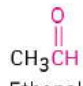

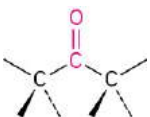

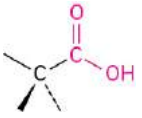

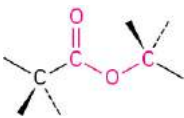

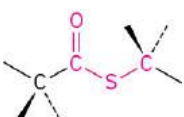

Name	Structure*	Name ending	Example
Amine		-amine	CH ₃ NH ₂ Methylamine
Imine (Schiff base)		None	 CH ₃ CCH ₃ Acetone imine
Nitrile	-C≡N	-nitrile	CH ₃ C≡N Ethanenitrile
Thiol		-thiol	CH ₃ SH Methanethiol
Sulfide		sulfide	CH ₃ SCH ₃ Dimethyl sulfide
Disulfide		disulfide	CH ₃ SSCH ₃ Dimethyl disulfide
Sulfoxide		sulfoxide	 CH ₃ SCH ₃ Dimethyl sulfoxide
Aldehyde		-al	 CH ₃ CH Ethanal
Ketone		-one	 CH ₃ CCH ₃ Propanone
Carboxylic acid		-oic acid	 CH ₃ COH Ethanoic acid
Ester		-oate	 CH ₃ COCH ₃ Methyl ethanoate
Thioester		-thioate	 CH ₃ CSCH ₃ Methyl ethanethioate

TABLE 3.1 Structures of Some Common Functional Groups

Name	Structure*	Name ending	Example
Amide		-amide	 Ethanamide
Acid chloride		-oyl chloride	 Ethanoyl chloride
Carboxylic acid anhydride		-oic anhydride	 Ethanoic anhydride

*The bonds whose connections aren't specified are assumed to be attached to carbon or hydrogen atoms in the rest of the molecule.

Functional Groups with Carbon Singly Bonded to an Electronegative Atom

Alkyl halides (haloalkanes), alcohols, ethers, alkyl phosphates, amines, thiols, sulfides, and disulfides all have a carbon atom singly bonded to an electronegative atom—halogen, oxygen, nitrogen, or sulfur. **Alkyl halides** have a carbon atom bonded to halogen ($-X$), **alcohols** have a carbon atom bonded to the oxygen of a hydroxyl group ($-OH$), **ethers** have two carbon atoms bonded to the same oxygen, organophosphates have a carbon atom bonded to the oxygen of a phosphate group ($-OPO_3^{2-}$), **amines** have a carbon atom bonded to a nitrogen, **thiols** have a carbon atom bonded to the sulfur of an $-SH$ group, **sulfides** have two carbon atoms bonded to the same sulfur, and **disulfides** have carbon atoms bonded to two sulfurs that are joined together. In all cases, the bonds are polar, with the carbon atom bearing a partial positive charge (δ^+) and the electronegative atom bearing a partial negative charge (δ^-).

Functional Groups with a Carbon–Oxygen Double Bond (Carbonyl Groups)

The **carbonyl group**, C=O (pronounced car-bo-**neel**) is common to many of the families listed in [TABLE 3.1](#). Carbonyl groups are present in a majority of organic compounds and in practically all biological molecules. These compounds therefore behave similarly in many respects but differ depending on the identity of the other atoms bonded to the carbonyl-group carbon. **Aldehydes** have at least one hydrogen bonded to the C=O, **ketones** have two carbons bonded to the C=O, **carboxylic acids** have an –OH group bonded to the C=O, **esters** have an ether-like oxygen bonded to the C=O, **thioesters** have a sulfide-like sulfur bonded to the C=O, **amides** have an amine-like nitrogen bonded to the C=O, **acid chlorides** have a chlorine bonded to the C=O, and so on. In all these functional groups, the carbonyl carbon atom bears a partial positive charge (δ^+), and the oxygen bears a partial negative charge (δ^-).

Acetone—a typical carbonyl compound

PROBLEM Use Table 3.1 to identify the functional groups in each of the following molecules:

- 3-1 (a)** Methionine, an amino acid: **(b)** Ibuprofen, a pain reliever:

- (c)** Capsaicin, the pungent substance in chili peppers:

PROBLEM Propose structures for simple molecules that contain the following functional groups:

- 3-2 (a)** Alcohol **(b)** Aromatic ring **(c)** Carboxylic acid **(d)** Amine **(e)** Both ketone and amine
(f) Two double bonds

PROBLEM Identify the functional groups in the following model of arecoline, a veterinary drug used to control worms in animals. Convert the drawing into a line-bond structure and a molecular formula (red = O, blue = N, black = C, gray = H).

Compounds like butane and pentane, whose carbons are all connected in a row, are called **straight-chain alkanes**, or *normal alkanes*. Compounds like 2-methylpropane (isobutane), 2-methylbutane, and 2,2-dimethylpropane, whose carbon chains branch, are called **branched-chain alkanes**.

Compounds like the two C_4H_{10} molecules and the three C_5H_{12} molecules, which have the same formula but different structures, are called **isomers**, from the Greek *isos* + *meros*, meaning “made of the same parts.” Isomers have the same numbers and kinds of atoms but differ in the way the atoms are arranged. Compounds like butane and isobutane, whose atoms are connected differently, are called **constitutional isomers**. We’ll see shortly that other kinds of isomers are also possible, even among compounds whose atoms are connected in the same order. As **TABLE 3.2** shows, the number of possible alkane isomers increases dramatically with the number of carbon atoms.

TABLE 3.2 Number of Alkane Isomers

Formula	Number of isomers	Formula	Number of isomers
C_6H_{14}	5	$\text{C}_{10}\text{H}_{22}$	75
C_7H_{16}	9	$\text{C}_{15}\text{H}_{32}$	4347
C_8H_{18}	18	$\text{C}_{20}\text{H}_{42}$	366,319
C_9H_{20}	35	$\text{C}_{30}\text{H}_{62}$	4,111,846,763

Constitutional isomerism is not limited to alkanes—it occurs widely throughout organic chemistry. Constitutional isomers may have different carbon skeletons (as in isobutane and butane), different functional groups (as in ethanol and dimethyl ether), or different locations of a functional group along the chain (as in isopropylamine and propylamine). Regardless of the reason for the isomerism, constitutional isomers are always different compounds with different properties but with the same formula.

A given alkane can be drawn in many ways. For example, the straight-chain, four-carbon alkane called butane can be represented by any of the structures shown in **FIGURE 3.3**. These structures don't imply any particular three-dimensional geometry for butane; they indicate only the connections among atoms. In practice, as noted in **Section 1.12**, chemists rarely draw all the bonds in a molecule and usually refer to butane by the condensed structure, $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_3$ or $\text{CH}_3(\text{CH}_2)_2\text{CH}_3$. Still more simply, butane can be represented as $n\text{-C}_4\text{H}_{10}$, where n denotes *normal* (straight-chain) butane.

FIGURE 3.3 Some representations of butane, C_4H_{10} . The molecule is the same regardless of how it's drawn. These structures imply only that butane has a continuous chain of four carbon atoms; they do not imply any specific geometry.

Straight-chain alkanes are named according to the number of carbon atoms they contain, as shown in **TABLE 3.3**. With the exception of the first four compounds—methane, ethane, propane, and butane—whose names have historical roots, the alkanes are named based on Greek numbers. The suffix *-ane* is added to the end of each name to indicate that the molecule identified is an alkane. Thus, *pentane* is the five-carbon alkane, *hexane* is the six-carbon alkane, and so on. We'll soon see that these alkane names form the basis for naming all other organic compounds, so at least the first ten should be memorized.

TABLE 3.3 Names of Straight-Chain Alkanes

Number of carbons (n)	Name	Formula (C_nH_{2n+2})	Number of carbons (n)	Name	Formula (C_nH_{2n+2})
1	Methane	CH_4	9	Nonane	C_9H_{20}
2	Ethane	C_2H_6	10	Decane	$\text{C}_{10}\text{H}_{22}$
3	Propane	C_3H_8	11	Undecane	$\text{C}_{11}\text{H}_{24}$
4	Butane	C_4H_{10}	12	Dodecane	$\text{C}_{12}\text{H}_{26}$
5	Pentane	C_5H_{12}	13	Tridecane	$\text{C}_{13}\text{H}_{28}$

TABLE 3.3 Names of Straight-Chain Alkanes

Number of carbons (<i>n</i>)	Name	Formula (C_nH_{2n+2})	Number of carbons (<i>n</i>)	Name	Formula (C_nH_{2n+2})
6	Hexane	C_6H_{14}	20	Icosane	$C_{20}H_{42}$
7	Heptane	C_7H_{16}	30	Triacontane	$C_{30}H_{62}$
8	Octane	C_8H_{18}			

WORKED EXAMPLE 3.1

Drawing the Structures of Isomers

Propose structures for two isomers with the formula C_2H_7N .

Strategy

We know that carbon forms four bonds, nitrogen forms three, and hydrogen forms one. Write down the carbon atoms first, and then use trial and error plus intuition to put the pieces together.

Solution

There are two isomeric structures. One has the connection C–C–N, and the other has the connection C–N–C.

PROBLEM Draw structures of the five isomers of C_6H_{14} .

3-4

PROBLEM Propose structures that meet the following descriptions:

- 3-5 (a) Two isomeric esters with the formula $C_5H_{10}O_2$:
 (b) Two isomeric nitriles with the formula C_4H_7N
 (c) Two isomeric disulfides with the formula $C_4H_{10}S_2$

PROBLEM How many isomers are there with the following descriptions?

- 3-6 (a) Alcohols with the formula C_3H_8O (b) Bromoalkanes with the formula C_4H_9Br
 (c) Thioesters with the formula C_4H_8OS

3.3 Alkyl Groups

If you imagine removing a hydrogen atom from an alkane, the partial structure that remains is called an **alkyl group**. Alkyl groups are not stable compounds themselves, they are simply parts of larger compounds and are named by replacing the *-ane* ending of the parent alkane with an *-yl* ending. For example, removal of a hydrogen from methane, CH_4 , generates a methyl group, $-CH_3$, and removal of a hydrogen from ethane, CH_3CH_3 , generates an ethyl group, $-CH_2CH_3$. Similarly, removal of a hydrogen atom from the end carbon of any straight-chain alkane gives the series of straight-chain alkyl groups shown in TABLE 3.4. Combining an alkyl group with any of the functional groups listed earlier makes it possible to generate and name many thousands of compounds. For example:

**TABLE 3.4** Some Straight-Chain Alkyl Groups

Alkane	Name	Alkyl group	Name (abbreviation)
CH ₄	Methane	-CH ₃	Methyl (Me)
CH ₃ CH ₃	Ethane	-CH ₂ CH ₃	Ethyl (Et)
CH ₃ CH ₂ CH ₃	Propane	-CH ₂ CH ₂ CH ₃	Propyl (Pr)
CH ₃ CH ₂ CH ₂ CH ₃	Butane	-CH ₂ CH ₂ CH ₂ CH ₃	Butyl (Bu)
CH ₃ CH ₂ CH ₂ CH ₂ CH ₃	Pentane	-CH ₂ CH ₂ CH ₂ CH ₂ CH ₃	Pentyl, or amyl

Just as straight-chain alkyl groups are generated by removing a hydrogen from an end carbon, branched alkyl groups are generated by removing a hydrogen atom from an internal carbon. Two 3-carbon alkyl groups and four 4-carbon alkyl groups are possible (FIGURE 3.4).

FIGURE 3.4 Alkyl groups generated from straight-chain alkanes.

One further comment about naming alkyl groups: the prefixes *sec-* (for secondary) and *tert-* (for tertiary) used for the C₄ alkyl groups in **FIGURE 3.4** refer to the number of other carbon atoms attached to the branching carbon atom. There are four possibilities: primary (1°), secondary (2°), tertiary (3°), and quaternary (4°).

The symbol **R** is used here and throughout organic chemistry to represent a generalized organic group. The **R** group can be methyl, ethyl, propyl, or any of a multitude of others. You might think of **R** as representing the **Rest** of the molecule, which isn't specified.

The terms *primary*, *secondary*, *tertiary*, and *quaternary* are routinely used in organic chemistry, and their meanings need to become second nature. For example, if we were to say, "Citric acid is a tertiary alcohol," we would mean that it has an alcohol functional group (–OH) bonded to a carbon atom that is itself bonded to three other carbons.

In addition to speaking of carbon atoms as being primary, secondary, or tertiary, we speak of hydrogens in the same way. Primary hydrogen atoms are attached to primary carbons (RCH_3), secondary hydrogens are attached to secondary carbons (R_2CH_2), and tertiary hydrogens are attached to tertiary carbons (R_3CH). There is, however, no such thing as a quaternary hydrogen. (Why not?)

PROBLEM Draw the eight 5-carbon alkyl groups (pentyl isomers).

3-7

PROBLEM Identify the carbon atoms in the following molecules as primary, secondary, tertiary, or quaternary:

PROBLEM Identify the hydrogen atoms on the compounds shown in Problem 3-8 as primary, secondary, or tertiary.

3-9

PROBLEM Draw structures of alkanes that meet the following descriptions:

- 3-10 (a) An alkane with two tertiary carbons (b) An alkane that contains an isopropyl group
(c) An alkane that has one quaternary and one secondary carbon

3.4 Naming Alkanes

In earlier times, when relatively few pure organic chemicals were known, new compounds were named at the whim of their discoverer. Thus, urea ($\text{CH}_4\text{N}_2\text{O}$) is a crystalline substance isolated from urine; morphine ($\text{C}_{17}\text{H}_{19}\text{NO}_3$) is an analgesic (painkiller) named after Morpheus, the Greek god of dreams; and acetic acid, the primary organic constituent of vinegar, is named from the Latin word for vinegar, *acetum*.

As the science of organic chemistry slowly grew in the 19th century, so too did the number of known compounds and the need for a systematic method of naming them. The system of naming (nomenclature) we'll use in this book is that devised by the International Union of Pure and Applied Chemistry (IUPAC, usually spoken as **eye-you-pac**).

A chemical name typically has four parts in the IUPAC system: parent, prefix, locant, and suffix. The **parent** name identifies the main part of the molecule and tells how many carbon atoms are in that part. **Prefixes** identify the various **substituent** groups attached to the parent. **Locants** give the positions of the attached substituents. And the **suffix** identifies the primary functional group attached to the parent.

As we cover new functional groups in later chapters, the applicable IUPAC rules of nomenclature will be given. In addition, **Appendix A** at the back of this book gives an overall view of organic nomenclature and shows how compounds that contain more than one functional group are named. (If preferred, you can study that appendix now.) For the present, let's see how to name branched-chain alkanes and learn some general rules that are applicable to all compounds.

All but the most complex branched-chain alkanes can be named by following four steps. For a very few compounds, a fifth step is needed.

STEP 1**Identify the parent hydrocarbon.**

(a) Find the longest continuous chain of carbon atoms in the molecule, and use the name of that chain as the parent name. The longest chain may not always be apparent from the manner of writing; you may have to “turn corners.”

(b) If two different chains of equal length are present, choose the one with the larger number of branch points as the parent.

**STEP 2****Number the atoms in the longest chain.**

(a) Beginning at the end nearer the first branch point, number each carbon atom in the parent chain.

The first branch occurs at C3 in the proper system of numbering, not at C4.

(b) If there is branching an equal distance away from both ends of the parent chain, begin numbering at the end nearer the second branch point.

**STEP 3****Identify and number the substituents.**

(a) Assign a number to each substituent to locate its point of attachment to the parent chain.

(b) If there are two substituents on the same carbon, give both the same number. There must be as many numbers in the name as there are substituents.

**STEP 4**

Write the name as a single word.

Use hyphens to separate the different prefixes, and use commas to separate numbers. If two or more different substituents are present, cite them in alphabetical order. If two or more identical substituents are present on the parent chain, use one of the multiplier prefixes *di-*, *tri-*, *tetra-*, and so forth, but don't use these prefixes for alphabetizing. Full names for some of the examples we have been using are as follows:

**STEP 5**

Name a branched substituent as though it were itself a compound.

In some particularly complex cases, a fifth step is necessary. It occasionally happens that a substituent on the main chain is itself branched. In the following case, for instance, the substituent at C6 is a three-carbon chain with a methyl group. To name the compound fully, the branched substituent must first be named.

Number the branched substituent beginning at the point of its attachment to the main chain, and identify it—in this case, a 2-methylpropyl group. The substituent is treated as a whole and is alphabetized according to the first letter of its complete name, including any numerical prefix. It is set off in parentheses when naming the entire molecule.

As a further example:

5-(1,2-Dimethylpropyl)-2-methylnonane

A 1,2-dimethylpropyl group

For historical reasons, some of the simpler branched-chain alkyl groups also have nonsystematic, common names, as noted earlier.

The common names of these simple alkyl groups are so well entrenched in the chemical literature that IUPAC rules make allowance for them. Thus, the following compound is properly named either 4-(1-methylethyl)heptane or 4-isopropylheptane. There's no choice but to memorize these common names; fortunately, there are only a few of them.

4-(1-Methylethyl)heptane or 4-Isopropylheptane

When writing an alkane name, the nonhyphenated prefix *iso-* is considered part of the alkyl-group name for alphabetizing purposes, but the hyphenated and italicized prefixes *sec-* and *tert-* are not. Thus, isopropyl and isobutyl are listed alphabetically under *i*, but *sec*-butyl and *tert*-butyl are listed under *b*.

WORKED EXAMPLE 3.2

Naming Alkanes

What is the IUPAC name for the following alkane?

Strategy

Find the longest continuous carbon chain in the molecule, and use that as the parent name. This molecule has a chain of eight carbons—octane—with two methyl substituents. (You have to turn corners to see it.) Numbering from the end nearer the first methyl substituent indicates that the methyls are at C2 and C6.

Solution**2,6-Dimethyloctane****WORKED EXAMPLE 3.3****Converting a Chemical Name into a Structure**

Draw the structure of 3-isopropyl-2-methylhexane.

Strategy

This is the reverse of **Worked Example 3.2** and uses a reverse strategy. Look at the parent name (hexane), and draw its carbon structure.

Next, find the substituents (3-isopropyl and 2-methyl), and place them on the proper carbons.

Finally, add hydrogens to complete the structure.

Solution**3-Isopropyl-2-methylhexane**

PROBLEM Give IUPAC names for the following compounds:

3-11 (a) The three isomers of C_5H_{12}

PROBLEM Draw structures corresponding to the following IUPAC names:

3-12 (a) 3,4-Dimethylnonane **(b)** 3-Ethyl-4,4-dimethylheptane **(c)** 2,2-Dimethyl-4-propyloctane
(d) 2,2,4-Trimethylpentane

PROBLEM Name the eight 5-carbon alkyl groups you drew in Problem 3-7.

3-13

PROBLEM Give the IUPAC name for the following hydrocarbon, and convert the drawing into a skeletal structure.

3-14

FIGURE 3.5 A plot of melting and boiling points versus number of carbon atoms for the C1–C14 straight-chain alkanes. There is a regular increase with molecular size.

Another effect seen in alkanes is that increased branching lowers an alkane's boiling point. Thus, pentane has no branches and boils at 36.1 °C, isopentane (2-methylbutane) has one branch and boils at 27.85 °C, and neopentane (2,2-dimethylpropane) has two branches and boils at 9.5 °C. Similarly, octane boils at 125.7 °C, whereas isooctane (2,2,4-trimethylpentane) boils at 99.3 °C. Branched-chain alkanes are lower-boiling because they are more nearly spherical than straight-chain alkanes, have smaller surface areas, and consequently have smaller dispersion forces.

3.6 Conformations of Ethane

Up until now, we've viewed molecules primarily in a two-dimensional way and have given little thought to any consequences that might arise from the spatial arrangement of atoms in molecules. Now it's time to add a third dimension to our study. **Stereochemistry** is the branch of chemistry concerned with the three-dimensional aspects of molecules. We'll see on many occasions in future chapters that the exact three-dimensional structure of a molecule is often crucial to determining its properties and biological behavior.

We know from **Section 1.5** that σ bonds are cylindrically symmetrical. In other words, the intersection of a plane cutting through a carbon–carbon single-bond orbital looks like a circle. Because of this cylindrical symmetry, rotation is possible around carbon–carbon bonds in open-chain molecules. In ethane, for instance, rotation around the C–C bond occurs freely, constantly changing the spatial relationships between the hydrogens on one carbon and those on the other (**FIGURE 3.6**).

FIGURE 3.6 Rotation occurs around the carbon–carbon single bond in ethane because of σ bond cylindrical symmetry.

The different arrangements of atoms that result from bond rotation are called **conformations**, and molecules that have different arrangements are called **conformational isomers**, or **conformers**. Unlike constitutional isomers, however, different conformers often can't be isolated because they interconvert too rapidly.

Conformational isomers are represented in two ways, as shown in **FIGURE 3.7**. A **sawhorse representation** views the carbon–carbon bond from an oblique angle and indicates spatial orientation by showing all C–H bonds. A **Newman projection** views the carbon–carbon bond directly end-on and represents the two carbon atoms by a circle. Bonds attached to the front carbon are represented by lines to the center of the circle, and bonds attached to the rear carbon are represented by lines to the edge of the circle.

FIGURE 3.7 A sawhorse representation and a Newman projection of ethane. The sawhorse representation views the molecule from an oblique angle, while the Newman projection views the molecule end-on. Note that the molecular model of the Newman projection appears at first to have six atoms attached to a single carbon. Actually, the front carbon, with three attached **green atoms**, is directly in front of the rear carbon, with three attached **red atoms**.

Despite what we've just said, we actually don't observe perfectly free rotation in ethane. Experiments show that there is a small (12 kJ/mol; 2.9 kcal/mol) barrier to rotation and that some conformations are more stable than others. The lowest-energy, most stable conformation is the one in which all six C–H bonds are as far away from one another as possible—*staggered* when viewed end-on in a Newman projection. The highest-energy, least stable conformation is the one in which the six C–H bonds are as close as possible—*eclipsed* in a Newman projection. At any given instant, about 99% of ethane molecules have an approximately **staggered conformation** and only about 1% are near the **eclipsed conformation**.

The extra 12 kJ/mol of energy present in the eclipsed conformation of ethane is called **torsional strain**. Its cause has been the subject of controversy, but the major factor is an interaction between C–H bonding orbitals on one carbon and antibonding orbitals on the adjacent carbon, which stabilizes the staggered conformation relative to the eclipsed one. Because a total strain of 12 kJ/mol arises from three equal hydrogen–hydrogen eclipsing interactions, we can assign a value of approximately 4.0 kJ/mol (1.0 kcal/mol) to each single interaction. The barrier to rotation that results can be represented on a graph of potential energy versus degree of rotation, in which the angle between C–H bonds on the front and back carbons as viewed end-on (the *dihedral angle*) goes full circle from 0 to 360°. Energy minima occur at staggered conformations, and energy maxima occur at eclipsed conformations, as shown in **FIGURE 3.8**.

FIGURE 3.8 A graph of potential energy versus bond rotation in ethane. The staggered conformations are 12 kJ/mol lower in energy than the eclipsed conformations.

3.7 Conformations of Other Alkanes

Propane, the next-higher member in the alkane series, also has a torsional barrier that results in hindered rotation around the carbon–carbon bonds. The barrier is slightly higher in propane than in ethane—a total of 14 kJ/mol (3.4 kcal/mol) versus 12 kJ/mol.

The eclipsed conformation of propane has three interactions—two ethane-type hydrogen–hydrogen interactions and one additional hydrogen–methyl interaction. Since each eclipsing $\text{H} \leftrightarrow \text{H}$ interaction is the same as that in ethane and thus has an energy “cost” of 4.0 kJ/mol, we can assign a value of $14 - (2 \times 4.0) = 6.0$ kJ/mol (1.4 kcal/mol) to the eclipsing $\text{H} \leftrightarrow \text{CH}_3$ interaction (**FIGURE 3.9**).

FIGURE 3.9 Newman projections of propane showing staggered and eclipsed conformations. The staggered conformer is lower in energy by 14 kJ/mol.

The conformational situation becomes more complex for larger alkanes because not all staggered conformations have the same energy and not all eclipsed conformations have the same energy. In butane, for instance, the lowest-energy arrangement, called the **anti conformation**, is the one in which the two methyl groups are as far apart as possible— 180° away from each other. As rotation around the C2–C3 bond occurs, an eclipsed conformation is reached where there are two $\text{CH}_3 \leftrightarrow \text{H}$ interactions and one $\text{H} \leftrightarrow \text{H}$ interaction. Using the energy values derived previously from ethane and propane, this eclipsed conformation is more strained than the anti conformation by 2×6.0 kJ/mol + 4.0 kJ/mol (two $\text{CH}_3 \leftrightarrow \text{H}$ interactions plus one $\text{H} \leftrightarrow \text{H}$ interaction), for a total of 16 kJ/mol (3.8 kcal/mol).

As bond rotation continues, an energy minimum is reached at the staggered conformation where the methyl groups are 60° apart. Called the **gauche conformation**, it lies 3.8 kJ/mol (0.9 kcal/mol) higher in energy than the anti conformation even though it has no eclipsing interactions. This energy difference occurs because the hydrogen atoms of the methyl groups are near one another in the gauche conformation, resulting in what is called *steric strain*. **Steric strain** is the repulsive interaction that occurs when atoms are forced closer together than their atomic radii allow. It's the result of trying to force two atoms to occupy the same space.

As the dihedral angle between the methyl groups approaches zero, an energy maximum is reached at a second eclipsed conformation. Because the methyl groups are forced even closer together than in the gauche conformation, both torsional strain and steric strain are present. A total strain energy of 19 kJ/mol (4.5 kcal/mol) has been estimated for this conformation, making it possible to calculate a value of 11 kJ/mol (2.6 kcal/mol) for the $\text{CH}_3 \leftrightarrow \text{CH}_3$ eclipsing interaction: total strain of 19 kJ/mol minus the strain of two $\text{H} \leftrightarrow \text{H}$ eclipsing interactions ($2 \times 4.0 \text{ kcal/mol}$) equals 11 kJ/mol .

After 0° , the rotation becomes a mirror image of what we've already seen: another gauche conformation is reached, another eclipsed conformation, and finally a return to the anti conformation. A plot of potential energy versus rotation about the C2–C3 bond is shown in **FIGURE 3.10**.

FIGURE 3.10 A plot of potential energy versus rotation for the C2–C3 bond in butane. The energy maximum occurs when the two methyl groups eclipse each other, and the energy minimum occurs when the two methyl groups are 180° apart (anti).

The notion of assigning definite energy values to specific interactions within a molecule is very useful, and we'll return to it in the next chapter. A summary of what we've seen thus far is given in [TABLE 3.5](#).

The same principles just developed for butane apply to pentane, hexane, and all higher alkanes. The most favorable conformation for any alkane has the carbon–carbon bonds in staggered arrangements, with large substituents arranged anti to one another. A generalized alkane structure is shown in [FIGURE 3.11](#).

TABLE 3.5 Energy Costs for Interactions in Alkane Conformers

Interaction	Cause	Energy cost	
		(kJ/mol)	(kcal/mol)
H ↔ H eclipsed	Torsional strain	4.0	1.0
H ↔ CH ₃ eclipsed	Mostly torsional strain	6.0	1.4
CH ₃ ↔ CH ₃ eclipsed	Torsional and steric strain	11.0	2.6
CH ₃ ↔ CH ₃ gauche	Steric strain	3.8	0.9

FIGURE 3.11 The most stable alkane conformation is the one in which all substituents are staggered and the carbon–carbon bonds are arranged anti, as shown in this model of decane.

One final point: saying that one particular conformer is “more stable” than another doesn’t mean the molecule adopts and maintains only the more stable conformation. At room temperature, rotations around σ bonds occur so rapidly that all conformers are in equilibrium. At any given instant, however, a larger percentage of molecules will be found in a more stable conformation than in a less stable one.

WORKED EXAMPLE 3.4

Newman Projections

Sight along the C1–C2 bond of 1-chloropropane, and draw Newman projections of the most stable and least stable conformations.

Strategy

The most stable conformation of a substituted alkane is generally a staggered one in which large groups have an anti relationship. The least stable conformation is generally an eclipsed one in which large groups are as close as possible.

Solution

PROBLEM 3-15 Make a graph of potential energy versus angle of bond rotation for propane, and assign values to the energy maxima.

PROBLEM 3-16 Sight along the C2–C1 bond of 2-methylpropane (isobutane).

- (a) Draw a Newman projection of the most stable conformation.
- (b) Draw a Newman projection of the least stable conformation.
- (c) Make a graph of energy versus angle of rotation around the C2–C1 bond.
- (d) Assign relative values to the maxima and minima in your graph, given that an H \leftrightarrow H eclipsing interaction costs 4.0 kJ/mol and an H \leftrightarrow CH₃ eclipsing interaction costs 6.0 kJ/mol.

PROBLEM 3-17 Sight along the C2–C3 bond of 2,3-dimethylbutane, and draw a Newman projection of the most stable conformation.

PROBLEM 3-18 Draw a Newman projection along the C2–C3 bond of the following conformation of 2,3-dimethylbutane, and calculate a total strain energy:

CHEMISTRY MATTERS

Gasoline

British Foreign Minister Ernest Bevin once said that “The Kingdom of Heaven runs on righteousness, but the Kingdom of Earth runs on alkanes.” (Actually, he said “runs on oil” not “runs on alkanes,” but they’re essentially the same.) By far, the major sources of alkanes are the world’s natural gas and petroleum deposits. Laid down eons ago, these deposits are thought to be derived primarily from the decomposition of tiny single-celled marine organisms called foraminifera. Natural gas consists chiefly of methane but also contains ethane, propane, and butane. Petroleum is a complex mixture of hydrocarbons that must be separated into fractions and then further refined before it can be used.

FIGURE 3.12 Gasoline is a finite resource. It won’t be around forever. (credit: “The first oil well” (<https://www.loc.gov/item/2010649522/>) by Unknown/Library of Congress)

The petroleum era began in August 1859, when the world’s first oil well was drilled by Edwin Drake near Titusville, Pennsylvania. The petroleum was distilled into fractions according to boiling point, but it was high-boiling kerosene, or lamp oil, rather than gasoline that was primarily sought. Literacy was becoming widespread at the time, and people wanted better light for reading than was available from candles. Gasoline was too volatile for use in lamps and was initially considered a waste by-product. The world has changed greatly since those early days, however, and it is now gasoline rather than lamp oil that is prized.

Petroleum refining begins by fractional distillation of crude oil into three principal cuts according to boiling point (bp): straight-run gasoline (bp 30–200 °C), kerosene (bp 175–300 °C), and heating oil, or diesel fuel (bp 275–400 °C). Further distillation under reduced pressure then yields lubricating oils and waxes and leaves a tarry residue of asphalt. The distillation of crude oil is only the first step in gasoline production, however. Straight-run gasoline turns out to be a poor fuel in automobiles because of engine knock, an uncontrolled combustion that can occur in a hot engine causing potentially serious damage.

The *octane number* of a fuel is the measure by which its antiknock properties are judged. It was recognized long ago that straight-chain hydrocarbons are far more prone to inducing engine knock than highly branched compounds. Heptane, a particularly bad fuel, is assigned a base value of 0 octane number, and 2,2,4-trimethylpentane, commonly known as isooctane, has a rating of 100.

Because straight-run gasoline burns so poorly in engines, petroleum chemists have devised numerous methods for producing higher-quality fuels. One of these methods, *catalytic cracking*, involves taking the high-boiling kerosene cut (C_{11} – C_{14}) and “cracking” it into smaller branched molecules suitable for use in gasoline. Another process, called *reforming*, is used to convert C_6 – C_8 alkanes to aromatic compounds such as benzene and toluene, which have substantially higher octane numbers than alkanes. The final product that goes in your tank has an approximate composition of 15% C_4 – C_8 straight-chain alkanes, 25% to 40% C_4 – C_{10} branched-chain alkanes, 10% cyclic alkanes, 10% straight-chain and cyclic alkenes, and 25% arenes (aromatics).

- aliphatic
- alkane
- alkene
- alkyl group
- alkyl halide
- alkyne
- amide
- amine
- anti conformation
- arene
- branched-chain alkane
- carbonyl group
- carboxylic acid
- conformation
- conformational isomer
- conformer
- constitutional isomer
- eclipsed conformation
- ester
- ether
- functional group
- gauche conformation
- hydrocarbon
- isomer
- ketone
- Newman projection
- nitrile
- R group
- saturated
- sawhorse representation
- staggered conformation
- stereochemistry
- steric strain
- straight-chain alkane
- substituent
- sulfide
- thiol
- torsional strain

Summary

Alkanes are relatively unreactive and rarely involved in chemical reactions, but they nevertheless provide a useful vehicle for introducing some important general ideas. In this chapter, we’ve used alkanes to introduce the basic approach to naming organic compounds and to take an initial look at some of the three-dimensional aspects of molecules.

A **functional group** is a group of atoms within a larger molecule that has a characteristic chemical reactivity. Because functional groups behave in approximately the same way in all molecules where they occur, the chemical reactions of an organic molecule are largely determined by its functional groups.

Alkanes are a class of **saturated hydrocarbons** with the general formula $\text{C}_n\text{H}_{2n+2}$. They contain no functional groups, are relatively inert, and can be either **straight-chain** (*normal*) or **branched**. Alkanes are named by a series of IUPAC rules of nomenclature. Compounds that have the same chemical formula but different

structures are called **isomers**. More specifically, compounds such as butane and isobutane, which differ in their connections between atoms, are called **constitutional isomers**.

Carbon–carbon single bonds in alkanes are formed by σ overlap of carbon sp^3 hybrid orbitals. Rotation is possible around σ bonds because of their cylindrical symmetry, and alkanes therefore exist in a large number of rapidly interconverting **conformations**. **Newman projections** make it possible to visualize the spatial consequences of bond rotation by sighting directly along a carbon–carbon bond axis. Not all alkane conformations are equally stable. The **staggered conformation** of ethane is 12 kJ/mol (2.9 kcal/mol) more stable than the **eclipsed conformation** because of **torsional strain**. In general, any alkane is most stable when all its bonds are staggered.

Additional Problems

Visualizing Chemistry

PROBLEM 3-19 Identify the functional groups in the following substances, and convert each drawing into a molecular formula (red = O, blue = N).

Phenylalanine

Lidocaine

PROBLEM 3-20 Give IUPAC names for the following alkanes, and convert each drawing into a skeletal structure.

PROBLEM 3-21 Draw a Newman projection along the C2–C3 bond of the following conformation of 2-butanol.

Functional Groups

PROBLEM Locate and identify the functional groups in the following molecules.

PROBLEM Propose structures that meet the following descriptions:

- 3-23 (a) A ketone with five carbons (b) A four-carbon amide (c) A five-carbon ester
(d) An aromatic aldehyde (e) A keto ester (f) An amino alcohol

PROBLEM Propose structures for the following:

- 3-24 (a) A ketone, C_4H_8O (b) A nitrile, C_5H_9N (c) A dialdehyde, $C_4H_6O_2$
(d) A bromoalkene, $C_6H_{11}Br$ (e) An alkane, C_6H_{14} (f) *cyclic* saturated hydrocarbon, C_6H_{12}
(g) A diene (dialkene), C_5H_8 (h) A keto alkene, C_5H_8O

PROBLEM Predict the hybridization of the carbon atom in each of the following functional groups:

- 3-25 (a) Ketone (b) Nitrile (c) Carboxylic acid

PROBLEM Draw the structures of the following molecules:

- 3-26 (a) Biacetyl, $C_4H_6O_2$, a substance with the aroma of butter; it contains no rings or carbon-carbon multiple bonds.
(b) Ethylenimine, C_2H_5N , a substance used in the synthesis of melamine polymers; it contains no multiple bonds.
(c) Glycerol, $C_3H_8O_3$, a substance isolated from fat and used in cosmetics; it has an -OH group on each carbon.

Isomers

PROBLEM Draw structures that meet the following descriptions (there are many possibilities):

- 3-27 (a) Three isomers with the formula C_8H_{18} (b) Two isomers with the formula $C_4H_8O_2$

PROBLEM Draw structures of the nine isomers of C_7H_{16} .

3-28

PROBLEM In each of the following sets, which structures represent the same compound and which represent different compounds?

PROBLEM Seven constitutional isomers have the formula $C_4H_{10}O$. Draw as many as you can.

3-30

PROBLEM Draw as many compounds as you can that fit the following descriptions:

- 3-31** (a) Alcohols with formula $C_4H_{10}O$ (b) Amines with formula $C_5H_{13}N$
 (c) Ketones with formula $C_5H_{10}O$ (d) Aldehydes with formula $C_5H_{10}O$
 (e) Esters with formula $C_4H_8O_2$ (f) Ethers with formula $C_4H_{10}O$

PROBLEM Draw compounds that contain the following:

- 3-32** (a) A primary alcohol (b) A tertiary nitrile (c) A secondary thiol
 (d) Both primary and secondary alcohols (e) An isopropyl group (f) A quaternary carbon

Naming Compounds

PROBLEM Draw and name all monobromo derivatives of pentane, $C_5H_{11}Br$.

3-33

PROBLEM Draw and name all monochloro derivatives of 2,5-dimethylhexane, $C_8H_{17}Cl$.

3-34

PROBLEM Draw structures for the following:

- 3-35** (a) 2-Methylheptane (b) 4-Ethyl-2,2-dimethylhexane (c) 4-Ethyl-3,4-dimethyloctane
 (d) 2,4,4-Trimethylheptane (e) 3,3-Diethyl-2,5-dimethylnonane
 (f) 4-Isopropyl-3-methylheptane

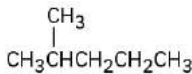

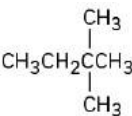

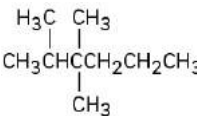

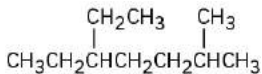

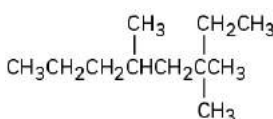

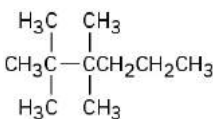

PROBLEM Draw a compound that:

- 3-36** (a) Has only primary and tertiary carbons (b) Has no secondary or tertiary carbons
 (c) Has no secondary or tertiary carbons

PROBLEM Draw a compound that:

- 3-37** (a) Has nine primary hydrogens (b) Has only primary hydrogens

PROBLEM Give IUPAC names for the following compounds:

- 3-38** (a)  (b)  (c)  (d) 
 (e)  (f) 

PROBLEM Name the five isomers of C_6H_{14} .

3-39

PROBLEM Explain why each of the following names is incorrect:

- 3-40** (a) 2,2-Dimethyl-6-ethylheptane (b) 4-Ethyl-5,5-dimethylpentane
 (c) 3-Ethyl-4,4-dimethylhexane (d) 5,5,6-Trimethyloctane (e) 2-Isopropyl-4-methylheptane

PROBLEM Propose structures and give IUPAC names for the following:

- 3-41** (a) A diethyldimethylhexane (b) A (3-methylbutyl)-substituted alkane

Conformations

PROBLEM Consider 2-methylbutane (isopentane). Sighting along the C_2-C_3 bond:

- 3-42** (a) Draw a Newman projection of the most stable conformation.
 (b) Draw a Newman projection of the least stable conformation.
 (c) If a $CH_3 \leftrightarrow CH_3$ eclipsing interaction costs 11 kJ/mol (2.5 kcal/mol) and a $CH_3 \leftrightarrow CH_3$ gauche interaction costs 3.8 kJ/mol (0.9 kcal/mol), make a quantitative plot of energy versus rotation about the C_2-C_3 bond.

PROBLEM 3-43 What are the relative energies of the three possible staggered conformations around the C2–C3 bond in 2,3-dimethylbutane? (See Problem 3-42.)

PROBLEM 3-44 Construct a qualitative potential-energy diagram for rotation about the C–C bond of 1,2-dibromoethane. Which conformation would you expect to be most stable? Label the anti and gauche conformations of 1,2-dibromoethane.

PROBLEM 3-45 Which conformation of 1,2-dibromoethane (Problem 3-44) would you expect to have the largest dipole moment? The observed dipole moment of 1,2-dibromoethane is $\mu = 1.0$ D. What does this tell you about the actual conformation of the molecule?

PROBLEM 3-46 Draw the most stable conformation of pentane, using wedges and dashes to represent bonds coming out of the paper and going behind the paper, respectively.

PROBLEM 3-47 Draw the most stable conformation of 1,4-dichlorobutane, using wedges and dashes to represent bonds coming out of the paper and going behind the paper, respectively.

General Problems

PROBLEM 3-48 For each of the following compounds, draw an isomer that has the same functional groups.

PROBLEM 3-49 Malic acid, $\text{C}_4\text{H}_6\text{O}_5$, has been isolated from apples. Because this compound reacts with 2 molar equivalents of base, it is a dicarboxylic acid.

- (a) Draw at least five possible structures.
 (b) If malic acid is a secondary alcohol, what is its structure?

PROBLEM 3-50 Formaldehyde, $\text{H}_2\text{C}=\text{O}$, is known to all biologists because of its usefulness as a tissue preservative.

When pure, formaldehyde trimerizes to give trioxane, $\text{C}_3\text{H}_6\text{O}_3$, which, surprisingly enough, has no carbonyl groups. Only one monobromo derivative ($\text{C}_3\text{H}_5\text{BrO}_3$) of trioxane is possible. Propose a structure for trioxane.

PROBLEM 3-51 The barrier to rotation about the C–C bond in bromoethane is 15 kJ/mol (3.6 kcal/mol).

- (a) What energy value can you assign to an H \leftrightarrow Br eclipsing interaction?
 (b) Construct a quantitative diagram of potential energy versus bond rotation for bromoethane.

PROBLEM 3-52 Increased substitution around a bond leads to increased strain. Take the four substituted butanes listed below, for example. For each compound, sight along the C2–C3 bond and draw Newman projections of the most stable and least stable conformations. Use the data in Table 3.5 to assign strain-energy values to each conformation. Which of the eight conformations is most strained? Which is least strained?

- (a) 2-Methylbutane (b) 2,2-Dimethylbutane (c) 2,3-Dimethylbutane
 (d) 2,2,3-Trimethylbutane

PROBLEM 3-53 The cholesterol-lowering agents called *statins*, such as simvastatin (Zocor) and pravastatin (Pravachol), are among the most widely prescribed drugs in the world, with annual sales estimated at approximately \$25 billion. Identify the functional groups in both, and tell how the two substances differ.

PROBLEM 3-54 In the next chapter we'll look at *cycloalkanes*—saturated cyclic hydrocarbons—and we'll see that the molecules generally adopt puckered, nonplanar conformations. Cyclohexane, for instance, has a puckered shape like a lounge chair rather than a flat shape. Why?

PROBLEM 3-55 We'll see in the next chapter that there are two isomeric substances, both named 1,2-dimethylcyclohexane. Explain.

CHAPTER 4

Organic Compounds: Cycloalkanes and Their Stereochemistry

WHY THIS CHAPTER? We'll see numerous instances in future chapters where the chemistry of a given functional group is affected by being in a ring rather than an open chain. Because cyclic molecules are encountered in most pharmaceuticals and in all classes of biomolecules, including proteins, lipids, carbohydrates, and nucleic acids, it's important to understand the behavior of cyclic structures.

Although we've only discussed open-chain compounds up to now, most organic compounds contain *rings* of carbon atoms. Chrysanthemic acid, for instance, whose esters occur naturally as the active insecticidal constituents of chrysanthemum flowers, contains a three-membered (cyclopropane) ring.

Prostaglandins, potent hormones that control an extraordinary variety of physiological functions in humans, contain a five-membered (cyclopentane) ring.

Steroids, such as cortisone, contain four rings joined together—three six-membered (cyclohexane) and one five-membered. We'll discuss steroids and their properties in more detail in **Sections 27.6** and **27.7**.

4.1 Naming Cycloalkanes

Saturated cyclic hydrocarbons are called **cycloalkanes**, or **alicyclic** compounds (**aliphatic cyclic**). Because cycloalkanes consist of rings of $-\text{CH}_2-$ units, they have the general formula $(\text{CH}_2)_n$, or C_nH_{2n} , and can be represented by polygons in skeletal drawings.

Substituted cycloalkanes are named by rules similar to those we saw in (**Section 3.4**) for open-chain alkanes. For most compounds, there are only two steps.

STEP 1

Find the parent.

Count the number of carbon atoms in the ring and the number in the largest substituent. If the number of carbon atoms in the ring is equal to or greater than the number in the substituent, the compound is named as an alkyl-substituted cycloalkane. If the number of carbon atoms in the largest substituent is greater than the number in the ring, the compound is named as a cycloalkyl-substituted alkane. For example:

STEP 2**Number the substituents, and write the name.**

For an alkyl- or halo-substituted cycloalkane, choose a point of attachment as carbon 1 and number the substituents on the ring so that the *second* substituent has as low a number as possible. If ambiguity still exists, number so that the third or fourth substituent has as low a number as possible, until a point of difference is found.

(a) When two or more different alkyl groups are present that could potentially take the same numbers, number them by alphabetical priority, ignoring numerical prefixes such as di- and tri-.

(b) If halogens are present, treat them just like alkyl groups.

Some additional examples follow:

1-Bromo-3-ethyl-5-methylcyclohexane

(1-Methylpropyl)cyclobutane or sec-butylcyclobutane

1-Chloro-3-ethyl-2-methylcyclopentane

PROBLEM Give IUPAC names for the following cycloalkanes:

PROBLEM Draw structures corresponding to the following IUPAC names:

- 4-2 (a)** 1,1-Dimethylcyclooctane **(b)** 3-Cyclobutylhexane **(c)** 1,2-Dichlorocyclopentane
(d) 1,3-Dibromo-5-methylcyclohexane

PROBLEM Name the following cycloalkane:

4-3

4.2 Cis-Trans Isomerism in Cycloalkanes

In many respects, the chemistry of cycloalkanes is like that of open-chain alkanes: both are nonpolar and fairly inert. There are, however, some important differences. One difference is that cycloalkanes are less flexible than open-chain alkanes. In contrast with the relatively free rotation around single bonds in open-chain alkanes (Section 3.6 and Section 3.7), there is much less freedom in cycloalkanes. Cyclopropane, for example, must be a rigid, planar molecule because three points (the carbon atoms) define a plane. No bond rotation can take place around a cyclopropane carbon-carbon bond without breaking open the ring (FIGURE 4.2).

FIGURE 4.2 Bond rotation in ethane and cyclopropane. **(a)** Rotation occurs around the carbon-carbon bond in ethane, but **(b)** no rotation is possible around the carbon-carbon bonds in cyclopropane without breaking open the ring.

Larger cycloalkanes have increasing rotational freedom, and very large rings (C_{25} and up) are so floppy that they are nearly indistinguishable from open-chain alkanes. The common ring sizes (C_3 – C_7), however, are severely restricted in their molecular motions.

Because of their cyclic structures, cycloalkanes have two faces when viewed edge-on, a “top” face and a “bottom” face. As a result, isomerism is possible in substituted cycloalkanes. For example, there are two different 1,2-dimethylcyclopropane isomers, one with the two methyl groups on the same face of the ring and one with the methyl groups on opposite faces (FIGURE 4.3). Both isomers are stable compounds, and neither can be converted into the other without breaking and reforming chemical bonds.

FIGURE 4.3 There are two different 1,2-dimethylcyclopropane isomers, one with the methyl groups on the same face of the ring (*cis*) and the other with the methyl groups on opposite faces of the ring (*trans*). The two isomers do not interconvert.

Unlike the constitutional isomers butane and isobutane, which have their atoms connected in a different order (Section 3.2), the two 1,2-dimethylcyclopropanes have the same order of connections but differ in the spatial orientation of the atoms. Such compounds, with atoms connected in the same order but differing in three-dimensional orientation, are called stereochemical isomers, or **stereoisomers**. As we saw in Section 3.6, the term stereochemistry is used generally to refer to the three-dimensional aspects of structure and reactivity.

Constitutional isomers
(different connections
between atoms)

Stereoisomers
(same connections
but different three-
dimensional geometry)

The 1,2-dimethylcyclopropanes are members of a subclass of stereoisomers called **cis-trans isomers**. The prefixes *cis*- (Latin “on the same side”) and *trans*- (Latin “across”) are used to distinguish between them. Cis-trans isomerism is a common occurrence in substituted cycloalkanes and in many cyclic biological molecules.

WORKED EXAMPLE 4.1

Naming Cycloalkanes

Name the following substances, including the *cis*- or *trans*- prefix:

Strategy

In these views, the ring is roughly in the plane of the page, a wedged bond protrudes out of the page, and a dashed bond recedes into the page. Two substituents are *cis* if they are both out of or both into the page, and they are *trans* if one is out of and one is into the page.

Are the two hydroxyl groups ($-OH$) on the cyclopentane ring *cis* or *trans* to each other? What about the two carbon chains attached to the ring?**PROBLEM** Name the following substances, including the *cis*- or *trans*- prefix (red-brown = Br):

4.3 Stability of Cycloalkanes: Ring Strain

Chemists in the late 1800s knew that cyclic molecules existed, but the limitations on ring size were unclear. Although numerous compounds containing five-membered and six-membered rings were known, smaller and larger ring sizes had not been prepared, despite many attempts.

A theoretical interpretation of this observation was proposed in 1885 by Adolf von Baeyer, who suggested that small and large rings might be unstable due to **angle strain**—the strain induced in a molecule when bond angles are forced to deviate from the ideal 109° tetrahedral value. Baeyer based his suggestion on the simple geometric notion that a three-membered ring (cyclopropane) should be an equilateral triangle with bond angles of 60° rather than 109° , a four-membered ring (cyclobutane) should be a square with bond angles of 90° , a five-membered ring should be a regular pentagon with bond angles of 108° , and so on. Continuing this argument, large rings should be strained by having bond angles that are much greater than 109° .

What are the facts? To measure the amount of strain in a compound, we have to measure the total energy of the compound and then subtract the energy of a strain-free reference compound. The difference between the two values should represent the amount of extra energy in the molecule due to strain. The simplest experimental way to do this for a cycloalkane is to measure its *heat of combustion*, the amount of heat released when the compound burns completely with oxygen. The more energy (strain) the compound contains, the more energy (heat) is released by combustion.

Because the heat of combustion of a cycloalkane depends on size, we need to look at heats of combustion per CH_2 unit. Subtracting a reference value derived from a strain-free acyclic alkane and then multiplying by the number of CH_2 units in the ring gives the overall strain energy. **FIGURE 4.4** shows the results.

FIGURE 4.4 Cycloalkane strain energies, as calculated by taking the difference between cycloalkane heat of combustion per CH_2 and acyclic alkane heat of combustion per CH_2 , and multiplying by the number of CH_2 units in a ring. Small and medium rings are strained, but cyclohexane rings and very large rings are strain-free.

The data in **FIGURE 4.4** show that Baeyer's theory is only partially correct. Cyclopropane and cyclobutane are indeed strained, just as predicted, but cyclopentane is more strained than predicted, and cyclohexane is strain-free. Cycloalkanes of intermediate size have only modest strain, and rings of 14 carbons or more are strain-free. Why is Baeyer's theory wrong?

Baeyer's theory is wrong for the simple reason that he assumed all cycloalkanes to be flat. In fact, as we'll see in the next section, most cycloalkanes are not flat; instead, they adopt puckered three-dimensional conformations that allow bond angles to be nearly tetrahedral. As a result, angle strain occurs only in three- and four-membered rings, which have little flexibility. For most ring sizes, particularly the medium-ring (C_7 – C_{11}) cycloalkanes, torsional strain caused by $\text{H} \leftrightarrow \text{H}$ eclipsing interactions at adjacent carbons (**Section 3.6**) and steric strain caused by the repulsion between nonbonded atoms that approach too closely (**Section 3.7**) are the most important factors. Thus, three kinds of strain contribute to the overall energy of a cycloalkane.

- **Angle strain**—the strain due to expansion or compression of bond angles
- **Torsional strain**—the strain due to eclipsing of bonds between neighboring atoms
- **Steric strain**—the strain due to repulsive interactions when atoms approach each other too closely

PROBLEM 4-8 Each $\text{H} \leftrightarrow \text{H}$ eclipsing interaction in ethane costs about 4.0 kJ/mol. How many such interactions are present in cyclopropane? What fraction of the overall 115 kJ/mol (27.5 kcal/mol) strain energy of cyclopropane is due to torsional strain?

PROBLEM 4-9 *cis*-1,2-Dimethylcyclopropane has more strain than *trans*-1,2-dimethylcyclopropane. How can you account for this difference? Which of the two compounds is more stable?

4.4 Conformations of Cycloalkanes

Cyclopropane

Cyclopropane is the most strained of all rings, primarily due to the angle strain caused by its 60° C–C–C bond angles. In addition, cyclopropane has considerable torsional strain because the C–H bonds on neighboring carbon atoms are eclipsed (FIGURE 4.5).

FIGURE 4.5 The structure of cyclopropane, showing the eclipsing of neighboring C–H bonds that gives rise to torsional strain. Part (b) is a Newman projection along a C–C bond.

How can the hybrid-orbital model of bonding account for the large distortion of bond angles from the normal 109° tetrahedral value to 60° in cyclopropane? The answer is that cyclopropane has *bent bonds*. In an unstrained alkane, maximum bonding is achieved when two atoms have their overlapping orbitals pointing directly toward each other. In cyclopropane, though, the orbitals can't point directly toward each other; instead, they overlap at a slight angle. The result is that cyclopropane bonds are weaker and more reactive than typical alkane bonds— 255 kJ/mol (61 kcal/mol) for a C–C bond in cyclopropane versus 370 kJ/mol (88 kcal/mol) for a C–C bond in open-chain propane.

Cyclobutane

Cyclobutane has less angle strain than cyclopropane but has more torsional strain because of its larger number of ring hydrogens. As a result, the total strain for the two compounds is nearly the same— 110 kJ/mol (26.4 kcal/mol) for cyclobutane versus 115 kJ/mol (27.5 kcal/mol) for cyclopropane. Cyclobutane is not quite flat but is slightly bent so that one carbon atom lies about 25° above the plane of the other three (FIGURE 4.6). The effect of this slight bend is to increase angle strain but to decrease torsional strain, until a minimum-energy balance between the two opposing effects is achieved.

FIGURE 4.6 The conformation of cyclobutane. Part (c) is a Newman projection along a C–C bond, showing that neighboring C–H bonds are

not quite eclipsed.

Cyclopentane

Cyclopentane was predicted by Baeyer to be nearly strain-free, but it actually has a total strain energy of 26 kJ/mol (6.2 kcal/mol). Although planar cyclopentane has practically no angle strain, it has a large torsional strain. Cyclopentane therefore twists to adopt a puckered, nonplanar conformation that strikes a balance between increased angle strain and decreased torsional strain. Four of the cyclopentane carbon atoms are in approximately the same plane, with the fifth carbon atom bent out of the plane. Most of the hydrogens are nearly staggered with respect to their neighbors (FIGURE 4.7).

FIGURE 4.7 The conformation of cyclopentane. Carbons 1, 2, 3, and 4 are nearly coplanar, but carbon 5 is out of the plane. Part (c) is a Newman projection along the C1–C2 bond, showing that neighboring C–H bonds are nearly staggered.

PROBLEM 4-10 How many H ↔ H eclipsing interactions would be present if cyclopentane were planar? Assuming an energy cost of 4.0 kJ/mol for each eclipsing interaction, how much torsional strain would planar cyclopentane have? Since the measured total strain of cyclopentane is 26 kJ/mol, how much of the torsional strain is relieved by puckering?

PROBLEM 4-11 Two conformations of *cis*-1,3-dimethylcyclobutane are shown. What is the difference between them, and which do you think is likely to be more stable?

4.5 Conformations of Cyclohexane

Substituted cyclohexanes are the most common cycloalkanes and occur widely in nature. A large number of compounds, including steroids and many pharmaceutical agents, have cyclohexane rings. The flavoring agent menthol, for instance, has three substituents on a six-membered ring.

Cyclohexane adopts a strain-free, three-dimensional shape that is called a **chair conformation** because of its similarity to a lounge chair, with a back, seat, and footrest (**FIGURE 4.8**). Chair cyclohexane has neither angle strain nor torsional strain—all C–C–C bond angles are near the 109° tetrahedral value, and all neighboring C–H bonds are staggered.

FIGURE 4.8 The strain-free chair conformation of cyclohexane. All C–C–C bond angles are 111.5° , close to the ideal 109° tetrahedral angle, and all neighboring C–H bonds are staggered.

The easiest way to visualize chair cyclohexane is to build a molecular model if you have access to a model kit, or alternatively to explore with one of the many computer-based modeling programs you may have access to.

The chair conformation of cyclohexane can be drawn in three steps.

STEP 1

Draw two parallel lines, slanted downward and slightly offset from each other. This means that four of the cyclohexane carbons lie in a plane.

STEP 2

Place the topmost carbon atom above and to the right of the plane of the other four, and connect the bonds.

STEP 3

Place the bottommost carbon atom below and to the left of the plane of the middle four, and connect the bonds. Note that the bonds to the bottommost carbon atom are parallel to the bonds to the topmost carbon.

When viewing cyclohexane, it's helpful to remember that the lower bond is in front and the upper bond is in back. If this convention isn't defined, it can appear that the reverse is true. For clarity, all cyclohexane rings drawn in this book will have the front (lower) bond heavily shaded to indicate nearness to the viewer.

In addition to the chair conformation of cyclohexane, there is an alternative conformation of cyclohexane that bears a slight resemblance to a twisted boat. Called the **twist-boat conformation**, it is nearly free of angle strain. It does, however, have both steric strain and torsional strain and is about 23 kJ/mol (5.5 kcal/mol) higher in

energy than the chair conformation. As a result, molecules adopt the twist-boat geometry only rarely.

4.6 Axial and Equatorial Bonds in Cyclohexane

The chair conformation of cyclohexane has many consequences. We'll see in **Section 11.9**, for instance, that the chemical behavior of many substituted cyclohexanes is influenced by their conformation. In addition, we'll see in **Section 25.5** that simple carbohydrates, such as glucose, adopt a conformation based on the cyclohexane chair and that their chemistry is directly affected as a result.

Another trait of the chair conformation is that there are two kinds of positions for substituents on the cyclohexane ring: *axial* positions and *equatorial* positions (as shown in **FIGURE 4.9**). The six **axial** positions are parallel to the ring **axis**, while the six **equatorial** positions are in the rough plane of the ring, around the ring **equator**.

FIGURE 4.9 Axial and equatorial positions in chair cyclohexane. The six axial hydrogens are parallel to the ring axis, and the six equatorial hydrogens are in a band around the ring equator.

As shown in **FIGURE 4.9**, each carbon atom in chair cyclohexane has one axial and one equatorial hydrogen. Furthermore, each side of the ring has three axial and three equatorial hydrogens in an alternating arrangement. For example, if the top side of the ring has axial hydrogens on carbons 1, 3, and 5, then it has equatorial hydrogens on carbons 2, 4, and 6. The reverse is true for the bottom side: carbons 1, 3, and 5 have equatorial hydrogens, but carbons 2, 4, and 6 have axial hydrogens (**FIGURE 4.10**).

FIGURE 4.10 Alternating axial and equatorial positions in chair cyclohexane, looking directly down the ring axis. Each carbon atom has one axial and one equatorial position, and each face has alternating axial and equatorial positions.

Note that we haven't used the words *cis* and *trans* in this discussion of cyclohexane conformation. Two hydrogens on the same side of the ring are always *cis*, regardless of whether they're axial or equatorial and regardless of whether they're adjacent. Similarly, two hydrogens on opposite sides of the ring are always *trans*.

Axial and equatorial bonds can be drawn following the procedure shown in **FIGURE 4.11**. If possible, look at a molecular model as you practice.

FIGURE 4.11 A procedure for drawing axial and equatorial bonds in chair cyclohexane.

Because chair cyclohexane has two kinds of positions—axial and equatorial—we might expect to find two isomeric forms of a monosubstituted cyclohexane. In fact, we don't. There is only one methylcyclohexane, one bromocyclohexane, one cyclohexanol (hydroxycyclohexane), and so on, because cyclohexane rings are conformationally mobile at room temperature. Different chair conformations readily interconvert, exchanging axial and equatorial positions. This interconversion, called a **ring-flip**, is shown in **FIGURE 4.12**.

FIGURE 4.12 A ring-flip in chair cyclohexane interconverts axial and equatorial positions. What is **axial** in the starting structure becomes **equatorial** in the ring-flipped structure, and what is **equatorial** in the starting structure is **axial** after ring-flip.

As shown in **FIGURE 4.12**, a chair cyclohexane can be ring-flipped by keeping the middle four carbon atoms in place while folding the two end carbons in opposite directions. In so doing, an axial substituent in one chair form becomes an equatorial substituent in the ring-flipped chair form and vice versa. For example, axial bromocyclohexane becomes equatorial bromocyclohexane after a ring-flip. Since the energy barrier to chair–chair interconversion is only about 45 kJ/mol (10.8 kcal/mol), the process is rapid at room temperature and we see what appears to be a single structure rather than distinct axial and equatorial isomers.

WORKED EXAMPLE 4.2

Drawing the Chair Conformation of a Substituted Cyclohexane

Draw 1,1-dimethylcyclohexane in a chair conformation, indicating which methyl group in your drawing is axial and which is equatorial.

Strategy

Draw a chair cyclohexane ring using the procedure in **FIGURE 4.11**, and then put two methyl groups on the same carbon. The methyl group in the rough plane of the ring is equatorial, and the one directly above or below the ring is axial.

Solution

PROBLEM 4-12 Draw two different chair conformations of cyclohexanol (hydroxycyclohexane), showing all hydrogen atoms. Identify each position as axial or equatorial.

PROBLEM 4-13 Draw two different chair conformations of *trans*-1,4-dimethylcyclohexane, and label all positions as axial or equatorial.

PROBLEM 4-14 Identify each of the colored positions—red, blue, and green—as axial or equatorial. Then carry out a ring-flip, and show the new positions occupied by each color.

4.7 Conformations of Monosubstituted Cyclohexanes

Even though cyclohexane rings flip rapidly between chair conformations at room temperature, the two conformations of a monosubstituted cyclohexane aren't equally stable. In methylcyclohexane, for instance, the equatorial conformation is more stable than the axial conformation by 7.6 kJ/mol (1.8 kcal/mol). The same is true of other monosubstituted cyclohexanes: a substituent is almost always more stable in an equatorial position than in an axial position.

You might recall from your general chemistry course that it's possible to calculate the percentages of two isomers at equilibrium using the equation $\Delta E = -RT \ln K$, where ΔE is the energy difference between isomers, R is the gas constant [8.315 J/(K·mol)], T is the Kelvin temperature, and K is the equilibrium constant between isomers. For example, an energy difference of 7.6 kJ/mol means that about 95% of methylcyclohexane molecules have an equatorial methyl group at any given instant while only 5% have an axial methyl group.

FIGURE 4.13 plots the relationship between energy and isomer percentages.

FIGURE 4.13 A plot of the percentages of two isomers at equilibrium versus the energy difference between them. The curves are calculated using the equation $\Delta E = -RT \ln K$.

The energy difference between axial and equatorial conformations is due to steric strain caused by **1,3-diaxial interactions**. The axial methyl group on C1 is too close to the axial hydrogens three carbons away on C3 and C5, resulting in 7.6 kJ/mol of steric strain (**FIGURE 4.14**).

FIGURE 4.14 Interconversion of axial and equatorial methylcyclohexane, represented in several formats. The equatorial conformation is more stable than the axial conformation by 7.6 kJ/mol.

The 1,3-diaxial steric strain in substituted methylcyclohexane is already familiar—we saw it previously as the steric strain between methyl groups in gauche in [Section 3.7](#). Gauche butane is less stable than anti butane by 3.8 kJ/mol (0.9 kcal/mol) because of steric interference between hydrogen atoms on the two methyl groups. Comparing a four-carbon fragment of axial methylcyclohexane with gauche butane shows that the steric interaction is the same in both ([FIGURE 4.15](#)). Because axial methylcyclohexane has two such interactions, it has $2 \times 3.8 = 7.6$ kJ/mol of steric strain. Equatorial methylcyclohexane has no such interactions and is therefore more stable.

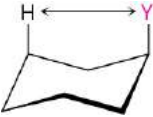

FIGURE 4.15 The origin of 1,3-diaxial interactions in methylcyclohexane. The steric strain between an axial methyl group and an axial hydrogen atom three carbons away is identical to the steric strain in gauche butane. (To display clearly the diaxial interactions in methylcyclohexane, two of the equatorial hydrogens are not shown.)

The exact amount of 1,3-diaxial steric strain in a given substituted cyclohexane depends on the nature and size of the substituent, as indicated in [TABLE 4.1](#). Not surprisingly, the amount of steric strain increases through the series $\text{H}_3\text{C}- < \text{CH}_3\text{CH}_2- < (\text{CH}_3)_2\text{CH}- < (\text{CH}_3)_3\text{C}-$, paralleling the increasing size of the alkyl groups. Note that the values given in [TABLE 4.1](#) refer to 1,3-diaxial interactions of the substituent with a single hydrogen atom. These values must be doubled to arrive at the amount of strain in a monosubstituted cyclohexane.

TABLE 4.1 Steric Strain in Monosubstituted Cyclohexanes

1,3-Diaxial strain		
Y	(kJ/mol) (kcal/mol)	
F	0.5 (0.12)	

TABLE 4.1 Steric Strain in Monosubstituted Cyclohexanes

Y	1,3-Diaxial strain		
	(kJ/mol)	(kcal/mol)	
Cl, Br	1.0	0.25	
OH	2.1	0.5	
CH ₃	3.8	0.9	
CH ₂ CH ₃	4.0	0.95

C(CH ₃) ₃	11.4	2.7	
C ₆ H ₅	6.3	1.5	
CO ₂ H	2.9	0.7	
CN	0.4	0.1	

PROBLEM 4-15 What is the energy difference between the axial and equatorial conformations of cyclohexanol (hydroxycyclohexane)?

PROBLEM 4-16 Why do you suppose an axial cyano (–CN) substituent causes practically no 1,3-diaxial steric strain (0.4 kJ/mol)?

PROBLEM 4-17 Look back at Figure 4.13 and estimate the percentages of axial and equatorial conformations present at equilibrium in bromocyclohexane.

4.8 Conformations of Disubstituted Cyclohexanes

Monosubstituted cyclohexanes are always more stable with their substituent in an equatorial position, but the situation with disubstituted cyclohexanes is more complex because the steric effects of both substituents must be taken into account. All steric interactions for both possible chair conformations must be analyzed before deciding which conformation is favored.

Let's look at 1,2-dimethylcyclohexane as an example. There are two isomers, *cis*-1,2-dimethylcyclohexane and *trans*-1,2-dimethylcyclohexane, which must be considered separately. In the *cis* isomer, both methyl groups are on the same face of the ring and the compound can exist in either of the two chair conformations shown in **FIGURE 4.16**. (It may be easier for you to see whether a compound is *cis*- or *trans*-disubstituted by first drawing the ring as a flat representation and then converting it to a chair conformation.)

interactions (7.6 kJ/mol)

Total strain: 3.8 + 7.6 = 11.4 kJ/mol

FIGURE 4.16 Conformations of *cis*-1,2-dimethylcyclohexane. The two chair conformations are equal in energy because each has one axial methyl group and one equatorial methyl group.

Both chair conformations of *cis*-1,2-dimethylcyclohexane have one axial methyl group and one equatorial methyl group. The top conformation in **FIGURE 4.16** has an axial methyl group at C2, which has 1,3-diaxial interactions with hydrogens on C4 and C6. The ring-flipped conformation has an axial methyl group at C1, which has 1,3-diaxial interactions with hydrogens on C3 and C5. In addition, both conformations have gauche butane interactions between the two methyl groups. The two conformations are equal in energy, with a total steric strain of $3 \times 3.8 \text{ kJ/mol} = 11.4 \text{ kJ/mol}$ (2.7 kcal/mol).

In *trans*-1,2-dimethylcyclohexane, the two methyl groups are on opposite sides of the ring and the compound can exist in either of the two chair conformations shown in **FIGURE 4.17**. The situation here is quite different from that of the *cis* isomer. The top conformation in **FIGURE 4.17** has both methyl groups equatorial with only a gauche butane interaction between them (3.8 kJ/mol) but no 1,3-diaxial interactions. The ring-flipped conformation, however, has both methyl groups axial. The axial methyl group at C1 interacts with axial hydrogens at C3 and C5, and the axial methyl group at C2 interacts with axial hydrogens at C4 and C6. These four 1,3-diaxial interactions produce a steric strain of $4 \times 3.8 \text{ kJ/mol} = 15.2 \text{ kJ/mol}$ and make the diaxial conformation $15.2 - 3.8 = 11.4 \text{ kJ/mol}$ less favorable than the diequatorial conformation. We therefore predict that *trans*-1,2-dimethylcyclohexane will exist almost exclusively in the diequatorial conformation.

***trans*-1,2-Dimethylcyclohexane**

One gauche
interaction (3.8 kJ/mol)

↕ Ring-flip

Four CH₃ ↔ H diaxial
interactions (15.2 kJ/mol)

FIGURE 4.17 Conformations of *trans*-1,2-dimethylcyclohexane. The conformation with both methyl groups equatorial (top) is favored by 11.4 kJ/mol (2.7 kcal/mol) over the conformation with both methyl groups axial (bottom).

The same kind of **conformational analysis** just carried out for *cis*- and *trans*-1,2-dimethylcyclohexane can be done for any substituted cyclohexane, such as *cis*-1-*tert*-butyl-4-chlorocyclohexane (see **Worked Example 4.3**).

As you might imagine, though, the situation becomes more complex as the number of substituents increases. For instance, compare glucose with mannose, a carbohydrate present in seaweed. Which do you think is more strained? In glucose, all substituents on the six-membered ring are equatorial, while in mannose, one of the -OH groups is axial, making it more strained.

A summary of the various axial and equatorial relationships among substituent groups in the different possible cis and trans substitution patterns for disubstituted cyclohexanes is given in [TABLE 4.2](#).

TABLE 4.2 Axial and Equatorial Relationships in Cis- and Trans-Disubstituted Cyclohexanes

Cis/trans substitution pattern	Axial/equatorial relationships	
1,2-Cis disubstituted	a,e	or e,a
1,2-Trans disubstituted	a,a	or e,e
1,3-Cis disubstituted	a,a	or e,e
1,3-Trans disubstituted	a,e	or e,a
1,4-Cis disubstituted	a,e	or e,a
1,4-Trans disubstituted	a,a	or e,e

WORKED EXAMPLE 4.3

Drawing the Most Stable Conformation of a Substituted Cyclohexane

Draw the more stable chair conformation of *cis*-1-*tert*-butyl-4-chlorocyclohexane. By how much is it favored?

Strategy

Draw the two possible chair conformations, and calculate the strain energy in each. Remember that equatorial substituents cause less strain than axial substituents.

Solution

First draw the two chair conformations of the molecule:

In the conformation on the left, the *tert*-butyl group is equatorial and the chlorine is axial. In the conformation

on the right, the *tert*-butyl group is axial and the chlorine is equatorial. These conformations aren't of equal energy because an axial *tert*-butyl substituent and an axial chloro substituent produce different amounts of steric strain. TABLE 4.1 shows that the 1,3-diaxial interaction between a hydrogen and a *tert*-butyl group costs 11.4 kJ/mol (2.7 kcal/mol), whereas the interaction between a hydrogen and a chlorine costs only 1.0 kJ/mol (0.25 kcal/mol). An axial *tert*-butyl group therefore produces $(2 \times 11.4 \text{ kJ/mol}) - (2 \times 1.0 \text{ kJ/mol}) = 20.8 \text{ kJ/mol}$ (4.9 kcal/mol) more steric strain than an axial chlorine, and the compound preferentially adopts the conformation with the chlorine axial and the *tert*-butyl equatorial.

PROBLEM Draw the more stable chair conformation of the following molecules, and estimate the amount of strain in each:

4-18

- (a) *trans*-1-Chloro-3-methylcyclohexane (b) *cis*-1-Ethyl-2-methylcyclohexane
 (c) *cis*-1-Bromo-4-ethylcyclohexane (d) *cis*-1-*tert*-Butyl-4-ethylcyclohexane

PROBLEM Identify each substituent in the following compound as axial or equatorial, and tell whether the conformation shown is the more stable or less stable chair form (green = Cl):

4-19

4.9 Conformations of Polycyclic Molecules

The final point we'll consider about cycloalkane stereochemistry is to see what happens when two or more cycloalkane rings are fused together along a common bond to construct a **polycyclic molecule**—for example, decalin.

Decalin—two fused cyclohexane rings

Decalin consists of two cyclohexane rings joined to share two carbon atoms (the *bridgehead* carbons, C1 and C6) and a common bond. Decalin can exist in either of two isomeric forms, depending on whether the rings are *trans* fused or *cis* fused. In *cis*-decalin, the hydrogen atoms at the bridgehead carbons are on the same side of the rings; in *trans*-decalin, the bridgehead hydrogens are on opposite sides. FIGURE 4.18 shows how both compounds can be represented using chair cyclohexane conformations. Note that the two decalin isomers are not interconvertible by ring-flips or other rotations. They are *cis*–*trans* stereoisomers and have the same relationship to each other that *cis*- and *trans*-1,2-dimethylcyclohexane have.

FIGURE 4.18 Representations of *cis*- and *trans*-decalin. Hydrogen atoms at the bridgehead carbons are on the same face of the rings in the *cis* isomer but on opposite faces in the *trans* isomer.

Polycyclic compounds are common in nature, and many valuable substances have fused-ring structures. For example, steroids, such as testosterone, the primary sex hormone in males, have three six-membered rings and one five-membered ring fused together. Although steroids look complicated compared with cyclohexane or decalin, the same principles that apply to the conformational analysis of simple cyclohexane rings apply equally well (and often better) to steroids.

Another common ring system is the norbornane, or bicyclo[2.2.1]heptane, structure. Like decalin, norbornane is a bicycloalkane, so called because two rings would have to be broken open to generate an acyclic structure. Its systematic name, bicyclo[2.2.1]heptane, reflects the fact that the molecule has seven carbons, is bicyclic, and has three “bridges” of 2, 2, and 1 carbon atoms connecting the two bridgehead carbons.

Norbornane has a conformationally locked boat cyclohexane ring (Section 4.5) in which carbons 1 and 4 are joined by an additional CH_2 group. In drawing this structure, a break in the rear bond indicates that the vertical bond crosses in front of it. Making a molecular model is particularly helpful when trying to see the three-

dimensionality of norbornane.

Substituted norbornanes, such as camphor, are found widely in nature, and many have been important historically in developing organic structural theories.

PROBLEM Which isomer is more stable, *cis*-decalin or *trans*-decalin (Figure 4.18)? Explain.

4-20

PROBLEM Look at the following structure of estrone, the primary sex hormone in females, and tell whether

4-21 each of the two indicated (red) ring-fusions is *cis* or *trans*.

CHEMISTRY MATTERS

Molecular Mechanics

All the structural models in this book are computer-drawn. To make sure they accurately represent bond angles, bond lengths, torsional interactions, and steric interactions, the most stable geometry of each molecule has been calculated on a desktop computer using a commercially available *molecular mechanics* program based on work by Norman Allinger at the University of Georgia.

The idea behind molecular mechanics is to begin with a rough geometry for a molecule and then calculate a total strain energy for that starting geometry, using mathematical equations that assign values to specific kinds of molecular interactions. Bond angles that are too large or too small cause angle strain; bond lengths that are too short or too long cause stretching or compressing strain; unfavorable eclipsing interactions around single bonds cause torsional strain; and nonbonded atoms that approach each other too closely cause steric, or *van der Waals*, strain.

$$E_{\text{total}} = E_{\text{bond stretching}} + E_{\text{angle strain}} + E_{\text{torsional strain}} + E_{\text{van der Waals}}$$

FIGURE 4.19 Computer programs make it possible to accurately represent molecular geometry. (Credit: “Molecular geometry” by Jane Whitney/Flickr, CC BY 4.0)

After calculating a total strain energy for the starting geometry, the program automatically changes the geometry slightly in an attempt to lower strain—perhaps by lengthening a bond that is too short or decreasing an angle that is too large. Strain is recalculated for the new geometry, more changes are made, and more calculations are done. After dozens or hundreds of iterations, the calculation ultimately converges on a minimum energy that corresponds to the most favorable, least strained conformation of the molecule.

Similar calculations have proven to be particularly useful in pharmaceutical research, where a complementary fit between a drug molecule and a receptor molecule in the body is often the key to designing new pharmaceutical agents (**FIGURE 4.20**).

FIGURE 4.20 The structure of Tamiflu (oseltamivir), an antiviral agent active against type A influenza, along with a molecular model of its minimum-energy conformation as calculated by molecular mechanics.

Key Terms

- Bridgehead atom
- **chair conformation**
- **cis–trans isomers**
- **conformational analysis**
- **cycloalkanes**
- **1,3-diaxial interaction**
- **Equatorial position (cyclohexane)**
- **polycyclic molecule**
- **ring-flip (cyclohexane)**
- **stereoisomer**
- **steric strain**
- **torsional strain**
- **twist-boat conformation**

Summary

Cyclic molecules are so commonly encountered throughout organic and biological chemistry that it's important to understand the consequences of their cyclic structures. Thus, we've taken a close look at cyclic structures in this chapter.

Cycloalkanes are saturated cyclic hydrocarbons with the general formula C_nH_{2n} . In contrast to open-chain alkanes, where nearly free rotation occurs around C–C bonds, rotation is greatly reduced in cycloalkanes. Disubstituted cycloalkanes can therefore exist as **cis–trans isomers**. The cis isomer has both substituents on the same side of the ring; the trans isomer has substituents on opposite sides. Cis–trans isomers are just one kind of **stereoisomer**—compounds that have the same connections between atoms but different three-dimensional arrangements.

Not all cycloalkanes are equally stable. Three kinds of strain contribute to the overall energy of a cycloalkane: (1) **angle strain** is the resistance of a bond angle to compression or expansion from the normal 109° tetrahedral value, (2) torsional strain is the energy cost of having neighboring C–H bonds eclipsed rather than staggered, and (3) steric strain is the repulsive interaction that arises when two groups attempt to occupy the same space.

Cyclopropane (115 kJ/mol strain) and cyclobutane (110.4 kJ/mol strain) have both angle strain and torsional strain. Cyclopentane is free of angle strain but has a substantial torsional strain due to its large number of eclipsing interactions. Both cyclobutane and cyclopentane pucker slightly away from planarity to relieve torsional strain.

Cyclohexane is strain-free because it adopts a puckered **chair conformation**, in which all bond angles are near 109° and all neighboring C–H bonds are staggered. Chair cyclohexane has two kinds of positions: **axial** and **equatorial**. Axial positions are oriented up and down, parallel to the ring axis, while equatorial positions lie in a belt around the equator of the ring. Each carbon atom has one axial and one equatorial position.

Chair cyclohexanes are conformationally mobile and can undergo a **ring-flip**, which interconverts axial and equatorial positions. Substituents on the ring are more stable in the equatorial position because axial substituents cause **1,3-diaxial interactions**. The amount of 1,3-diaxial steric strain caused by an axial substituent depends on its size.

Additional Problems

Visualizing Chemistry

PROBLEM Name the following cycloalkanes:

4-22 (a)

(b)

PROBLEM Name the following compound, identify each substituent as axial or equatorial, and tell whether the

4-23 conformation shown is the more stable or less stable chair form (green = Cl):

PROBLEM A trisubstituted cyclohexane with three substituents—red, green, and blue—undergoes a ring-flip

4-24 to its alternate chair conformation. Identify each substituent as axial or equatorial, and show the positions occupied by the three substituents in the ring-flipped form.

PROBLEM The following cyclohexane derivative has three substituents—red, green, and blue. Identify each

4-25 substituent as axial or equatorial, and identify each pair of relationships (red–blue, red–green, and blue–green) as cis or trans.

PROBLEM Glucose exists in two forms having a 36:64 ratio at equilibrium. Draw a skeletal structure of each,

4-26 describe the difference between them, and tell which of the two you think is more stable (red = O).

 α -Glucose β -Glucose

Cycloalkane Isomers

PROBLEM Draw the five cycloalkanes with the formula C_5H_{10} .

4-27

PROBLEM Give IUPAC names for the following compounds.

4-28 (a)

(b)

(c)

(d)

(e)

PROBLEM Draw a stereoisomer of *trans*-1,3-dimethylcyclobutane.

4-29

PROBLEM Tell whether the following pairs of compounds are identical, constitutional isomers, stereoisomers, or unrelated.

4-30

(a) *cis*-1,3-Dibromocyclohexane and *trans*-1,4-dibromocyclohexane

(b) 2,3-Dimethylhexane and 2,3,3-trimethylpentane

(c)

and

PROBLEM Draw three isomers of *trans*-1,2-dichlorocyclobutane, and label them as either constitutional isomers or stereoisomers.

4-31

PROBLEM Identify each pair of relationships among the -OH groups in glucose (red-blue, red-green, red-black, blue-green, blue-black, green-black) as *cis* or *trans*.

4-32

Glucose

PROBLEM Draw 1,3,5-trimethylcyclohexane using a hexagon to represent the ring. How many *cis*-*trans* stereoisomers are possible?

4-33

Cycloalkane Conformation and Stability

PROBLEM Hydrocortisone, a naturally occurring hormone produced in the adrenal glands, is often used to treat inflammation, severe allergies, and numerous other conditions. Is the indicated -OH group axial or equatorial?

4-34

PROBLEM 4-35 A 1,2-*cis* disubstituted cyclohexane, such as *cis*-1,2-dichlorocyclohexane, must have one group axial and one group equatorial. Explain.

PROBLEM 4-36 A 1,2-*trans* disubstituted cyclohexane must have either both groups axial or both groups equatorial. Explain.

PROBLEM 4-37 Why is a 1,3-*cis* disubstituted cyclohexane more stable than its *trans* isomer?

PROBLEM 4-38 Which is more stable, a 1,4-*trans* disubstituted cyclohexane or its *cis* isomer?

PROBLEM 4-39 *cis*-1,2-Dimethylcyclobutane is less stable than its *trans* isomer, but *cis*-1,3-dimethylcyclobutane is more stable than its *trans* isomer. Draw the most stable conformations of both, and explain.

PROBLEM 4-40 From the data in Figure 4.13 and Table 4.1, estimate the percentages of molecules that have their substituents in an axial orientation for the following compounds:

(a) Isopropylcyclohexane (b) Fluorocyclohexane (c) Cyclohexanecarbonitrile, C₆H₁₁CN

PROBLEM 4-41 Assume that you have a variety of cyclohexanes substituted in the positions indicated. Identify the substituents as either axial or equatorial. For example, a 1,2-*cis* relationship means that one substituent must be axial and one equatorial, whereas a 1,2-*trans* relationship means that both substituents are axial or both are equatorial.

(a) 1,3-*Trans* disubstituted (b) 1,4-*Cis* disubstituted (c) 1,3-*Cis* disubstituted
(d) 1,5-*Trans* disubstituted (e) 1,5-*Cis* disubstituted (f) 1,6-*Trans* disubstituted

Cyclohexane Conformational Analysis

PROBLEM 4-42 Draw the two chair conformations of *cis*-1-chloro-2-methylcyclohexane. Which is more stable, and by how much?

PROBLEM 4-43 Draw the two chair conformations of *trans*-1-chloro-2-methylcyclohexane. Which is more stable?

PROBLEM 4-44 Galactose, a sugar related to glucose, contains a six-membered ring in which all the substituents except the -OH group, indicated below in red, are equatorial. Draw galactose in its more stable chair conformation.

PROBLEM 4-45 Draw the two chair conformations of menthol, and tell which is more stable.

PROBLEM 4-46 There are four *cis*-*trans* isomers of menthol (Problem 4-45), including the one shown. Draw the other three.

PROBLEM 4-47 The diaxial conformation of *cis*-1,3-dimethylcyclohexane is approximately 23 kJ/mol (5.4 kcal/mol) less stable than the diequatorial conformation. Draw the two possible chair conformations, and suggest a reason for the large energy difference.

PROBLEM 4-48 Approximately how much steric strain does the 1,3-diaxial interaction between the two methyl groups introduce into the diaxial conformation of *cis*-1,3-dimethylcyclohexane? (See Problem 4-47.)

PROBLEM 4-49 In light of your answer to Problem 4-48, draw the two chair conformations of 1,1,3-trimethylcyclohexane and estimate the amount of strain energy in each. Which conformation is favored?

PROBLEM 4-50 One of the two chair structures of *cis*-1-chloro-3-methylcyclohexane is more stable than the other by 15.5 kJ/mol (3.7 kcal/mol). Which is it? What is the energy cost of a 1,3-diaxial interaction between a chlorine and a methyl group?

General Problems

PROBLEM 4-51 We saw in Problem 4-20 that *cis*-decalin is less stable than *trans*-decalin. Assume that the 1,3-diaxial interactions in *cis*-decalin are similar to those in axial methylcyclohexane [that is, one CH₂⇌H interaction costs 3.8 kJ/mol (0.9 kcal/mol)], and calculate the magnitude of the energy difference between *cis*- and *trans*-decalin.

PROBLEM 4-52 Using molecular models as well as structural drawings, explain why *trans*-decalin is rigid and cannot ring-flip whereas *cis*-decalin can easily ring-flip.

PROBLEM 4-53 *trans*-Decalin is more stable than its *cis* isomer, but *cis*-bicyclo[4.1.0]heptane is more stable than its *trans* isomer. Explain.

trans-Decalin

cis-Bicyclo[4.1.0]heptane

PROBLEM 4-54 As mentioned in Problem 3-53, the statin drugs, such as simvastatin (Zocor), pravastatin (Pravachol), and atorvastatin (Lipitor) are the most widely prescribed drugs in the world.

Simvastatin
(Zocor)

Pravastatin
(Pravachol)

Atorvastatin
(Lipitor)

- Are the two indicated bonds on simvastatin *cis* or *trans*?
- What are the *cis/trans* relationships among the three indicated bonds on pravastatin?
- Why can't the three indicated bonds on atorvastatin be identified as *cis* or *trans*?

PROBLEM 4-55 *myo*-Inositol, one of the isomers of 1,2,3,4,5,6-hexahydroxycyclohexane, acts as a growth factor in both animals and microorganisms. Draw the most stable chair conformation of *myo*-inositol.

PROBLEM 4-56 How many cis–trans stereoisomers of *myo*-inositol (Problem 4-55) are there? Draw the structure of the most stable isomer.

PROBLEM 4-57 Julius Brecht, discoverer of the structure of camphor, proposed in 1935 that bicycloalkenes such as 1-norbornene, which have a double bond to a bridgehead carbon, are too strained to exist. Explain. (Making a molecular model will be helpful.)

PROBLEM 4-58 Tell whether each of the following substituents on a steroid is axial or equatorial. (A substituent that is “up” is on the top side of the molecule as drawn, and a substituent that is “down” is on the bottom side.)

- (a) Substituent up at C3 (b) Substituent down at C7
(c) Substituent down at C11

PROBLEM 4-59 Amantadine is an antiviral agent that is active against influenza type A infection. Draw a three-dimensional representation of amantadine, showing the chair cyclohexane rings.

PROBLEM 4-60 There are two different isomers named *trans*-1,2-dimethylcyclopentane. Similarly, you have two different appendages called hands. What is the relationship between them? (We’ll explore this kind of isomerism in the next chapter.)

PROBLEM 4-61 Ketones react with alcohols to yield products called *ketals*. Why does the all-cis isomer of 4-*tert*-butyl-1,3-cyclohexanediol react readily with acetone and an acid catalyst to form a ketal, but other stereoisomers do not react? In formulating your answer, draw the more stable chair conformations of all four stereoisomers and the product ketal for each one.

PROBLEM Alcohols undergo an *oxidation* reaction to yield carbonyl compounds when treatment with CrO_3 .

4-62 For example, 2-*tert*-butylcyclohexanol gives 2-*tert*-butylcyclohexanone. If axial $-\text{OH}$ groups are generally more reactive than their equatorial isomers, which do you think reacts faster, the *cis* isomer of 2-*tert*-butylcyclohexanol or the *trans* isomer? Explain.

WHY THIS CHAPTER? Understanding the causes and consequences of molecular handedness is crucial to understanding organic and biological chemistry. The subject can be a bit complex at first, but the material covered in this chapter nevertheless forms the basis for much of the remainder of the book.

Are you right-handed or left-handed? You may not spend much time thinking about it, but handedness plays a surprisingly large role in your daily activities. Many musical instruments, such as oboes and clarinets, have a handedness to them; the last available softball glove always fits the wrong hand. The reason for these difficulties is that our hands aren’t identical; rather, they’re *mirror images*. When you hold a left hand up to a mirror, the image you see looks like a right hand. Try it.

Handedness is also important in organic and biological chemistry, where it arises primarily as a consequence of the tetrahedral stereochemistry of sp^3 -hybridized carbon atoms. Many drugs and almost all the molecules in our bodies—amino acids, carbohydrates, nucleic acids, and many more—have a handedness. Furthermore, molecular handedness enables the precise interactions between enzymes and their substrates that are involved in the hundreds of thousands of chemical reactions on which life is based.

5.1 Enantiomers and the Tetrahedral Carbon

What causes molecular handedness? Look at generalized molecules of the type CH_3X , CH_2XY , and CHXYZ shown in **FIGURE 5.2**. On the left are three molecules, and on the right are their images reflected in a mirror. The CH_3X and CH_2XY molecules are identical to their mirror images and thus are not handed. If you make a molecular model of each molecule and its mirror image, you find that you can superimpose one on the other so that all atoms coincide. The CHXYZ molecule, by contrast, is not identical to its mirror image. You can't superimpose a model of this molecule on a model of its mirror image for the same reason that you can't superimpose a left hand on a right hand: they simply aren't the same.

FIGURE 5.2 Tetrahedral carbon atoms and their mirror images. Molecules of the type CH_3X and CH_2XY are identical to their mirror images, but a molecule of the type CHXYZ is not. A CHXYZ molecule is related to its mirror image in the same way a right hand is related to a left hand.

A molecule that is not identical to its mirror image is a kind of stereoisomer (**Section 4.2**) called an **enantiomer** (e-**nan**-tee-oh-mer, from the Greek *enantio*, meaning “opposite”). Enantiomers are related to each other as a right hand is related to a left hand and result whenever a tetrahedral carbon is bonded to four different substituents (one need not be H). For example, lactic acid (2-hydroxypropanoic acid) exists as a pair of enantiomers because there are four different groups ($-\text{H}$, $-\text{OH}$, $-\text{CH}_3$, $-\text{CO}_2\text{H}$) bonded to the central carbon atom. The enantiomers are called (+)-lactic acid and (–)-lactic acid. Both are found in sour milk, but only the (+) enantiomer occurs in muscle tissue.

No matter how hard you try, you can't superimpose a molecule of (+)-lactic acid on a molecule of (-)-lactic acid. If any two groups match up, say -H and -CO₂H, the remaining two groups don't match (**FIGURE 5.3**).

FIGURE 5.3 Attempts at superimposing the mirror-image forms of lactic acid. (a) When the -H and -OH substituents match up, the -CO₂H and -CH₃ substituents don't; (b) when -CO₂H and -CH₃ match up, -H and -OH don't. Regardless of how the molecules are oriented, they aren't identical.

5.2 The Reason for Handedness in Molecules: Chirality

A molecule that is not identical to its mirror image is said to be **chiral** (**ky**-ral, from the Greek *cheir*, meaning "hand"). You can't take a chiral molecule and its enantiomer and place one on the other so that all atoms coincide.

How can you predict whether a given molecule is or is not chiral? A molecule is not chiral if it has a plane of symmetry. A plane of symmetry is a plane that cuts through the middle of a molecule (or any object) in such a way that one half of the molecule or object is a mirror image of the other half. A coffee mug, for example, has a plane of symmetry. If you were to cut the coffee mug in half from top to bottom, one half would be a mirror image of the other half. A hand, however, does not have a plane of symmetry. One "half" of a hand is not a mirror image of the other half (**FIGURE 5.4**).

FIGURE 5.4 The meaning of symmetry plane. (a) An object like the coffee mug has a symmetry plane cutting through it so that right and left halves are mirror images. (b) An object like a hand has no symmetry plane; the right "half" of a hand is not a mirror image of the left half.

A molecule that has a plane of symmetry in any conformation must be identical to its mirror image and must be nonchiral, or **achiral**. Thus, propanoic acid, CH₃CH₂CO₂H, has a plane of symmetry when lined up as shown in **FIGURE 5.5** and is achiral, while lactic acid, CH₃CH(OH)CO₂H, has no plane of symmetry in any conformation

and is chiral.

FIGURE 5.5 The achiral propanoic acid molecule versus the chiral lactic acid molecule. Propanoic acid has a plane of symmetry that makes one side of the molecule a mirror image of the other. Lactic acid has no such symmetry plane.

The most common, although not the only, cause of chirality in organic molecules is the presence of a tetrahedral carbon atom bonded to four different groups—for example, the central carbon atom in lactic acid. Such carbons are referred to as **chirality centers**, although other terms such as stereocenter, asymmetric center, and stereogenic center have also been used. Note that *chirality* is a property of the entire molecule, whereas a *chirality center* is the *cause* of chirality.

Detecting a chirality center in a complex molecule takes practice because it's not always immediately apparent whether four different groups are bonded to a given carbon. The differences don't necessarily appear right next to the chirality center. For example, 5-bromodecane is a chiral molecule because four different groups are bonded to C5, the chirality center (marked with an asterisk). A butyl substituent is similar to a pentyl substituent, but it isn't identical. The difference isn't apparent until looking four carbon atoms away from the chirality center, but there's still a difference.

As other possible examples, look at methylcyclohexane and 2-methylcyclohexanone. Methylcyclohexane is achiral because no carbon atom in the molecule is bonded to four different groups. You can immediately eliminate all $-\text{CH}_2-$ carbons and the $-\text{CH}_3$ carbon from consideration, but what about C1 on the ring? The C1 carbon atom is bonded to a $-\text{CH}_3$ group, to an $-\text{H}$ atom, and to C2 and C6 of the ring. Carbons 2 and 6 are equivalent, however, as are carbons 3 and 5. Thus, the C6–C5–C4 “substituent” is equivalent to the C2–C3–C4 substituent, and methylcyclohexane is achiral. Another way of reaching the same conclusion is to realize that methylcyclohexane has a symmetry plane, which passes through the methyl group and through C1 and C4 of the ring.

The situation is different for 2-methylcyclohexanone. 2-Methylcyclohexanone has no symmetry plane and is chiral because its C2 is bonded to four different groups: a $-\text{CH}_3$ group, an $-\text{H}$ atom, a $-\text{COCH}_2-$ ring bond (C1), and a $-\text{CH}_2\text{CH}_2-$ ring bond (C3).

Several more examples of chiral molecules are shown below. Check for yourself that the labeled carbons are chirality centers. You might note that carbons in $-\text{CH}_2-$, $-\text{CH}_3$, $\text{C}=\text{O}$, $\text{C}=\text{C}$, and $\text{C}\equiv\text{C}$ groups can't be chirality centers. (Why not?)

Draw the structure of a chiral alcohol.

Strategy

An alcohol is a compound that contains the $-\text{OH}$ functional group. To make an alcohol chiral, we need to have four different groups bonded to a single carbon atom, say $-\text{H}$, $-\text{OH}$, $-\text{CH}_3$, and $-\text{CH}_2\text{CH}_3$.

Solution

PROBLEM Which of the following objects are chiral?

- 5-1 (a) Soda can (b) Screwdriver (c) Screw (d) Shoe

PROBLEM Which of the following molecules are chiral? Identify the chirality center(s) in each.

5-2

PROBLEM 5-3 Alanine, an amino acid found in proteins, is chiral. Draw the two enantiomers of alanine using the standard convention of solid, wedged, and dashed lines.

PROBLEM 5-4 Identify the chirality centers in the following molecules (gray = H, black = C, red = O, green = Cl, yellow-green = F):

5.3 Optical Activity

The study of chirality originated in the early 19th century during investigations by the French physicist Jean-Baptiste Biot into the nature of *plane-polarized light*. A beam of ordinary light consists of electromagnetic waves that oscillate in an infinite number of planes at right angles to its direction of travel. When a beam of ordinary light passes through a device called a polarizer, however, only the light waves oscillating in a single plane pass through and the light is said to be plane-polarized. Light waves in all other planes are blocked out.

Biot made the remarkable observation that when a beam of plane-polarized light passes through a solution of certain organic molecules, such as sugar or camphor, the plane of polarization is rotated through an angle, α . Not all organic substances exhibit this property, but those that do are said to be **optically active**.

The angle of rotation can be measured with an instrument called a polarimeter, represented in **FIGURE 5.6**. A solution of optically active organic molecules is placed in a sample tube, plane-polarized light is passed through the tube, and rotation of the polarization plane occurs. The light then goes through a second polarizer called the analyzer. By rotating the analyzer until the light passes through *it*, we can find the new plane of polarization and can tell to what extent rotation has occurred.

FIGURE 5.6 Schematic representation of a polarimeter. Plane-polarized light passes through a solution of optically active molecules, which rotate the plane of polarization.

In addition to determining the extent of rotation, we can also find the direction. From the vantage point of the observer looking directly at the analyzer, some optically active molecules rotate polarized light to the left (counterclockwise) and are said to be **levorotatory**, whereas others rotate polarized light to the right (clockwise) and are said to be **dextrorotatory**. By convention, rotation to the left is given a minus sign (–) and rotation to the right is given a plus sign (+). (–)-Morphine, for example, is levorotatory, and (+)-sucrose is dextrorotatory.

The extent of rotation observed in a polarimetry experiment depends on the number of optically active molecules encountered by the light beam. This number, in turn, depends on sample concentration and sample pathlength. If the concentration of the sample is doubled, the observed rotation doubles. If the concentration is kept constant but the length of the sample tube is doubled, the observed rotation doubles. It also happens that the angle of rotation depends on the wavelength of the light used.

To express optical rotations in a meaningful way so that comparisons can be made, we have to choose standard conditions. The **specific rotation**, $[\alpha]_D$, of a compound is defined as the observed rotation when light of 589.6 nanometer (nm; $1 \text{ nm} = 10^{-9} \text{ m}$) wavelength is used with a sample pathlength l of 1 decimeter (dm; $1 \text{ dm} = 10 \text{ cm}$) and a sample concentration c of 1 g/cm^3 . (Light of 589.6 nm, the so-called sodium D line, is the yellow light emitted from common sodium street lamps.)

$$[\alpha]_D = \frac{\text{Observed rotation (degrees)}}{\text{Pathlength, } l \text{ (dm)} \times \text{Concentration, } c \text{ (g/cm}^3\text{)}} = \frac{\alpha}{l \times c}$$

When optical rotations are expressed in this standard way, the specific rotation, $[\alpha]_D$, is a physical constant characteristic of a given optically active compound. For example, (+)-lactic acid has $[\alpha]_D = +3.82$, and (–)-lactic acid has $[\alpha]_D = -3.82$. That is, the two enantiomers rotate plane-polarized light to exactly the same extent but in opposite directions. Note that the units of specific rotation are $(\text{deg} \cdot \text{cm}^2)/\text{g}$ but the values are usually expressed without units. Some additional examples are listed in [TABLE 5.1](#).

TABLE 5.1 Specific Rotations of Some Organic Molecules

Compound	$[\alpha]_D$	Compound	$[\alpha]_D$
Penicillin V	+233	Cholesterol	–31.5
Sucrose	+66.47	Morphine	–132
Camphor	+44.26	Cocaine	–16
Chloroform	0	Acetic acid	0

WORKED EXAMPLE 5.2

Calculating an Optical Rotation

A 1.20 g sample of cocaine, $[\alpha]_D = -16$, was dissolved in 7.50 mL of chloroform and placed in a sample tube having a pathlength of 5.00 cm. What was the observed rotation?

Strategy

$$\text{Since } [\alpha]_D = \frac{\alpha}{l \times c}$$

$$\text{Then } \alpha = l \times c \times [\alpha]_D$$

$$\text{where } [\alpha]_D = -16; l = 5.00 \text{ cm} = 0.500 \text{ dm}; c = 1.20 \text{ g}/7.50 \text{ cm}^3 = 0.160 \text{ g/cm}^3$$

Solution

$$\alpha = (-16) (0.500) (0.160) = -1.3^\circ.$$

PROBLEM 5-5 Is cocaine (Worked Example 5.2) dextrorotatory or levorotatory?

PROBLEM 5-6 A 1.50 g sample of coniine, the toxic extract of poison hemlock, was dissolved in 10.0 mL of ethanol and placed in a sample cell with a 5.00 cm pathlength. The observed rotation at the sodium D line was $+1.21^\circ$. Calculate $[\alpha]_D$ for coniine.

5.4 Pasteur's Discovery of Enantiomers

Little was done to build on Biot's discovery of optical activity until 1848, when Louis Pasteur began work on a study of crystalline tartaric acid salts derived from wine. On crystallizing a concentrated solution of sodium ammonium tartrate below 28°C , Pasteur made the surprising observation that two distinct kinds of crystals were obtained. Furthermore, the two kinds of crystals were nonsuperimposable mirror images and were related in the same way that a right hand is related to a left hand.

Working carefully with tweezers, Pasteur was able to separate the crystals into two piles, one of "right-handed" crystals and one of "left-handed" crystals, like those shown in **FIGURE 5.7**. Although the original sample, a 50 : 50 mixture of right and left, was optically inactive, solutions of the crystals from each of the sorted piles were optically active and their specific rotations were equal in magnitude but opposite in sign.

FIGURE 5.7 Drawings of sodium ammonium tartrate crystals taken from Pasteur's original sketches. One of the crystals is dextrorotatory

in solution, and the other is levorotatory.

Pasteur was far ahead of his time. Although the structural theory of Kekulé had not yet been proposed, Pasteur explained his results by speaking of the molecules themselves, saying, “There is no doubt that [in the *dextro* tartaric acid] there exists an asymmetric arrangement having a nonsuperimposable image. It is no less certain that the atoms of the *levo* acid have precisely the inverse asymmetric arrangement.” Pasteur’s vision was extraordinary, for it was not until 25 years later that his ideas regarding asymmetric carbon atoms were confirmed.

Today, we would describe Pasteur’s work by saying that he had discovered enantiomers. **Enantiomers**, also called **optical isomers**, have identical physical properties, such as melting point and boiling point, but differ in the direction in which their solutions rotate plane-polarized light.

5.5 Sequence Rules for Specifying Configuration

Structural drawings provide a visual representation of stereochemistry, but a written method for indicating the three-dimensional arrangement, or **configuration**, of substituents at a chirality center is also needed. The method used a set of **sequence rules** to rank the four groups attached to the chirality center and then looks at the handedness with which those groups are attached. Called the **Cahn–Ingold–Prelog rules** after the chemists who proposed them, the sequence rules are as follows:

RULE 1

Look at the four atoms directly attached to the chirality center, and rank them according to atomic number.

The atom with the highest atomic number has the highest ranking (first), and the atom with the lowest atomic number (usually hydrogen) has the lowest ranking (fourth). When different isotopes of the same element are compared, such as deuterium (^2H) and protium (^1H), the heavier isotope ranks higher than the lighter isotope. Thus, atoms commonly found in organic compounds have the following order:

Atomic number	35	17	16	15	8	7	6	(2)	(1)	
Higher rank	Br	> Cl	> S	> P	> O	> N	> C	> ^2H	> ^1H	Lower rank

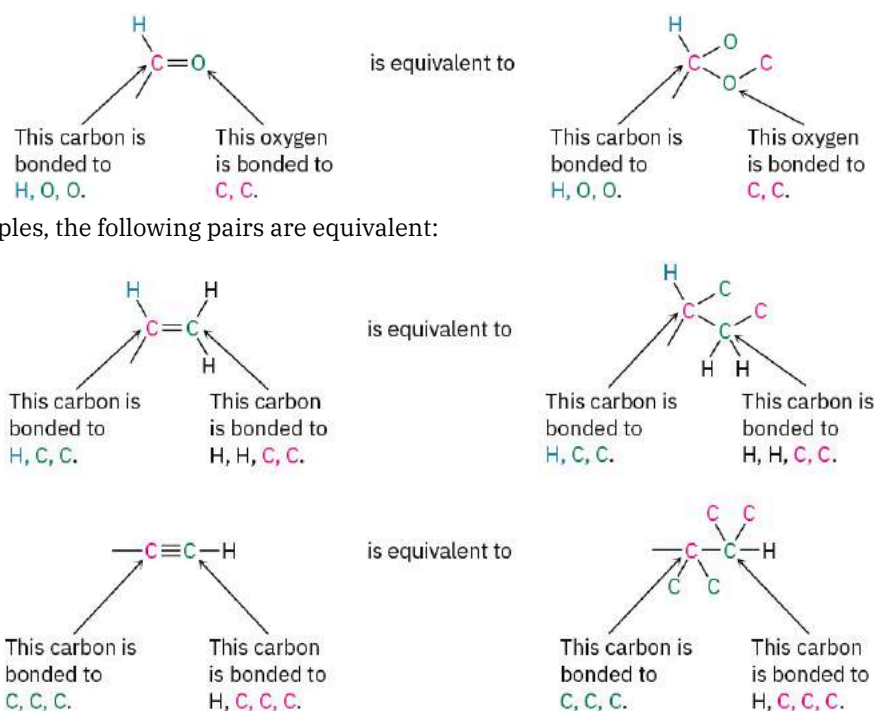

RULE 2

If a decision can’t be reached by ranking the first atoms in the substituent, look at the second, third, or fourth atoms away from the chirality center until the first difference is found. A $-\text{CH}_2\text{CH}_3$ substituent and a $-\text{CH}_3$ substituent are equivalent by rule 1 because both have carbon as the first atom. By rule 2, however, ethyl ranks higher than methyl because ethyl has a carbon as its highest second atom, while methyl has only hydrogen as its second atom. Look at the following pairs of examples to see how the rule works:

RULE 3

Multiple-bonded atoms are equivalent to the same number of single-bonded atoms. For example, an aldehyde substituent ($-\text{CH}=\text{O}$), which has a carbon atom *doubly* bonded to *one* oxygen, is equivalent to a substituent having a carbon atom *singly* bonded to *two* oxygens:

Having ranked the four groups attached to a chiral carbon, we describe the stereochemical configuration around the carbon by orienting the molecule so that the group with the lowest ranking (4) points directly away from us. We then look at the three remaining substituents, which now appear to radiate toward us like the spokes on a steering wheel (FIGURE 5.8). If a curved arrow drawn from the highest to second-highest to third-highest ranked substituent ($1 \rightarrow 2 \rightarrow 3$) is clockwise, we say that the chirality center has the **R configuration** (*S* for the Latin *rectus*, meaning “right”). If an arrow from $1 \rightarrow 2 \rightarrow 3$ is counterclockwise, the chirality center has the **S configuration** (Latin *sinister*, meaning “left”). To remember these assignments, think of a car’s steering wheel when making a Right (clockwise) turn.

FIGURE 5.8 Assigning **R** and **S** configurations to chirality centers. When the molecule is oriented so that the lowest-ranked group (4) is toward the rear, the remaining three groups radiate toward the viewer like the spokes of a steering wheel. If the direction of travel $1 \rightarrow 2 \rightarrow 3$ is clockwise (right turn), the center has the **R** configuration. If the direction of travel $1 \rightarrow 2 \rightarrow 3$ is counterclockwise (left turn), the center is **S**.

Look at (–)-lactic acid in FIGURE 5.9 for an example of how to assign configuration. Sequence rule 1 says that –OH is ranked 1 and –H is ranked 4, but it doesn’t allow us to distinguish between –CH₃ and –CO₂H because both groups have carbon as their first atom. Sequence rule 2, however, says that –CO₂H ranks higher than –CH₃ because O (the highest second atom in –CO₂H) outranks H (the highest second atom in –CH₃). Now, turn the

molecule so that the fourth-ranked group ($-H$) is oriented toward the rear, away from the observer. Since a curved arrow from 1 ($-OH$) to 2 ($-CO_2H$) to 3 ($-CH_3$) is clockwise (right turn of the steering wheel), ($-$)-lactic acid has the *R* configuration. Applying the same procedure to ($+$)-lactic acid leads to the opposite assignment.

FIGURE 5.9 Assigning configuration to (a) (*R*)-($-$)-lactic acid and (b) (*S*)-($+$)-lactic acid.

Further examples are provided by naturally occurring ($-$)-glyceraldehyde and ($+$)-alanine, which both have the *S* configuration as shown in **FIGURE 5.10**. Note that the sign of optical rotation, ($+$) or ($-$), is not related to the *R,S* designation. (*S*)-Glyceraldehyde happens to be levorotatory ($-$), and (*S*)-alanine happens to be dextrorotatory ($+$). There is no simple correlation between *R,S* configuration and direction or magnitude of optical rotation.

FIGURE 5.10 Assigning configuration to (a) ($-$)-glyceraldehyde. (b) ($+$)-alanine. Both happen to have the *S* configuration, although one is levorotatory and the other is dextrorotatory.

One additional point needs to be mentioned—the matter of **absolute configuration**. How do we know that the assignments of *R* and *S* configuration are correct in an absolute sense, rather than a relative, sense? Since

there is no correlation between the *R,S* configuration and the direction or magnitude of optical rotation, how do we know that the *R* configuration belongs to the levorotatory enantiomer of lactic acid? This difficult question was finally solved in 1951, when an X-ray diffraction method was found for determining the absolute spatial arrangement of atoms in a molecule. Based on those results, we can say with certainty that the *R,S* conventions are correct.

WORKED EXAMPLE 5.3

Assigning Configuration to Chirality Centers

Orient each of the following drawings so that the lowest-ranked group is toward the rear, and then assign *R* or *S* configuration to each:

Strategy

It takes practice to be able to visualize and orient a chirality center in three dimensions. You might start by indicating where the observer must be located— 180° opposite the lowest-ranked group. Then imagine yourself in the position of the observer, and redraw what you would see.

Solution

In (a), you would be located in front of the page toward the top right of the molecule, and you would see group 2 to your left, group 3 to your right, and group 1 below you. This corresponds to an *R* configuration.

In (b), you would be located behind the page toward the top left of the molecule from your point of view, and you would see group 3 to your left, group 1 to your right, and group 2 below you. This also corresponds to an *R* configuration.

WORKED EXAMPLE 5.4

Drawing the Three-Dimensional Structure of a Specific Enantiomer

Draw a tetrahedral representation of (*R*)-2-chlorobutane.

Strategy

Begin by ranking the four substituents bonded to the chirality center: (1) $-\text{Cl}$, (2) $-\text{CH}_2\text{CH}_3$, (3) $-\text{CH}_3$, (4) $-\text{H}$. To draw a tetrahedral representation of the molecule, orient the lowest-ranked group ($-\text{H}$) away from you and imagine that the other three groups are coming out of the page toward you. Then, place the remaining three substituents such that the direction of travel $1 \rightarrow 2 \rightarrow 3$ is clockwise (right turn), and tilt the molecule toward you to bring the rear hydrogen into view. Using molecular models is a real help in working problems of this sort.

Solution

PROBLEM Which member in each of the following sets ranks higher?

- 5-7 (a) $-\text{H}$ or $-\text{Br}$ (b) $-\text{Cl}$ or $-\text{Br}$ (c) $-\text{CH}_3$ or $-\text{CH}_2\text{CH}_3$ (d) $-\text{NH}_2$ or $-\text{OH}$ (e) $-\text{CH}_2\text{OH}$ or $-\text{CH}_3$
 (f) $-\text{CH}_2\text{OH}$ or $-\text{CH}=\text{O}$

PROBLEM Rank each of the following sets of substituents:

- 5-8 (a) $-\text{H}$, $-\text{OH}$, $-\text{CH}_2\text{CH}_3$, $-\text{CH}_2\text{CH}_2\text{OH}$ (b) $-\text{CO}_2\text{H}$, $-\text{CO}_2\text{CH}_3$, $-\text{CH}_2\text{OH}$, $-\text{OH}$
 (c) $-\text{CN}$, $-\text{CH}_2\text{NH}_2$, $-\text{CH}_2\text{NHCH}_3$, $-\text{NH}_2$ (d) $-\text{SH}$, $-\text{CH}_2\text{SCH}_3$, $-\text{CH}_3$, $-\text{SSCH}_3$

PROBLEM Orient each of the following drawings so that the lowest-ranked group is toward the rear, and then assign *R* or *S* configuration:

- 5-9

PROBLEM Assign *R* or *S* configuration to the chirality center in each of the following molecules:

PROBLEM Draw a tetrahedral representation of (*S*)-2-pentanol (2-hydroxypentane).

5-11

PROBLEM Assign *R* or *S* configuration to the chirality center in the following molecular model of the amino acid methionine (blue = N, yellow = S):

5-12

5.6 Diastereomers

Molecules like lactic acid, alanine, and glyceraldehyde are relatively simple because each has only one chirality center and thus only two stereoisomers. The situation becomes more complex, however, with molecules that have more than one chirality center. As a general rule, a molecule with n chirality centers can have up to

2^n stereoisomers (although it may have fewer, as we'll see below). Take the amino acid threonine (2-amino-3-hydroxybutanoic acid), for example. Since threonine has two chirality centers (C2 and C3), there are four possible stereoisomers, as shown in **FIGURE 5.11**. Check for yourself that the *R,S* configurations of all stereoisomers are correct.

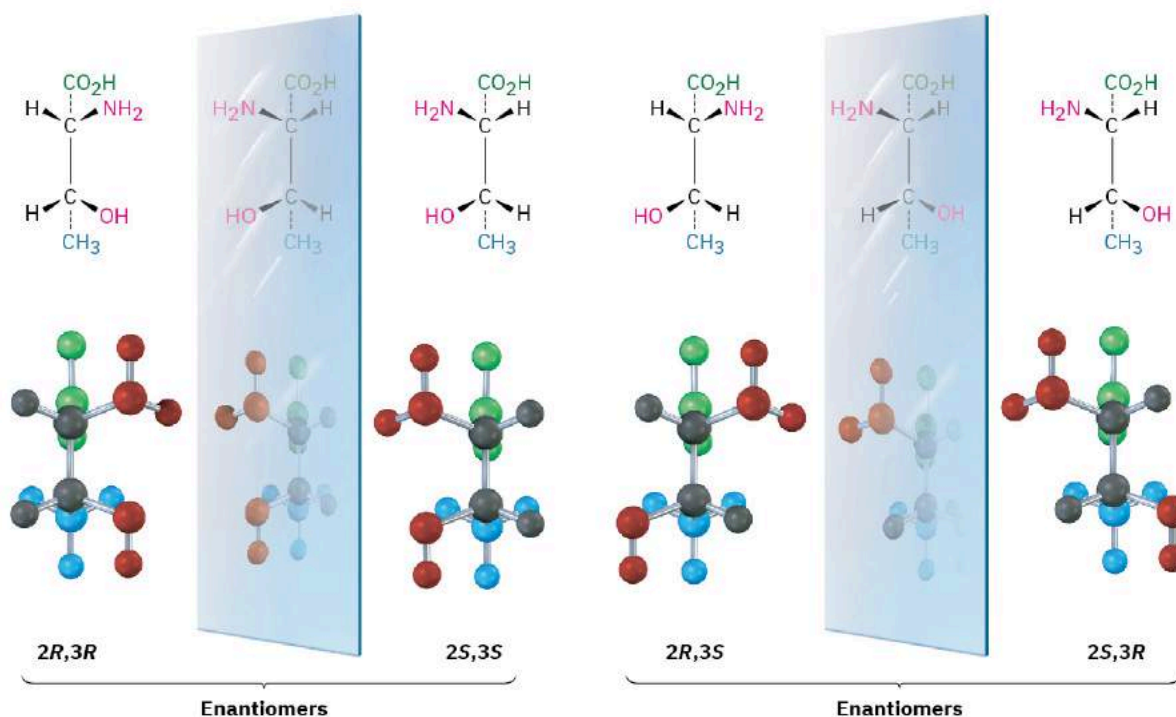

FIGURE 5.11 The four stereoisomers of 2-amino-3-hydroxybutanoic acid.

The four stereoisomers of 2-amino-3-hydroxybutanoic acid can be grouped into two pairs of enantiomers. The *2R,3R* stereoisomer is the mirror image of *2S,3S*, and the *2R,3S* stereoisomer is the mirror image of *2S,3R*. But what is the relationship between any two molecules that are not mirror images? What, for instance, is the relationship between the *2R,3R* isomer and the *2R,3S* isomer? They are stereoisomers, yet they aren't enantiomers. To describe such a relationship, we need a new term—*diastereomer*.

Diastereomers (dia-**stair**-e-oh-mers) are stereoisomers that are not mirror images. Since we used the right-hand/left-hand analogy to describe the relationship between two enantiomers, we might extend the analogy by saying that the relationship between diastereomers is like that of hands from different people. Your hand and your friend's hand look similar, but they aren't identical and they aren't mirror images. The same is true of diastereomers: they're similar, but they aren't identical and they aren't mirror images.

Note carefully the difference between enantiomers and diastereomers: enantiomers have opposite configurations at *all* chirality centers, whereas diastereomers have opposite configurations at *some* (one or more) chirality centers but the same configuration at others. A full description of the four stereoisomers of threonine is given in **TABLE 5.2**. Of the four, only the *2S,3R* isomer, $[\alpha]_D = -28.3$, occurs naturally in plants and animals and is an essential nutrient for humans. This result is typical: most biological molecules are chiral, and usually only one stereoisomer is found in nature.

TABLE 5.2 Relationships among the Four Stereoisomers of Threonine

Stereoisomer	Enantiomer	Diastereomer
<i>2R,3R</i>	<i>2S,3S</i>	<i>2R,3S</i> and <i>2S,3R</i>
<i>2S,3S</i>	<i>2R,3R</i>	<i>2R,3S</i> and <i>2S,3R</i>

TABLE 5.2 Relationships among the Four Stereoisomers of Threonine

Stereoisomer	Enantiomer	Diastereomer
2 <i>R</i> ,3 <i>S</i>	2 <i>S</i> ,3 <i>R</i>	2 <i>R</i> ,3 <i>R</i> and 2 <i>S</i> ,3 <i>S</i>
2 <i>S</i> ,3 <i>R</i>	2 <i>R</i> ,3 <i>S</i>	2 <i>R</i> ,3 <i>R</i> and 2 <i>S</i> ,3 <i>S</i>

In the special case where two diastereomers differ at only one chirality center but are the same at all others, we say that the compounds are **epimers**. Cholesterol and coprostanol, for instance, are both found in human feces, and both have nine chirality centers. Eight of the nine are identical, but the one at C5 is different. Thus, cholesterol and coprostanol are *epimeric* at C5.

PROBLEM 5-13 One of the following molecules (a)–(d) is D-erythrose 4-phosphate, an intermediate in the Calvin photosynthetic cycle by which plants incorporate CO₂ into carbohydrates. If D-erythrose 4-phosphate has *R* stereochemistry at both chirality centers, which of the structures is it? Which of the remaining three structures is the enantiomer of D-erythrose 4-phosphate, and which are diastereomers?

PROBLEM 5-14 How many chirality centers does morphine have? How many stereoisomers of morphine are possible in principle?

PROBLEM 5-15 Assign *R* or *S* configuration to each chirality center in the following molecular model of the amino acid isoleucine (blue = N):

5.7 Meso Compounds

Let's look at another example (Section 5.4) of a compound with more than one chirality center: the tartaric acid used by Pasteur. The four stereoisomers can be drawn as follows:

The $2R,3R$ and $2S,3S$ structures are nonsuperimposable mirror images and therefore represent a pair of enantiomers. A close look at the $2R,3S$ and $2S,3R$ structures, however, shows that they *are* superimposable, and thus identical, as can be seen by rotating one structure 180° .

The $2R,3S$ and $2S,3R$ structures are identical because the molecule has a plane of symmetry and is therefore achiral. The symmetry plane cuts through the C2–C3 bond, making one half of the molecule a mirror image of the other half (FIGURE 5.12). Because of the plane of symmetry, the molecule is achiral, despite the fact that it has two chirality centers. Such compounds, which are achiral, yet contain chirality centers, are called **meso compounds (me-zo)**. Thus, tartaric acid exists in three stereoisomeric forms: two enantiomers and one meso form.

FIGURE 5.12 A symmetry plane through the C2–C3 bond of *meso*-tartaric acid makes the molecule achiral.

Some physical properties of the three stereoisomers are listed in TABLE 5.3. The (+)- and (–)-tartaric acids have identical melting points, solubilities, and densities, but they differ in the sign of their rotation of plane-polarized light. The meso isomer, by contrast, is diastereomeric with the (+) and (–) forms. It has no mirror-image relationship to (+)- and (–)-tartaric acids, is a different compound altogether, and thus has different

physical properties.

TABLE 5.3 Some Properties of the Stereoisomers of Tartaric Acid

Stereoisomer	Melting point (°C)	$[\alpha]_D$	Density (g/cm ³)	Solubility at 20 °C (g/100 mL H ₂ O)
(+)	168–170	+12	1.7598	139.0
(-)	168–170	-12	1.7598	139.0
Meso	146–148	0	1.6660	125.0

WORKED EXAMPLE 5.5

Distinguishing Chiral Compounds from Meso Compounds

Does *cis*-1,2-dimethylcyclobutane have any chirality centers? Is it chiral?

Strategy

To see whether a chirality center is present, look for a carbon atom bonded to four different groups. To see whether the molecule is chiral, look for the presence or absence of a symmetry plane. Not all molecules with chirality centers are chiral overall—meso compounds are an exception.

Solution

A look at the structure of *cis*-1,2-dimethylcyclobutane shows that both methyl-bearing ring carbons (C1 and C2) are chirality centers. Overall, though, the compound is achiral because there is a symmetry plane bisecting the ring between C1 and C2. Thus, the molecule is a meso compound.

PROBLEM Which of the following structures represent meso compounds?

5-16

PROBLEM Which of the following have a meso form? (Recall that the *-ol* suffix refers to an alcohol, ROH.)

5-17

PROBLEM Does the following structure represent a meso compound? If so, indicate the symmetry plane.

5-18

5.8 Racemic Mixtures and the Resolution of Enantiomers

To end this discussion of stereoisomerism, let's return for a last look at Pasteur's pioneering work, described in [Section 5.4](#). Pasteur took an optically inactive tartaric acid salt and found that he could crystallize from it two optically active forms having what we would now call $2R,3R$ and $2S,3S$ configurations. But what was the optically inactive form he started with? It couldn't have been *meso*-tartaric acid, because *meso*-tartaric acid is a different chemical compound and can't interconvert with the two chiral enantiomers without breaking and re-forming chemical bonds.

The answer is that Pasteur started with a 50:50 mixture of the two chiral tartaric acid enantiomers. Such a mixture is called a **racemate** (**rass-uh-mate**), or **racemic mixture**, and is denoted by either the symbol (\pm) or the prefix *d,l* to indicate an equal mixture of dextrorotatory and levorotatory forms. Racemates show no optical rotation because the (+) rotation from one enantiomer exactly cancels the (–) rotation from the other. Through good luck, Pasteur was able to separate, or resolve, racemic tartaric acid into its (+) and (–) enantiomers. Unfortunately, the fractional crystallization technique he used doesn't work for most racemates, so other methods are needed.

The most common method for resolving the racemate of a chiral carboxylic acid (RCO_2H) is to carry out an acid-base reaction between the acid and an amine base (RNH_2) to yield an ammonium salt:

To understand how this method of resolution works, let's see what happens when a racemic mixture of chiral acids, such as (+)- and (–)-lactic acids, reacts with an achiral amine base, such as methylamine, CH_3NH_2 . The situation is analogous to what happens when left and right hands (chiral) pick up a ball (achiral). Both left and right hands pick up the ball equally well, and the products—ball in right hand versus ball in left hand—are mirror images. In the same way, both (+)- and (–)-lactic acid react with methylamine equally well, and the product is a racemic mixture of the two enantiomers methylammonium (+)-lactate and methylammonium (–)-lactate ([FIGURE 5.13](#)).

FIGURE 5.13 Reaction of racemic lactic acid with achiral methylamine gives a racemic mixture of ammonium salts.

Now let's see what happens when the racemic mixture of (+)- and (–)-lactic acids reacts with a single enantiomer of a chiral amine base, such as (R) -1-phenylethylamine. The situation is analogous to what happens when left and right hands (chiral) put on a right-handed glove (*also chiral*). Left and right hands don't put on the right-handed glove in the same way, so the products—right hand in right glove versus left hand in right glove—are not mirror images; they're similar but different.

In the same way, (+)- and (–)-lactic acids react with (R) -1-phenylethylamine to give two different products (**FIGURE 5.14**). (R) -Lactic acid reacts with (R) -1-phenylethylamine to give the R,R salt, and (S) -lactic acid reacts with the R amine to give the S,R salt. The two salts are diastereomers, not enantiomers. They have different chemical and physical properties, and it may therefore be possible to separate them by crystallization or some other means. Once separated, acidification of the two diastereomeric salts with a strong acid makes it possible to isolate the two pure enantiomers of lactic acid and to recover the chiral amine for reuse.

FIGURE 5.14 Reaction of racemic lactic acid with (R) -1-phenylethylamine yields a mixture of diastereomeric ammonium salts, which have different properties and can be separated.

WORKED EXAMPLE 5.6

Predicting the Chirality of a Reaction Product

We'll see in **Section 21.3** that carboxylic acids (RCO_2H) react with alcohols ($\text{R}'\text{OH}$) to form esters ($\text{RCO}_2\text{R}'$).

Suppose that (\pm)-lactic acid reacts with CH_3OH to form the ester, methyl lactate. What stereochemistry would you expect the product(s) to have? What is the relationship of the products?

Solution

Reaction of a racemic acid with an achiral alcohol such as methanol yields a racemic mixture of mirror-image (enantiomeric) products.

PROBLEM 5-19 Suppose that acetic acid ($\text{CH}_3\text{CO}_2\text{H}$) reacts with (*S*)-2-butanol to form an ester (see Worked Example 5.6). What stereochemistry would you expect the product(s) to have? What is the relationship of the products?

PROBLEM 5-20 What stereoisomers would result from reaction of (\pm)-lactic acid with (*S*)-1-phenylethylamine, and what is the relationship between them?

5.9 A Review of Isomerism

As noted on several previous occasions, isomers are compounds with the same chemical formula but different structures. We've seen several kinds of isomers in the past few chapters, and it's a good idea at this point to see how they relate to one another (FIGURE 5.15).

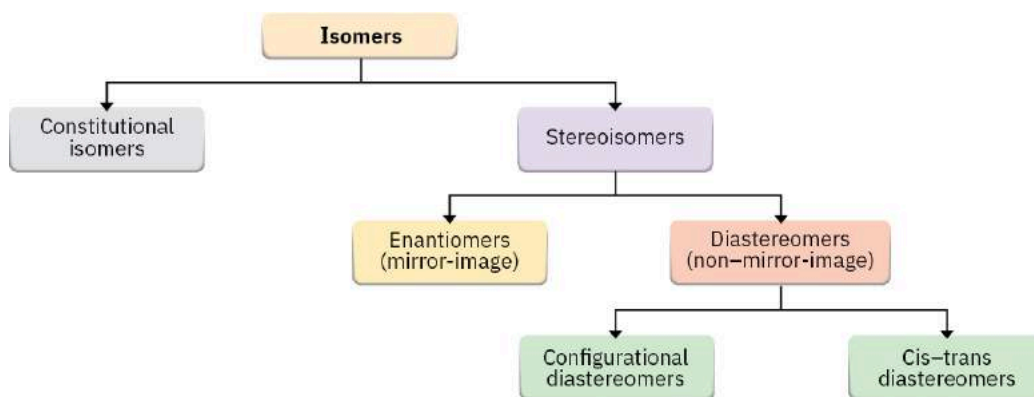

FIGURE 5.15 A summary of the different kinds of isomers.

There are two fundamental types of isomers, both of which we've now encountered: constitutional isomers and stereoisomers.

Constitutional isomers (Section 3.2) are compounds whose atoms are connected differently. Among the kinds of constitutional isomers we've seen are skeletal, functional, and positional isomers.

Stereoisomers (Section 4.2) are compounds whose atoms are connected in the same order but with a different spatial arrangement. Among the kinds of stereoisomers we've seen are enantiomers, diastereomers, and cis–trans isomers of cycloalkanes. Actually, cis–trans isomers are just a subclass of diastereomers because they are non–mirror-image stereoisomers:

Enantiomers
(nonsuperimposable mirror-image stereoisomers)

(R)-Lactic acid

(S)-Lactic acid

Diastereomers
(nonsuperimposable non–mirror-image stereoisomers)

Configurational diastereomers

(2R,3R)-2-Amino-3-hydroxybutanoic acid

(2R,3S)-2-Amino-3-hydroxybutanoic acid

Cis–trans diastereomers
(substituents on same side or opposite side of double bond or ring)

trans-1,3-Dimethylcyclopentane

cis-1,3-Dimethylcyclopentane

PROBLEM What kinds of isomers are the following pairs?

- 5-21** (a) (*S*)-5-Chloro-2-hexene and chlorocyclohexane
(b) (*2R,3R*)-Dibromopentane and (*2S,3R*)-dibromopentane

5.10 Chirality at Nitrogen, Phosphorus, and Sulfur

As noted previously, the most common cause of chirality in a molecule is the presence of four different substituents bonded to a tetrahedral atom. Although that atom is usually carbon, it doesn't necessarily have to be. Nitrogen, phosphorus, and sulfur atoms are all commonly encountered in organic molecules, and can all be chirality centers. We know, for instance, that trivalent nitrogen is tetrahedral, with its lone pair of electrons acting as the fourth “substituent” (Section 1.10). Is trivalent nitrogen chiral? Does a compound such as ethylmethylaniline exist as a pair of enantiomers?

The answer is both yes and no. Yes in principle, but no in practice. It turns out that most trivalent nitrogen compounds undergo a rapid umbrella-like inversion that interconverts enantiomers, so we can't isolate individual enantiomers except in special cases.

A similar situation occurs in trivalent phosphorus compounds, called phosphines, but the inversion at phosphorus is substantially slower than inversion at nitrogen, so stable chiral phosphines can be isolated. (*R*)- and (*S*)-methylpropylphenylphosphine, for instance, are configurationally stable for several hours at 100 °C. We'll see the importance of phosphine chirality in **Section 26.7** in connection with the synthesis of chiral amino acids.

Divalent sulfur compounds are achiral, but trivalent sulfur compounds called *sulfonium salts* (R_3S^+) can be chiral. Like phosphines, sulfonium salts undergo relatively slow inversion, so chiral sulfonium salts are configurationally stable and can be isolated. Perhaps the best known example is the coenzyme *S*-adenosylmethionine, the so-called biological methyl donor, which is involved in many metabolic pathways as a source of CH_3 groups. (The “*S*” in the name *S*-adenosylmethionine stands for *sulfur* and means that the adenosyl group is attached to the sulfur atom of the amino acid methionine.) The molecule has *S* stereochemistry at sulfur and is configurationally stable for several days at room temperature. Its *R* enantiomer is also known but is not biologically active.

5.11 Prochirality

Closely related to the concept of chirality, and particularly important in biological chemistry, is the notion of *prochirality*. A molecule is said to be **prochiral** if it can be converted from achiral to chiral in a single chemical step. For instance, an unsymmetrical ketone like 2-butanone is prochiral because it can be converted to the chiral alcohol 2-butanol by the addition of hydrogen, as we'll see in **Section 17.4**.

Which enantiomer of 2-butanol is produced depends on which face of the planar carbonyl group undergoes reaction. To distinguish between the possibilities, we use the stereochemical descriptors *Re* and *Si*. Rank the

three groups attached to the trigonal, sp^2 -hybridized carbon, and imagine curved arrows from the highest to second-highest to third-highest ranked substituents. The face on which the arrows curve clockwise is designated the **Re face** (similar to *R*), and the face on which the arrows curve counterclockwise is designated the **Si face** (similar to *S*). In this example, addition of hydrogen from the Re face gives (*S*)-2-butane, and addition from the Si face gives (*R*)-2-butane.

In addition to compounds with planar, sp^2 -hybridized atoms, compounds with tetrahedral, sp^3 -hybridized atoms can also be prochiral. An sp^3 -hybridized atom is said to be a **prochirality center** if, by changing one of its attached groups, it becomes a chirality center. The $-\text{CH}_2\text{OH}$ carbon atom of ethanol, for instance, is a prochirality center because changing one of its attached $-\text{H}$ atoms converts it into a chirality center.

To distinguish between the two identical atoms (or groups of atoms) on a prochirality center, we imagine a change that will raise the ranking of one atom over the other without affecting its rank with respect to other attached groups. On the $-\text{CH}_2\text{OH}$ carbon of ethanol, for instance, we might imagine replacing one of the ^1H atoms (protium) by ^2H (deuterium). The newly introduced ^2H atom ranks higher than the remaining ^1H atom, but it remains lower than other groups attached to the carbon. Of the two identical atoms in the original compound, the atom whose replacement leads to an *R* chirality center is said to be **pro-*R*** and the atom whose replacement leads to an *S* chirality center is **pro-*S***.

A large number of biological reactions involve prochiral compounds. One of the steps in the citric acid cycle by which food is metabolized, for instance, is the addition of H_2O to fumarate to give malate. Addition of $-\text{OH}$ occurs on the Si face of a fumarate carbon and gives (*S*)-malate as product.

As another example, studies with deuterium-labeled substrates have shown that the reaction of ethanol with the coenzyme nicotinamide adenine dinucleotide (NAD^+), catalyzed by yeast alcohol dehydrogenase, occurs with exclusive removal of the pro-*R* hydrogen from ethanol and with addition only to the Re face of NAD^+ .

Determining the stereochemistry of reactions at prochirality centers is a powerful method for studying detailed mechanisms in biochemical reactions. As just one example, the conversion of citrate to *cis*-aconitate in the citric acid cycle has been shown to occur with loss of a pro-*R* hydrogen, implying that the OH and H groups leave from opposite sides of the molecule.

PROBLEM Identify the indicated hydrogens in the following molecules as pro-*R* or pro-*S*:

PROBLEM Identify the indicated faces of carbon atoms in the following molecules as Re or Si:

PROBLEM The lactic acid that builds up in tired muscles is formed from pyruvate. If the reaction occurs with addition of hydrogen to the Re face of pyruvate, what is the stereochemistry of the product?

PROBLEM The aconitase-catalyzed addition of water to *cis*-aconitate in the citric acid cycle occurs with the following stereochemistry. Does the addition of the OH group occur on the Re or Si face of the substrate? What about the addition of the H? Do the H and OH groups add from the same side of the double bond or from opposite sides?

5.12 Chirality in Nature and Chiral Environments

Although the different enantiomers of a chiral molecule have the same physical properties, they usually have different biological properties. For example, a change in chirality can affect the biological properties of many drugs, such as fluoxetine, a heavily prescribed medication sold under the trade name Prozac. Racemic fluoxetine is an effective antidepressant but has no activity against migraine. The pure *S* enantiomer, however, works remarkably well in preventing migraine. Other examples of how chirality affects biological properties are given in the Chapter 5 *Chemistry Matters* at the end of this chapter.

Why do different enantiomers have different biological properties? To have a biological effect, a substance typically must fit into an appropriate receptor that has a complementary shape. But because biological receptors are chiral, only one enantiomer of a chiral substrate can fit, just as only a right hand can fit into a right-handed glove. The mirror-image enantiomer will be a misfit, like a left hand in a right-handed glove. A representation of the interaction between a chiral molecule and a chiral biological receptor is shown in **FIGURE 5.16**: one enantiomer fits the receptor perfectly, but the other does not.

FIGURE 5.16 Interaction of a chiral object with a chiral receptor. A left hand interacts with a chiral object, much as a biological receptor interacts with a chiral molecule. **(a)** One enantiomer fits into the hand perfectly: **green thumb, red palm, and gray pinkie finger**, with the **blue substituent exposed**. **(b)** The other enantiomer, however, can't fit into the hand. When the green thumb and gray pinkie finger interact appropriately, the palm holds a blue substituent rather than a red one, with the **red substituent exposed**.

The hand-in-glove fit of a chiral substrate into a chiral receptor is relatively straightforward, but it's less obvious how a prochiral substrate can undergo a selective reaction. Take the reaction of ethanol with NAD^+ catalyzed by yeast alcohol dehydrogenase. As we saw at the end of **Section 5.11**, this reaction occurs with exclusive removal of the pro-*R* hydrogen from ethanol and with addition only to the Re face of the NAD^+ carbon.

We can understand this result by imagining that the chiral enzyme receptor again has three binding sites, as in

FIGURE 5.16. When green and gray substituents of a prochiral substrate are held appropriately, however, only one of the two red substituents—say, the pro-*S* one—is also held while the other, pro-*R*, substituent is exposed for reaction.

We describe the situation by saying that the receptor provides a **chiral environment** for the substrate. In the absence of a chiral environment, the two red substituents are chemically identical, but in the presence of a chiral environment, they are chemically distinctive (**FIGURE 5.17a**). The situation is similar to what happens when you pick up a coffee mug. By itself, the mug has a plane of symmetry and is achiral. When you pick up the mug, however, your hand provides a chiral environment so that one side becomes much more accessible and easier to drink from than the other (**FIGURE 5.17b**).

FIGURE 5.17 (a) When a prochiral molecule is held in a chiral environment, the two seemingly identical substituents are distinguishable. (b) Similarly, when an achiral coffee mug is held in the chiral environment of your hand, it's much easier to drink from one side than the other because the two sides of the mug are now distinguishable.

CHEMISTRY MATTERS

Chiral Drugs

The many hundreds of different pharmaceutical agents approved for use by the U.S. Food and Drug Administration come from many sources. Many drugs are isolated directly from plants or bacteria, and others are made by chemical modification of naturally occurring compounds. An estimated 33%, however, are made entirely in the laboratory and have no relatives in nature.

FIGURE 5.18 The *S* enantiomer of ibuprofen soothes the aches and pains of athletic injuries much more effectively than the *R* enantiomer. (credit: “World Athletic Championships 2007 in Osaka” by Eckhard Pecher/Wikimedia Commons, CC BY 2.5)

Those drugs that come from natural sources, either directly or after laboratory modification, are usually chiral and are generally found only as a single enantiomer rather than as a racemate. Penicillin V, for example, an antibiotic isolated from the *Penicillium* mold, has the *2S,5R,6R* configuration. Its enantiomer, which does not occur naturally but can be made in the laboratory, has no antibiotic activity.

Penicillin V (*2S,5R,6R* configuration)

In contrast to drugs from natural sources, drugs that are made entirely in the laboratory are either achiral or, if chiral, are often produced and sold as racemates. Ibuprofen, for example, has one chirality center and is sold commercially under such trade names as Advil, Nuprin, and Motrin as a 50 : 50 mixture of *R* and *S*. It turns out, however, that only the *S* enantiomer is active as an analgesic and anti-inflammatory agent. The *R* enantiomer of ibuprofen is inactive, although it is slowly converted in the body to the active *S* form.

(S)-Ibuprofen
(an active analgesic agent)

Not only is it chemically wasteful to synthesize and administer an enantiomer that does not serve the intended purpose, many instances are now known where the presence of the “wrong” enantiomer in a racemic mixture either affects the body’s ability to utilize the “right” enantiomer or has unintended pharmacological effects of its own. The presence of (*R*)-ibuprofen in the racemic mixture, for instance, slows the rate at which the *S* enantiomer takes effect in the body, from 12 minutes to 38 minutes.

To get around this problem, pharmaceutical companies attempt to devise methods of *enantioselective* synthesis, which allow them to prepare only a single enantiomer rather than a racemic mixture. Viable methods have been developed for the preparation of (*S*)-ibuprofen, which is marketed in Europe. We’ll look further into enantioselective synthesis in the Chapter 19 *Chemistry Matters*.

Key Terms

- absolute configuration
- achiral
- Cahn–Ingold–Prelog rules
- chiral
- chiral environment
- chirality center
- configuration
- dextrorotatory
- diastereomer
- enantiomer
- epimer
- levorotatory
- meso compound
- optically active
- prochiral
- prochirality center
- pro-*R* configuration
- pro-*S* configuration
- *R* configuration
- racemate
- *Re* face
- resolution
- *S* configuration
- *Si* face
- specific rotation, $[\alpha]_D$

Summary

In this chapter, we’ve looked at some of the causes and consequences of molecular handedness—a topic of particular importance in understanding biological chemistry. The subject can be a bit complex but is so important that it’s worthwhile spending time to become familiar with it.

An object or molecule that is not superimposable on its mirror image is said to be **chiral**, meaning “handed.” A chiral molecule is one that does not have a plane of symmetry cutting through it so that one half is a mirror image of the other half. The most common cause of chirality in organic molecules is the presence of a tetrahedral, sp^3 -hybridized carbon atom bonded to four different groups—a so-called **chirality center**. Chiral compounds can exist as a pair of nonsuperimposable mirror-image stereoisomers called **enantiomers**. Enantiomers are identical in all physical properties except for the direction in which they rotate plane-polarized light.

The stereochemical **configuration** of a chirality center can be specified as either **R** (*rectus*) or **S** (*sinister*) by using the **Cahn–Ingold–Prelog rules**. First rank the four substituents on the chiral carbon atom, and then orient the molecule so that the lowest-ranked group points directly back. If a curved arrow drawn in the direction of decreasing rank (1 → 2 → 3) for the remaining three groups is clockwise, the chirality center has the *R* configuration. If the direction is counterclockwise, the chirality center has the *S* configuration.

Some molecules have more than one chirality center. **Enantiomers** have opposite configuration at all chirality centers, whereas **diastereomers** have the same configuration in at least one center but opposite configurations at the others. **Epimers** are diastereomers that differ in configuration at only one chirality center. A compound with *n* chirality centers can have a maximum of 2^n stereoisomers.

A **meso compound** contains a chirality center but is achiral overall because it has a plane of symmetry. Racemic mixtures, or **racemates**, are 50 : 50 mixtures of (+) and (–) enantiomers. Racemates and individual diastereomers differ in their physical properties, such as solubility, melting point, and boiling point.

A molecule is **prochiral** if it can be converted from achiral to chiral in a single chemical step. A prochiral sp^2 -hybridized atom has two faces, described as either **Re** or **Si**. An sp^3 -hybridized atom is a **prochirality center** if, by changing one of its attached atoms, a chirality center results. The atom whose replacement leads to an *R* chirality center is **pro-R**, and the atom whose replacement leads to an *S* chirality center is **pro-S**.

Additional Problems

Visualizing Chemistry

PROBLEM Which of the following structures are identical? (Green = Cl.)

5-26

PROBLEM Assign *R* or *S* configurations to the chirality centers in the following molecules (blue = N):

5-27 (a)

Serine

(b)

Adrenaline

PROBLEM Which, if any, of the following structures represent meso compounds? (Blue = N, green = Cl.)

5-28

PROBLEM 5-29 Assign *R* or *S* configuration to each chirality center in pseudoephedrine, an over-the-counter decongestant found in cold remedies (blue = N).

PROBLEM 5-30 Orient each of the following drawings so that the lowest-ranked group is toward the rear, and then assign *R* or *S* configuration:

Chirality and Optical Activity

PROBLEM 5-31 Which of the following objects are chiral?

- (a) A basketball (b) A fork (c) A wine glass (d) A golf club (e) A spiral staircase
(f) A snowflake

PROBLEM 5-32 Which of the following compounds are chiral? Draw them, and label the chirality centers.

- (a) 2,4-Dimethylheptane (b) 5-Ethyl-3,3-dimethylheptane (c) *cis*-1,4-Dichlorocyclohexane

PROBLEM 5-33 Draw chiral molecules that meet the following descriptions:

- (a) A chloroalkane, $C_5H_{11}Cl$ (b) An alcohol, $C_6H_{14}O$ (c) An alkene, C_6H_{12}
(d) An alkane, C_8H_{18}

PROBLEM 5-34 Eight alcohols have the formula $C_5H_{12}O$. Draw them. Which are chiral?

PROBLEM 5-35 Draw compounds that fit the following descriptions:

- (a) A chiral alcohol with four carbons (b) A chiral carboxylic acid with the formula $C_5H_{10}O_2$

(c) A compound with two chirality centers (d) A chiral aldehyde with the formula C_3H_5BrO

PROBLEM 5-36 Erythronolide B is the biological precursor of erythromycin, a broad-spectrum antibiotic. How many chirality centers does erythronolide B have? Identify them.

Assigning Configuration to Chirality Centers

PROBLEM 5-37 Which of the following pairs of structures represent the same enantiomer, and which represent different enantiomers?

PROBLEM 5-38 What is the relationship between the specific rotations of (2*R*,3*R*)-dichloropentane and (2*S*,3*S*)-dichloropentane? Between (2*R*,3*S*)-dichloropentane and (2*R*,3*R*)-dichloropentane?

PROBLEM 5-39 What is the stereochemical configuration of the enantiomer of (2*S*,4*R*)-2,4-octanediol?

PROBLEM 5-40 What are the stereochemical configurations of the two diastereomers of (2*S*,4*R*)-2,4-octanediol? (A diol is a compound with two -OH groups.)

PROBLEM 5-41 Orient each of the following drawings so that the lowest-ranked group is toward the rear, and then assign *R* or *S* configuration:

PROBLEM 5-42 Assign Cahn-Ingold-Prelog rankings to the following sets of substituents:

PROBLEM 5-43 Assign *R* or *S* configurations to each chirality center in the following molecules:

PROBLEM Assign *R* or *S* configuration to each chirality center in the following molecules:

PROBLEM Assign *R* or *S* configuration to each chirality center in the following biological molecules:

PROBLEM Draw tetrahedral representations of the following molecules:

PROBLEM Assign *R* or *S* configuration to each chirality center in the following molecules:

PROBLEM Assign *R* or *S* configurations to the chirality centers in ascorbic acid (vitamin C).

PROBLEM Assign *R* or *S* stereochemistry to the chirality centers in the following Newman projections:

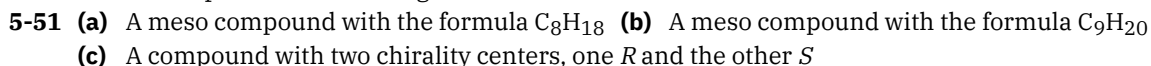

PROBLEM Xylose is a common sugar found in many types of wood, including maple and cherry. Because it is much less prone to cause tooth decay than sucrose, xylose has been used in candy and chewing gum. Assign *R* or *S* configurations to the chirality centers in xylose.

Meso Compounds

PROBLEM Draw examples of the following:

PROBLEM Draw the meso form of each of the following molecules, and indicate the plane of symmetry in each:
5-52

PROBLEM Draw the structure of a meso compound that has five carbons and three chirality centers.

5-53

PROBLEM Ribose, an essential part of ribonucleic acid (RNA), has the following structure:

5-54

(a) How many chirality centers does ribose have? Identify them.

(b) How many stereoisomers of ribose are there?

(c) Draw the structure of the enantiomer of ribose.

(d) Draw the structure of a diastereomer of ribose.

PROBLEM On reaction with hydrogen gas in the presence of a platinum catalyst, ribose (Problem 5-54) is

5-55

converted into ribitol. Is ribitol optically active or inactive? Explain.

Prochirality

PROBLEM Identify the indicated hydrogens in the following molecules as pro-*R* or pro-*S*:

5-56

PROBLEM Identify the indicated faces in the following molecules as Re or Si:

5-57

PROBLEM One of the steps in fat metabolism is the hydration of crotonate to yield 3-hydroxybutyrate. The

5-58

reaction occurs by addition of $-\text{OH}$ to the Si face at C3, followed by protonation at C2, also from the Si face. Draw the product of the reaction, showing the stereochemistry of each step.

PROBLEM 5-59 The dehydration of citrate to yield *cis*-aconitate, a step in the citric acid cycle, involves the pro-*R* “arm” of citrate rather than the pro-*S* arm. Which of the following two products is formed?

PROBLEM 5-60 The first step in the metabolism of glycerol, formed by digestion of fats, is phosphorylation of the pro-*R* -CH₂OH group by reaction with adenosine triphosphate (ATP) to give the corresponding glycerol phosphate plus adenosine diphosphate (ADP). Show the stereochemistry of the product.

PROBLEM 5-61 One of the steps in fatty-acid biosynthesis is the dehydration of (*R*)-3-hydroxybutyryl ACP to give *trans*-crotonyl ACP. Does the reaction remove the pro-*R* or the pro-*S* hydrogen from C2?

General Problems

PROBLEM 5-62 Draw all possible stereoisomers of 1,2-cyclobutanedicarboxylic acid, and indicate the interrelationships. Which, if any, are optically active? Do the same for 1,3-cyclobutanedicarboxylic acid.

PROBLEM 5-63 Draw tetrahedral representations of the two enantiomers of the amino acid cysteine, HSCH₂CH(NH₂)CO₂H, and identify each as *R* or *S*.

PROBLEM 5-64 The naturally occurring form of the amino acid cysteine (Problem 5-63) has the *R* configuration at its chirality center. On treatment with a mild oxidizing agent, two cysteines join to give cystine, a disulfide. Assuming that the chirality center is not affected by the reaction, is cystine optically active? Explain.

PROBLEM 5-65 Draw tetrahedral representations of the following molecules:

(a) The 2*S*,3*R* enantiomer of 2,3-dibromopentane **(b)** The meso form of 3,5-heptanediol

PROBLEM 5-66 Assign *R* or *S* configurations to the chiral centers in cephalixin, trade-named Keflex, the most widely prescribed antibiotic in the United States.

PROBLEM 5-67 Chloramphenicol, a powerful antibiotic isolated in 1947 from the *Streptomyces venezuelae* bacterium, is active against a broad spectrum of bacterial infections and is particularly valuable against typhoid fever. Assign *R* or *S* configurations to the chirality centers in chloramphenicol.

PROBLEM 5-68 Allenes are compounds with adjacent carbon-carbon double bonds. Many allenes are chiral, even though they don't contain chirality centers. Mycomycin, for example, a naturally occurring antibiotic isolated from the bacterium *Nocardia acidophilus*, is chiral and has $[\alpha]_D = -130$. Explain why mycomycin is chiral.

Mycomycin

PROBLEM 5-69 Long before chiral allenes were known (Problem 5-68), the resolution of 4-methylcyclohexylideneacetic acid into two enantiomers had been carried out. Why is it chiral? What geometric similarity does it have to allenes?

4-Methylcyclohexylideneacetic acid

PROBLEM 5-70 (*S*)-1-Chloro-2-methylbutane undergoes light-induced reaction with Cl_2 to yield a mixture of products, among which are 1,4-dichloro-2-methylbutane and 1,2-dichloro-2-methylbutane.

(a) Write the reaction, showing the correct stereochemistry of the reactant.

(b) One of the two products is optically active, but the other is optically inactive. Which is which?

PROBLEM 5-71 How many stereoisomers of 2,4-dibromo-3-chloropentane are there? Draw them, and indicate which are optically active.

PROBLEM 5-72 Draw both *cis*- and *trans*-1,4-dimethylcyclohexane in their more stable chair conformations.

(a) How many stereoisomers are there of *cis*-1,4-dimethylcyclohexane, and how many of *trans*-1,4-dimethylcyclohexane?

(b) Are any of the structures chiral?

(c) What are the stereochemical relationships among the various stereoisomers of 1,4-dimethylcyclohexane?

PROBLEM 5-73 Draw both *cis*- and *trans*-1,3-dimethylcyclohexane in their more stable chair conformations.

(a) How many stereoisomers are there of *cis*-1,3-dimethylcyclohexane, and how many of *trans*-1,3-dimethylcyclohexane?

(b) Are any of the structures chiral?

(c) What are the stereochemical relationships among the various stereoisomers of 1,3-dimethylcyclohexane?

PROBLEM 5-74 *cis*-1,2-Dimethylcyclohexane is optically inactive even though it has two chirality centers. Explain.

PROBLEM 5-75 We'll see in Chapter 11 that alkyl halides react with hydrosulfide ion (HS^-) to give a product whose stereochemistry is inverted from that of the reactant.

Draw the reaction of (*S*)-2-bromobutane with HS^- ion to yield 2-butanethiol, $\text{CH}_3\text{CH}_2\text{CH}(\text{SH})\text{CH}_3$. Is the stereochemistry of the product *R* or *S*?

**An alkyl
bromide**

PROBLEM Ketones react with sodium acetylide (the sodium salt of acetylene, $\text{Na}^+ : \text{C} \equiv \text{CH}$) to give alcohols.

5-76 For example, the reaction of sodium acetylide with 2-butanone yields 3-methyl-1-pentyn-3-ol:

2-Butanone

3-Methyl-1-pentyn-3-ol

- (a) Is the product chiral?
 (b) Assuming that the reaction takes place with equal likelihood from both Re and Si faces of the carbonyl group, is the product optically active? Explain.

PROBLEM Imagine that a reaction similar to that in Problem 5-76 is carried out between sodium acetylide and

5-77 (*R*)-2-phenylpropanal to yield 4-phenyl-1-pentyn-3-ol:

(*R*)-2-Phenylpropanal

4-Phenyl-1-pentyn-3-ol

- (a) Is the product chiral?
 (b) Draw both major and minor reaction products, assuming that the reaction takes place preferentially from the Re face of the carbonyl group. Is the product mixture optically active? Explain.

6.11 A Comparison Between Biological Reactions and Laboratory Reactions

WHY THIS CHAPTER? All chemical reactions, whether they take place in the laboratory or in living organisms, follow the same “rules.” Reactions in living organisms often look more complex than laboratory reactions because of the size of the biomolecules and the involvement of biological catalysts called enzymes, but the principles governing all chemical reactions are the same.

To understand both organic and biological chemistry, it’s necessary to know not just *what* occurs but also *why* and *how* chemical reactions take place. In this chapter, we’ll start with an overview of the fundamental kinds of organic reactions, we’ll see why reactions occur, and we’ll see how reactions can be described. Once this

background is out of the way, we'll then be ready to begin studying the details of organic chemistry in future chapters.

When first approached, organic chemistry might seem overwhelming. It's not so much that any one part is difficult to understand, it's that there are so many parts: tens of millions of compounds, dozens of functional groups, and an apparently endless number of reactions. With study, though, it becomes evident that there are only a few fundamental ideas that underlie all organic reactions. Far from being a collection of isolated facts, organic chemistry is a beautifully logical subject that is unified by a few broad themes. When these themes are understood, learning organic chemistry becomes much easier and memorization is minimized. The aim of this book is to describe the themes and clarify the patterns that unify organic chemistry in future chapters.

6.1 Kinds of Organic Reactions

Organic chemical reactions can be organized broadly in two ways—by what kinds of reactions occur and by how those reactions occur. Let's look first at the kinds of reactions that take place. There are four general types of organic reactions: *additions*, *eliminations*, *substitutions*, and *rearrangements*.

- **Addition reactions** occur when two reactants add together to form a single product with no atoms “left over.” An example that we'll be studying soon is the reaction of an alkene, such as ethylene, with HBr to yield an alkyl bromide.

- **Elimination reactions** are, in a sense, the opposite of addition reactions. They occur when a single reactant splits into two products, often with the formation of a small molecule such as water or HBr. An example is the acid-catalyzed reaction of an alcohol to yield water and an alkene.

- **Substitution reactions** occur when two reactants exchange parts to give two new products. An example is the reaction of an ester such as methyl acetate with water to yield a carboxylic acid plus an alcohol. Similar reactions occur in many biological pathways, including the metabolism of dietary fats.

- **Rearrangement reactions** occur when a single reactant undergoes a reorganization of bonds and atoms to yield an isomeric product. An example is the conversion of dihydroxyacetone phosphate into its constitutional isomer glyceraldehyde 3-phosphate, a step in the glycolysis pathway by which carbohydrates are metabolized.

PROBLEM Classify each of the following reactions as an addition, elimination, substitution, or rearrangement:

6.2 How Organic Reactions Occur: Mechanisms

Having looked at the kinds of reactions that take place, let's now see how they occur. An overall description of how a reaction occurs is called a **reaction mechanism**. A mechanism describes in detail exactly what takes place at each stage of a chemical transformation—which bonds are broken and in what order, which bonds are formed and in what order, and what the relative rates are for each step. A complete mechanism must also account for all reactants used and all products formed.

All chemical reactions involve bond-breaking and bond-making. When two molecules come together, react, and yield products, specific bonds in the reactant molecules are broken and specific bonds in the product molecules are formed. Fundamentally, there are two ways in which a covalent two-electron bond can break. A bond can break in an electronically unsymmetrical way so that both bonding electrons remain with one product fragment, leaving the other with a vacant orbital, or a bond can break in an electronically symmetrical way so that one electron remains with each product fragment. The unsymmetrical cleavage is said to be *heterolytic*, and the symmetrical cleavage is said to be *homolytic*.

We'll develop this point in more detail later, but note for now that the movement of *two* electrons in the unsymmetrical process is indicated using a full-headed curved arrow (\curvearrowright), whereas the movement of *one* electron in the symmetrical process is indicated using a half-headed, or “fishhook,” arrow (\frown).

Just as there are two ways in which a bond can break, there are two ways in which a covalent two-electron bond can form. A bond can form in an electronically unsymmetrical way if both bonding electrons are donated to the new bond by one reactant, or in a symmetrical way if one electron is donated by each reactant.

Processes that involve unsymmetrical bond-breaking and bond-making are called **polar reactions**. Polar reactions involve species that have an even number of electrons and thus have only electron pairs in their orbitals. Polar processes are by far the more common reaction type in both organic and biological chemistry, and a large part of this book is devoted to their description.

Processes that involve symmetrical bond-breaking and bond-making are called **radical reactions**. A **radical**, often called a **free radical**, is a neutral chemical species that contains an odd number of electrons and thus has a single, unpaired electron in one of its orbitals.

In addition to polar and radical reactions, there is a third, less commonly encountered process called a *pericyclic reaction*. Rather than explain pericyclic reactions now, though, we'll look at them more carefully in Chapter 30.

6.3 Polar Reactions

Polar reactions occur because of the electrical attraction between positively polarized and negatively polarized centers on functional groups in molecules. To see how these reactions take place, let's first recall the discussion of polar covalent bonds in [Section 2.1](#) and then look more deeply into the effects of bond polarity on organic molecules.

Most organic compounds are electrically neutral; they have no net charge, either positive or negative. We saw in [Section 2.1](#), however, that certain bonds within a molecule, particularly the bonds in functional groups, are polar. Bond polarity is a consequence of an unsymmetrical electron distribution in a bond and is due to the difference in electronegativity of the bonded atoms.

Elements such as oxygen, nitrogen, fluorine, and chlorine are more electronegative than carbon, so a carbon atom bonded to one of these atoms has a partial positive charge (δ^+). Metals are less electronegative than carbon, so a carbon atom bonded to a metal has a partial negative charge (δ^-). Electrostatic potential maps of chloromethane and methyllithium illustrate these charge distributions, showing that the carbon atom in chloromethane is electron-poor (blue) while the carbon in methyllithium is electron-rich (red).

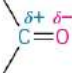

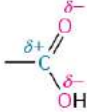

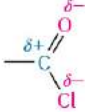

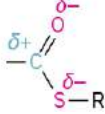

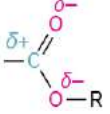

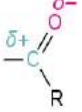

The polarity patterns of some common functional groups are shown in [TABLE 6.1](#). Note that carbon is always positively polarized except when bonded to a metal.

TABLE 6.1 Polarity Patterns in Some Common Functional Groups

Compound type	Functional group structure
Alcohol	
Alkene	 Symmetrical, nonpolar
Alkyl halide	
Amine	
Ether	
Thiol	
Nitrile	
Grignard reagent	
Alkyl lithium	

TABLE 6.1 Polarity Patterns in Some Common Functional Groups

Compound type	Functional group structure
Carbonyl	
Carboxylic acid	
Carboxylic acid chloride	
Thioester	
Aldehyde	
Ester	
Ketone	

This discussion of bond polarity is oversimplified in that we've considered only bonds that are inherently polar due to differences in electronegativity. Polar bonds can also result from the interaction of functional groups with acids or bases. Take an alcohol such as methanol, for example. In neutral methanol, the carbon atom is somewhat electron-poor because the electronegative oxygen attracts the electrons in the C–O bond. On protonation of the methanol oxygen by an acid, however, a full positive charge on oxygen attracts the electrons in the C–O bond much more strongly and makes the carbon much more electron-poor. We'll see numerous examples throughout this book of reactions that are catalyzed by acids because of the resultant increase in bond polarity upon protonation.

Yet a further consideration is the polarizability (as opposed to polarity) of atoms in a molecule. As the electric field around a given atom changes because of changing interactions with solvent or other polar molecules nearby, the electron distribution around that atom also changes. The measure of this response to an external electrical influence is called the **polarizability** of the atom. Larger atoms with more loosely held electrons are more polarizable, and smaller atoms with fewer, tightly held electrons are less polarizable. Thus, sulfur is more polarizable than oxygen, and iodine is more polarizable than chlorine. The effect of this higher polarizability of sulfur and iodine is that carbon–sulfur and carbon–iodine bonds, although nonpolar according to electronegativity values (**FIGURE 2.3**), nevertheless usually react as if they were polar.

What does functional-group polarity mean with respect to chemical reactivity? Because unlike charges attract, the fundamental characteristic of all polar organic reactions is that electron-rich sites react with electron-poor sites. Bonds are made when an electron-rich atom donates a pair of electrons to an electron-poor atom, and bonds are broken when one atom leaves with both electrons from the former bond.

As we saw in **Section 2.11**, the movement of an electron pair during a polar reaction is indicated using a curved, full-headed arrow to show where electrons move when reactant bonds are broken and product bonds are formed during the reaction.

In referring to the electron-rich and electron-poor species involved in polar reactions, chemists use the words *nucleophile* and *electrophile*. A **nucleophile** is a substance that is “nucleus-loving.” (Remember that a nucleus is positively charged.) A nucleophile has a negatively polarized, electron-rich atom and can form a bond by donating a pair of electrons to a positively polarized, electron-poor atom. Nucleophiles can be either neutral or negatively charged; ammonia, water, hydroxide ion, and chloride ion are examples. An **electrophile**, by contrast, is “electron-loving.” An electrophile has a positively polarized, electron-poor atom and can form a bond by accepting a pair of electrons from a nucleophile. Electrophiles can be either neutral or positively charged. Acids (H^+ donors), alkyl halides, and carbonyl compounds are examples (**FIGURE 6.2**).

FIGURE 6.2 Some nucleophiles and electrophiles. Electrostatic potential maps identify the nucleophilic (negative) and electrophilic (positive) atoms.

Note that neutral compounds can often react either as nucleophiles or as electrophiles, depending on the circumstances. After all, if a compound is neutral yet has an electron-rich nucleophilic site, it must also have a corresponding electron-poor electrophilic site. Water, for instance, acts as an electrophile when it donates H^+ but acts as a nucleophile when it donates a nonbonding pair of electrons. Similarly, a carbonyl compound acts as an electrophile when it reacts at its positively polarized carbon atom, yet acts as a nucleophile when it reacts at its negatively polarized oxygen atom.

If the definitions of nucleophiles and electrophiles sound similar to those given in Section 2.11 for Lewis acids and Lewis bases, that's because there is indeed a correlation. Lewis bases are electron donors and behave as nucleophiles, whereas Lewis acids are electron acceptors and behave as electrophiles. Thus, much of organic chemistry is explainable in terms of acid–base reactions. The main difference is that the words *acid* and *base* are used broadly in all fields of chemistry, while the words *nucleophile* and *electrophile* are used primarily in organic chemistry when carbon bonding is involved.

WORKED EXAMPLE 6.1

Identifying Electrophiles and Nucleophiles

Which of the following species is likely to behave as a nucleophile and which as an electrophile?

- (a) NO_2^+ (b) CN^- (c) CH_3NH_2 (d) $(\text{CH}_3)_3\text{S}^+$

Strategy

A nucleophile has an electron-rich site, either because it is negatively charged or because it has a functional group containing an atom that has a lone pair of electrons. An electrophile has an electron-poor site, either because it is positively charged or because it has a functional group containing an atom that is positively polarized.

Solution

- (a) NO_2^+ (nitronium ion) is likely to be an electrophile because it is positively charged.
 (b) $:\text{C}\equiv\text{N}^-$ (cyanide ion) is likely to be a nucleophile because it is negatively charged.

(c) CH_3NH_2 (methylamine) might be either a nucleophile or an electrophile, depending on the circumstances. The lone pair of electrons on the nitrogen atom makes methylamine a potential nucleophile, while positively polarized N–H hydrogens make methylamine a potential acid (electrophile).

(d) $(\text{CH}_3)_3\text{S}^+$ (trimethylsulfonium ion) is likely to be an electrophile because it is positively charged.

PROBLEM 6-2 Which of the following species are likely to be nucleophiles and which electrophiles? Which might be both?

PROBLEM 6-3 An electrostatic potential map of boron trifluoride is shown. Is BF_3 likely to be a nucleophile or an electrophile? Draw a Lewis structure for BF_3 , and explain your answer.

6.4 An Example of a Polar Reaction: Addition of HBr to Ethylene

Let's look at a typical polar process—the addition reaction of an alkene, such as ethylene, with hydrogen bromide. When ethylene is treated with HBr at room temperature, bromoethane is produced. Overall, the reaction can be formulated as

The reaction is an example of a polar reaction type known as an *electrophilic addition reaction* and can be understood using the general ideas discussed in the previous section. Let's begin by looking at the two reactants.

What do we know about ethylene? We know from [Section 1.8](#) that a carbon–carbon double bond results from the orbital overlap of two sp^2 -hybridized carbon atoms. The σ part of the double bond results from sp^2 – sp^2 overlap, and the π part results from p – p overlap.

What kind of chemical reactivity might we expect from a $\text{C}=\text{C}$ bond? We know that alkanes, such as ethane, are relatively inert because all valence electrons are tied up in strong, nonpolar, C–C and C–H bonds. Furthermore, the bonding electrons in alkanes are relatively inaccessible to approaching reactants because they are sheltered in σ bonds between nuclei. The electronic situation in alkenes is quite different, however. For one thing, double

bonds have a greater electron density than single bonds—four electrons in a double bond versus only two in a single bond. In addition, the electrons in the π bond are accessible to approaching reactants because they are located above and below the plane of the double bond rather than being sheltered between the nuclei (FIGURE 6.3). As a result, the double bond is nucleophilic and the chemistry of alkenes is dominated by reactions with electrophiles.

FIGURE 6.3 A comparison of carbon-carbon single and double bonds. A double bond is both more accessible to approaching reactants than a single bond and more electron-rich (more nucleophilic). An electrostatic potential map of ethylene indicates that the double bond is the region of **highest negative charge**.

What about the second reactant, HBr? As a strong acid, HBr is a powerful proton (H^+) donor and electrophile. Thus, the reaction between HBr and ethylene is a typical electrophile–nucleophile combination, characteristic of all polar reactions.

We'll see more details about alkene electrophilic addition reactions shortly, but for the present we can imagine the reaction as taking place by the pathway shown in FIGURE 6.4. The reaction begins when the alkene nucleophile donates a pair of electrons from its $\text{C}=\text{C}$ bond to HBr to form a new $\text{C}-\text{H}$ bond plus Br^- , as indicated by the path of the curved arrows in the first step of FIGURE 6.4. One curved arrow begins at the middle of the double bond (the source of the electron pair) and points to the hydrogen atom in HBr (the atom to which a bond will form). This arrow indicates that a new $\text{C}-\text{H}$ bond forms using electrons from the former $\text{C}=\text{C}$ bond. Simultaneously, a second curved arrow begins in the middle of the $\text{H}-\text{Br}$ bond and points to the Br, indicating that the $\text{H}-\text{Br}$ bond breaks and the electrons remain with the Br atom, giving Br^- .

FIGURE 6.4 MECHANISM

The electrophilic addition reaction of ethylene and HBr. The reaction takes place in two steps, both of which involve electrophile–nucleophile interactions.

- 1 A hydrogen atom on the electrophile HBr is attacked by π electrons from the nucleophilic double bond, forming a new C–H bond. This leaves the other carbon atom with a + charge and a vacant p orbital. Simultaneously, two electrons from the H–Br bond move onto bromine, giving bromide anion.

- 2 Bromide ion donates an electron pair to the positively charged carbon atom, forming a C–Br bond and yielding the neutral addition product.

When one of the alkene carbon atoms bonds to the incoming hydrogen, the other carbon atom, having lost its share of the double-bond electrons, now has only six valence electrons and is left with a positive charge. This positively charged species—a carbon-cation, or **carbocation**—is itself an electrophile that can accept an electron pair from nucleophilic Br^- anion in a second step, forming a C–Br bond and yielding the observed addition product. Once again, a curved arrow in **FIGURE 6.4** shows the electron-pair movement from Br^- to the positively charged carbon.

The electrophilic addition of HBr to ethylene is only one example of a polar process; there are many others that we'll study in depth in later chapters. But regardless of the details of individual reactions, all polar reactions take place between an electron-poor site and an electron-rich site and involve the donation of an electron pair from a nucleophile to an electrophile.

PROBLEM What product would you expect from reaction of cyclohexene with HBr? With HCl?

PROBLEM Reaction of HBr with 2-methylpropene yields 2-bromo-2-methylpropane. What is the structure of
6-5 the carbocation formed during the reaction? Show the mechanism of the reaction.

6.5 Using Curved Arrows in Polar Reaction Mechanisms

It takes practice to use curved arrows properly in reaction mechanisms, but there are a few rules and a few common patterns you should look for that will help you become more proficient:

RULE 1

Electrons move from a nucleophilic source (Nu: or Nu:⁻) to an electrophilic sink (E or E⁺). The nucleophilic source must have an electron pair available, usually either as a lone pair or in a multiple bond. For example:

The electrophilic sink must be able to accept an electron pair, usually because it has either a positively charged atom or a positively polarized atom in a functional group. For example:

RULE 2

The nucleophile can be either negatively charged or neutral. If the nucleophile is negatively charged, the atom that donates an electron pair becomes neutral. For example:

If the nucleophile is neutral, the atom that donates the electron pair acquires a positive charge. For example:

RULE 3

The electrophile can be either positively charged or neutral. If the electrophile is positively charged, the atom bearing that charge becomes neutral after accepting an electron pair. For example:

If the electrophile is neutral, the atom that ultimately accepts the electron pair acquires a negative charge. For this to happen, however, the negative charge must be stabilized by being on an electronegative atom such as oxygen, nitrogen, or a halogen. Carbon and hydrogen do not typically stabilize a negative charge. For example:

PROBLEM Predict the products of the following polar reaction, a step in the citric acid cycle for food 6-7 metabolism, by interpreting the flow of electrons indicated by the curved arrows:

6.6 Radical Reactions

Radical reactions are much less common than polar reactions but are nevertheless important in some industrial processes and biological pathways. We'll look at them in more detail in **Sections 10.2** and **10.3** but will briefly see how they occur at this point.

A radical is highly reactive because it contains an atom with an odd number of electrons (usually seven) in its valence shell, rather than a noble-gas octet. The radical can achieve a valence-shell octet in several ways however. For instance, it might abstract an atom and one bonding electron from another reactant, leaving behind a new radical. The net result is a radical substitution reaction.

Alternatively, a reactant radical might add to a double bond, taking one electron from the double bond and yielding a new radical. The net result is a radical addition reaction.

An example of an industrially useful radical reaction is the reaction of chlorine with methane to yield chloromethane, which is used to manufacture the solvents dichloromethane (CH_2Cl_2) and chloroform (CHCl_3). The process begins with irradiation of Cl_2 with ultraviolet light to break the relatively weak Cl-Cl bond of Cl_2 and produce chlorine radicals ($\cdot\text{Cl}$).

Chlorine radicals then react with methane by abstracting a hydrogen atom to give HCl and a methyl radical ($\cdot\text{CH}_3$) that reacts further with Cl_2 to give chloromethane plus a new chlorine radical that cycles back and repeats the first step. Thus, once the sequence has started, it becomes a self-sustaining cycle of repeating steps (a) and (b), making the overall process a chain reaction.

As a biological example of a radical reaction, look at the synthesis of *prostaglandins*, a large class of molecules found in virtually all body tissues and fluids. A number of pharmaceuticals are based on or derived from prostaglandins, including medicines that induce labor during childbirth, reduce intraocular pressure in glaucoma, control bronchial asthma, and help treat congenital heart defects.

Prostaglandin biosynthesis is initiated by the abstraction of a hydrogen atom from arachidonic acid by an iron–oxygen radical, thereby generating a carbon radical in a substitution reaction. Don't be intimidated by the size of the molecules; focus on the changes that occur in each step. (To help you do that, the unchanged part of the molecule is “ghosted,” with only the reactive part clearly visible.)

Following the initial abstraction of a hydrogen atom, the carbon radical then reacts with O_2 to give an oxygen radical, which reacts with a $\text{C}=\text{C}$ bond within the same molecule in an addition reaction. Several further transformations ultimately yield prostaglandin H_2 .

PROBLEM 6-8 Radical chlorination of alkanes is not generally useful because mixtures of products often result when more than one kind of C–H bond is present in the substrate. Draw and name all monochloro substitution products $\text{C}_6\text{H}_{13}\text{Cl}$ you might obtain by reaction of 2-methylpentane with Cl_2 .

PROBLEM Using curved fishhook arrows, propose a mechanism for the formation of the cyclopentane ring of 6-9 prostaglandin H₂.

6.7 Describing a Reaction: Equilibria, Rates, and Energy Changes

Every chemical reaction can go in either a forward or reverse direction. Reactants can go forward to products, and products can revert to reactants. As you may remember from your general chemistry course, the position of the resulting chemical equilibrium is expressed by an equation in which K_{eq} , the equilibrium constant, is equal to the product concentrations multiplied together, divided by the reactant concentrations multiplied together, with each concentration raised to the power of its coefficient in the balanced equation. For the generalized reaction

we have

$$K_{\text{eq}} = \frac{[C]^c [D]^d}{[A]^a [B]^b}$$

The value of the equilibrium constant tells which side of the reaction arrow is energetically favored. If K_{eq} is much larger than 1, then the product concentration term $[C]^c [D]^d$ is much larger than the reactant concentration term $[A]^a [B]^b$, and the reaction proceeds as written from left to right. If K_{eq} is near 1, appreciable amounts of both reactant and product are present at equilibrium. And if K_{eq} is much smaller than 1, the reaction does not take place as written but instead goes in the reverse direction, from right to left.

In the reaction of ethylene with HBr, for example, we can write the following equilibrium expression and determine experimentally that the equilibrium constant at room temperature is approximately 7.1×10^7 :

Because K_{eq} is relatively large, the reaction proceeds as written and more than 99.999 99% of the ethylene is converted into bromoethane. For practical purposes, an equilibrium constant greater than about 10^3 means that the amount of reactant left over will be barely detectable (less than 0.1%).

What determines the magnitude of the equilibrium constant? For a reaction to have a favorable equilibrium constant and proceed as written, the energy of the products must be lower than the energy of the reactants. In other words, energy must be released. This situation is analogous to that of a rock poised precariously in a high-energy position near the top of a hill. When it rolls downhill, the rock releases energy until it reaches a more stable, low-energy position at the bottom.

The energy change that occurs during a chemical reaction is called the **Gibbs free-energy change (ΔG)**, which is equal to the free energy of the products minus the free energy of the reactants: $\Delta G = G_{\text{products}} - G_{\text{reactants}}$. For a favorable reaction, ΔG has a negative value, meaning that energy is lost by the chemical system and released to the surroundings, usually as heat. Such reactions are said to be **exergonic**. For an unfavorable reaction, ΔG has a positive value, meaning that energy is absorbed by the chemical system from the surroundings. Such reactions are said to be **endergonic**.

You might also recall from general chemistry that the *standard* free-energy change for a reaction is denoted as ΔG° , where the superscript $^\circ$ means that the reaction is carried out under standard conditions, with pure substances in their most stable form at 1 atm pressure and a specified temperature, usually 298 K. For biological reactions, the standard free-energy change is denoted as $\Delta G^{\circ'}$ and refers to a reaction carried out at

pH = 7.0 with solute concentrations of 1.0 M.

Because the equilibrium constant, K_{eq} , and the standard free-energy change, ΔG° , both measure whether a reaction is favorable, they are mathematically related by the equation

$$\Delta G^\circ = -RT \ln K_{\text{eq}} \quad \text{or} \quad K_{\text{eq}} = e^{-\Delta G^\circ/RT}$$

where

$$R = 8.314 \text{ J}/(\text{K} \cdot \text{mol}) = 1.987 \text{ cal}/(\text{K} \cdot \text{mol})$$

T = Kelvin temperature

$$e = 2.718$$

$\ln K_{\text{eq}}$ = natural logarithm of K_{eq}

For example, the reaction of ethylene with HBr has $K_{\text{eq}} = 7.1 \times 10^7$, so $\Delta G^\circ = -44.8 \text{ kJ/mol}$ (-10.7 kcal/mol) at 298 K:

$$K_{\text{eq}} = 7.1 \times 10^7 \quad \text{and} \quad \ln K_{\text{eq}} = 18.08$$

$$\Delta G^\circ = -RT \ln K_{\text{eq}} = -[8.314 \text{ J}/(\text{K} \cdot \text{mol})](298 \text{ K})(18.08)$$

$$= -44,800 \text{ J/mol} = -44.8 \text{ kJ/mol}$$

The free-energy change ΔG is made up of two terms, an *enthalpy* term, ΔH , and a temperature-dependent *entropy* term, $T\Delta S$. Of the two terms, the enthalpy term is often larger and more dominant.

$$\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$$

For the reaction of ethylene with HBr at room temperature (298 K), the approximate values are

The **enthalpy change (ΔH)**, also called the **heat of reaction**, is a measure of the change in total bonding energy during a reaction. If ΔH is negative, as in the reaction of HBr with ethylene, the products have less energy than the reactants. Thus, the products are more stable and have stronger bonds than the reactants, heat is released, and the reaction is said to be **exothermic**. If ΔH is positive, the products are less stable and have weaker bonds than the reactants, heat is absorbed, and the reaction is said to be **endothermic**. For example, if a reaction breaks reactant bonds with a total strength of 380 kJ/mol and forms product bonds with a total strength of 400 kJ/mol, then ΔH for the reaction is 400 kJ/mol $-$ 380 kJ/mol = -20 kJ/mol and the reaction is exothermic.

The **entropy change (ΔS)** is a measure of the change in the amount of molecular randomness, or freedom of motion, that accompanies a reaction. For example, in an elimination reaction of the type

there is more freedom of movement and molecular randomness in the products than in the reactant because one molecule has split into two. Thus, there is a net increase in entropy during the reaction and ΔS has a positive value.

On the other hand, for an addition reaction of the type

the opposite is true. Because such reactions restrict the freedom of movement of two molecules by joining them together, the product has less randomness than the reactants and ΔS has a negative value. The reaction of ethylene and HBr to yield bromoethane, which has $\Delta S^\circ = -0.132 \text{ kJ}/(\text{K} \cdot \text{mol})$, is an example. **TABLE 6.2** describes the thermodynamic terms more fully.

TABLE 6.2 Explanation of Thermodynamic Quantities: $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$

Term	Name	Explanation
ΔG°	Gibbs free-energy change	The energy difference between reactants and products. When ΔG° is negative, the reaction is exergonic , has a favorable equilibrium constant, and can occur spontaneously. When ΔG° is positive, the reaction is endergonic , has an unfavorable equilibrium constant, and cannot occur spontaneously.
ΔH°	Enthalpy change	The heat of reaction, or difference in strength between the bonds broken in a reaction and the bonds formed. When ΔH° is negative, the reaction releases heat and is exothermic . When ΔH° is positive, the reaction absorbs heat and is endothermic .
ΔS°	Entropy change	The change in molecular randomness during a reaction. When ΔS° is negative, randomness decreases. When ΔS° is positive, randomness increases.

Knowing the value of K_{eq} for a reaction is useful, but it's important to realize its limitations. An equilibrium constant tells only the position of the equilibrium, or how much product is theoretically possible. It doesn't tell the rate of reaction, or how fast the equilibrium is established. Some reactions are extremely slow even though they have favorable equilibrium constants. Gasoline is stable at room temperature, for instance, because the rate of its reaction with oxygen is slow at 298 K. Only at higher temperatures, such as contact with a lighted match, does gasoline react rapidly with oxygen and undergo complete conversion to the equilibrium products water and carbon dioxide. Rates (how fast a reaction occurs) and equilibria (how much a reaction occurs) are entirely different.

Rate → Is the reaction fast or slow?

Equilibrium → In what direction does the reaction proceed?

PROBLEM 6-10 Which reaction is more energetically favored, one with $\Delta G^\circ = -44 \text{ kJ/mol}$ or one with $\Delta G^\circ = +44 \text{ kJ/mol}$?

PROBLEM 6-11 Which reaction is more exergonic, one with $K_{\text{eq}} = 1000$ or one with $K_{\text{eq}} = 0.001$?

6.8 Describing a Reaction: Bond Dissociation Energies

We've just seen that heat is released (negative ΔH) when a bond is formed because the products are more stable and have stronger bonds than the reactants. Conversely, heat is absorbed (positive ΔH) when a bond is broken because the products are less stable and have weaker bonds than the reactants. The amount of energy needed to break a given bond to produce two radical fragments when the molecule is in the gas phase at 25 °C is a quantity called the **bond strength**, or **bond dissociation energy (D)**.

Each specific bond has its own characteristic strength, and extensive tables of such data are available. For example, a C–H bond in methane has a bond dissociation energy $D = 439.3 \text{ kJ/mol}$ (105.0 kcal/mol), meaning that 439.3 kJ/mol must be added to break a C–H bond of methane to give the two radical fragments $\cdot\text{CH}_3$ and $\cdot\text{H}$. Conversely, 439.3 kJ/mol of energy is released when a methyl radical and a hydrogen atom combine to form methane. **TABLE 6.3** lists some other bond strengths.

TABLE 6.3 Some Bond Dissociation Energies, *D*

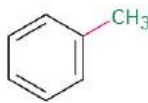

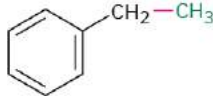

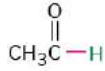

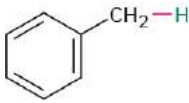

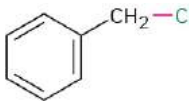

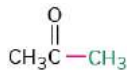

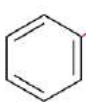

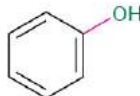

Bond	<i>D</i> (kJ/mol)	Bond	<i>D</i> (kJ/mol)	Bond	<i>D</i> (kJ/mol)
H—H	436	(CH ₃) ₂ CH—H	410	C ₂ H ₅ —CH ₃	370

C ₂ H ₅ —H	421		300		352
C ₂ H ₅ —Cl	352		336	CH ₃ CH ₂ O—CH ₃	355

TABLE 6.3 Some Bond Dissociation Energies, D

Bond	D (kJ/mol)	Bond	D (kJ/mol)	Bond	D (kJ/mol)
$\text{C}_2\text{H}_5\text{—Br}$	293		464	$\text{NH}_2\text{—H}$	450
$\text{C}_2\text{H}_5\text{—I}$	233	$\text{HC}\equiv\text{C—H}$	558	H—CN	528
$\text{C}_2\text{H}_5\text{—OH}$	391	$\text{CH}_3\text{—CH}_3$	377		

Think again about the connection between bond strengths and chemical reactivity. In an exothermic reaction, more heat is released than is absorbed. But because making bonds in the products releases heat and breaking bonds in the reactants absorbs heat, the bonds in the products must be stronger than the bonds in the reactants. In other words, exothermic reactions are favored by products with strong bonds and by reactants with weak, easily broken bonds.

Sometimes, particularly in biochemistry, reactive substances that undergo highly exothermic reactions, such as ATP (adenosine triphosphate), are referred to as “energy-rich” or “high-energy” compounds. Such a label doesn’t mean that ATP is special or different from other compounds, it only means that ATP has relatively weak bonds that require a relatively small amount of heat to break, thus leading to a larger release of heat when a strong new bond forms in a reaction. When a typical organic phosphate such as glycerol 3-phosphate reacts with water, for instance, only 9 kJ/mol of heat is released ($\Delta H^\circ = -9$ kJ/mol), but when ATP reacts with water, 30 kJ/mol of heat is released ($\Delta H^\circ = -30$ kJ/mol). The difference between the two reactions is due to the fact that the bond broken in ATP is substantially weaker than the bond broken in glycerol 3-phosphate. We’ll see the metabolic importance of this reaction in later chapters.

$$\Delta H^\circ = -9 \text{ kJ/mol}$$

$$\Delta H^\circ = -30 \text{ kJ/mol}$$

6.9 Describing a Reaction: Energy Diagrams and Transition States

For a reaction to take place, reactant molecules must collide and reorganization of atoms and bonds must occur. Let’s again look at the addition reaction of HBr and ethylene.

As the reaction proceeds, ethylene and HBr approach each other, the ethylene π bond and the H–Br bond break, a new C–H bond forms in step **1** and a new C–Br bond forms in step **2**.

To depict graphically the energy changes that occur during a reaction, chemists use energy diagrams, such as that in **FIGURE 6.5**. The vertical axis of the diagram represents the total energy of all reactants, and the horizontal axis, called the **reaction coordinate**, represents the progress of the reaction from beginning to end. Let's see how the addition of HBr to ethylene can be described in an energy diagram.

FIGURE 6.5 An energy diagram for the first step in the reaction of ethylene with HBr. The energy difference between reactants and the transition state, ΔG^\ddagger , defines the reaction rate. The energy difference between reactants and carbocation product, ΔG° , defines the position of the equilibrium.

At the beginning of the reaction, ethylene and HBr have the total amount of energy indicated by the reactant level on the left side of the diagram in **FIGURE 6.5**. As the two reactants collide and reaction commences, their electron clouds repel each other, causing the energy level to rise. If the collision has occurred with enough force and proper orientation, however, the reactants continue to approach each other despite the rising repulsion until the new C–H bond starts to form. At some point, a structure of maximum energy is reached, a structure called the **transition state**.

The transition state represents the highest-energy structure involved in this step of the reaction. It is unstable and can't be isolated, but we can imagine it to be an activated complex of the two reactants in which both the C=C π bond and H–Br bond are partially broken and the new C–H bond is partially formed (**FIGURE 6.6**).

FIGURE 6.6 A hypothetical transition-state structure for the first step of the reaction of ethylene with HBr. The C=C π bond and H–Br bond are just beginning to break, and the C–H bond is just beginning to form.

The energy difference between reactants and the transition state is called the **activation energy**, ΔG^\ddagger , and determines how rapidly the reaction occurs at a given temperature. (The double-dagger superscript, \ddagger , always

refers to the transition state.) A high activation energy results in a slow reaction because few collisions occur with enough energy for the reactants to reach the transition state. A low activation energy results in a rapid reaction because almost all collisions occur with enough energy for the reactants to reach the transition state.

As an analogy, you might think of reactants that need enough energy to climb the activation barrier to the transition state as hikers who need enough energy to climb to the top of a mountain pass. If the pass is a high one, the hikers need a lot of energy and surmount the barrier with difficulty. If the pass is low, the hikers need less energy and reach the top easily.

As a rough generalization, many organic reactions have activation energies in the range 40 to 150 kJ/mol (10–35 kcal/mol). The reaction of ethylene with HBr, for example, has an activation energy of approximately 140 kJ/mol (34 kcal/mol). Reactions with activation energies less than 80 kJ/mol take place at or below room temperature, while reactions with higher activation energies normally require a higher temperature to give the reactants enough energy to climb the activation barrier.

Once the transition state is reached, the reaction can either continue on to give the carbocation product or revert back to reactants. When reversion to reactants occurs, the transition-state structure comes apart and an amount of free energy corresponding to $-\Delta G^\ddagger$ is released. When the reaction continues on to give the carbocation, the new C–H bond forms fully and an amount of energy is released corresponding to the difference between the transition state and carbocation product. The net energy change for the step, ΔG° , is represented in the diagram as the difference in level between reactant and product. Since the carbocation is higher in energy than the starting alkene, the step is endergonic, has a positive value of ΔG° , and absorbs energy.

Not all energy diagrams are like that shown for the reaction of ethylene and HBr. Each reaction has its own energy profile. Some reactions are fast (small ΔG^\ddagger) and some are slow (large ΔG^\ddagger); some have a negative ΔG° , and some have a positive ΔG° . **FIGURE 6.7** illustrates some different possibilities.

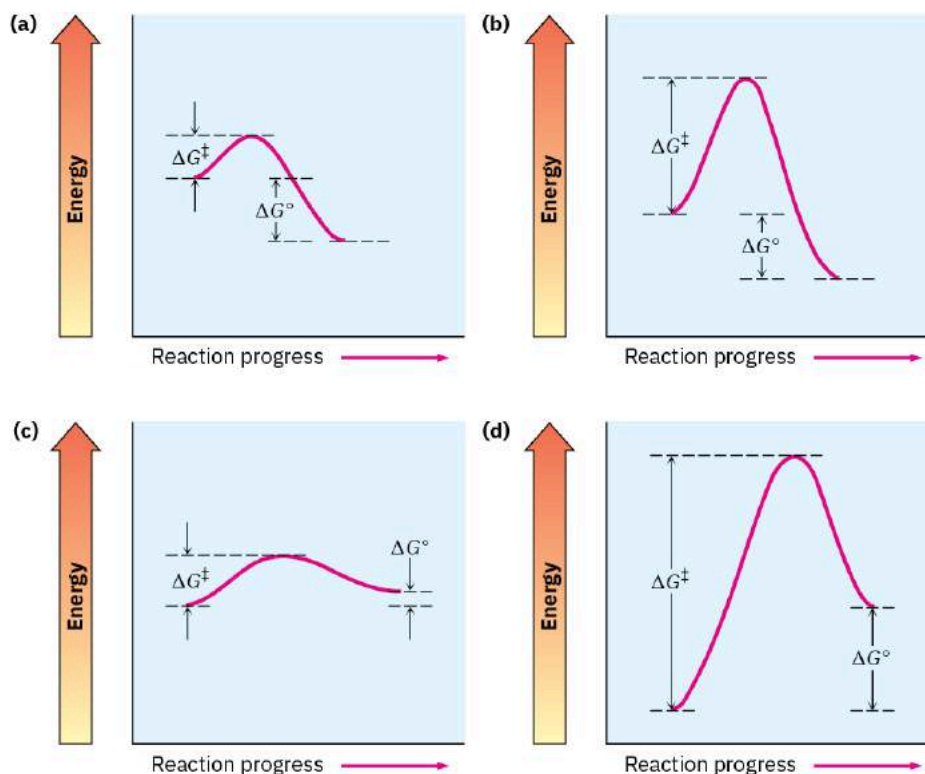

FIGURE 6.7 Some hypothetical energy diagrams: (a) a fast exergonic reaction (low ΔG^\ddagger , negative ΔG°); (b) a slow exergonic reaction (high ΔG^\ddagger , negative ΔG°); (c) a fast endergonic reaction (small ΔG^\ddagger , small positive ΔG°); (d) a slow endergonic reaction (high ΔG^\ddagger , positive ΔG°).

PROBLEM Which reaction is faster, one with $\Delta G^\ddagger = +45$ kJ/mol or one with $\Delta G^\ddagger = +70$ kJ/mol?

6-12

6.10 Describing a Reaction: Intermediates

How can we describe the carbocation formed in the first step of the reaction of ethylene with HBr? The carbocation is clearly different from the reactants, yet it isn't a transition state and it isn't a final product.

We call the carbocation, which exists only transiently during the course of the multistep reaction, a **reaction intermediate**. As soon as the intermediate is formed in the first step by reaction of ethylene with H^+ , it reacts further with Br^- in a second step to give the final product, bromoethane. This second step has its own activation energy (ΔG_2^\ddagger), its own transition state, and its own energy change (ΔG°). We can picture the second transition state as an activated complex between the electrophilic carbocation intermediate and the nucleophilic bromide anion, in which Br^- donates a pair of electrons to the positively charged carbon atom as the new C-Br bond just starts to form.

A complete energy diagram for the overall reaction of ethylene with HBr is shown in **FIGURE 6.8**. In essence, we draw a diagram for each of the individual steps and then join them so that the carbocation product of step 1 is the reactant for step 2. As indicated in **FIGURE 6.8**, the reaction intermediate lies at an energy minimum between steps. Because the energy level of the intermediate is higher than the level of either the reactant that formed it or the product it yields, the intermediate can't normally be isolated. It is, however, more stable than its two neighboring transition states.

FIGURE 6.8 An energy diagram for the reaction of ethylene with HBr. Two separate steps are involved, each with its own activation energy (ΔG^\ddagger) and free-energy change (ΔG°). The overall ΔG^\ddagger for the complete reaction is the energy difference between reactants and the highest transition state (which corresponds to ΔG_1^\ddagger in this case), and the overall ΔG° for the reaction is the energy difference between reactants and final products.

Each step in a multistep process can always be considered separately. Each step has its own ΔG^\ddagger and its own ΔG° . The overall activation energy that controls the rate of the reaction, however, is the energy difference between initial reactants and the highest transition state, regardless of which step it occurs in. The overall ΔG° of the reaction is the energy difference between reactants and final products.

The biological reactions that take place in living organisms have the same energy requirements as reactions that take place in the laboratory and can be described in similar ways. They are, however, constrained by the fact that they must have low enough activation energies to occur at moderate temperatures, and they must release

energy in relatively small amounts to avoid overheating the organism. These constraints can be met through the use of large, structurally complex, enzyme catalysts that alter the mechanism of a reaction to a pathway that can proceed through a series of small steps rather than one or two large steps. Thus, an energy diagram for a biological reaction might look like that in **FIGURE 6.9**.

FIGURE 6.9 Energy diagrams for a typical, enzyme-catalyzed biological reaction and an uncatalyzed laboratory reaction. The biological reaction involves many steps, each of which has a relatively small activation energy and small energy change. The end result is the same, however.

WORKED EXAMPLE 6.3

Drawing a Reaction Energy Diagram

Sketch an energy diagram for a one-step reaction that is fast and highly exergonic.

Strategy

A fast reaction has a small ΔG^\ddagger , and a highly exergonic reaction has a large negative ΔG° .

Solution

WORKED EXAMPLE 6.4

Drawing a Reaction Energy Diagram

Sketch an energy diagram for a two-step exergonic reaction whose second step has a higher-energy transition state than its first step. Show ΔG^\ddagger and ΔG° for the overall reaction.

Strategy

A two-step reaction has two transition states and an intermediate between them. The ΔG^\ddagger for the overall reaction is the energy change between reactants and the highest-energy transition state—the second one in this case. An exergonic reaction has a negative overall ΔG° .

Solution

PROBLEM Sketch an energy diagram for a two-step reaction in which both steps are exergonic and in which **6-13** the second step has a higher-energy transition state than the first. Label the parts of the diagram corresponding to reactant, product, intermediate, overall ΔG^\ddagger , and overall ΔG° .

6.11 A Comparison Between Biological Reactions and Laboratory Reactions

Beginning in the next chapter, we'll be seeing a lot of reactions, some that are important in laboratory chemistry yet don't occur in nature and others that have counterparts in biological pathways. In comparing laboratory reactions with biological reactions, several differences are apparent. For one, laboratory reactions are usually carried out in an organic solvent such as diethyl ether or dichloromethane to dissolve the reactants and bring them into contact, whereas biological reactions occur in the aqueous medium within cells. For another, laboratory reactions often take place over a wide range of temperatures without catalysts, while biological reactions take place at the temperature of the organism and are catalyzed by enzymes.

We'll look at **enzymes** in more detail in **Section 26.10**, but you may already be aware that an enzyme is a large, globular, protein molecule that contains in its structure a protected pocket called its **active site**. The active site is lined by acidic or basic groups as needed for catalysis and has precisely the right shape to bind and hold a substrate molecule in the orientation necessary for reaction. **FIGURE 6.10** shows a molecular model of hexokinase, along with an X-ray crystal structure of the glucose substrate and adenosine diphosphate (ADP) bound in the active site. Hexokinase is an enzyme that catalyzes the initial step of glucose metabolism—the transfer of a phosphate group from ATP to glucose, giving glucose 6-phosphate and ADP. The structures of ATP and ADP were shown at the end of **Section 6.8**.

Note how the hexokinase-catalyzed phosphorylation reaction of glucose is written. It's common when writing biological equations to show only the structures of the primary reactant and product, while abbreviating the structures of various biological "reagents" and by-products such as ATP and ADP. A curved arrow intersecting the straight reaction arrow indicates that ATP is also a reactant and ADP also a product.

FIGURE 6.10 Models of hexokinase in space-filling and wire-frame formats, showing the cleft that contains the active site where substrate binding and reaction catalysis occur. At the bottom is an X-ray crystal structure of the enzyme active site, showing the positions of both glucose and ADP as well as a lysine amino acid that acts as a base to deprotonate glucose.

Yet a third difference between laboratory and biological reactions is that laboratory reactions are often done using relatively small, simple reagents such as Br_2 , HCl , NaBH_4 , CrO_3 , and so forth, while biological reactions usually involve relatively complex “reagents” called *coenzymes*. In the hexokinase-catalyzed phosphorylation of glucose just shown, ATP is the coenzyme. As another example, compare the H_2 molecule, a laboratory reagent that adds to a carbon–carbon double bond to yield an alkane, with the reduced nicotinamide adenine dinucleotide (NADH) molecule, a coenzyme that effects an analogous addition of hydrogen to a double bond in many biological pathways. Of all the atoms in the coenzyme, only the one hydrogen atom shown in red is transferred to the double-bond substrate.

Don't be intimidated by the size of the ATP or NADH molecule; most of the structure is there to provide an overall shape for binding to the enzyme and to provide appropriate solubility behavior. When looking at biological molecules, focus on the small part of the molecule where the chemical change takes place.

One final difference between laboratory and biological reactions is in their specificity. A catalyst might be used in the laboratory to catalyze the reaction of thousands of different substances, but an enzyme, because it can only bind a specific substrate molecule having a specific shape, will usually catalyze only a specific reaction. It's this exquisite specificity that makes biological chemistry so remarkable and that makes life possible. [TABLE 6.4](#) summarizes some of the differences between laboratory and biological reactions.

TABLE 6.4 A Comparison of Typical Laboratory and Biological Reactions A Comparison of Typical Laboratory and Biological Reactions

	Laboratory reaction	Biological reaction
Solvent	Organic liquid, such as ether	Aqueous environment in cells
Temperature	Wide range; -80 to 150 °C	Temperature of organism
Catalyst	Either none, or very simple	Large, complex enzymes needed
Reagent size	Usually small and simple	Relatively complex coenzymes
Specificity	Little specificity for substrate	Very high specificity for substrate

CHEMISTRY MATTERS

Where Do Drugs Come From?

It has been estimated that major pharmaceutical companies in the United States spent some \$200 billion on drug research and development in 2020, while government agencies and private foundations spent another \$28 billion. What does this money buy? From 1983 to 2022, the money resulted in a total of 1237 new molecular entities (NMEs)—new biologically active chemical substances approved for sale as drugs by the U.S. Food and Drug Administration (FDA).

Where do the new drugs come from? According to a study carried out several years ago at the U.S. National Cancer Institute, only about 33% of new drugs are entirely synthetic and completely unrelated to any naturally occurring substance. The remaining 67% take their lead, to a greater or lesser extent, from nature. Vaccines and genetically engineered proteins of biological origin account for 15% of NMEs, but most new drugs come from *natural products*, a catchall term generally taken to mean small molecules found in bacteria, plants, algae, and other living organisms. Unmodified natural products isolated directly from the producing organism account for 24% of NMEs, while natural products that have been chemically modified in the laboratory account for the remaining 28%.

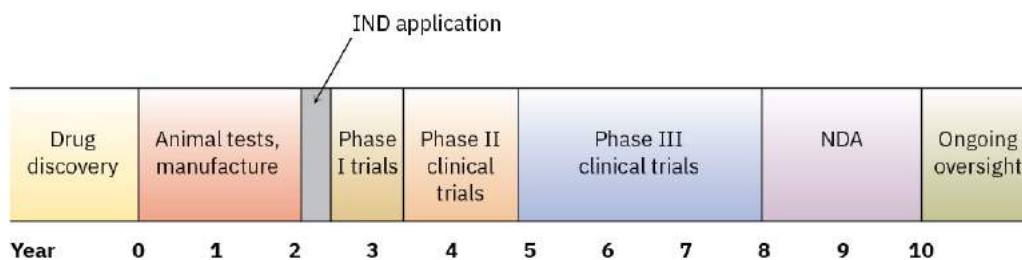

Many years of work go into screening many thousands of substances to identify a single compound that might ultimately gain approval as an NME. But after that single compound has been identified, the work has just begun because it takes an average of 9 to 10 years for a drug to make it through the approval process. First, the safety of the drug in animals must be demonstrated and an economical method of manufacture must be devised. With these preliminaries out of the way, an Investigational New Drug (IND) application is submitted to the FDA for permission to begin testing in humans.

FIGURE 6.11 Introduced in June, 2006, Gardasil is the first vaccine ever approved for the prevention of cancer. Where do new drugs like this come from? (credit: modification of work “COVIran Barekat vaccine production” by Sadegh Nigostar/Wikimedia Commons, CC BY 4.0)

Human testing takes, or should take, 5 to 7 years and is divided into three phases. Phase I clinical trials are

carried out on a small group of healthy volunteers to establish safety and look for side effects. Several months to a year are needed, and only about 70% of drugs pass at this point. Phase II clinical trials next test the drug for 1 to 2 years in several hundred patients with the target disease or condition, looking both for safety and efficacy, and only about 33% of the original group pass. Finally, phase III trials are undertaken on a large sample of patients to document definitively the drug's safety, dosage, and efficacy. If the drug is one of the 25% of the original group that make it to the end of phase III, all the data are then gathered into a New Drug Application (NDA) and sent to the FDA for review and approval, which can take another 2 years. Ten years have elapsed and at least \$500 million has been spent, with only a 20% success rate for the drugs that began testing. Finally, though, the drug will begin to appear in medicine cabinets. The following timeline shows the process.

Key Terms

- activation energy (ΔG^\ddagger)
- active site
- addition reaction
- bond dissociation energy (D)
- carbocation
- electrophile
- elimination reaction
- endergonic
- endothermic
- enthalpy change (ΔH)
- entropy change (ΔS)
- enzyme
- exergonic
- exothermic
- Gibbs free-energy change (ΔG)
- heat of reaction
- nucleophile
- polar reaction
- polarizability
- radical
- radical reaction
- reaction coordinate
- reaction intermediate
- reaction mechanism
- rearrangement reaction
- substitution reaction
- transition state

Summary

All chemical reactions, whether in the laboratory or in living organisms, follow the same chemical rules. To understand both organic and biological chemistry, it's necessary to know not just *what* occurs but also *why* and *how* chemical reactions take place. In this chapter, we've taken a brief look at the fundamental kinds of organic reactions, we've seen why reactions occur, and we've seen how reactions can be described.

There are four common kinds of reactions: **addition reactions** take place when two reactants add together to give a single product; **elimination reactions** take place when one reactant splits apart to give two products; **substitution reactions** take place when two reactants exchange parts to give two new products; and **rearrangement reactions** take place when one reactant undergoes a reorganization of bonds and atoms to give an isomeric product.

A full description of how a reaction occurs is called its **mechanism**. There are two general kinds of mechanisms by which most reactions take place: **radical** mechanisms and **polar** mechanisms. Polar reactions, the more common type, occur because of an attractive interaction between a **nucleophilic** (electron-rich) site in one molecule and an **electrophilic** (electron-poor) site in another molecule. A bond is formed in a polar reaction when the nucleophile donates an electron pair to the electrophile. This transfer of electrons is indicated by a curved arrow showing the direction of electron travel from the nucleophile to the electrophile. Radical reactions involve species that have an odd number of electrons. A bond is formed when each reactant donates one

electron.

The energy changes that take place during reactions can be described by considering both rates (how fast the reactions occur) and equilibria (how much the reactions occur). The position of a chemical equilibrium is determined by the value of the **free-energy change (ΔG)** for the reaction, where $\Delta G = \Delta H - T\Delta S$. The **enthalpy** term (ΔH) corresponds to the net change in strength of chemical bonds broken and formed during the reaction; the **entropy** term (ΔS) corresponds to the change in the amount of molecular randomness during the reaction. Reactions that have negative values of ΔG release energy, are said to be **exergonic**, and have favorable equilibria. Reactions that have positive values of ΔG absorb energy, are said to be **endergonic**, and have unfavorable equilibria.

A reaction can be described pictorially using an energy diagram that follows the reaction course from reactants through transition state to product. The **transition state** is an activated complex occurring at the highest-energy point of a reaction. The amount of energy needed by reactants to reach this high point is the **activation energy, ΔG^\ddagger** . The higher the activation energy, the slower the reaction.

Many reactions take place in more than one step and involve the formation of a **reaction intermediate**. An intermediate is a species that lies at an energy minimum between steps on the reaction curve and is formed briefly during the course of a reaction.

Additional Problems

Visualizing Chemistry

PROBLEM The following alkyl halide can be prepared by addition of HBr to two different alkenes. Draw the structures of both (reddish-brown = Br).

PROBLEM The following structure represents the carbocation intermediate formed in the addition reaction of HBr to two different alkenes. Draw the structures of both.

PROBLEM Electrostatic potential maps of (a) formaldehyde (CH_2O) and (b) methanethiol (CH_3SH) are shown.

6-16 Is the formaldehyde carbon atom likely to be electrophilic or nucleophilic? What about the methanethiol sulfur atom? Explain.

PROBLEM Look at the following energy diagram:

6-17

- (a) Is ΔG° for the reaction positive or negative? Label it on the diagram.
 (b) How many steps are involved in the reaction?
 (c) How many transition states are there? Label them on the diagram.

PROBLEM Look at the following energy diagram for an enzyme-catalyzed reaction:

6-18

- (a) How many steps are involved? (b) Which step is most exergonic?
 (c) Which step is slowest?

Energy Diagrams and Reaction Mechanisms

PROBLEM What is the difference between a transition state and an intermediate?

6-19

PROBLEM Draw an energy diagram for a one-step reaction with $K_{\text{eq}} < 1$. Label the parts of the diagram corresponding to reactants, products, transition state, ΔG° , and ΔG^\ddagger . Is ΔG° positive or negative?

6-20

PROBLEM Draw an energy diagram for a two-step reaction with $K_{\text{eq}} > 1$. Label the overall ΔG° , transition states, and intermediate. Is ΔG° positive or negative?

6-21

PROBLEM Draw an energy diagram for a two-step exergonic reaction whose second step is faster than its first step.

6-22

PROBLEM Draw an energy diagram for a reaction with $K_{\text{eq}} = 1$. What is the value of ΔG° in this reaction?

6-23

PROBLEM The addition of water to ethylene to yield ethanol has the following thermodynamic parameters:

6-24

- (a) Is the reaction exothermic or endothermic?
 (b) Is the reaction favorable (spontaneous) or unfavorable (nonspontaneous) at room temperature (298 K)?

PROBLEM 6-25 When isopropylidenecyclohexane is treated with strong acid at room temperature, isomerization occurs by the mechanism shown below to yield 1-isopropylcyclohexene:

Isopropylidenecyclohexane

1-Isopropylcyclohexene

At equilibrium, the product mixture contains about 30% isopropylidenecyclohexane and about 70% 1-isopropylcyclohexene.

- (a) What is an approximate value of K_{eq} for the reaction?
 (b) Since the reaction occurs slowly at room temperature, what is its approximate ΔG^\ddagger ?
 (c) Draw an energy diagram for the reaction.

PROBLEM 6-26 Add curved arrows to the mechanism shown in Problem 6-25 to indicate the electron movement in each step.

PROBLEM 6-27 Draw the complete mechanism for each of the following polar reactions.

PROBLEM 6-28 Use curved arrows to show the flow of electrons, and draw the carbon radical that is formed when the halogen radicals below add to the corresponding alkenes.

Polar Reactions

PROBLEM 6-29 Identify the functional groups in the following molecules, and show the polarity of each:

PROBLEM Identify the following reactions as additions, eliminations, substitutions, or rearrangements:

PROBLEM Identify the likely electrophilic and nucleophilic sites in each of the following molecules:

6-31 (a)

(b)

PROBLEM Identify the electrophile and the nucleophile.

PROBLEM Add curved arrows to the following polar reactions to indicate the flow of electrons in each:

PROBLEM Follow the flow of electrons indicated by the curved arrows in each of the following polar reactions, 6-34 and predict the products that result:

Radical Reactions

PROBLEM 6-35 Radical chlorination of pentane is a poor way to prepare 1-chloropentane, but radical chlorination of neopentane, $(\text{CH}_3)_4\text{C}$, is a good way to prepare neopentyl chloride, $(\text{CH}_3)_3\text{CCH}_2\text{Cl}$. Explain.

PROBLEM 6-36 Despite the limitations of radical chlorination of alkanes, the reaction is still useful for synthesizing certain halogenated compounds. For which of the following compounds does radical chlorination give a single monochloro product?

PROBLEM 6-37 Draw the different monochlorinated constitutional isomers you would obtain by the radical chlorination of the following compounds.

PROBLEM 6-38 Answer question 6-37 taking all stereoisomers into account.

PROBLEM 6-39 Show the structure of the carbocation that would result when each of the following alkenes reacts with an acid, H^+ .

General Problems

PROBLEM 6-40 2-Chloro-2-methylpropane reacts with water in three steps to yield 2-methyl-2-propanol. The first step is slower than the second, which in turn is much slower than the third. The reaction takes place slowly at room temperature, and the equilibrium constant is approximately 1.

- (a) Give approximate values for ΔG^\ddagger and ΔG° that are consistent with the above information.
- (b) Draw an energy diagram for the reaction, labeling all points of interest and placing relative energy levels on the diagram consistent with the information given.

PROBLEM 6-41 Add curved arrows to the mechanism shown in Problem 6-40 to indicate the electron movement in each step.

PROBLEM 6-42 The reaction of hydroxide ion with chloromethane to yield methanol and chloride ion is an example of a general reaction type called a nucleophilic substitution reaction:

The value of ΔH° for the reaction is -75 kJ/mol , and the value of ΔS° is $+54 \text{ J/(K}\cdot\text{mol)}$. What is the value of ΔG° (in kJ/mol) at 298 K ? Is the reaction exothermic or endothermic? Is it exergonic or endergonic?

PROBLEM 6-43 Methoxide ion (CH_3O^-) reacts with bromoethane in a single step according to the following equation:

Identify the bonds broken and formed, and draw curved arrows to represent the flow of electrons during the reaction.

PROBLEM 6-44 Ammonia reacts with acetyl chloride (CH_3COCl) to give acetamide (CH_3CONH_2). Identify the bonds broken and formed in each step of the reaction, and draw curved arrows to represent the flow of electrons in each step.

Acetyl chloride

PROBLEM 6-45 The naturally occurring molecule α -terpineol is biosynthesized by a route that includes the following step:

- (a) Propose a likely structure for the isomeric carbocation intermediate.

- (b) Show the mechanism of each step in the biosynthetic pathway, using curved arrows to indicate electron flow.

PROBLEM 6-46 Predict the product(s) of each of the following biological reactions by interpreting the flow of electrons as indicated by the curved arrows:

PROBLEM 6-47 Reaction of 2-methylpropene with HBr might, in principle, lead to a mixture of two alkyl bromide addition products. Name them, and draw their structures.

PROBLEM 6-48 Draw the structures of the two carbocation intermediates that might form during the reaction of 2-methylpropene with HBr (Problem 6-47). We'll see in the next chapter that the stability of carbocations depends on the number of alkyl substituents attached to the positively charged carbon—the more alkyl substituents there are, the more stable the cation. Which of the two carbocation intermediates you drew is more stable?

CHAPTER 7

Alkenes: Structure and Reactivity

7.11 Evidence for the Mechanism of Electrophilic Additions: Carbocation Rearrangements

WHY THIS CHAPTER? Carbon–carbon double bonds are present in most organic and biological molecules, so a good understanding of their behavior is needed. In this chapter, we’ll look at some consequences of alkene stereoisomerism and then focus on the broadest and most general class of alkene reactions, the electrophilic addition reaction. Carbon–carbon triple bonds, by contrast, occur much less commonly, so we’ll not spend much time on their chemistry.

An **alkene**, sometimes called an *olefin* from the German term for oil forming, is a hydrocarbon that contains a carbon–carbon double bond, while an **alkyne** is a hydrocarbon that contains a carbon–carbon triple bond. Alkenes occur abundantly in nature. Ethylene, for instance, is a plant hormone that induces ripening in fruit, and α -pinene is the major component of turpentine. Lycopene, found in fruits such as watermelon and papaya

as well as tomatoes, is an antioxidant with numerous health benefits such as sun protection and cardiovascular protection.

7.1 Industrial Preparation and Use of Alkenes

Ethylene and propylene, the simplest alkenes, are the two most important organic chemicals produced industrially. Approximately 220 million tons of ethylene and 138 million tons of propylene are produced worldwide each year for use in the synthesis of polyethylene, polypropylene, ethylene glycol, acetic acid, acetaldehyde, and a host of other substances (FIGURE 7.2).

FIGURE 7.2 Compounds derived industrially from ethylene and propylene.

Ethylene, propylene, and butene are synthesized from (C_2 – C_8) alkanes by a process called *steam cracking* at temperatures up to 900 °C.

The cracking process is complex, although it undoubtedly involves radical reactions. The high-temperature

reaction conditions cause spontaneous breaking of C–C and C–H bonds, with the resultant formation of smaller fragments. We might imagine, for instance, that a molecule of butane splits into two ethyl radicals, each of which then loses a hydrogen atom to generate two molecules of ethylene.

Steam cracking is an example of a reaction whose energetics are dominated by entropy (ΔS°) rather than by enthalpy (ΔH°) in the free-energy equation $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$ discussed in [Section 6.7](#). Although the bond dissociation energy D for a carbon–carbon single bond is relatively high (about 370 kJ/mol) and cracking is endothermic, the large positive entropy change resulting from the fragmentation of one large molecule into several smaller pieces, together with the high temperature, makes the $T\Delta S^\circ$ term larger than the ΔH° term, thereby favoring the cracking reaction.

7.2 Calculating the Degree of Unsaturation

Because of its double bond, an alkene has fewer hydrogens than an alkane with the same number of carbons— C_nH_{2n} for an alkene versus C_nH_{2n+2} for an alkane—and is therefore referred to as **unsaturated**. Ethylene, for example, has the formula C_2H_4 , whereas ethane has the formula C_2H_6 .

In general, each ring or double bond in a molecule corresponds to a loss of two hydrogens from the alkane formula C_nH_{2n+2} . Knowing this relationship, it's possible to work backward from a molecular formula to calculate a molecule's **degree of unsaturation**—the number of rings and/or multiple bonds present in the molecule.

Let's assume that we want to find the structure of an unknown hydrocarbon. A molecular weight determination yields a value of 82 amu, which corresponds to a molecular formula of C_6H_{10} . Since the saturated C_6 alkane (hexane) has the formula C_6H_{14} , the unknown compound has two fewer pairs of hydrogens ($H_{14} - H_{10} = H_4 = 2 H_2$) so its degree of unsaturation is 2. The unknown therefore contains either two double bonds, one ring and one double bond, two rings, or one triple bond. There's still a long way to go to establish its structure, but the simple calculation has told us a lot about the molecule.

Similar calculations can be carried out for compounds containing elements other than just carbon and hydrogen.

- **Organohalogen compounds (C, H, X, where X = F, Cl, Br, or I)** A halogen substituent acts as a replacement for hydrogen in an organic molecule, so we can add the number of halogens and hydrogens to arrive at an equivalent hydrocarbon formula from which the degree of unsaturation can be found. For example, the formula $C_4H_6Br_2$ is equivalent to the hydrocarbon formula C_4H_8 and thus corresponds to one degree of unsaturation.

- **Organooxygen compounds (C, H, O)** Oxygen forms two bonds, so it doesn't affect the formula of an equivalent hydrocarbon and can be ignored when calculating the degree of unsaturation. You can convince yourself of this by seeing what happens when an oxygen atom is inserted into an alkane bond: C–C becomes C–O–C or C–H becomes C–O–H, and there is no change in the number of hydrogen atoms. For example, the formula C₅H₈O is equivalent to the hydrocarbon formula C₅H₈ and thus corresponds to two degrees of unsaturation.

- **Organonitrogen compounds (C, H, N)** Nitrogen forms three bonds, so an organonitrogen compound has one more hydrogen than a related hydrocarbon. We therefore subtract the number of nitrogens from the number of hydrogens to arrive at the equivalent hydrocarbon formula. Again, you can convince yourself of this by seeing what happens when a nitrogen atom is inserted into an alkane bond: C–C becomes C–NH–C or C–H becomes C–NH₂, meaning that one additional hydrogen atom has been added. We must therefore subtract this extra hydrogen atom to arrive at the equivalent hydrocarbon formula. For example, the formula C₅H₉N is equivalent to C₅H₈ and thus has two degrees of unsaturation.

To summarize:

- **Add** the number of **halogens** to the number of hydrogens.
- **Ignore** the number of **oxygens**.
- **Subtract** the number of **nitrogens** from the number of hydrogens.

PROBLEM Calculate the degree of unsaturation in each of the following formulas, and then draw as many

7-1 structures as you can for each:

(a) C₄H₈ (b) C₄H₆ (c) C₃H₄

PROBLEM Calculate the degree of unsaturation in each of the following formulas:

7-2 (a) C₆H₅N (b) C₆H₅NO₂ (c) C₈H₉Cl₃ (d) C₉H₁₆Br₂ (e) C₁₀H₁₂N₂O₃ (f) C₂₀H₃₂ClN

PROBLEM Diazepam, marketed as an antianxiety medication under the name Valium, has three rings, eight

7-3 double bonds, and the formula C₁₆H₁₇ClN₂O. How many hydrogens does diazepam have? (Calculate the answer; don't count hydrogens in the structure.)

7.3 Naming Alkenes

Alkenes are named using a series of rules similar to those for alkanes (Section 3.4), with the suffix *-ene* used instead of *-ane* to identify the functional group. There are three steps to this process.

STEP 1

Name the parent hydrocarbon. Find the longest carbon chain containing the double bond, and name the compound accordingly, using the suffix *-ene*:

STEP 2

Number the carbon atoms in the chain. Begin at the end nearer the double bond or, if the double bond is equidistant from the two ends, begin at the end nearer the first branch point. This rule ensures that the double-bond carbons receive the lowest possible numbers.

STEP 3

Write the full name. Number the substituents according to their positions in the chain, and list them alphabetically. Indicate the position of the double bond by giving the number of the first alkene carbon and placing that number directly before the parent name. If more than one double bond is present, indicate the position of each and use one of the suffixes *-diene*, *-triene*, and so on.

We should also note that IUPAC changed their naming recommendations in 1993 to place the locant indicating the position of the double bond immediately before the *-ene* suffix rather than before the parent name: but-2-ene rather than 2-butene, for instance. This change has not been widely accepted by the chemical community in the United States, however, so we'll stay with the older but more commonly used names. Be aware, though, that you may occasionally encounter the newer system.

Cycloalkenes are named similarly, but because there is no chain end to begin from, we number the cycloalkene so that the double bond is between C1 and C2 and the first substituent has as low a number as possible. It's not necessary to indicate the position of the double bond in the name because it's always between C1 and C2. As with open-chain alkenes, the newer but not yet widely accepted naming rules place the locant immediately before the suffix in a cyclic alkene.

For historical reasons, there are a few alkenes whose names are firmly entrenched in common usage but don't conform to the rules. For example, the alkene derived from ethane should be called *ethene*, but the name *ethylene* has been used for so long that it is accepted by IUPAC. **TABLE 7.1** lists several other common names that are often used and are recognized by IUPAC. Note also that a =CH₂ substituent is called a **methylene group**, a H₂C=CH– substituent is called a **vinyl group**, and a H₂C=CHCH₂– substituent is called an **allyl group**.

TABLE 7.1 Common Names of Some Alkenes

Compound	Systematic name	Common name
$\text{H}_2\text{C}=\text{CH}_2$	Ethene	Ethylene
$\text{CH}_3\text{CH}=\text{CH}_2$	Propene	Propylene
$\begin{array}{c} \text{CH}_3 \\ \\ \text{CH}_3\text{C}=\text{CH}_2 \end{array}$	2-Methylpropene	Isobutylene
$\begin{array}{c} \text{CH}_3 \\ \\ \text{H}_2\text{C}=\text{C}-\text{CH}=\text{CH}_2 \end{array}$	2-Methyl-1,3-butadiene	Isoprene

PROBLEM Give IUPAC names for the following compounds:

PROBLEM Draw structures corresponding to the following IUPAC names:

- 7-5 (a) 2-Methyl-1,5-hexadiene (b) 3-Ethyl-2,2-dimethyl-3-heptene
 (c) 2,3,3-Trimethyl-1,4,6-octatriene (d) 3,4-Diisopropyl-2,5-dimethyl-3-hexene

PROBLEM Name the following cycloalkenes:

PROBLEM Change the following old names to new, post-1993 names, and draw the structure of each 7-7 compound:

(a) 2,5,5-Trimethyl-2-hexene (b) 2,3-Dimethyl-1,3-cyclohexadiene

7.4 Cis–Trans Isomerism in Alkenes

We saw in the chapter on **Structure and Bonding** that the carbon–carbon double bond can be described in two ways. In valence bond language (**Section 1.8**), the carbons are sp^2 -hybridized and have three equivalent hybrid orbitals that lie in a plane at angles of 120° to one another. The carbons form a σ bond by a head-on overlap of sp^2 orbitals and form a π bond by sideways overlap of unhybridized p orbitals oriented perpendicular to the sp^2 plane, as shown in **FIGURE 1.15**.

In molecular orbital language (**Section 1.11**), interaction between the p orbitals leads to one bonding and one antibonding π molecular orbital. The π bonding MO has no node between nuclei and results from a combination of p orbital lobes with the same algebraic sign. The π antibonding MO has a node between nuclei and results from a combination of lobes with different algebraic signs, as shown in **FIGURE 1.19**.

Although essentially free rotation around single bonds is possible (**Section 3.6**), the same is not true of double bonds. For rotation to occur around a double bond, the π bond must break and re-form (**FIGURE 7.3**). Thus, the barrier to double-bond rotation must be at least as great as the strength of the π bond itself, an estimated 350 kJ/mol (84 kcal/mol). Recall that the barrier to bond rotation in ethane is only 12 kJ/mol.

FIGURE 7.3 The π bond must break for rotation to take place around a carbon–carbon double bond.

The lack of rotation around carbon–carbon double bonds is of more than just theoretical interest; it also has chemical consequences. Imagine the situation for a disubstituted alkene such as 2-butene. (Disubstituted means that two substituents other than hydrogen are bonded to the double-bond carbons.) The two methyl groups in 2-butene can either be on the same side of the double bond or on opposite sides, a situation similar to that in disubstituted cycloalkanes (**Section 4.2**).

Since bond rotation can't occur, the two 2-butenes can't spontaneously interconvert; they are different, isolable compounds. As with disubstituted cycloalkanes, we call such compounds *cis–trans* stereoisomers. The compound with substituents on the same side of the double bond is called *cis*-2-butene, and the isomer with substituents on opposite sides is *trans*-2-butene (**FIGURE 7.4**).

FIGURE 7.4 Cis and trans isomers of 2-butene. The cis isomer has the two methyl groups on the same side of the double bond, and the trans isomer has methyl groups on opposite sides.

Cis–trans isomerism is not limited to disubstituted alkenes. It can occur whenever both double-bond carbons are attached to two different groups. If one of the double-bond carbons is attached to two identical groups, however, cis–trans isomerism is not possible (FIGURE 7.5).

FIGURE 7.5 The requirement for cis–trans isomerism in alkenes. Compounds that have one of their carbons bonded to two identical groups can't exist as cis–trans isomers. Only when both carbons are bonded to two different groups is cis–trans isomerism possible.

PROBLEM The sex attractant of the common housefly is an alkene named *cis*-9-tricosene. Draw its structure.
7-8 (Tricosane is the straight-chain alkane $C_{23}H_{48}$.)

PROBLEM Which of the following compounds can exist as pairs of cis–trans isomers? Draw each pair, and
7-9 indicate the geometry of each isomer.

- (a) $CH_3CH=CH_2$ (b) $(CH_3)_2C=CHCH_3$ (c) $CH_3CH_2CH=CHCH_3$ (d) $(CH_3)_2C=C(CH_3)CH_2CH_3$
 (e) $ClCH=CHCl$ (f) $BrCH=CHCl$

PROBLEM Name the following alkenes, including a cis or trans designation:

7-10 (a)

(b)

7.5 Alkene Stereochemistry and the *E,Z* Designation

The cis–trans naming system used in the previous section works only with disubstituted alkenes—compounds that have two substituents other than hydrogen on the double bond. With trisubstituted and tetrasubstituted double bonds, a more general method is needed for describing double-bond geometry. (*Trisubstituted* means three substituents other than hydrogen on the double bond; *tetrasubstituted* means four substituents other than hydrogen.)

The method used for describing alkene stereochemistry is called the ***E,Z* system** and employs the same Cahn–Ingold–Prelog sequence rules given in Section 5.5 for specifying the configuration of a chirality center. Let's briefly review the sequence rules and then see how they're used to specify double-bond geometry. For a more thorough review, reread Section 5.5.

RULE 1

Considering each of the double-bond carbons separately, look at the two substituents attached and rank them according to the atomic number of the first atom in each (8 for oxygen, 6 for carbon, 1 for hydrogen, and so forth). An atom with higher atomic number ranks higher than an atom with lower atomic number.

RULE 2

If a decision can't be reached by ranking the first atoms in the two substituents, look at the second, third, or fourth atoms away from the double-bond until the first difference is found.

RULE 3

Multiple-bonded atoms are equivalent to the same number of single-bonded atoms.

Once the two groups attached to each double-bonded carbon have been ranked as either higher or lower, look at the entire molecule. If the higher-ranked groups on each carbon are on the same side of the double bond, the alkene is said to have a **Z configuration**, for the German *zusammen*, meaning “together.” If the higher-ranked groups are on opposite sides, the alkene has an **E configuration**, for the German *entgegen*, meaning “opposite.” (For a simple way to remember which is which, note that the groups are on “ze zame zide” in the Z isomer.)

As an example, look at the following two isomers of 2-chloro-2-butene. Because chlorine has a higher atomic number than carbon, a $-\text{Cl}$ substituent is ranked higher than a $-\text{CH}_3$ group. Methyl is ranked higher than hydrogen, however, so isomer **(a)** is designated *E* because the higher-ranked groups are on opposite sides of the double bond. Isomer **(b)** has a *Z* configuration because its higher-ranked groups are on ze zame zide of the double bond.

For further practice, work through each of the following examples to convince yourself that the assignments are correct:

**WORKED EXAMPLE 7.1****Assigning *E* and *Z* Configurations to Alkenes**

Assign *E* or *Z* configuration to the double bond in the following compound:

**Strategy**

Look at the two substituents connected to each double-bonded carbon, and determine their ranking using the Cahn–Ingold–Prelog rules. Then, check whether the two higher-ranked groups are on the same or opposite sides of the double bond.

Solution

The left-hand carbon has $-H$ and $-CH_3$ substituents, of which $-CH_3$ ranks higher by sequence rule 1. The right-hand carbon has $-CH(CH_3)_2$ and $-CH_2OH$ substituents, which are equivalent by rule 1. By rule 2, however, $-CH_2OH$ ranks higher than $-CH(CH_3)_2$ because the substituent $-CH_2OH$ has an oxygen as its highest second atom, but $-CH(CH_3)_2$ has a carbon as its highest second atom. The two higher-ranked groups are on the same side of the double bond, so we assign a *Z* configuration.

PROBLEM Which member in each of the following sets ranks higher?

- 7-11 (a) $-H$ or $-CH_3$ (b) $-Cl$ or $-CH_2Cl$ (c) $-CH_2CH_2Br$ or $-CH=CH_2$ (d) $-NHCH_3$ or $-OCH_3$
 (e) $-CH_2OH$ or $-CH=O$ (f) $-CH_2OCH_3$ or $-CH=O$

PROBLEM Rank the substituents in each of the following sets according to the sequence rules:

- 7-12 (a) $-CH_3$, $-OH$, $-H$, $-Cl$ (b) $-CH_3$, $-CH_2CH_3$, $-CH=CH_2$, $-CH_2OH$
 (c) $-CO_2H$, $-CH_2OH$, $-C\equiv N$, $-CH_2NH_2$ (d) $-CH_2CH_3$, $-C\equiv CH$, $-C\equiv N$, $-CH_2OCH_3$

PROBLEM Assign *E* or *Z* configuration to the following alkenes:

- 7-13 (a) (b) (c)
- (d)

PROBLEM Assign stereochemistry (*E* or *Z*) to the double bond in the following compound, and convert the drawing into a skeletal structure (red = O):

7-14

7.6 Stability of Alkenes

Although the *cis*–*trans* interconversion of alkene isomers does not occur spontaneously, it can often be made to happen by treating the alkene with a strong acid catalyst. If we interconvert *cis*-2-butene with *trans*-2-butene and allow them to reach equilibrium, we find that they aren't of equal stability. The *trans* isomer is more stable than the *cis* isomer by 2.8 kJ/mol (0.66 kcal/mol) at room temperature, corresponding to a 76 : 24 ratio.

Cis alkenes are less stable than their *trans* isomers because of steric strain between the two larger substituents on the same side of the double bond. This is the same kind of steric interference that we saw previously in the axial conformation of methylcyclohexane (Section 4.7).

Although it's sometimes possible to find relative stabilities of alkene isomers by establishing a *cis*–*trans* equilibrium through treatment with strong acid, a more general method is to take advantage of the fact that alkenes undergo a *hydrogenation* reaction to give the corresponding alkane when treated with H_2 gas in the presence of a catalyst such as palladium or platinum.

Energy diagrams for the hydrogenation reactions of *cis*- and *trans*-2-butene are shown in **FIGURE 7.6**. Because *cis*-2-butene is less stable than *trans*-2-butene by 2.8 kJ/mol, the energy diagram shows the *cis* alkene at a higher energy level. After reaction, however, both curves are at the same energy level (butane). It therefore follows that ΔG° for reaction of the *cis* isomer must be larger than ΔG° for reaction of the *trans* isomer by 2.8 kJ/mol. In other words, more energy is released in the hydrogenation of the *cis* isomer than the *trans* isomer because the *cis* isomer has more energy to begin with.

FIGURE 7.6 Energy diagrams for hydrogenation of *cis*- and *trans*-2-butene. The *cis* isomer is higher in energy than the *trans* isomer by about 2.8 kJ/mol and therefore releases more energy when hydrogenated.

If we were to measure the so-called heats of hydrogenation ($\Delta H^\circ_{\text{hydrog}}$) for two double-bond isomers and find their difference, we could determine the relative stabilities of *cis* and *trans* isomers without having to measure an equilibrium position. *cis*-2-Butene, for instance, has $\Delta H^\circ_{\text{hydrog}} = -119$ kJ/mol (−28.3 kcal/mol), while *trans*-2-butene has $\Delta H^\circ_{\text{hydrog}} = -115$ kJ/mol (−27.4 kcal/mol)—a difference of 4 kJ/mol.

The 4 kJ/mol energy difference between the 2-butene isomers calculated from heats of hydrogenation agrees reasonably well with the 2.8 kJ/mol energy difference calculated from equilibrium data, but the values aren't exactly the same for two reasons. First, there is probably some experimental error, because heats of hydrogenation are difficult to measure accurately. Second, heats of reaction and equilibrium constants don't measure exactly the same thing. Heats of reaction measure enthalpy changes, ΔH° , whereas equilibrium constants measure free-energy changes, ΔG° , so we might expect a slight difference between the two.

TABLE 7.2 Heats of Hydrogenation of Some Alkenes

Substitution	Alkene	$\Delta H^\circ_{\text{hydrog}}$	
		(kJ/mol)	(kcal/mol)
Ethylene	$\text{H}_2\text{C}=\text{CH}_2$	-136	-32.6
Monosubstituted	$\text{CH}_3\text{CH}=\text{CH}_2$	-125	-29.9
Disubstituted	$\text{CH}_3\text{CH}=\text{CHCH}_3$ (<i>cis</i>)	-119	-28.3
	$\text{CH}_3\text{CH}=\text{CHCH}_3$ (<i>trans</i>)	-115	-27.4
	$(\text{CH}_3)_2\text{C}=\text{CH}_2$	-118	-28.2
Trisubstituted	$(\text{CH}_3)_2\text{C}=\text{CHCH}_3$	-112	-26.7
Tetrasubstituted	$(\text{CH}_3)_2\text{C}=\text{C}(\text{CH}_3)_2$	-110	-26.4

TABLE 7.2 lists some representative data for the hydrogenation of different alkenes and shows that alkenes become more stable with increasing substitution. That is, alkenes follow the stability order:

The stability order of substituted alkenes is due to a combination of two factors. One is a stabilizing interaction between the $C=C$ π orbital and adjacent $C-H$ σ bonds on substituents. In valence-bond language, the interaction is called **hyperconjugation**. In a molecular orbital description, there is a bonding MO that extends over the four-atom $C=C-C-H$ grouping, as shown in **FIGURE 7.7**. The more substituents present on the double bond, the more hyperconjugation occurs and the more stable the alkene.

FIGURE 7.7 Hyperconjugation is a stabilizing interaction between the $C=C$ π orbital and adjacent $C-H$ σ bonds on substituents. The more substituents there are, the greater the stabilization of the alkene.

A second factor that contributes to alkene stability involves bond strengths. A bond between a sp^2 carbon and a sp^3 carbon is somewhat stronger than a bond between two sp^3 carbons. Thus, in comparing 1-butene and 2-butene, the monosubstituted isomer has one sp^3-sp^3 bond and one sp^3-sp^2 bond, while the disubstituted isomer has two sp^3-sp^2 bonds. More highly substituted alkenes always have a higher ratio of sp^3-sp^2 bonds to sp^3-sp^3 bonds than less highly substituted alkenes and are therefore more stable.

PROBLEM Name the following alkenes, and tell which compound in each pair is more stable:

7.7 Electrophilic Addition Reactions of Alkenes

Before beginning a detailed discussion of alkene reactions, let's review briefly some conclusions from the previous chapter. We said in **Section 6.5** that alkenes behave as nucleophiles (Lewis bases) in polar reactions, donating a pair of electrons from their electron-rich $C=C$ bond to an electrophile (Lewis acid). For example, reaction of 2-methylpropene with HBr yields 2-bromo-2-methylpropane. A careful study of this and similar reactions by the British chemist Christopher Ingold and others in the 1930s led to the generally accepted mechanism shown in **FIGURE 7.8** for an **electrophilic addition reaction**.

FIGURE 7.8 MECHANISM

Mechanism of the electrophilic addition of HBr to 2-methylpropene. The reaction occurs in two steps, protonation and bromide addition, and involves a carbocation intermediate.

- 1 A hydrogen atom on the electrophile HBr is attacked by π electrons from the nucleophilic double bond, forming a new C–H bond. This leaves the other carbon atom with a + charge and a vacant p orbital. Simultaneously, two electrons from the H–Br bond move onto bromine, giving bromide anion.
- 2 The bromide ion donates an electron pair to the positively charged carbon atom, forming a C–Br bond and yielding the neutral addition product.

The reaction begins with an attack on the hydrogen of the electrophile HBr by the electrons of the nucleophilic π bond. Two electrons from the π bond form a new σ bond between the entering hydrogen and an alkene carbon, as shown by the curved arrow at the top of **FIGURE 7.8**. The resulting carbocation intermediate is itself an electrophile, which can accept an electron pair from nucleophilic Br^- ion to form a C–Br bond and yield a neutral addition product.

An energy diagram for the overall electrophilic addition reaction (**FIGURE 7.9**) has two peaks (transition states) separated by a valley (carbocation intermediate). The energy level of the intermediate is higher than that of the starting alkene, but the reaction as a whole is exergonic (negative ΔG°). The first step, protonation of the alkene to yield the intermediate cation, is relatively slow. But once the cation intermediate is formed, it rapidly reacts to yield the final alkyl bromide product. The relative rates of the two steps are indicated in **FIGURE 7.9** by the fact that ΔG_1^\ddagger is larger than ΔG_2^\ddagger .

FIGURE 7.9 Energy diagram for the two-step electrophilic addition of HBr to 2-methylpropene. The first step is slower than the second step.

Electrophilic addition to alkenes is successful not only with HBr but with HCl, HI, and H₂O as well. Note that HI is usually generated in the reaction mixture by treating potassium iodide with phosphoric acid and that a strong acid catalyst is needed for the addition of water.

WRITING ORGANIC REACTIONS

This is a good place to mention that the equations for organic reactions are sometimes written in different ways to emphasize different points. In describing a laboratory process, for instance, the reaction of 2-methylpropene with HCl might be written in the format $A + B \rightarrow C$ to emphasize that both reactants are equally important for the purposes of the discussion. The solvent and notes about other reaction conditions such as temperature are written either above or below the reaction arrow.

Alternatively, we might write the same reaction in a format to emphasize that 2-methylpropene is the reactant whose chemistry is of greater interest. The second reactant, HCl, is placed above the reaction arrow together with notes about solvent and reaction conditions.

In describing a biological process, the reaction is almost always written to show only the structures of the primary reactant and product, while abbreviating the structures of various biological “reagents” and by-products with a curved arrow that intersects the straight reaction arrow. As discussed in [Section 6.11](#), the reaction of glucose with ATP to give glucose 6-phosphate plus ADP would then be written as

7.8 Orientation of Electrophilic Additions: Markovnikov's Rule

Look carefully at the electrophilic addition reactions shown in the previous section. In each case, an unsymmetrically substituted alkene has given a single addition product rather than the mixture that might be expected. For example, 2-methylpropene might react with HCl to give both 2-chloro-2-methylpropane and 1-chloro-2-methylpropane, but it doesn't. It gives only 2-chloro-2-methylpropane as the sole product. Similarly, it's invariably the case in biological alkene addition reactions that only a single product is formed. We say that such reactions are **regiospecific** (**ree**-jee-oh-specific) when only one of two possible orientations of an addition occurs.

After looking at the results of many such reactions, the Russian chemist Vladimir Markovnikov proposed in 1869 what has become known as:

Markovnikov's rule

In the addition of HX to an alkene, the H attaches to the carbon with fewer alkyl substituents and the X attaches to the carbon with more alkyl substituents.

When both double-bonded carbon atoms have the same degree of substitution, a mixture of addition products results.

Because carbocations are involved as intermediates in these electrophilic addition reactions, Markovnikov's rule can be restated in the following way:

Markovnikov's rule restated

In the addition of HX to an alkene, the more highly substituted carbocation is formed as the intermediate rather than the less highly substituted one.

For example, addition of H^+ to 2-methylpropene yields the intermediate *tertiary* carbocation rather than the alternative primary carbocation, and addition to 1-methylcyclohexene yields a tertiary cation rather than a secondary one. Why should this be?

WORKED EXAMPLE 7.2

Predicting the Product of an Electrophilic Addition Reaction

What product would you expect from reaction of HCl with 1-ethylcyclopentene?

Strategy

When solving a problem that asks you to predict a reaction product, begin by looking at the functional group(s) in the reactants and deciding what kind of reaction is likely to occur. In the present instance, the reactant is an alkene that will probably undergo an electrophilic addition reaction with HCl. Next, recall what you know about electrophilic addition reactions to predict the product. You know that electrophilic addition reactions follow Markovnikov's rule, so H^+ will add to the double-bond carbon that has one alkyl group (C2 on the ring) and the Cl will add to the double-bond carbon that has two alkyl groups (C1 on the ring).

Solution

The expected product is 1-chloro-1-ethylcyclopentane.

WORKED EXAMPLE 7.3

Synthesizing a Specific Compound

What alkene would you start with to prepare the following alkyl halide? There may be more than one possibility.

Strategy

When solving a problem that asks how to prepare a given product, always work backward. Look at the product, identify the functional group(s) it contains, and ask yourself, "How can I prepare that functional group?" In the present instance, the product is a tertiary alkyl chloride, which can be prepared by reaction of an alkene with HCl. The carbon atom bearing the -Cl atom in the product must be one of the double-bond carbons in the reactant. Draw and evaluate all possibilities.

Solution

There are three possibilities, all of which could give the desired product according to Markovnikov's rule.

PROBLEM Predict the products of the following reactions:

PROBLEM What alkenes would you start with to prepare the following products?

7.9 Carbocation Structure and Stability

To understand why Markovnikov's rule works, we need to learn more about the structure and stability of carbocations and about the general nature of reactions and transition states. The first point to explore involves structure.

A great deal of experimental evidence has shown that carbocations are planar. The trivalent carbon is sp^2 -hybridized, and the three substituents are oriented toward the corners of an equilateral triangle, as indicated in **FIGURE 7.10**. Because there are only six valence electrons on carbon and all six are used in the three σ bonds, the p orbital extending above and below the plane is unoccupied.

FIGURE 7.10 The structure of a carbocation. The trivalent carbon is sp^2 -hybridized and has a vacant p orbital perpendicular to the plane of the carbon and three attached groups.

The second point to explore involves carbocation stability. 2-Methylpropene might react with H^+ to form a carbocation having three alkyl substituents (a tertiary ion, 3°), or it might react to form a carbocation having one alkyl substituent (a primary ion, 1°). Since the tertiary alkyl chloride, 2-chloro-2-methylpropane, is the only product observed, formation of the tertiary cation is evidently favored over formation of the primary cation. Thermodynamic measurements show that, indeed, the stability of carbocations increases with increasing substitution so that the stability order is tertiary > secondary > primary > methyl.

One way of determining carbocation stabilities is to measure the amount of energy required to form a carbocation by dissociation of the corresponding alkyl halide, $R - X \rightarrow R^+ + :X^-$. As shown in **FIGURE 7.11**, tertiary alkyl halides dissociate to give carbocations more easily than secondary or primary ones. Thus, trisubstituted carbocations are more stable than disubstituted ones, which are more stable than monosubstituted ones. The data in **FIGURE 7.11** are taken from measurements made in the gas phase, but a similar stability order is found for carbocations in solution. The dissociation enthalpies are much lower in solution because polar solvents can stabilize the ions, but the order of carbocation stability remains the same.

FIGURE 7.11 A plot of dissociation enthalpy versus substitution pattern for the gas-phase dissociation of alkyl chlorides to yield carbocations. More highly substituted alkyl halides dissociate more easily than less highly substituted ones.

Why are more highly substituted carbocations more stable than less highly substituted ones? There are at least two reasons. Part of the answer has to do with inductive effects, and part has to do with hyperconjugation. Inductive effects, discussed in [Section 2.1](#) in connection with polar covalent bonds, result from the shifting of electrons in a σ bond in response to the electronegativity of nearby atoms. In the present instance, electrons from a relatively larger and more polarizable alkyl group can shift toward a neighboring positive charge more easily than the electron from a hydrogen. Thus, the more alkyl groups attached to the positively charged carbon, the more electron density shifts toward the charge and the more inductive stabilization of the cation occurs (**FIGURE 7.12**).

FIGURE 7.12 A comparison of inductive stabilization for methyl, primary, secondary, and tertiary carbocations. The more alkyl groups that are bonded to the positively charged carbon, the more electron density shifts toward the charge, making the charged carbon less electron-poor (blue in electrostatic potential maps).

Hyperconjugation, discussed in [Section 7.6](#) in connection with the stabilities of substituted alkenes, is the stabilizing interaction between a p orbital and properly oriented C–H σ bonds on neighboring carbons that are roughly parallel to the p orbital. The more alkyl groups there are on the carbocation, the more possibilities there are for hyperconjugation and the more stable the carbocation. **FIGURE 7.13** shows the molecular orbital for the ethyl carbocation, CH₃CH₂⁺, and indicates the difference between the C–H bond perpendicular to the cation p orbital and the two C–H bonds more parallel to the cation p orbital. Only these roughly parallel C–H bonds are oriented properly to take part in hyperconjugation.

FIGURE 7.13 Stabilization of the ethyl carbocation, CH_3CH_2^+ , through hyperconjugation. Interaction of neighboring C–H σ bonds with the vacant p orbital stabilizes the cation and lowers its energy. The molecular orbital shows that only the two C–H bonds more parallel to the cation p orbital are oriented properly. The C–H bond perpendicular to the cation p orbital can't take part properly.

PROBLEM Show the structures of the carbocation intermediates you would expect in the following reactions:

PROBLEM Draw a skeletal structure of the following carbocation. Identify it as primary, secondary, or tertiary, and identify the hydrogen atoms that have the proper orientation for hyperconjugation in the conformation shown.

7.10 The Hammond Postulate

Let's summarize what we've learned of electrophilic addition reactions to this point:

- **Electrophilic addition to an unsymmetrically substituted alkene gives the more substituted carbocation intermediate.** A more substituted carbocation forms faster than a less substituted one and, once formed, rapidly goes on to give the final product.
- **A more substituted carbocation is more stable than a less substituted one.** That is, the stability order of carbocations is tertiary > secondary > primary > methyl.

What we have not yet seen is how these two points are related. Why does the stability of the carbocation intermediate affect the rate at which it's formed and thereby determine the structure of the final product? After all, carbocation stability is determined by the free-energy change ΔG° , but reaction rate is determined by the activation energy ΔG^\ddagger . The two quantities aren't directly related.

Although there is no simple quantitative relationship between the stability of a carbocation intermediate and the rate of its formation, there *is* an intuitive relationship. It's generally true when comparing two similar reactions that the more stable intermediate forms faster than the less stable one. The situation is shown graphically in **FIGURE 7.14**, where the energy profile in part **(a)** represents the typical situation, as opposed to the profile in part **(b)**. That is, the curves for two similar reactions don't cross one another.

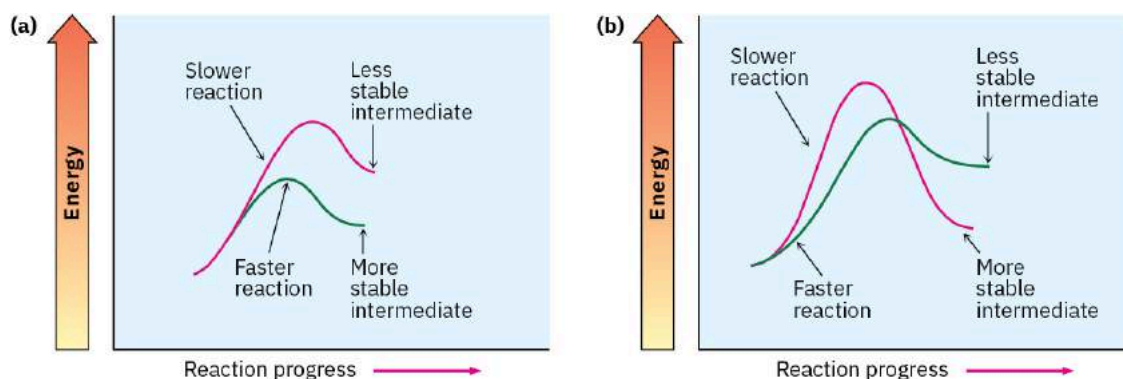

FIGURE 7.14 Energy diagrams for two similar competing reactions. In (a), the faster reaction yields the more stable intermediate. In (b), the slower reaction yields the more stable intermediate. The curves shown in (a) represent the typical situation.

Called the **Hammond postulate**, the explanation of the relationship between reaction rate and intermediate stability goes like this: Transition states represent energy maxima. They are high-energy activated complexes that occur transiently during the course of a reaction and immediately go on to a more stable species. Although we can't actually observe transition states because they have no finite lifetime, the Hammond postulate says that we can get an idea of a particular transition state's structure by looking at the structure of the nearest stable species. Imagine the two cases shown in **FIGURE 7.15**, for example. The reaction profile in part (a) shows the energy curve for an endergonic reaction step, and the profile in part (b) shows the curve for an exergonic step.

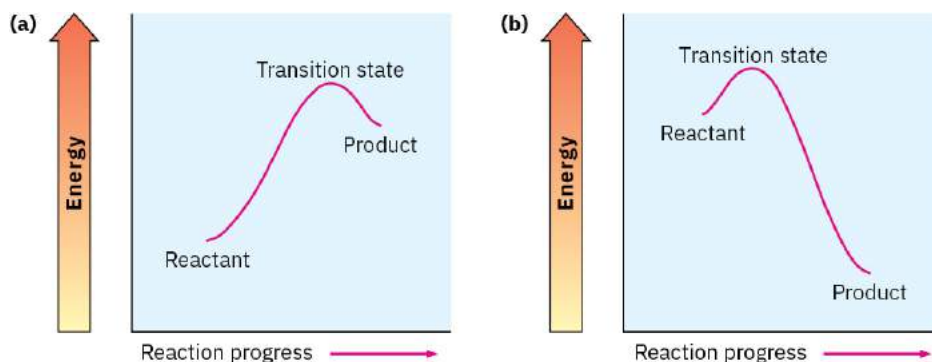

FIGURE 7.15 Energy diagrams for endergonic and exergonic steps. (a) In an endergonic step, the energy levels of transition state and product are closer. (b) In an exergonic step, the energy levels of transition state and reactant are closer.

In an endergonic reaction (**FIGURE 7.15a**), the energy level of the transition state is closer to that of the product than that of the reactant. Since the transition state is closer energetically to the product, we make the natural assumption that it's also closer structurally. In other words, the transition state for an endergonic reaction step structurally resembles the product of that step. Conversely, the transition state for an exergonic reaction step (**FIGURE 7.15b**), is closer energetically, and thus structurally, to the reactant than to the product. We therefore say that the transition state for an exergonic reaction step structurally resembles the reactant for that step.

Hammond postulate:

The structure of a transition state resembles the structure of the nearest stable species. Transition states for endergonic steps structurally resemble products, and transition states for exergonic steps structurally resemble reactants.

How does the Hammond postulate apply to electrophilic addition reactions? The formation of a carbocation by protonation of an alkene is an endergonic step. Thus, the transition state for alkene protonation structurally resembles the carbocation intermediate, and any factor that stabilizes the carbocation will also stabilize the nearby transition state. Since increasing alkyl substitution stabilizes carbocations, it also stabilizes the transition states leading to those ions, thus resulting in a faster reaction. In other words, more stable carbocations form faster because their greater stability is reflected in the lower-energy transition state leading to them (**FIGURE 7.16**).

FIGURE 7.16 Energy diagrams for carbocation formation. The more stable tertiary carbocation is formed faster (green curve) because its increased stability lowers the energy of the transition state leading to it.

We can imagine the transition state for alkene protonation to be a structure in which one of the alkene carbon atoms has almost completely rehybridized from sp^2 to sp^3 and the remaining alkene carbon bears much of the positive charge (FIGURE 7.17). This transition state is stabilized by hyperconjugation and inductive effects in the same way as the product carbocation. The more alkyl groups that are present, the greater the extent of stabilization and the faster the transition state forms.

FIGURE 7.17 The hypothetical structure of a transition state for alkene protonation. The transition state is closer in both energy and structure to the carbocation than to the alkene. Thus, an increase in carbocation stability (lower ΔG°) also causes an increase in transition-state stability (lower ΔG^\ddagger), thereby increasing the rate of its formation.

PROBLEM 7-20 What about the second step in the electrophilic addition of HCl to an alkene—the reaction of chloride ion with the carbocation intermediate? Is this step exergonic or endergonic? Does the transition state for this second step resemble the reactant (carbocation) or product (alkyl chloride)? Make a rough drawing of what the transition-state structure might look like.

7.11 Evidence for the Mechanism of Electrophilic Additions: Carbocation Rearrangements

How do we know that the carbocation mechanism for electrophilic addition reactions of alkenes is correct? The answer is that we *don't* know it's correct; at least we don't know with complete certainty. Although an incorrect reaction mechanism can be disproved by demonstrating that it doesn't account for observed data, a correct reaction mechanism can never be entirely proven. The best we can do is to show that a proposed mechanism is consistent with all known facts. If enough facts are accounted for, the mechanism is probably correct.

One of the best pieces of evidence supporting the carbocation mechanism for the electrophilic addition reaction was discovered during the 1930s by F. C. Whitmore of Pennsylvania State University, who found that structural rearrangements often occur during the reaction of HX with an alkene. For example, reaction of HCl with 3-methyl-1-butene yields a substantial amount of 2-chloro-2-methylbutane in addition to the “expected” product, 2-chloro-3-methylbutane.

As always, when looking at any complex chemical transformation, whether biochemical or not, focus on the part of the molecule where the change is occurring and don't worry about the rest. The tertiary carbocation just pictured looks complicated, but all the chemistry is taking place in the small part of the molecule inside the red circle.

PROBLEM On treatment with HBr, vinylcyclohexane undergoes addition and rearrangement to yield **7-21** 1-bromo-1-ethylcyclohexane. Using curved arrows, propose a mechanism to account for this result.

CHEMISTRY MATTERS

Bioprospecting: Hunting for Natural Products

Most people know the names of the common classes of biomolecules—proteins, carbohydrates, lipids, and nucleic acids—but there are many more kinds of compounds in living organisms than just those four. All living organisms also contain a vast diversity of substances usually grouped under the heading *natural products*. The term **natural product** really refers to any naturally occurring substance but is generally taken to mean a so-called secondary metabolite—a small molecule that is not essential to the growth and development of the producing organism and is not classified by structure.

FIGURE 7.18 Rapamycin, an immunosuppressant natural product used during organ transplants, was originally isolated from a soil sample found on Rapa Nui (Easter Island), an island 2200 miles off the coast of Chile known for its giant Moai statues. (credit: modification of work “Moai facing inland at Ahu Tongariki” by Ian Sewell/Wikimedia Commons, CC BY 2.5)

It has been estimated that well over 300,000 secondary metabolites exist, and it’s thought that their primary function is to increase the likelihood of an organism’s survival by repelling or attracting other organisms. Alkaloids, such as morphine; antibiotics, such as erythromycin and the penicillins; and immunosuppressive agents, such as rapamycin (sirolimus) prescribed for liver transplant recipients, are examples.

Where do these natural products come from, and how are they found? Although most chemists and biologists spend their working time in the laboratory, a few spend their days scuba diving on South Pacific islands or trekking through the rainforests of South America and Southeast Asia at work as bioprospectors. Their job is to

hunt for new and unusual natural products that might be useful as drugs.

As noted in the **Chapter 6 Chemistry Matters**, more than half of all new drug candidates come either directly or indirectly from natural products. Morphine from the opium poppy, prostaglandin E₁ from sheep prostate glands, erythromycin A from a *Streptomyces erythreus* bacterium cultured from a Philippine soil sample, and benzylpenicillin from the mold *Penicillium notatum* are examples. The immunosuppressive agent rapamycin, whose structure is shown previously, was first isolated from a *Streptomyces hygroscopicus* bacterium found in a soil sample from Rapa Nui (Easter Island), located 2200 miles off the coast of Chile.

With less than 1% of living organisms yet investigated, bioprospectors have a lot of work to do. But there is a race going on. Rainforests throughout the world are being destroyed at an alarming rate, causing many species of both plants and animals to become extinct before they can even be examined. The governments in many countries seem aware of the problem, but there is as yet no international treaty on biodiversity that could help preserve vanishing species.

- **Z configuration**

Summary

Carbon–carbon double bonds are present in most organic and biological molecules, so a good understanding of their behavior is needed. In this chapter, we've looked at some consequences of alkene stereoisomerism and at the details of the broadest class of alkene reactions—the electrophilic addition reaction.

An **alkene** is a hydrocarbon that contains a carbon–carbon double bond. Because they contain fewer hydrogens than alkanes with the same number of carbons, alkenes are said to be **unsaturated**.

Because rotation around the double bond can't occur, substituted alkenes can exist as cis–trans stereoisomers. The configuration of a double bond can be specified by applying the Cahn–Ingold–Prelog sequence rules, which rank the substituents on each double-bond carbon. If the higher-ranking groups on each carbon are on the same side of the double bond, the configuration is **Z** (*zusammen*, “together”); if the higher-ranking groups on each carbon are on opposite sides of the double bond, the configuration is **E** (*entgegen*, “apart”).

Alkene chemistry is dominated by **electrophilic addition reactions**. When HX reacts with an unsymmetrically substituted alkene, **Markovnikov's rule** predicts that the H will add to the carbon having fewer alkyl substituents and the X group will add to the carbon having more alkyl substituents. Electrophilic additions to alkenes take place through carbocation intermediates formed by reaction of the nucleophilic alkene π bond with electrophilic H⁺. Carbocation stability follows the order

Tertiary (3°) > Secondary (2°) > Primary (1°) > Methyl

Markovnikov's rule can be restated by saying that, in the addition of HX to an alkene, a more stable carbocation intermediate is formed. This result is explained by the **Hammond postulate**, which says that the transition state of an exergonic reaction step structurally resembles the reactant, whereas the transition state of an endergonic reaction step structurally resembles the product. Since an alkene protonation step is endergonic, the stability of the more highly substituted carbocation is reflected in the stability of the transition state leading to its formation.

Evidence in support of a carbocation mechanism for electrophilic additions comes from the observation that structural rearrangements often take place during reaction. Rearrangements occur by shift of either a hydride ion, :H^- (a **hydride shift**), or an alkyl anion, :R^- , from a carbon atom to the neighboring positively charged carbon. This results in isomerization of a less stable carbocation to a more stable one.

Additional Problems

Visualizing Chemistry

PROBLEM Name the following alkenes, and convert each drawing into a skeletal structure:

7-22 (a)

(b)

PROBLEM Assign *E* or *Z* stereochemistry to the double bonds in each of the following alkenes, and convert each drawing into a skeletal structure (red = O, green = Cl):

7-23

(a)

(b)

PROBLEM The following carbocation is an intermediate in the electrophilic addition reaction of HCl with two different alkenes. Identify both, and tell which C–H bonds in the carbocation are aligned for hyperconjugation with the vacant *p* orbital on the positively charged carbon.

7-24

PROBLEM The following alkyl bromide can be made by HBr addition to three different alkenes. Show their structures.

7-25

Mechanism Problems

PROBLEM 7-26 Predict the major product and show the complete mechanism for each of the following electrophilic addition reactions.

PROBLEM 7-27 Each of the following electrophilic addition reactions involves a carbocation rearrangement. Predict the product and draw the complete mechanism of each using curved arrows.

PROBLEM 7-28 When 1,3-butadiene reacts with 1 mol of HBr, two isolable products result. Propose mechanisms for both.

PROBLEM 7-29 When methyl vinyl ether reacts with a strong acid, H^+ adds to C2 instead of C1 or the oxygen atom. Explain.

Methyl vinyl ether

PROBLEM 7-30 Addition of HCl to 1-isopropylcyclohexene yields a rearranged product. Propose a mechanism, showing the structures of the intermediates and using curved arrows to indicate electron flow in each step.

PROBLEM 7-31 Addition of HCl to 1-isopropenyl-1-methylcyclopentane yields 1-chloro-1,2,2-trimethylcyclohexane. Propose a mechanism, showing the structures of the intermediates and using curved arrows to indicate electron flow in each step.

PROBLEM 7-32 Limonene, a fragrant hydrocarbon found in lemons and oranges, is biosynthesized from geranyl diphosphate by the following pathway. Add curved arrows to show the mechanism of each step. Which step involves an alkene electrophilic addition? (The ion $\text{OP}_2\text{O}_6^{4-}$ is the diphosphate ion, and “Base” is an unspecified base in the enzyme that catalyzes the reaction.)

PROBLEM 7-33 *epi*-Aristolochene, a hydrocarbon found in both pepper and tobacco, is biosynthesized by the following pathway. Add curved arrows to show the mechanism of each step. Which steps involve alkene electrophilic addition(s), and which involve carbocation rearrangement(s)? (The abbreviation H–A stands for an unspecified acid, and “Base” is an unspecified base in the enzyme.)

Calculating a Degree of Unsaturation

PROBLEM 7-34 Calculate the degree of unsaturation in the following formulas, and draw five possible structures for each:

- (a) $\text{C}_{10}\text{H}_{16}$ (b) $\text{C}_8\text{H}_8\text{O}$ (c) $\text{C}_7\text{H}_{10}\text{Cl}_2$ (d) $\text{C}_{10}\text{H}_{16}\text{O}_2$ (e) $\text{C}_5\text{H}_9\text{NO}_2$ (f) $\text{C}_8\text{H}_{10}\text{ClNO}$

PROBLEM 7-35 How many hydrogens does each of the following compounds have?

- (a) $\text{C}_8\text{H}_? \text{O}_2$, has two rings and one double bond (b) $\text{C}_7\text{H}_? \text{N}$, has two double bonds
(c) $\text{C}_9\text{H}_? \text{NO}$, has one ring and three double bonds

PROBLEM 7-36 Loratadine, marketed as an antiallergy medication under the brand name Claritin, has four rings, eight double bonds, and the formula $\text{C}_{22}\text{H}_? \text{ClN}_2\text{O}_2$. How many hydrogens does loratadine have? (Calculate your answer; don't count hydrogens in the structure.)

Naming Alkenes

PROBLEM Name the following alkenes:

PROBLEM Draw structures corresponding to the following systematic names:

- 7-38 (a)** (4*E*)-2,4-Dimethyl-1,4-hexadiene **(b)** *cis*-3,3-Dimethyl-4-propyl-1,5-octadiene
(c) 4-Methyl-1,2-pentadiene **(d)** (3*E*,5*Z*)-2,6-Dimethyl-1,3,5,7-octatetraene
(e) 3-Butyl-2-heptene **(f)** *trans*-2,2,5,5-Tetramethyl-3-hexene

PROBLEM Name the following cycloalkenes:

PROBLEM Ocimene is a triene found in the essential oils of many plants. What is its IUPAC name, including stereochemistry?

PROBLEM α -Farnesene is a constituent of the natural wax found on apples. What is its IUPAC name, including stereochemistry?

PROBLEM Menthene, a hydrocarbon found in mint plants, has the systematic name

7-42 1-isopropyl-4-methylcyclohexene. Draw its structure.

PROBLEM Draw and name the six alkene isomers, C_5H_{10} , including *E,Z* isomers.

7-43

PROBLEM Draw and name the 17 alkene isomers, C_6H_{12} , including *E,Z* isomers.

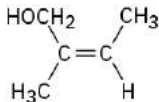

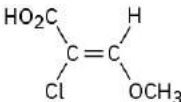

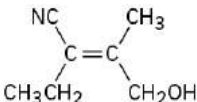

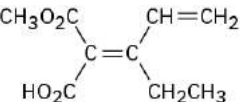

7-44

Alkene Isomers and Their Stability

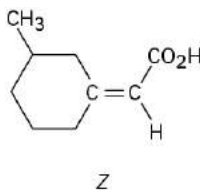

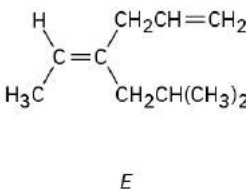

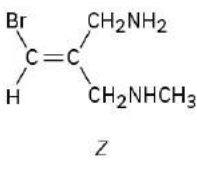

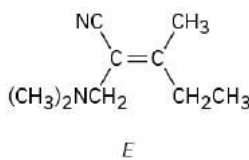

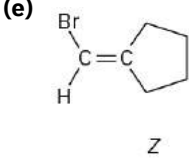

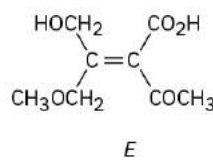

PROBLEM Rank the following sets of substituents according to the Cahn–Ingold–Prelog sequence rules:

- 7-45 (a) $-\text{CH}_3, -\text{Br}, -\text{H}, -\text{I}$ (b) $-\text{OH}, -\text{OCH}_3, -\text{H}, -\text{CO}_2\text{H}$ (c) $-\text{CO}_2\text{H}, -\text{CO}_2\text{CH}_3, -\text{CH}_2\text{OH}, -\text{CH}_3$
 (d) $-\text{CH}_3, -\text{CH}_2\text{CH}_3, -\text{CH}_2\text{CH}_2\text{OH}, -\overset{\text{O}}{\parallel}{\text{C}}\text{CH}_3$ (e) $-\text{CH}=\text{CH}_2, -\text{CN}, -\text{CH}_2\text{NH}_2, -\text{CH}_2\text{Br}$
 (f) $-\text{CH}=\text{CH}_2, -\text{CH}_2\text{CH}_3, -\text{CH}_2\text{OCH}_3, -\text{CH}_2\text{OH}$

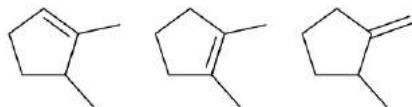

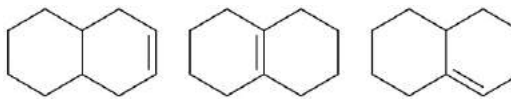

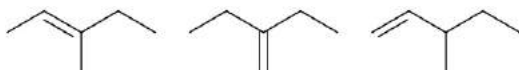

PROBLEM Assign *E* or *Z* configuration to each of the following compounds:

- 7-46 (a)  (b)  (c)  (d) 

PROBLEM Which of the following *E,Z* designations are correct, and which are incorrect?

- 7-47 (a)  (b)  (c) 
 (d)  (e)  (f) 

PROBLEM Rank the double bonds according to their increasing stability.

- 7-48 (a)  (b) 
 (c) 

PROBLEM *trans*-2-Butene is more stable than *cis*-2-butene by only 4 kJ/mol, but
 7-49 *trans*-2,2,5,5-tetramethyl-3-hexene is more stable than its *cis* isomer by 39 kJ/mol. Explain.

PROBLEM Cyclodecene can exist in both *cis* and *trans* forms, but cyclohexene cannot. Explain.
 7-50

PROBLEM Normally, a *trans* alkene is more stable than its *cis* isomer. *trans*-Cyclooctene, however, is less stable
 7-51 than *cis*-cyclooctene by 38.5 kJ/mol. Explain.

PROBLEM *trans*-Cyclooctene is less stable than *cis*-cyclooctene by 38.5 kJ/mol, but *trans*-cyclononene is less
 7-52 stable than *cis*-cyclononene by only 12.2 kJ/mol. Explain.

PROBLEM Tamoxifen, a drug used in the treatment of breast cancer, and clomiphene, a drug used in fertility
 7-53 treatment, have similar structures but very different effects. Assign *E* or *Z* configuration to the double bonds in both compounds.

Carbocations and Electrophilic Addition Reactions

PROBLEM Rank the following carbocations according to their increasing stability.

PROBLEM Use the Hammond Postulate to determine which alkene in each pair would be expected to form a carbocation faster in an electrophilic addition reaction.

PROBLEM The following carbocations can be stabilized by resonance. Draw all the resonance forms that would stabilize each carbocation.

PROBLEM Predict the major product in each of the following reactions:

PROBLEM Predict the major product from addition of HBr to each of the following alkenes:

PROBLEM 7-59 Alkenes can be converted into alcohols by acid-catalyzed addition of water. Assuming that Markovnikov's rule is valid, predict the major alcohol product from each of the following alkenes.

PROBLEM 7-60 Each of the following carbocations can rearrange to a more stable ion. Propose structures for the likely rearrangement products.

General Problems

PROBLEM 7-61 Allene (1,2-propadiene), $\text{H}_2\text{C}=\text{C}=\text{CH}_2$, has two adjacent double bonds. What kind of hybridization must the central carbon have? Sketch the bonding π orbitals in allene. What shape do you predict for allene?

PROBLEM 7-62 The heat of hydrogenation for allene (Problem 7-61) to yield propane is -295 kJ/mol, and the heat of hydrogenation for a typical monosubstituted alkene, such as propene, is -125 kJ/mol. Is allene more stable or less stable than you might expect for a diene? Explain.

PROBLEM 7-63 Retin A, or retinoic acid, is a medication commonly used to reduce wrinkles and treat severe acne. How many different isomers arising from *E,Z* double-bond isomerizations are possible?

Retin A (retinoic acid)

PROBLEM 7-64 Fucoserratene and ectocarpene are sex pheromones produced by marine brown algae. What are their systematic names? (Ectocarpene is difficult; make your best guess, and then check your answer in the *Student Solutions Manual*.)

Fucoserratene

Ectocarpene

PROBLEM 7-65 *tert*-Butyl esters [$\text{RCO}_2\text{C}(\text{CH}_3)_3$] are converted into carboxylic acids (RCO_2H) by reaction with trifluoroacetic acid, a reaction useful in protein synthesis (**Section 26.7**). Assign *E,Z* designation to the double bonds of both reactant and product in the following scheme, and explain why there is an apparent change in double-bond stereochemistry:

PROBLEM 7-66 Vinylcyclopropane reacts with HBr to yield a rearranged alkyl bromide. Follow the flow of electrons as represented by the curved arrows, show the structure of the carbocation intermediate in brackets, and show the structure of the final product.

Vinylcyclopropane

PROBLEM Calculate the degree of unsaturation in each of the following formulas:

- 7-67** (a) Cholesterol, $C_{27}H_{46}O$ (b) DDT, $C_{14}H_9Cl_5$ (c) Prostaglandin E_1 , $C_{20}H_{34}O_5$
 (d) Caffeine, $C_8H_{10}N_4O_2$ (e) Cortisone, $C_{21}H_{28}O_5$ (f) Atropine, $C_{17}H_{23}NO_3$

PROBLEM The isobutyl cation spontaneously rearranges to the *tert*-butyl cation by a hydride shift. Is the rearrangement exergonic or endergonic? Draw what you think the transition state for the hydride shift might look like according to the Hammond postulate.

Isobutyl cation

tert-Butyl cation

PROBLEM Draw an energy diagram for the addition of HBr to 1-pentene. Let one curve on your diagram show the formation of 1-bromopentane product and another curve on the same diagram show the formation of 2-bromopentane product. Label the positions for all reactants, intermediates, and products. Which curve has the higher-energy carbocation intermediate? Which curve has the higher-energy first transition state?

7-69

PROBLEM Sketch the transition-state structures involved in the reaction of HBr with 1-pentene (Problem 7-69). Tell whether each structure resembles reactant or product.

7-70

PROBLEM Aromatic compounds such as benzene react with alkyl chlorides in the presence of $AlCl_3$ catalyst to yield alkylbenzenes. This reaction occurs through a carbocation intermediate, formed by reaction of the alkyl chloride with $AlCl_3$ ($R-Cl + AlCl_3 \rightarrow R^+ + AlCl_4^-$). How can you explain the observation that reaction of benzene with 1-chloropropane yields isopropylbenzene as the major product?

7-71

PROBLEM Reaction of 2,3-dimethyl-1-butene with HBr leads to an alkyl bromide, $C_6H_{13}Br$. On treatment of this alkyl bromide with KOH in methanol, elimination of HBr occurs and a hydrocarbon that is isomeric with the starting alkene is formed. What is the structure of this hydrocarbon, and how do you think it is formed from the alkyl bromide?

7-72

- 8.13 Reaction Stereochemistry: Addition of H_2O to a Chiral Alkene

WHY THIS CHAPTER? Much of the background needed to understand organic reactions has now been covered, and it's time to begin a systematic description of the major functional groups. In this chapter on alkenes, and in future chapters on other functional groups, we'll discuss a variety of reactions, but try to focus on the general principles and patterns of reactivity that tie organic chemistry together. There are no shortcuts; you have to know the reactions to understand organic and biological chemistry.

Alkene addition reactions occur widely, both in the laboratory and in living organisms. Although we've studied

only the addition of HX thus far, many closely related reactions also take place. In this chapter, we'll see briefly how alkenes are prepared and we'll discuss further examples of alkene addition reactions. Particularly important are the addition of a halogen (X_2) to give a 1,2-dihalide, addition of a hypohalous acid (HOX) to give a halohydrin, addition of water to give an alcohol, addition of hydrogen to give an alkane, addition of a single oxygen to give a three-membered cyclic ether called an **epoxide**, and addition of two hydroxyl groups to give a 1,2-diol.

FIGURE 8.2 Some useful alkene reactions.

8.1 Preparing Alkenes: A Preview of Elimination Reactions

Before getting to the main subject of this chapter—the reactions of alkenes—let's take a brief look at how alkenes are prepared. The subject is a bit complex, though, so we'll return to it in Chapter 11 for a more detailed study. For the present, it's enough to realize that alkenes are readily available from simple precursors—usually alcohols in biological systems and either alcohols or alkyl halides in the laboratory.

Just as the chemistry of alkenes is dominated by addition reactions, the preparation of alkenes is dominated by elimination reactions. Additions and eliminations are, in many respects, two sides of the same coin. That is, an addition reaction might involve the addition of HBr or H_2O to an alkene to form an alkyl halide or alcohol, whereas an elimination reaction might involve the loss of HBr or H_2O from an alkyl halide or alcohol to form an alkene.

The two most common elimination reactions are dehydrohalogenation—the loss of HX from an alkyl halide—and dehydration—the loss of water from an alcohol. Dehydrohalogenation usually occurs by reaction of an alkyl halide with strong base such as potassium hydroxide. For example, bromocyclohexane yields cyclohexene when treated with KOH in ethanol solution.

Dehydration is often carried out in the laboratory by treatment of an alcohol with a strong acid. For example, when 1-methylcyclohexanol is warmed with aqueous sulfuric acid in tetrahydrofuran (THF) solvent, loss of

water occurs and 1-methylcyclohexene is formed.

In biological pathways, dehydrations rarely occur with isolated alcohols. Instead, they normally take place on substrates in which the -OH is positioned two carbons away from a C=O group. In the biosynthesis of fats, for instance, β -hydroxybutyryl ACP is converted by dehydration to *trans*-crotonyl ACP, where ACP is an abbreviation for *acyl carrier protein*. We'll see the reason for this requirement in **Section 11.10**.

PROBLEM 8-1 One problem with elimination reactions is that mixtures of products are often formed. For example, treatment of 2-bromo-2-methylbutane with KOH in ethanol yields a mixture of two alkene products. What are their likely structures?

PROBLEM 8-2 How many alkene products, including *E,Z* isomers, might be obtained by dehydration of 3-methyl-3-hexanol with aqueous sulfuric acid?

8.2 Halogenation of Alkenes: Addition of X₂

Bromine and chlorine add rapidly to alkenes to yield 1,2-dihalides, a process called *halogenation*. For example, nearly 50 million tons of 1,2-dichloroethane (ethylene dichloride) are synthesized worldwide each year, much of it by addition of Cl₂ to ethylene. The product is used both as a solvent and as starting material for the manufacture of poly(vinyl chloride), PVC, the third most widely synthesized polymer in the world after polyethylene and polypropylene. Fluorine is too reactive and difficult to control for most laboratory applications, and iodine does not react with most alkenes.

Based on what we've seen thus far, a possible mechanism for the reaction of bromine with alkenes might involve electrophilic addition of Br⁺ to the alkene, giving a carbocation intermediate that could undergo further reaction with Br⁻ to yield the dibromo addition product.

Although this mechanism seems plausible, it's not fully consistent with known facts. In particular, it doesn't explain the stereochemistry of the addition reaction. That is, the mechanism doesn't account for which product stereoisomer is formed.

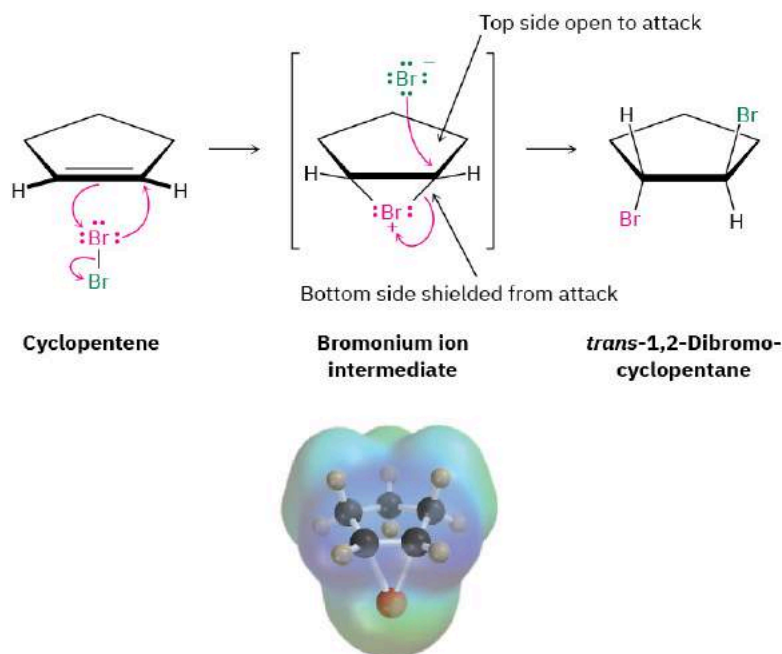

When the halogenation reaction is carried out on a cycloalkene, such as cyclopentene, only the *trans* stereoisomer of the dihalide addition product is formed, rather than the mixture of *cis* and *trans* isomers that might have been expected if a planar carbocation intermediate were involved. We say that the reaction occurs with **anti stereochemistry**, meaning that the two bromine atoms come from opposite faces of the double bond—one from the top face and one from the bottom face.

An explanation for the observed stereochemistry of addition was suggested in 1937 by George Kimball and Irving Roberts, who proposed that the reaction intermediate is not a carbocation but is instead a **bromonium ion**, R_2Br^+ , formed by electrophilic addition of Br^+ to the alkene. (Similarly, a chloronium ion contains a positively charged, divalent chlorine, R_2Cl^+ .) The bromonium ion is formed in a single step by interaction of the alkene with Br_2 and the simultaneous loss of Br^- .

How does the formation of a bromonium ion account for the observed anti stereochemistry of addition to cyclopentene? If a bromonium ion is formed as an intermediate, we can imagine that the large bromine atom might “shield” one side of the molecule. Reaction with Br^- ion in the second step could then occur only from the opposite, unshielded side to give the *trans* product.

The bromonium ion postulate, made more than 85 years ago to explain the stereochemistry of halogen addition to alkenes, is a remarkable example of deductive logic in chemistry. Arguing from experimental results, chemists were able to make a hypothesis about the intimate mechanistic details of alkene electrophilic reactions. Subsequently, strong evidence supporting the mechanism came from the work of George Olah at the University of Southern California, who prepared and studied stable solutions of cyclic bromonium ions in liquid SO_2 . There's no question that bromonium ions exist.

Alkene halogenation reactions occur in nature just as they do in the laboratory but are limited primarily to marine organisms living in halide-rich environments. These biological halogenation reactions are carried out by enzymes called *haloperoxidases*, which use H_2O_2 to oxidize Br^- or Cl^- ions to a biological equivalent of Br^+ or Cl^+ . Electrophilic addition to the double bond of a substrate molecule then yields a bromonium or chloronium ion intermediate just as in the laboratory, and reaction with another halide ion completes the process. Halomon, for example, an antitumor pentahalide isolated from red alga, is thought to arise by a route that involves twofold addition of BrCl through the corresponding bromonium ions.

PROBLEM 8-3 What product would you expect to obtain from addition of Cl_2 to 1,2-dimethylcyclohexene? Show the stereochemistry of the product.

PROBLEM 8-4 Addition of HCl to 1,2-dimethylcyclohexene yields a mixture of two products. Show the stereochemistry of each, and explain why a mixture is formed.

8.3 Halohydrins from Alkenes: Addition of HO-X

Another example of an electrophilic addition is the reaction an alkene with either Br_2 or Cl_2 in the presence of

water to yield a 1,2-halo alcohol, called a **halohydrin**.

We saw in the previous section that when Br_2 reacts with an alkene, the cyclic bromonium ion intermediate reacts with the only nucleophile present, Br^- ion. If the reaction is carried out in the presence of an additional nucleophile, however, the intermediate bromonium ion can be intercepted by the added nucleophile and diverted to a different product. In the presence of a high concentration of water, for instance, water competes with Br^- ion as a nucleophile and reacts with the bromonium ion intermediate to yield a *bromohydrin*. The net effect is addition of $\text{HO}-\text{Br}$ to the alkene by the pathway shown in **FIGURE 8.3**.

FIGURE 8.3 MECHANISM

Bromohydrin formation by reaction of an alkene with Br_2 in the presence of water.
Water acts as a nucleophile in step 2 to react with the intermediate bromonium ion.

- 1 Reaction of the alkene with Br_2 yields a bromonium ion intermediate, as previously discussed.

- 2 Water acts as a nucleophile, using a lone pair of electrons to open the bromonium ion ring and form a bond to carbon. Since oxygen donates its electrons in this step, it now has the positive charge.

- 3 Loss of a proton (H^+) from oxygen then gives H_3O^+ and the neutral bromohydrin addition product.

In practice, few alkenes are soluble in water, and bromohydrin formation is often carried out in a solvent such as aqueous dimethyl sulfoxide, CH_3SOCH_3 (DMSO), using a reagent called *N*-bromosuccinimide (NBS) as a source of Br_2 . NBS is a stable, easily handled compound that slowly decomposes in water to yield Br_2 at a controlled rate. Bromine itself can also be used in the addition reaction, but it is more dangerous and more difficult to handle than NBS.

Notice that the aromatic ring in the above example does not react with Br₂, even though it appears to have three carbon–carbon double bonds. As we'll see in Section 15.2, aromatic rings are a good deal more stable and less reactive than might be expected.

There are a number of biological examples of halohydrin formation, particularly in marine organisms. As with halogenation (Section 8.2), halohydrin formation is carried out by *haloperoxidases*. For example:

PROBLEM 8-5 What product would you expect from the reaction of cyclopentene with NBS and water? Show the stereochemistry.

PROBLEM 8-6 When an unsymmetrical alkene such as propene is treated with *N*-bromosuccinimide in aqueous dimethyl sulfoxide, the major product has the bromine atom bonded to the less highly substituted carbon atom. Is this Markovnikov or non-Markovnikov orientation? (Section 7.8) Explain.

8.4 Hydration of Alkenes: Addition of H₂O by Oxymercuration

Water adds to alkenes to yield alcohols, a process called hydration. The reaction takes place on treatment of the alkene with water and a strong acid catalyst, such as H₂SO₄, by a mechanism similar to that of HX addition. Thus, as shown in **FIGURE 8.4**, protonation of an alkene double bond yields a carbocation intermediate, which reacts with water to yield a protonated alcohol product, ROH₂⁺. Loss of H⁺ from this protonated alcohol gives the neutral alcohol and regenerates the acid catalyst.

FIGURE 8.4 MECHANISM**Mechanism of the acid-catalyzed hydration of an alkene to yield an alcohol.**

Protonation of the alkene gives a carbocation intermediate, which reacts with water. The initial product is then deprotonated.

- 1 A hydrogen atom on the electrophile H_3O^+ is attacked by π electrons from the nucleophilic double bond, forming a new C–H bond. This leaves the other carbon atom with a + charge and a vacant p orbital. Simultaneously, two electrons from the H–O bond move onto oxygen, giving neutral water.

- 2 The nucleophile H_2O donates an electron pair to the positively charged carbon atom, forming a C–O bond and leaving a positive charge on oxygen in the protonated alcohol addition product.

- 3 Water acts as a base to remove H^+ , regenerating H_3O^+ and yielding the neutral alcohol addition product.

Most ethanol throughout the world is now made by fermentation of biological precursors, such as corn and sugar, but acid-catalyzed alkene hydration is particularly suited to large-scale industrial procedures, and approximately 90,000 tons of ethanol is manufactured each year in the United States by hydration of ethylene. The reaction is of little value in the laboratory, however, because it requires high temperatures—250 °C in the case of ethylene—and strongly acidic conditions.

Acid-catalyzed hydration of double bonds is also uncommon in biological pathways. Instead, biological

hydrations usually require that the double bond be adjacent to a carbonyl group for reaction to proceed. Fumarate, for instance, is hydrated to give malate as one step in the citric acid cycle of food metabolism. Note that the requirement for an adjacent carbonyl group in the addition of water is the same as in [Section 8.1](#) for the elimination of water. We'll see the reason for this requirement in [Section 19.13](#), but will note for now that the reaction is not an electrophilic addition but instead occurs through a mechanism that involves formation of an anion intermediate followed by protonation by an acid HA.

When it comes to circumventing problems like those with acid-catalyzed alkene hydrations, laboratory chemists have a great advantage over the cellular “chemists” in living organisms. Laboratory chemists are not constrained to carry out their reactions in water solution; they can choose from any of a large number of solvents. Laboratory reactions don't need to be carried out at a fixed temperature; they can take place over a wide range of temperatures. And laboratory reagents aren't limited to containing carbon, oxygen, nitrogen, and a few other elements; they can contain any element in the periodic table.

In the laboratory, alkenes are often hydrated by the **oxymercuration–demercuration** procedure, which involves electrophilic addition of Hg²⁺ to the alkene on reaction with mercury(II) acetate [(CH₃CO₂)₂Hg]. The intermediate organomercury compound is then treated with sodium borohydride, NaBH₄, and demercuration occurs to produce an alcohol. For example:

Alkene oxymercuration is closely analogous to halohydrin formation. The reaction is initiated by electrophilic addition of Hg²⁺ (mercuric) ion to the alkene to give an intermediate *mercurinium ion*, whose structure resembles that of a bromonium ion ([FIGURE 8.5](#)). Nucleophilic addition of water as in halohydrin formation, followed by the loss of a proton, then yields a stable organomercury product. The final step, demercuration of the organomercury compound by reaction with sodium borohydride, is complex and involves radicals. Note that the regiochemistry of the reaction corresponds to Markovnikov addition of water; that is, the –OH group attaches to the more highly substituted carbon atom, and the –H attaches to the less highly substituted carbon. The hydrogen that replaces mercury in the demercuration step can attach from either side of the molecule depending on the exact circumstances.

FIGURE 8.5 Mechanism of the oxymercuration of an alkene to yield an alcohol. (1) Electrophilic addition of Hg²⁺ gives a mercurinium ion, which (2) reacts with water as in halohydrin formation. Loss of a proton gives an organomercury product, and (3) reaction with NaBH₄ removes the mercury. The product of the reaction is a more highly substituted alcohol, corresponding to Markovnikov regiochemistry.

PROBLEM What products would you expect from oxymercuration–demercuration of the following alkenes?

PROBLEM From what alkenes might the following alcohols have been prepared?

8.5 Hydration of Alkenes: Addition of H₂O by Hydroboration

In addition to the oxymercuration–demercuration method, which yields the Markovnikov product, a complementary method that yields the non-Markovnikov product is also useful. Discovered in 1959 by H.C. Brown at Purdue University and called **hydroboration**, the reaction involves addition of a B–H bond of borane, BH₃, to an alkene to yield an organoborane intermediate, RBH₂. Oxidation of the organoborane by reaction with basic hydrogen peroxide, H₂O₂, then gives an alcohol. For example:

Borane is very reactive as a Lewis acid because the boron atom has only six electrons in its valence shell rather than an octet. In tetrahydrofuran solution, BH₃ accepts an electron pair from a solvent molecule in a Lewis acid–base reaction to complete its octet and form a stable BH₃–THF complex.

When an alkene reacts with BH₃ in THF solution, rapid addition to the double bond occurs three times and a trialkylborane, R₃B, is formed. For example, 1 molar equivalent of BH₃ adds to 3 molar equivalents of cyclohexene to yield tricyclohexylborane. When tricyclohexylborane is then treated with aqueous hydrogen H₂O₂ in basic solution, an oxidation takes place. The three C–B bonds are broken, –OH groups bond to the three carbons, and 3 equivalents of cyclohexanol are produced. The net effect of the two-step hydroboration–oxidation sequence is hydration of the alkene double bond.

One of the features that makes the hydroboration reaction so useful is the regiochemistry that results when an unsymmetrical alkene is hydroborated. For example, hydroboration–oxidation of 1-methylcyclopentene yields *trans*-2-methylcyclopentanol. In this process, boron and hydrogen add to the alkene from the same face of the double bond—that is, with **syn stereochemistry**, the opposite of anti—with boron attaching to the less highly substituted carbon. During the oxidation step, the boron is replaced by an –OH with the same stereochemistry, resulting in an overall syn non-Markovnikov addition of water. This stereochemical result is particularly useful because it is complementary to the Markovnikov regiochemistry observed for oxymercuration–demercuration.

Why does alkene hydroboration take place with syn, non-Markovnikov regiochemistry to yield the less highly substituted alcohol? Hydroboration differs from many other alkene addition reactions in that it occurs in a single step without a carbocation intermediate (FIGURE 8.6). Because the C–H and C–B bonds form at the same time and from the same face of the alkene, syn stereochemistry results. Non-Markovnikov regiochemistry occurs because attachment of boron is favored at the less sterically crowded carbon atom of the alkene.

FIGURE 8.6 Mechanism of alkene hydroboration. The reaction occurs in a single step in which the C–H and C–B bonds form at the same time and on the same face of the double bond. The lower energy, more rapidly formed transition state is the one with less steric crowding, leading to non-Markovnikov regiochemistry.

WORKED EXAMPLE 8.1

Predicting the Products of a Hydration Reaction

What products would you obtain from reaction of 2-methyl-2-pentene with:

- (a) BH_3 , followed by $\text{H}_2\text{O}_2, \text{OH}^-$ (b) $\text{Hg}(\text{OAc})_2$, followed by NaBH_4

Strategy

When predicting the product of a reaction, you have to recall what you know about the kind of reaction being carried out and apply that knowledge to the specific case you're dealing with. In the present instance, recall that the two methods of hydration—hydroboration–oxidation and oxymercuration–demercuration—give complementary products. Hydroboration–oxidation occurs with syn stereochemistry and gives the non-Markovnikov addition product; oxymercuration–demercuration gives the Markovnikov product.

Solution

WORKED EXAMPLE 8.2
Synthesizing an Alcohol

How might you prepare the following alcohol?

**Strategy**

Problems that require the synthesis of a specific target molecule should always be worked backward. Look at the target, identify its functional group(s), and ask yourself, “What are the methods for preparing that functional group?” In the present instance, the target molecule is a secondary alcohol (R_2CHOH), and we’ve seen that alcohols can be prepared from alkenes by either hydroboration–oxidation or oxymercuration–demercuration. The $-\text{OH}$ -bearing carbon in the product must have been a double-bond carbon in the alkene reactant, so there are two possibilities here: 4-methyl-2-hexene and 3-methyl-3-hexene.

4-Methyl-2-hexene has a disubstituted double bond, $\text{RCH}=\text{CHR}'$, and will probably give a mixture of two alcohols with either hydration method since Markovnikov’s rule does not apply to symmetrically substituted alkenes. 3-Methyl-3-hexene, however, has a trisubstituted double bond, and should give only the desired product on non-Markovnikov hydration using the hydroboration–oxidation method.

Solution

PROBLEM 8-9 Show the structures of the products you would obtain by hydroboration–oxidation of the following alkenes:

PROBLEM What alkenes might be used to prepare the following alcohols by hydroboration–oxidation?

PROBLEM The following cycloalkene gives a mixture of two alcohols on hydroboration followed by oxidation.

8-11 Draw the structures of both, and explain the result.

8.6 Reduction of Alkenes: Hydrogenation

Alkenes react with H_2 in the presence of a metal catalyst such as palladium or platinum to yield the corresponding saturated alkanes. We describe the result by saying that the double bond has been **hydrogenated**, or *reduced*. Note that the word *reduction* is used somewhat differently in organic chemistry from what you might have learned previously. In general chemistry, a reduction is defined as the gain of one or more electrons by an atom. In organic chemistry, however, a **reduction** is a reaction that results in a gain of electron density for carbon, caused either by bond formation between carbon and a less electronegative atom—usually hydrogen—or by bond-breaking between carbon and a more electronegative atom—usually oxygen, nitrogen, or a halogen. We'll explore this topic in more detail in **Section 10.8**.

Reduction Increases electron density on carbon by:

–forming this: C–H

–or breaking one of these: C–O C–N C–X

A reduction:

Platinum and palladium are the most common laboratory catalysts for alkene hydrogenations. Palladium is normally used as a very fine powder “supported” on an inert material such as charcoal (Pd/C) to maximize surface area. Platinum is normally used as PtO_2 , a reagent known as *Adams' catalyst* after its discoverer, Roger Adams at the University of Illinois.

Catalytic hydrogenation, unlike most other organic reactions, is a *heterogeneous* process rather than a homogeneous one. That is, the hydrogenation reaction does not occur in a homogeneous solution but instead takes place on the surface of solid catalyst particles. Hydrogenation usually occurs with *syn* stereochemistry: both hydrogens add to the double bond from the same face.

As shown in **FIGURE 8.7**, hydrogenation begins with adsorption of H_2 onto the catalyst surface. Complexation between catalyst and alkene then occurs as a vacant orbital on the metal interacts with the filled alkene π orbital

on the alkene. In the final steps, hydrogen is inserted into the double bond and the saturated product diffuses away from the catalyst. The stereochemistry of hydrogenation is syn because both hydrogens add to the double bond from the same catalyst surface.

FIGURE 8.7 MECHANISM

Mechanism of alkene hydrogenation. The reaction takes place with syn stereochemistry on the surface of insoluble catalyst particles.

An interesting feature of catalytic hydrogenation is that the reaction is extremely sensitive to the steric environment around the double bond. As a result, the catalyst usually approaches the more accessible face of an alkene, giving rise to a single product. In α -pinene, for example, one of the methyl groups attached to the four-membered ring hangs over the top face of the double bond and blocks approach of the hydrogenation catalyst from that side. Reduction therefore occurs exclusively from the bottom face to yield the product shown.

Alkenes are much more reactive toward catalytic hydrogenation than most other unsaturated functional groups, and the reaction is therefore quite selective. Other functional groups, such as aldehydes, ketones, esters, and nitriles, often survive alkene hydrogenation conditions unchanged, although reaction with these groups does occur under more vigorous conditions. Note that, particularly in the hydrogenation of methyl 3-phenylpropenoate shown below, the aromatic ring is not reduced by hydrogen and palladium even though it contains apparent double bonds.

In addition to its usefulness in the laboratory, catalytic hydrogenation is also important in the food industry, where unsaturated vegetable oils are reduced on a large scale to produce the saturated fats used in margarine and cooking products (FIGURE 8.8). As we'll see in Section 27.1, vegetable oils are triesters of glycerol, $\text{HOCH}_2\text{CH}(\text{OH})\text{CH}_2\text{OH}$, with three long-chain carboxylic acids called *fatty acids*. The fatty acids are generally polyunsaturated, and their double bonds have *cis* stereochemistry. Complete hydrogenation yields the corresponding saturated fatty acids, but incomplete hydrogenation often results in partial *cis*-*trans* isomerization of a remaining double bond. When eaten and digested, the free *trans* fatty acids are released, raising blood cholesterol levels and potentially contributing to coronary problems.

FIGURE 8.8 Catalytic hydrogenation of polyunsaturated fats leads primarily to saturated products, along with a small amount of isomerized trans fats.

Double-bond reductions are very common in biological pathways, although the mechanism is completely different from that of laboratory catalytic hydrogenation over palladium. As with biological hydrations (Section 8.4), biological reductions usually occur in two steps and require that the double bond be adjacent to a carbonyl group. In the first step, the biological reducing agent NADPH (reduced nicotinamide adenine dinucleotide phosphate), adds a hydride ion (H^-) to the double bond to give an anion. In the second, the anion is protonated by acid HA, leading to overall addition of H_2 . An example is the reduction of *trans*-crotonyl ACP to yield butyryl ACP, a step involved in the biosynthesis of fatty acids (FIGURE 8.9).

FIGURE 8.9 Reduction of the carbon–carbon double bond in *trans*-crotonyl ACP, a step in the biosynthesis of fatty acids. One hydrogen is delivered from NADPH as a hydride ion, H^- ; the other hydrogen is delivered by protonation of the anion intermediate with an acid, HA.

PROBLEM What product would you obtain from catalytic hydrogenation of the following alkenes?

8.7 Oxidation of Alkenes: Epoxidation and Hydroxylation

Like the word *reduction* used in the previous section for the addition of hydrogen to a double bond, the word *oxidation* has a slightly different meaning in organic chemistry than what you might have previously learned. In general chemistry, an oxidation is defined as the loss of one or more electrons by an atom. In organic chemistry, however, an **oxidation** is a reaction that results in a loss of electron density for carbon, caused either by bond formation between carbon and a more electronegative atom—usually oxygen, nitrogen, or a halogen—or by bond-breaking between carbon and a less electronegative atom—usually hydrogen. Note that an *oxidation* often adds oxygen, while a *reduction* often adds hydrogen.

Oxidation Decreases electron density on carbon by:

- forming one of these: C–O C–N C–X
- or breaking this: C–H

In the laboratory, alkenes are oxidized to give *epoxides* on treatment with a *peroxyacid*, RCO_3H , such as *meta*-chloroperoxybenzoic acid. An **epoxide**, also called an **oxirane**, is a cyclic ether with an oxygen atom in a three-membered ring. For example:

Peroxyacids transfer an oxygen atom to the alkene with *syn* stereochemistry—both C–O bonds form on the same face of the double bond—through a one-step mechanism without intermediates. The oxygen atom farthest from the carbonyl group is the one transferred.

Another method for the synthesis of epoxides involves the use of halohydrins, prepared by electrophilic addition of HO–X to alkenes (Section 8.3). When a halohydrin is treated with base, HX is eliminated and an epoxide is produced.

Epoxides undergo an acid-catalyzed ring-opening reaction with water (a hydrolysis) to give the corresponding 1,2-dialcohol, or *diol*, also called a **glycol**. Thus, the net result of the two-step alkene epoxidation/hydrolysis is **hydroxylation**—the addition of an –OH group to each of the two double-bond carbons. In fact, approximately 204 million tons of ethylene glycol, $\text{HOCH}_2\text{CH}_2\text{OH}$, most of it used for automobile antifreeze, are produced worldwide each year by the epoxidation of ethylene and subsequent hydrolysis.

Acid-catalyzed epoxide opening begins with protonation of the epoxide to increase its reactivity, followed by nucleophilic addition of water. This nucleophilic addition is analogous to the final step of alkene bromination, in which a cyclic bromonium ion is opened by a nucleophile (Section 8.2). That is, a *trans*-1,2-diol results when an epoxycycloalkane is opened by aqueous acid, just as a *trans*-1,2-dibromide results when a cycloalkene is brominated. We'll look at epoxide chemistry in more detail in Section 18.6.

Hydroxylation can also be carried out directly (without going through an intermediate epoxide) by treating an alkene with osmium tetroxide, OsO_4 . The reaction occurs with *syn* stereochemistry and does not involve a carbocation intermediate. Instead, it takes place through an intermediate cyclic *osmate*, which is formed in a single step by addition of OsO_4 to the alkene. This cyclic osmate is then cleaved using aqueous sodium bisulfite, NaHSO_3 .

Because OsO_4 is both very expensive and very toxic, the reaction is usually carried out using only a small, catalytic amount of OsO_4 in the presence of a stoichiometric amount of a safe and inexpensive co-oxidant such as *N*-methylmorpholine *N*-oxide, abbreviated NMO. The initially formed osmate intermediate reacts rapidly with NMO to yield the product diol plus *N*-methylmorpholine and reoxidized OsO_4 , which reacts with more alkene in a catalytic cycle.

PROBLEM 8-13 What product would you expect from reaction of *cis*-2-butene with *meta*-chloroperoxybenzoic acid? Show the stereochemistry.

PROBLEM 8-14 Starting with an alkene, how would you prepare each of the following compounds?

8.8 Oxidation of Alkenes: Cleavage to Carbonyl Compounds

In all the alkene addition reactions we've seen thus far, the carbon-carbon double bond has been converted into a single bond but the carbon skeleton has been unchanged. There are, however, powerful oxidizing reagents that will cleave C=C bonds and produce two carbonyl-containing fragments.

Ozone (O₃) is perhaps the most useful double-bond cleavage reagent. Prepared by passing a stream of oxygen through a high-voltage electrical discharge, ozone adds rapidly to a C=C bond at low temperature to give a cyclic intermediate called a *molozonide*. Once formed, the molozonide spontaneously rearranges to form an **ozonide**. Although we won't study the mechanism of this rearrangement in detail, it involves the molozonide coming apart into two fragments that then recombine in a different way.

Low-molecular-weight ozonides are explosive and therefore not isolated. Instead, the ozonide is immediately treated with a reducing agent, such as zinc metal in acetic acid, to produce carbonyl compounds. The net result of the ozonolysis/reduction sequence is that the C=C bond is cleaved and an oxygen atom becomes doubly bonded to each of the original alkene carbons. If an alkene with a tetrasubstituted double bond is ozonized, two ketone fragments result; if an alkene with a trisubstituted double bond is ozonized, one ketone and one aldehyde result; and so on.

Several oxidizing reagents other than ozone also cause double-bond cleavage, although such reactions are not often used. For example, potassium permanganate (KMnO_4) in neutral or acidic solution cleaves alkenes to give carbonyl-containing products. If hydrogens are present on the double bond, carboxylic acids are produced; if two hydrogens are present on one carbon, CO_2 is formed.

In addition to direct cleavage with ozone or KMnO_4 , an alkene can also be cleaved in a two-step process by initial hydroxylation to a 1,2-diol, as discussed in the previous section, followed by treatment of the diol with periodic acid, HIO_4 . If the two $-\text{OH}$ groups are in an open chain, two carbonyl compounds result. If the two $-\text{OH}$ groups are on a ring, a single, open-chain dicarbonyl compound is formed. As indicated in the following examples, the cleavage reaction takes place through a cyclic periodate intermediate.

WORKED EXAMPLE 8.3

Predicting the Reactant in an Ozonolysis Reaction

What alkene would yield a mixture of cyclopentanone and propanal on treatment with ozone followed by reduction with zinc?

Strategy

Reaction of an alkene with ozone, followed by reduction with zinc, cleaves the C=C bond and becomes two C=O bonds. Working backward from the carbonyl-containing products, the alkene precursor can be found by removing the oxygen from each product and joining the two carbon atoms.

Solution

PROBLEM 8-15 What products would you expect from reaction of 1-methylcyclohexene with the following reagents?

(a) Aqueous acidic KMnO_4 (b) O_3 , followed by Zn , $\text{CH}_3\text{CO}_2\text{H}$

PROBLEM 8-16 Propose structures for alkenes that yield the following products on reaction with ozone followed by treatment with Zn :

(a) $(\text{CH}_3)_2\text{C}=\text{O} + \text{H}_2\text{C}=\text{O}$ (b) 2 equiv $\text{CH}_3\text{CH}_2\text{CH}=\text{O}$

8.9 Addition of Carbenes to Alkenes: Cyclopropane Synthesis

Yet another kind of alkene addition is the reaction with a *carbene* to yield a cyclopropane. A **carbene**, $\text{R}_2\text{C}:$, is a neutral molecule containing a divalent carbon with only six electrons in its valence shell. It is therefore highly reactive and generated only as a reaction intermediate, rather than as an isolable molecule. Because they're electron-deficient, carbenes behave as electrophiles and react with nucleophilic C=C bonds. The reaction occurs in a single step without intermediates.

One of the simplest methods for generating a substituted carbene is by treatment of chloroform, CHCl_3 , with a strong base such as KOH . As shown in **FIGURE 8.10**, the loss of a proton from CHCl_3 gives trichloromethanide anion, $^-\text{CCl}_3$, which spontaneously expels a Cl^- ion to yield dichlorocarbene, $:\text{CCl}_2$.

FIGURE 8.10 MECHANISM

Mechanism of the formation of dichlorocarbene by reaction of chloroform with strong base. Deprotonation of CHCl_3 gives the trichloromethanide anion, $^-\text{CCl}_3$, which spontaneously expels a Cl^- ion.

1 Base abstracts the hydrogen from chloroform, leaving behind the electron pair from the C–H bond and forming the trichloromethanide anion.

2 Spontaneous loss of chloride ion then yields the neutral dichlorocarbene.

Chloroform

1

Trichloromethanide anion

2

Dichlorocarbene

The carbon atom in dichlorocarbene is sp^2 -hybridized, with a vacant p orbital extending above and below the plane of the three atoms and with an unshared pair of electrons occupying the third sp^2 lobe. Note that this electronic description of dichlorocarbene is similar to that of a carbocation (Section 7.9) with respect to both the sp^2 hybridization of carbon and the vacant p orbital. Electrostatic potential maps further illustrate the similarity (Figure 8.11).

FIGURE 8.11 The structure of dichlorocarbene. Electrostatic potential maps show how the positive region coincides with the empty p orbital in both dichlorocarbene and a carbocation (CH_3^+). The negative region in the dichlorocarbene map coincides with the lone-pair electrons.

If dichlorocarbene is generated in the presence of an alkene, addition to the double bond occurs and a dichlorocyclopropane is formed. As the reaction of dichlorocarbene with *cis*-2-pentene demonstrates, the addition is **stereospecific**, meaning that only a single stereoisomer is formed as product. Starting from a *cis* alkene, for instance, only *cis*-disubstituted cyclopropane is produced; starting from a *trans* alkene, only *trans*-disubstituted cyclopropane is produced.

The best method for preparing nonhalogenated cyclopropanes is by a process called the **Simmons–Smith reaction**. First investigated at the DuPont company, this reaction does not involve a free carbene. Rather, it utilizes a *carbenoid*—a metal-complexed reagent with carbene-like reactivity. When diiodomethane is treated with a specially prepared zinc–copper mix, (iodomethyl)zinc iodide, ICH_2ZnI , is formed. In the presence of an alkene, ICH_2ZnI transfers a CH_2 group to the double bond to yield cyclopropane. For example, cyclohexene reacts cleanly and with good yield to give the corresponding cyclopropane. Although we won't discuss the mechanistic details, carbene addition to an alkene is one of a general class of reactions called *cycloadditions*, which we'll study more carefully in Chapter 30.

PROBLEM What products would you expect from the following reactions?

8.10 Radical Additions to Alkenes: Chain-Growth Polymers

In our brief introduction to radical reactions in [Section 6.6](#), we said that radicals can add to $\text{C}=\text{C}$ bonds, taking one electron from the double bond and leaving one behind to yield a new radical. Let's now look at the process in more detail, focusing on the industrial synthesis of alkene polymers. A **polymer** is a large—sometimes very large—molecule, built up by repetitive joining together of many smaller molecules, called **monomers**.

Nature makes wide use of biological polymers. Cellulose, for instance, is a polymer built of repeating glucose monomer units; proteins are polymers built of repeating amino acid monomers; and nucleic acids are polymers built of repeating nucleotide monomers.

Cellulose—a glucose polymer**Protein—an amino acid polymer****Nucleic acid—a nucleotide polymer**

Synthetic polymers, such as polyethylene, are much simpler chemically than biopolymers, but there is still a great diversity to their structures and properties, depending on the identity of the monomers and on the reaction conditions used for polymerization. The simplest synthetic polymers are those that result when an alkene is treated with a small amount of a suitable catalyst. Ethylene, for example, yields polyethylene, an enormous alkane that may have a molecular weight up to *6 million* u and may contain as many as 200,000 monomer units. Worldwide production of polyethylene is approximately 88 million tons per year.

Polyethylene—a synthetic alkene polymer

Polyethylene and other simple alkene polymers are called **chain-growth polymers** because they are formed in a chain-reaction process in which an initiator adds to a carbon-carbon double bond to yield a reactive intermediate. The intermediate then reacts with a second molecule of monomer to yield a new intermediate, which reacts with a third monomer unit, and so on.

Historically, ethylene polymerization was carried out at high pressure (1000–3000 atm) and high temperature (100–250 °C) in the presence of a radical initiator such as benzoyl peroxide. Like many radical reactions, the mechanism of ethylene polymerization occurs in three steps: initiation, propagation, and termination:

- **Initiation** The polymerization reaction is initiated when a few radicals are generated on heating a small

amount of benzoyl peroxide catalyst to break the weak O–O bond. The initially formed benzoyloxy radical loses CO_2 and gives a phenyl radical ($\text{Ph}\cdot$), which adds to the $\text{C}=\text{C}$ bond of ethylene to start the polymerization process. One electron from the ethylene double bond pairs up with the odd electron on the phenyl radical to form a new C–C bond, and the other electron remains on carbon.

- **Propagation** Polymerization occurs when the carbon radical formed in the initiation step adds to another ethylene molecule to yield another radical. Repetition of the process for hundreds or thousands of times builds the polymer chain.

- **Termination** The chain process is eventually ended by a reaction that consumes the radical. The combination of two growing chains is one possible chain-terminating reaction.

Ethylene is not unique in its ability to form a polymer. Many substituted ethylenes, called vinyl monomers, also undergo polymerization to yield polymers with substituent groups regularly spaced on alternating carbon atoms along the chain. Propylene, for example, yields polypropylene, and styrene yields polystyrene.

When an unsymmetrically substituted vinyl monomer such as propylene or styrene is polymerized, the radical addition steps can take place at either end of the double bond to yield either a primary radical intermediate ($\text{RCH}_2\cdot$) or a secondary radical ($\text{R}_2\text{CH}\cdot$). Just as in electrophilic addition reactions, however, we find that only the more highly substituted, secondary radical is formed.

TABLE 8.1 shows some commercially important alkene polymers, their uses, and the monomers from which they are made.

TABLE 8.1 Some Alkene Polymers and Their Uses

Monomer	Formula	Trade or common name of polymer	Uses
Ethylene	$\text{H}_2\text{C}=\text{CH}_2$	Polyethylene	Packaging, bottles
Propene (propylene)	$\text{H}_2\text{C}=\text{CHCH}_3$	Polypropylene	Moldings, rope, carpets
Chloroethylene (vinyl chloride)	$\text{H}_2\text{C}=\text{CHCl}$	Poly(vinyl chloride)	Insulation, films, pipes
Styrene	$\text{H}_2\text{C}=\text{CHC}_6\text{H}_5$	Polystyrene	Foam, moldings
Tetrafluoroethylene	$\text{F}_2\text{C}=\text{CF}_2$	Teflon	Gaskets, nonstick coatings
Acrylonitrile	$\text{H}_2\text{C}=\text{CHCN}$	Orlon, Acrilan	Fibers
Methyl methacrylate	$\begin{array}{c} \text{CH}_3 \\ \\ \text{H}_2\text{C}=\text{CCO}_2\text{CH}_3 \end{array}$	Plexiglas, Lucite	Paint, sheets, moldings
Vinyl acetate	$\text{H}_2\text{C}=\text{CHOCOCH}_3$	Poly(vinyl acetate)	Paint, adhesives, foams

WORKED EXAMPLE 8.4

Predicting the Structure of a Polymer

Show the structure of poly(vinyl chloride), a polymer made from $\text{H}_2\text{C}=\text{CHCl}$, by drawing several repeating units.

Strategy

Mentally break the carbon–carbon double bond in the monomer unit, and form single bonds by connecting numerous units together.

Solution

The general structure of poly(vinyl chloride) is

8.11 Biological Additions of Radicals to Alkenes

The same high reactivity of radicals that enables the alkene polymerization we saw in the previous section also makes it difficult to carry out controlled radical reactions on complex molecules. As a result, there are severe limitations on the usefulness of radical addition reactions in the laboratory. In contrast to an electrophilic addition, where reaction occurs once and the reactive cation intermediate is rapidly quenched by a nucleophile, the reactive intermediate in a radical reaction is not usually quenched. Instead, it reacts again and again in a largely uncontrollable way.

Electrophilic addition
(Intermediate is quenched,
so reaction stops.)

Radical addition
(Intermediate is not quenched,
so reaction does not stop.)

In biological reactions, the situation is different from that in the laboratory. Only one substrate molecule at a time is present in the active site of an enzyme, and that molecule is held in a precise position, with other necessary reacting groups nearby. As a result, biological radical reactions are more controlled and more common than laboratory or industrial radical reactions. A particularly impressive example occurs in the biosynthesis of prostaglandins from arachidonic acid, where a sequence of four radical additions take place. Its reaction mechanism was discussed briefly in [Section 6.6](#).

As shown in [FIGURE 8.12](#), prostaglandin biosynthesis begins with abstraction of a hydrogen atom from C13 of arachidonic acid by an iron–oxy radical to give a carbon radical that reacts with O_2 at C11 through a resonance form. The oxygen radical that results adds to the C8–C9 double bond to give a carbon radical at C8, which adds to the C12–C13 double bond and gives a carbon radical at C13. A resonance form of this carbon radical adds at C15 to a second O_2 molecule, completing the prostaglandin skeleton. Reduction of the O–O bond then gives prostaglandin H_2 , called PGH_2 . The pathway looks complicated, but the entire process is catalyzed with exquisite control by a single enzyme.

FIGURE 8.12 Pathway for the biosynthesis of prostaglandins from arachidonic acid. Steps 2 and 5 are radical addition reactions to O₂; steps 3 and 4 are radical additions to carbon–carbon double bonds.

8.12 Reaction Stereochemistry: Addition of H₂O to an Achiral Alkene

Most of the biochemical reactions that take place in the body, as well as many organic reactions in the laboratory, yield products with chirality centers. For example, acid-catalyzed addition of H₂O to 1-butene in the laboratory yields 2-butanol, a chiral alcohol. What is the stereochemistry of this chiral product? If a single enantiomer is formed, is it *R* or *S*? If a mixture of enantiomers is formed, how much of each? In fact, the 2-butanol produced is a racemic mixture of *R* and *S* enantiomers. Let's see why.

To understand why a racemic product results from the reaction of H₂O with 1-butene, think about the reaction

mechanism. 1-Butene is first protonated to yield an intermediate secondary carbocation. Because the trivalent carbon is sp^2 -hybridized and planar, the cation has a plane of symmetry and is achiral. As a result, it can react with H₂O equally well from either the top or the bottom. Reaction from the top leads to (*S*)-2-butanol through transition state 1 (TS 1) in **FIGURE 8.13**, and reaction from the bottom leads to (*R*)-2-butanol through TS 2. But the two transition states are mirror images, so they have identical energies, form at identical rates, and are equally likely to occur.

FIGURE 8.13 Reaction of H₂O with the carbocation resulting from protonation of 1-butene. Reaction from the top leads to *S* product and is the mirror image of reaction from the bottom, which leads to *R* product. Because they are energetically identical, they are equally likely and lead to a racemic mixture of products. The dotted C···O bond in the transition state indicates partial bond formation.

As a general rule, the formation of a new chirality center by achiral reactants always leads to a racemic mixture of enantiomeric products. Put another way, optical activity can't appear from nowhere; an optically active product can only result by starting with an optically active reactant or chiral environment (**Section 5.12**).

In contrast to laboratory reactions, enzyme-catalyzed biological reactions often give a single enantiomer of a chiral product, even when the substrate is achiral. One step in the citric acid cycle of food metabolism, for instance, is the aconitase-catalyzed addition of water to (*Z*)-aconitate (usually called *cis*-aconitate) to give isocitrate.

Even though *cis*-aconitate is achiral, only the (*2R,3S*) enantiomer of the product is formed. As discussed in **Section 5.11** and **Section 5.12**, *cis*-aconitate is a prochiral molecule, which is held in a chiral environment by the aconitase enzyme during the reaction. In this environment, the two faces of the double bond are chemically distinct, and addition occurs on only the *Re* face at C2.

8.13 Reaction Stereochemistry: Addition of H₂O to a Chiral Alkene

The reaction discussed in the previous section involves an addition to an achiral reactant and forms an optically inactive, racemic mixture of two enantiomeric products. What would happen, though, if we were to carry out the reaction on a single enantiomer of a chiral reactant? For example, what stereochemical result would be obtained from addition of H₂O to a chiral alkene, such as (*R*)-4-methyl-1-hexene? The product of the reaction, 4-methyl-2-hexanol, has two chirality centers and so has four possible stereoisomers.

Let's think about the two chirality centers separately. What about the configuration at C4, the methyl-bearing carbon atom? Since C4 has the *R* configuration in the starting material and this chirality center is unaffected by the reaction, its configuration is unchanged. Thus, the configuration at C4 in the product remains *R* (assuming that the relative rankings of the four attached groups are not changed by the reaction).

What about the configuration at C2, the newly formed chirality center? As shown in **FIGURE 8.14**, the stereochemistry at C2 is established by reaction of H₂O with a carbocation intermediate in the usual manner. But this carbocation doesn't have a plane of symmetry; it is chiral because of the chirality center at C4. Because the carbocation is chiral and has no plane of symmetry, it doesn't react equally well from the top and bottom faces. One of the two faces is likely, for steric reasons, to be a bit more accessible than the other, leading to a mixture of *R* and *S* products in some ratio other than 50 : 50. Thus, two diastereomeric products, (*2R,4R*)-4-methyl-2-hexanol and (*2S,4R*)-4-methyl-2-hexanol, are formed in unequal amounts, and the mixture is optically active.

FIGURE 8.14 Stereochemistry of the acid-catalyzed addition of H₂O to the chiral alkene, (*R*)-4-methyl-1-hexene. A mixture of diastereomeric *2R,4R* and *2S,4R* products is formed in unequal amounts because reaction of the chiral carbocation intermediate is not equally likely from top and bottom. The product mixture is optically active.

As a general rule, the formation of a new chirality center by a chiral reactant leads to unequal amounts of diastereomeric products. If the chiral reactant is optically active because only one enantiomer is used rather than a racemic mixture, then the products are also optically active.

PROBLEM 8-20 What products are formed from acid-catalyzed hydration of racemic (\pm)-4-methyl-1-hexene? What can you say about the relative amounts of the products? Is the product mixture optically active?

PROBLEM 8-21 What products are formed from hydration of 4-methylcyclopentene? What can you say about the relative amounts of the products?

CHEMISTRY MATTERS

Terpenes: Naturally Occurring Alkenes

Ever since its discovery in Persia around 1000 A.D., it has been known that *steam distillation*, the distillation of plant materials together with water, produces a fragrant mixture of liquids called essential oils. The resulting oils have long been used as medicines, spices, and perfumes, and their investigation played a major role in the emergence of organic chemistry as a science during the 19th century.

FIGURE 8.15 The wonderful fragrance of leaves from the California bay laurel is due primarily to myrcene, a simple terpene. (credit: “California Bay Umbellularia californica” by Don Loaire/Flickr, CC BY 2.0)

Chemically, plant essential oils consist largely of mixtures of compounds called terpenoids—small organic molecules with an immense diversity of structure. More than 60,000 different terpenoids are known. Some are open-chain molecules, and others contain rings; some are hydrocarbons, and others contain oxygen. Hydrocarbon terpenoids, in particular, are known as terpenes, and all contain double bonds. For example:

Regardless of their apparent structural differences, all terpenoids are related. According to a formalism called

the isoprene rule, they can be thought of as arising from head-to-tail joining of 5-carbon isoprene units (2-methyl-1,3-butadiene). Carbon 1 is the head of the isoprene unit, and carbon 4 is the tail. For example, myrcene contains two isoprene units joined head to tail, forming an 8-carbon chain with two 1-carbon branches. α -Pinene similarly contains two isoprene units assembled into a more complex cyclic structure, and humulene contains three isoprene units. See if you can identify the isoprene units in α -pinene, humulene, and β -santalene.

Terpenes (and terpenoids) are further classified according to the number of 5-carbon units they contain. Thus, monoterpenes are 10-carbon substances derived from two isoprene units, sesquiterpenes are 15-carbon molecules derived from three isoprene units, diterpenes are 20-carbon substances derived from four isoprene units, and so on. Monoterpenes and sesquiterpenes are found primarily in plants, but the higher terpenoids occur in both plants and animals, and many have important biological roles. The triterpenoid lanosterol, for instance, is the biological precursor from which all steroid hormones are made.

Isoprene itself is not the true biological precursor of terpenoids. Nature instead uses two “isoprene equivalents”—isopentenyl diphosphate and dimethylallyl diphosphate—which are themselves made by two different routes depending on the organism. Lanosterol, in particular, is biosynthesized from acetic acid by a complex pathway that has been worked out in great detail. We’ll look at the subject more closely in **Sections 27.5 and 27.7**.

Key Terms

- anti stereochemistry
- bromonium ion
- carbene, R₂C
- chain-growth polymer
- epoxide
- glycol
- halohydrin
- hydroboration
- hydrogenated
- hydroxylation
- monomer
- oxidation
- oxirane
- oxymercuration–demercuration
- ozonide
- polymer
- reduction
- Simmons–Smith reaction
- stereospecific
- syn stereochemistry

Summary

With the background needed to understand organic reactions now covered, this chapter has begun the systematic description of major functional groups.

Alkenes are generally prepared by an elimination reaction, such as dehydrohalogenation, the elimination of HX from an alkyl halide, or dehydration, the elimination of water from an alcohol. The converse of this elimination reaction is the addition of various substances to the alkene double bond to give saturated products.

HCl, HBr, and HI add to alkenes by a two-step electrophilic addition mechanism. Initial reaction of the nucleophilic double bond with H^+ gives a carbocation intermediate, which then reacts with halide ion. Bromine and chlorine add to alkenes via three-membered-ring **bromonium ion** or chloronium ion intermediates to give addition products having **anti stereochemistry**. If water is present during the halogen addition reaction, a **halohydrin** is formed.

Hydration of an alkene—the addition of water—is carried out by either of two procedures, depending on the product desired. **Oxymercuration–demercuration** involves electrophilic addition of Hg^{2+} to an alkene, followed by trapping of the cation intermediate with water and subsequent treatment with $NaBH_4$. **Hydroboration** involves addition of borane (BH_3) followed by oxidation of the intermediate organoborane with alkaline H_2O_2 . The two hydration methods are complementary: oxymercuration–demercuration gives the product of Markovnikov addition, whereas hydroboration–oxidation gives the product with non-Markovnikov **syn stereochemistry**.

Alkenes are **reduced** by addition of H_2 in the presence of a catalyst such as platinum or palladium to yield alkanes, a process called catalytic **hydrogenation**. Alkenes are also **oxidized** by reaction with a peroxyacid to give **epoxides**, which can be converted into trans-1,2-diols by acid-catalyzed hydrolysis. The corresponding cis-1,2-diols can be made directly from alkenes by **hydroxylation** with OsO_4 . Alkenes can also be cleaved to produce carbonyl compounds by reaction with ozone, followed by reduction with zinc metal. In addition, alkenes react with divalent substances called **carbenes, $R_2C:$** , to give cyclopropanes. Nonhalogenated cyclopropanes are best prepared by treatment of the alkene with CH_2I_2 and zinc–copper, a process called the **Simmons–Smith reaction**.

Alkene **polymers**—large molecules resulting from repetitive bonding of many hundreds or thousands of small **monomer** units—are formed by chain-reaction polymerization of simple alkenes. Polyethylene, polypropylene, and polystyrene are examples. As a general rule, radical addition reactions are not common in the laboratory but occur frequently in biological pathways.

Many reactions give chiral products. If the reactants are optically inactive, the products are also optically inactive. If one or both of the reactants is optically active, the products can also be optically active.

LEARNING REACTIONS

What's seven times nine? Sixty-three, of course. You didn't have to stop and figure it out; you knew the answer immediately because you long ago learned the multiplication tables. Learning the reactions of organic chemistry requires the same approach: reactions have to be learned for quick recall if they are to be useful.

Different people take different approaches to learning reactions. Some people make flashcards; others find studying with friends to be helpful. To help guide your study, most chapters in this book end with a summary of the reactions just presented. In addition, the accompanying *Study Guide and Student Solutions Manual* has several appendixes that organize organic reactions from other perspectives. Fundamentally, though, there are no shortcuts. Learning organic chemistry does take effort.

Summary of Reactions

No stereochemistry is implied unless specifically indicated with wedged, solid, and dashed lines.

1. Addition reactions of alkenes

- a. Addition of HCl, HBr, and HI (Section 7.7 and Section 7.8)

Markovnikov regiochemistry occurs, with H adding to the less highly substituted alkene carbon and halogen adding to the more highly substituted carbon.

- b. Addition of halogens Cl₂ and Br₂ (Section 8.2)

Anti addition is observed through a halonium ion intermediate.

- c. Halohydrin formation (Section 8.3)

Markovnikov regiochemistry and anti stereochemistry occur.

- d. Addition of water by oxymercuration–demercuration (Section 8.4)

Markovnikov regiochemistry occurs.

- e. Addition of water by hydroboration–oxidation (Section 8.5)

Non-Markovnikov syn addition occurs.

- f. Catalytic hydrogenation (Section 8.6)

Syn addition occurs.

- g. Epoxidation with a peroxyacid (Section 8.7)

Syn addition occurs.

- h. Hydroxylation with OsO₄ (Section 8.7)

Syn addition occurs.

- i. Addition of carbenes to yield cyclopropanes (Section 8.9)

(1) Dichlorocarbene addition

(2) Simmons–Smith reaction

2. Hydroxylation by acid-catalyzed epoxide hydrolysis (Section 8.7)

Anti stereochemistry occurs.

3. Oxidative cleavage of alkenes (Section 8.8)

a. Reaction with ozone followed by zinc in acetic acid

b. Reaction with KMnO_4 in acidic solution

4. Cleavage of 1,2-diols (Section 8.8)

Additional Problems

Visualizing Chemistry

PROBLEM Name the following alkenes, and predict the products of their reaction with (1)**8-22** *meta*-chloroperoxybenzoic acid, (2) KMnO_4 in aqueous acid, (3) O_3 , followed by Zn in acetic acid:

(a)

(b)

**PROBLEM** Draw the structures of alkenes that would yield the following alcohols on hydration (red = O). Tell in**8-23** each case whether you would use hydroboration-oxidation or oxymercuration-demercuration.

(a)

(b)

**PROBLEM** The following alkene undergoes hydroboration-oxidation to yield a single product rather than a**8-24** mixture. Explain the result, and draw the product showing its stereochemistry.

PROBLEM 8-25 From what alkene was the following 1,2-diol made, and what method was used, epoxide hydrolysis or OsO_4 ?

Mechanism Problems

PROBLEM 8-26 Predict the products for the following reactions, showing the complete mechanism and appropriate stereochemistry:

PROBLEM 8-27 Draw the structures of the organoboranes formed when borane reacts with the following alkenes, including the regiochemistry and stereochemistry as appropriate. Propose a mechanism for each reaction.

PROBLEM 8-28 *meta*-Chlorobenzoic acid is not the only peroxyacid capable of epoxide formation. For each reaction below, predict the products and show the mechanism.

PROBLEM 8-29 Give the mechanism and products for the following acid-catalyzed epoxide-opening reactions, including appropriate stereochemistry.

PROBLEM 8-30 Which of the reactions below would result in a product mixture that would rotate plane-polarized light?

PROBLEM 8-31 Reaction of 2-methylpropene with CH_3OH in the presence of H_2SO_4 catalyst yields methyl *tert*-butyl ether, $\text{CH}_3\text{OC}(\text{CH}_3)_3$, by a mechanism analogous to that of acid-catalyzed alkene hydration. Write the mechanism, using curved arrows for each step.

PROBLEM 8-32 Iodine azide, IN_3 , adds to alkenes by an electrophilic mechanism similar to that of bromine. If a monosubstituted alkene such as 1-butene is used, only one product results:

- Add lone-pair electrons to the structure shown for IN_3 , and draw a second resonance form for the molecule.
- Calculate formal charges for the atoms in both resonance structures you drew for IN_3 in part (a).
- In light of the result observed when IN_3 adds to 1-butene, what is the polarity of the $\text{I}-\text{N}_3$ bond? Propose a mechanism for the reaction using curved arrows to show the electron flow in each step.

PROBLEM 8-33 10-Bromo- α -chamigrene, a compound isolated from marine algae, is thought to be biosynthesized from γ -bisabolene by the following route:

Draw the structures of the intermediate bromonium and cyclic carbocation, and propose mechanisms for all three steps.

PROBLEM 8-34 Isolated from marine algae, prelaureatin is thought to be biosynthesized from laurediol by the following route. Propose a mechanism.

PROBLEM 8-35 Dichlorocarbene can be generated by heating sodium trichloroacetate. Propose a mechanism for the reaction, and use curved arrows to indicate the movement of electrons in each step. What relationship does your mechanism bear to the base-induced elimination of HCl from chloroform?

PROBLEM 8-36 Reaction of cyclohexene with mercury(II) acetate in CH_3OH rather than H_2O , followed by treatment with NaBH_4 , yields cyclohexyl methyl ether rather than cyclohexanol. Suggest a mechanism.

PROBLEM 8-37 Use your general knowledge of alkene chemistry to suggest a mechanism for the following reaction.

PROBLEM 8-38 Treatment of 4-penten-1-ol with aqueous Br_2 yields a cyclic bromo ether rather than the expected bromohydrin. Suggest a mechanism, using curved arrows to show electron movement.

PROBLEM 8-39 Hydroboration of 2-methyl-2-pentene at 25°C , followed by oxidation with alkaline H_2O_2 , yields 2-methyl-3-pentanol, but hydroboration at 160°C followed by oxidation yields 4-methyl-1-pentanol. Suggest a mechanism.

Reactions of Alkenes

PROBLEM 8-40 Predict the products of the following reactions (the aromatic ring is unreactive in all cases). Indicate regiochemistry when relevant.

PROBLEM 8-41 Suggest structures for alkenes that give the following reaction products. There may be more than one answer for some cases.

PROBLEM 8-42 Predict the products of the following reactions, showing both regiochemistry and stereochemistry where appropriate:

PROBLEM 8-43 Which reaction would you expect to be faster, addition of HBr to cyclohexene or to 1-methylcyclohexene? Explain.

PROBLEM 8-44 What product will result from hydroboration–oxidation of 1-methylcyclopentene with deuterated borane, BD_3 ? Show both the stereochemistry (spatial arrangement) and the regiochemistry (orientation) of the product.

PROBLEM 8-45 The *cis* and *trans* isomers of 2-butene give different cyclopropane products in the Simmons–Smith reaction. Show the structures of both, and explain the difference.

PROBLEM 8-46 Predict the products of the following reactions. Don't worry about the size of the molecule; concentrate on the functional groups.

PROBLEM Addition of HCl to 1-methoxycyclohexene yields 1-chloro-1-methoxycyclohexane as a sole product.

8-47 Use resonance structures of the carbocation intermediate to explain why none of the alternate regioisomer is formed.

Synthesis Using Alkenes

PROBLEM How would you carry out the following transformations? What reagents would you use in each case?

PROBLEM Draw the structure of an alkene that yields only acetone, $(\text{CH}_3)_2\text{C}=\text{O}$, on ozonolysis followed by treatment with Zn.

8-49

PROBLEM Show the structures of alkenes that give the following products on oxidative cleavage with KMnO_4 in acidic solution:

8-50

PROBLEM In planning the synthesis of one compound from another, it's just as important to know what not to do as to know what to do. The following reactions all have serious drawbacks to them. Explain the potential problems of each.

8-51

PROBLEM 8-52 Which of the following alcohols could not be made selectively by hydroboration–oxidation of an alkene? Explain.

Polymers

PROBLEM 8-53 Plexiglas, a clear plastic used to make many molded articles, is made by polymerization of methyl methacrylate. Draw a representative segment of Plexiglas.

PROBLEM 8-54 Poly(vinyl pyrrolidone), prepared from *N*-vinylpyrrolidone, is used both in cosmetics and as a component of a synthetic substitute for blood. Draw a representative segment of the polymer.

PROBLEM 8-55 When a single alkene monomer, such as ethylene, is polymerized, the product is a *homopolymer*. If a mixture of two alkene monomers is polymerized, however, a *copolymer* often results. The following structure represents a segment of a copolymer called *Saran*. What two monomers were copolymerized to make *Saran*?

General Problems

PROBLEM 8-56 Compound **A** has the formula $C_{10}H_{16}$. On catalytic hydrogenation over palladium, it reacts with only 1 molar equivalent of H_2 . Compound **A** also undergoes reaction with ozone, followed by zinc treatment, to yield a symmetrical diketone, **B** ($C_{10}H_{16}O_2$).

- (a) How many rings does **A** have? (b) What are the structures of **A** and **B**?
 (c) Write the reactions.

PROBLEM 8-57 An unknown hydrocarbon **A** with the formula C_6H_{12} reacts with 1 molar equivalent of H_2 over a palladium catalyst. Hydrocarbon **A** also reacts with OsO_4 to give diol **B**. When oxidized with $KMnO_4$

in acidic solution, **A** gives two fragments. One fragment is propanoic acid, $\text{CH}_3\text{CH}_2\text{CO}_2\text{H}$, and the other fragment is ketone **C**. What are the structures of **A**, **B**, and **C**? Write all reactions.

PROBLEM 8-58 Using an oxidative cleavage reaction, explain how you would distinguish between the following two isomeric dienes:

PROBLEM 8-59 Compound **A**, $\text{C}_{10}\text{H}_{18}\text{O}$, undergoes reaction with dilute H_2SO_4 at 50°C to yield a mixture of two alkenes, $\text{C}_{10}\text{H}_{16}$. The major alkene product, **B**, gives only cyclopentanone after ozone treatment followed by reduction with zinc in acetic acid. Identify **A** and **B**, and write the reactions.

PROBLEM 8-60 Draw the structure of a hydrocarbon that absorbs 2 molar equivalents of H_2 on catalytic hydrogenation and gives only butanedial on ozonolysis.

PROBLEM 8-61 Simmons–Smith reaction of cyclohexene with diiodomethane gives a single cyclopropane product, but the analogous reaction of cyclohexene with 1,1-diiodoethane gives (in low yield) a mixture of two isomeric methylcyclopropane products. What are the two products, and how do they differ?

PROBLEM 8-62 The sex attractant of the common housefly is a hydrocarbon with the formula $\text{C}_{23}\text{H}_{46}$. On treatment with aqueous acidic KMnO_4 , two products are obtained, $\text{CH}_3(\text{CH}_2)_{12}\text{CO}_2\text{H}$ and $\text{CH}_3(\text{CH}_2)_7\text{CO}_2\text{H}$. Propose a structure.

PROBLEM 8-63 Compound **A** has the formula C_8H_8 . It reacts rapidly with KMnO_4 to give CO_2 and a carboxylic acid, **B** ($\text{C}_7\text{H}_6\text{O}_2$), but reacts with only 1 molar equivalent of H_2 on catalytic hydrogenation over a palladium catalyst. On hydrogenation under conditions that reduce aromatic rings, 4 equivalents of H_2 are taken up and hydrocarbon **C** (C_8H_{16}) is produced. What are the structures of **A**, **B**, and **C**? Write the reactions.

PROBLEM 8-64 How would you distinguish between the following pairs of compounds using simple chemical tests? Tell what you would do and what you would see.
(a) Cyclopentene and cyclopentane (b) 2-Hexene and benzene

PROBLEM 8-65 α -Terpinene, $\text{C}_{10}\text{H}_{16}$, is a pleasant-smelling hydrocarbon that has been isolated from oil of marjoram. On hydrogenation over a palladium catalyst, α -terpinene reacts with 2 molar equivalents of H_2 to yield a hydrocarbon, $\text{C}_{10}\text{H}_{20}$. On ozonolysis, followed by reduction with zinc and acetic acid, α -terpinene yields two products, glyoxal and 6-methyl-2,5-heptanedione.

- How many degrees of unsaturation does α -terpinene have?
- How many double bonds and how many rings does it have?
- Propose a structure for α -terpinene.

PROBLEM 8-66 Evidence that cleavage of 1,2-diols by HIO_4 occurs through a five-membered cyclic periodate intermediate is based on the measurement of reaction rates. When diols **A** and **B** were prepared and the rates of their reaction with HIO_4 were measured, it was found that diol **A** cleaved approximately 1 million times faster than diol **B**. Make molecular models of **A** and **B** and of potential cyclic

periodate intermediates, and then explain the results.

PROBLEM 8-67 Reaction of HBr with 3-methylcyclohexene yields a mixture of four products: *cis*- and *trans*-1-bromo-3-methylcyclohexane and *cis*- and *trans*-1-bromo-2-methylcyclohexane. The analogous reaction of HBr with 3-bromocyclohexene yields *trans*-1,2-dibromocyclohexane as the sole product. Draw structures of the possible intermediates, and then explain why only a single product is formed in this reaction.

PROBLEM 8-68 We'll see in the next chapter that alkynes undergo many of the same reactions that alkenes do. What product might you expect from each of the following reactions?

PROBLEM 8-69 Hydroxylation of *cis*-2-butene with OsO_4 yields a different product than hydroxylation of *trans*-2-butene. Draw the structure, show the stereochemistry of each product, and explain the difference between them.

PROBLEM 8-70 Compound **A**, $\text{C}_{11}\text{H}_{16}\text{O}$, was found to be an optically active alcohol. Despite its apparent unsaturation, no hydrogen was absorbed on catalytic reduction over a palladium catalyst. On treatment of **A** with dilute sulfuric acid, dehydration occurred and an optically inactive alkene **B**, $\text{C}_{11}\text{H}_{14}$, was the major product. Alkene **B**, on ozonolysis, gave two products. One product was identified as propanal, $\text{CH}_3\text{CH}_2\text{CHO}$. Compound **C**, the other product, was shown to be a ketone, $\text{C}_8\text{H}_8\text{O}$. How many degrees of unsaturation does **A** have? Write the reactions, and identify **A**, **B**, and **C**.

CHAPTER 9

Alkynes: An Introduction to Organic Synthesis

FIGURE 9.1 Synthesizing organic compounds is like conducting a musical group. When in tune, chemists can create highly complex organic compounds. (credit: modification of work “Jazz great visits Navy” by U.S. Navy, Michael Worner/Wikimedia Commons, Public Domain)

9.8 Alkylation of Acetylide Anions

9.9 An Introduction to Organic Synthesis

WHY THIS CHAPTER? Alkynes are less common than alkenes, both in the laboratory and in living organisms, so we won't cover them in great detail. The real importance of this chapter is that we'll use alkyne chemistry as a vehicle to begin looking at some of the general strategies used in organic synthesis—the construction of complex molecules in the laboratory. Without the ability to design and synthesize new molecules in the laboratory, many of the medicines we take for granted would not exist and few new ones would be made.

An **alkyne** is a hydrocarbon that contains a carbon–carbon triple bond. Acetylene, $\text{H}-\text{C}\equiv\text{C}-\text{H}$, the simplest alkyne, was once widely used in industry as a starting material for the preparation of acetaldehyde, acetic acid, vinyl chloride, and other high-volume chemicals, but more efficient routes to these substances using ethylene as starting material are now available. Acetylene is still used in the preparation of acrylic polymers, such as

The starting vicinal dihalides are themselves readily available by addition of Br₂ or Cl₂ to alkenes. Thus, the overall halogenation/dehydrohalogenation sequence makes it possible to go from an alkene to an alkyne. For example, diphenylethylene is converted into diphenylacetylene by reaction with Br₂ and subsequent base treatment.

The twofold dehydrohalogenation takes place through a vinylic halide intermediate, which suggests that vinylic halides themselves should give alkynes when treated with strong base. (A vinylic substituent is one that is attached to a double-bond.) This is indeed the case. For example:

9.3 Reactions of Alkynes: Addition of HX and X₂

You might recall from Section 1.9 that a carbon–carbon triple bond results from the interaction of two *sp*-hybridized carbon atoms. The two *sp* hybrid orbitals of carbon lie at an angle of 180° to each other along an axis perpendicular to the axes of the two unhybridized 2*p_y* and 2*p_z* orbitals. When two *sp*-hybridized carbons approach each other, one *sp*–*sp* σ bond and two *p*–*p* π bonds are formed. The two remaining *sp* orbitals form bonds to other atoms at an angle of 180° from the carbon–carbon bond. Thus, acetylene is a linear molecule with H–C≡C bond angles of 180° (FIGURE 9.2). The length of the C≡C bond is 120 pm, and its strength is approximately 965 kJ/mol (231 kcal/mol), making it the shortest and strongest known carbon–carbon bond.

FIGURE 9.2 The structure of acetylene, H–C≡C–H. The H–C≡C bond angles are 180°, and the C≡C bond length is 120 pm. The electrostatic potential map shows that the π bonds create a **negative belt** around the molecule.

As a general rule, electrophiles undergo addition reactions with alkynes much as they do with alkenes. Take the reaction of alkynes with HX, for instance. The reaction often can be stopped with the addition of 1 equivalent of HX, but reaction with an excess of HX leads to a dihalide product. For example, reaction of 1-hexyne with 2 equivalents of HBr yields 2,2-dibromohexane. As the following examples indicate, the regiochemistry of addition follows Markovnikov's rule, with halogen adding to the more highly substituted side of the alkyne bond

and hydrogen adding to the less highly substituted side. Trans stereochemistry of H and X normally, although not always, occurs in the product.

HBr addition

1-Hexyne

2-Bromo-1-hexene

2,2-Dibromohexane

HCl addition

3-Hexyne

(Z)-3-Chloro-3-hexene

3,3-Dichlorohexane

Bromine and chlorine also add to alkynes to give addition products, and trans stereochemistry again results.

Br₂ addition

1-Butyne

(E)-1,2-Dibromo-1-butene

1,1,2,2-Tetrabromobutane

The mechanism of alkyne addition is similar but not identical to that of alkene addition. When an electrophile such as HBr adds to an alkene, the reaction takes place in two steps and involves an alkyl carbocation intermediate (Section 7.7 and Section 7.8). If HBr were to add by the same mechanism to an alkyne, an analogous vinylic carbocation would be formed as the intermediate.

A vinylic carbocation has an *sp*-hybridized carbon and generally forms less readily than an alkyl carbocation (FIGURE 9.3). As a rule, a secondary vinylic carbocation forms about as readily as a primary alkyl carbocation, but a primary vinylic carbocation is so difficult to form that there is no clear evidence it even exists. Thus, many alkyne additions occur through more complex mechanistic pathways.

FIGURE 9.3 The structure of a secondary vinylic carbocation. The cationic carbon atom is sp -hybridized and has a vacant p orbital perpendicular to the plane of the π bond orbitals. Only one R group is attached to the positively charged carbon rather than two, as in a secondary alkyl carbocation. The electrostatic potential map shows that the **most positive regions** coincide with lobes of the vacant p orbital and are perpendicular to the **most negative regions** associated with the π bond.

PROBLEM What products would you expect from the following reactions?

9.4 Hydration of Alkynes

Like alkenes (Section 8.4 and Section 8.5), alkynes can be hydrated by either of two methods. Direct addition of water catalyzed by mercury(II) ion yields the Markovnikov product, and indirect addition of water by a hydroboration–oxidation sequence yields the non-Markovnikov product.

Mercury(II)-Catalyzed Hydration of Alkynes

Alkynes don't react directly with aqueous acid but will undergo hydration readily in the presence of mercury(II) sulfate as a Lewis acid catalyst. The reaction occurs with Markovnikov regiochemistry, so the $-\text{OH}$ group adds to the more highly substituted carbon and the $-\text{H}$ attaches to the less highly substituted one.

Interestingly, the actual product isolated from alkyne hydration is not a vinylic alcohol, or **enol** (*ene* + *ol*), but is instead a ketone. Although the enol is an intermediate in the reaction, it immediately rearranges into a ketone by a process called *keto–enol tautomerism*. The individual keto and enol forms are said to be **tautomers**, a word used to describe two isomers that undergo spontaneous interconversion accompanied by the change in position of a hydrogen. With few exceptions, the keto–enol tautomeric equilibrium lies on the side of the ketone; enols are almost never isolated. We'll look more closely at this equilibrium in Section 22.1.

As shown in Figure 9.4, the mechanism of the mercury(II)-catalyzed alkyne hydration reaction is analogous to the oxymercuration reaction of alkenes (Section 8.4). Electrophilic addition of mercury(II) ion to the alkyne gives a vinylic cation, which reacts with water and loses a proton to yield a mercury-containing enol intermediate. In contrast with alkene oxymercuration, however, no treatment with NaBH_4 is necessary to remove the mercury. The acidic reaction conditions alone are sufficient to effect replacement of mercury by

hydrogen. Tautomerization then gives the ketone.

FIGURE 9.4 MECHANISM

Mechanism of the mercury(II)-catalyzed hydration of an alkyne to yield a ketone. The reaction occurs through initial formation of an intermediate enol, which tautomerizes to the ketone.

1 The alkyne uses a pair of electrons to attack the electrophilic mercury(II) ion, yielding a mercury-containing vinylic carbocation intermediate.

2 Nucleophilic attack of water on the carbocation forms a C–O bond and yields a protonated mercury-containing enol.

3 Abstraction of H^+ from the protonated enol by water gives an organomercury compound.

4 Replacement of Hg^{2+} by H^+ occurs to give a neutral enol.

5 The enol undergoes tautomerization to give the final ketone product.

A mixture of both possible ketones results when an unsymmetrically substituted internal alkyne ($\text{RC}\equiv\text{CR}'$) is hydrated. The reaction is therefore most useful when applied to a terminal alkyne ($\text{RC}\equiv\text{CH}$) because only a methyl ketone is formed.

An internal alkyne**A terminal alkyne**

PROBLEM What products would you obtain by mercury-catalyzed hydration of the following alkynes?

PROBLEM What alkynes would you start with to prepare the following ketones?

**Hydroboration–Oxidation of Alkynes**

Borane adds rapidly to an alkyne just as it does to an alkene, and the resulting vinylic borane can be oxidized by H_2O_2 to give an enol, which tautomerizes to either a ketone or an aldehyde, depending on the alkyne. Hydroboration–oxidation of an internal alkyne such as 3-hexyne is straightforward and gives a ketone, but hydroboration–oxidation of a terminal alkyne is more complex because two molecules of borane often add to the triple bond, complicating the situation. To prevent this double addition, a bulky, sterically encumbered borane such as bis(1,2-dimethylpropyl)borane, known commonly as disiamylborane is used in place of BH_3 . When a terminal alkyne such as 1-butyne reacts with disiamylborane, addition to the triple bond occurs normally, but a second addition is hindered by the bulk of the dialkylborane. Oxidation with H_2O_2 then gives an enol, which tautomerizes to the aldehyde.

The hydroboration–oxidation sequence is complementary to the direct, mercury(II)-catalyzed hydration reaction of a terminal alkyne because different products result. Direct hydration with aqueous acid and mercury(II) sulfate leads to a methyl ketone, whereas hydroboration–oxidation of the same terminal alkyne

leads to an aldehyde.

PROBLEM 9-6 What alkyne would you start with to prepare each of the following compounds by a hydroboration–oxidation reaction?

PROBLEM 9-7 How would you prepare the following carbonyl compounds starting from an alkyne (reddish brown = Br)?

9.5 Reduction of Alkynes

Alkynes are reduced to alkanes by addition of H_2 over a metal catalyst. The reaction occurs in two steps through an alkene intermediate, and measurements show that the first step in the reaction is more exothermic than the second.

Complete reduction to the alkane occurs when palladium on carbon (Pd/C) is used as catalyst, but hydrogenation can be stopped at the alkene stage if the less active *Lindlar catalyst* is used. The **Lindlar catalyst** is a finely divided palladium metal that has been precipitated onto a calcium carbonate support and then deactivated by treatment with lead acetate and quinoline, an aromatic amine. The hydrogenation occurs with syn stereochemistry (Section 8.5), giving a cis alkene product.

The alkyne hydrogenation reaction has been explored extensively by the Hoffmann–LaRoche pharmaceutical company, where it is used in the commercial synthesis of vitamin A. The *cis* isomer of vitamin A produced initially on hydrogenation is converted to the *trans* isomer by heating.

An alternative method for the conversion of an alkyne to an alkene uses sodium or lithium metal as the reducing agent in liquid ammonia as solvent. This method is complementary to the Lindlar reduction because it produces *trans* rather than *cis* alkenes. For example, 5-decyne gives *trans*-5-decene on treatment with lithium in liquid ammonia. The mechanism is explained below.

Alkali metals dissolve in liquid ammonia at $-33\text{ }^\circ\text{C}$ to produce a deep blue solution containing the metal cation and ammonia-solvated electrons. When an alkyne is then added to the solution, reduction occurs by the mechanism shown in **FIGURE 9.5**. An electron first adds to the triple bond to yield an intermediate anion radical—a species that is both an anion (has a negative charge) and a radical (has an odd number of electrons). This anion radical is a strong base, able to remove H^+ from ammonia to give a vinylic radical. Addition of a second electron to the vinylic radical gives a vinylic anion, which abstracts a second H^+ from ammonia to give *trans* alkene product.

FIGURE 9.5 MECHANISM

Mechanism of the lithium/ammonia reduction of an alkyne to produce a trans alkene.

1 Lithium metal donates an electron to the alkyne to give an anion radical . . .

2 . . . which abstracts a proton from ammonia solvent to yield a vinylic radical.

3 The vinylic radical accepts another electron from a second lithium atom to produce a vinylic anion . . .

4 . . . which abstracts another proton from ammonia solvent to yield the final trans alkene product.

A trans alkene

Trans stereochemistry of the alkene product is established during the second reduction step (3) when the less-hindered trans vinylic anion is formed from the vinylic radical. Vinylic radicals undergo rapid cis–trans equilibration, but vinylic anions equilibrate much less rapidly. Thus, the more stable trans vinylic anion is formed rather than the less stable cis anion and is then protonated without equilibration.

PROBLEM Using any alkyne needed, how would you prepare the following alkenes?

9-8 (a) *trans*-2-Octene (b) *cis*-3-Heptene (c) 3-Methyl-1-pentene

9.6 Oxidative Cleavage of Alkynes

Alkynes, like alkenes, can be cleaved by reaction with powerful oxidizing agents such as ozone or KMnO_4 , although the reaction is of little value and it is mentioned only for completeness. A triple bond is generally less reactive than a double bond, and yields of cleavage products can be low. The products obtained from cleavage of an internal alkyne are carboxylic acids; from a terminal alkyne, CO_2 is formed as one product.

An internal alkyne**A terminal alkyne**

9.7 Alkyne Acidity: Formation of Acetylide Anions

The most striking difference between alkenes and alkynes is that terminal alkynes are relatively acidic. When a terminal alkyne is treated with a strong base, such as sodium amide, $\text{Na}^+ \text{NH}_2^-$, the terminal hydrogen is removed and the corresponding **acetylide anion** is formed.

**Acetylide anion**

According to the Brønsted–Lowry definition ([Section 2.7](#)), an acid is a substance that donates H^+ . Although we usually think of oxyacids (H_2SO_4 , HNO_3) or halogen acids (HCl , HBr) in this context, any compound containing a hydrogen atom can be an acid under the right circumstances. By measuring dissociation constants of different acids and expressing the results as $\text{p}K_{\text{a}}$ values, an acidity order can be established. Recall from [Section 2.8](#) that a lower $\text{p}K_{\text{a}}$ corresponds to a stronger acid and a higher $\text{p}K_{\text{a}}$ corresponds to a weaker one.

Where do hydrocarbons lie on the acidity scale? As the data in [TABLE 9.1](#) show, both methane ($\text{p}K_{\text{a}} \approx 60$) and ethylene ($\text{p}K_{\text{a}} = 44$) are very weak acids and thus do not react with any of the common bases. Acetylene, however, has $\text{p}K_{\text{a}} = 25$ and can be deprotonated by the conjugate base of any acid whose $\text{p}K_{\text{a}}$ is greater than 25. Amide ion (NH_2^-), for example, the conjugate base of ammonia ($\text{p}K_{\text{a}} = 35$), is often used to deprotonate terminal alkynes.

TABLE 9.1 Acidity of Simple Hydrocarbons

Family	Example	K_{a}	$\text{p}K_{\text{a}}$	
Alkyne	$\text{HC}\equiv\text{CH}$	10^{-25}	25	
Alkene	$\text{H}_2\text{C}=\text{CH}_2$	10^{-44}	44	
Alkane	CH_4	10^{-60}	60	

Why are terminal alkynes more acidic than alkenes or alkanes? In other words, why are acetylide anions more stable than vinylic or alkyl anions? The simplest explanation involves the hybridization of the negatively charged carbon atom. An acetylide anion has an sp -hybridized carbon, so the negative charge resides in an orbital that has 50% “ s character.” A vinylic anion has a sp^2 -hybridized carbon with 33% s character, and an alkyl anion (sp^3) has only 25% s character. Because s orbitals are nearer the positive nucleus and lower in energy than p orbitals, the negative charge is stabilized to a greater extent in an orbital with higher s character ([FIGURE 9.6](#)).

FIGURE 9.6 A comparison of alkyl, vinylic, and acetylide anions. The acetylide anion, with sp hybridization, has more s character and is more stable. Electrostatic potential maps show that placing the negative charge closer to the carbon nucleus makes carbon appear less negative (red).

PROBLEM The pK_a of acetone, CH_3COCH_3 , is 19.3. Which of the following bases is strong enough to **9-9** deprotonate acetone?

- (a) KOH (pK_a of $\text{H}_2\text{O} = 15.7$) (b) $\text{Na}^+ \text{C}\equiv\text{CH}^-$ (pK_a of $\text{C}_2\text{H}_2 = 25$) (c) NaHCO_3 (pK_a of $\text{H}_2\text{CO}_3 = 6.4$)
 (d) NaOCH_3 (pK_a of $\text{CH}_3\text{OH} = 15.6$)

9.8 Alkylation of Acetylide Anions

The negative charge and unshared electron pair on carbon make an acetylide anion strongly nucleophilic. As a result, an acetylide anion can react with electrophiles, such as alkyl halides, in a process that replaces the halide and yields a new alkyne product.

We won't study the details of this substitution reaction until Chapter 11, but for now you can picture it as happening by the pathway shown in **FIGURE 9.7**. The nucleophilic acetylide ion uses an electron pair to form a bond to the positively polarized, electrophilic carbon atom of bromomethane. As the new $\text{C}-\text{C}$ bond forms, Br^- departs, taking with it the electron pair from the former $\text{C}-\text{Br}$ bond and yielding propyne as product. We call such a reaction an **alkylation** because a new alkyl group has become attached to the starting alkyne.

FIGURE 9.7 MECHANISM

A mechanism for the alkylation reaction of acetylide anion with bromomethane to give propyne.

- 1** The nucleophilic acetylide anion uses its electron lone pair to form a bond to the positively polarized, electrophilic carbon atom of bromomethane. As the new C–C bond begins to form, the C–Br bond begins to break in the transition state.

- 2** The new C–C bond is fully formed and the old C–Br bond is fully broken at the end of the reaction.

Alkyne alkylation is not limited to acetylene itself. Any terminal alkyne can be converted into its corresponding anion and then allowed to react with an alkyl halide to give an internal alkyne product. Hex-1-yne, for instance, gives dec-5-yne when treated first with NaNH_2 and then with 1-bromobutane.

Because of its generality, acetylide alkylation is a good method for preparing substituted alkynes from simpler precursors. A terminal alkyne can be prepared by alkylation of acetylene itself, and an internal alkyne can be prepared by further alkylation of a terminal alkyne.

The only limit to the alkylation reaction is that it can only use primary alkyl bromides and alkyl iodides because acetylide ions are sufficiently strong bases to cause elimination instead of substitution when they react with secondary and tertiary alkyl halides. For example, reaction of bromocyclohexane with propyne anion yields the elimination product cyclohexene rather than the substitution product 1-propynylcyclohexane.

PROBLEM Show the terminal alkyne and alkyl halide from which the following products can be obtained. If

9-10 two routes look feasible, list both.

PROBLEM How would you prepare *cis*-2-butene starting from propyne, an alkyl halide, and any other reagents

9-11 needed? This problem can't be worked in a single step. You'll have to carry out more than one reaction.

9.9 An Introduction to Organic Synthesis

As mentioned in the introduction, one of the purposes of this chapter is to use alkyne chemistry as a vehicle to begin looking at some of the general strategies used in organic synthesis—the construction of complex molecules in the laboratory. There are many reasons for carrying out the laboratory synthesis of an organic compound. In the pharmaceutical industry, new molecules are designed and synthesized in the hope that some might be useful new drugs. In the chemical industry, syntheses are done to devise more economical routes to known compounds. In academic laboratories, the synthesis of extremely complex molecules is sometimes done just for the intellectual challenge involved in mastering so difficult a subject. The successful synthesis route is a highly creative work that is sometimes described by such subjective terms as *elegant* or *beautiful*.

In this book, too, we will often devise syntheses of molecules from simpler precursors, but the purpose here is to learn. The ability to plan a successful multistep synthetic sequence requires a working knowledge of the uses and limitations of many different organic reactions. Furthermore, it requires the practical ability to piece together the steps in a sequence such that each reaction does only what is desired without causing changes elsewhere in the molecule. Planning a synthesis makes you approach a chemical problem in a logical way, draw on your knowledge of chemical reactions, and organize that knowledge into a workable plan—it helps you learn organic chemistry.

There's no secret to planning an organic synthesis: all it takes is a knowledge of the different reactions and some practice. The only real trick is to work backward in what is often called a **retrosynthetic** direction. Don't look at a potential starting material and ask yourself what reactions it might undergo. Instead, look at the final product and ask, "What was the immediate precursor of that product?" For example, if the final product is an alkyl halide, the immediate precursor might be an alkene, to which you could add HX . If the final product is a *cis* alkene, the immediate precursor might be an alkyne, which you could hydrogenate using the Lindlar catalyst. Having found an immediate precursor, work backward again, one step at a time, until you get back to the starting material. You have to keep the starting material in mind, of course, so that you can work back to it, but you don't want that starting material to be your main focus.

Let's work several examples of increasing complexity.

CHEMISTRY MATTERS

The Art of Organic Synthesis

FIGURE 9.8 Vitamin B₁₂ has been synthesized from scratch in the laboratory, but the bacteria growing on sludge from municipal sewage plants do a much better job. (credit: "Aeration and sludge-wasting" by U.S. Department of Agriculture/Flickr, Public Domain)

If you think some of the synthesis problems at the end of this chapter are difficult, try devising a synthesis of vitamin B₁₂ starting only from simple substances you can buy in a chemical catalog. This extraordinary achievement was reported in 1973 as the culmination of a collaborative effort headed by Robert B. Woodward of Harvard University and Albert Eschenmoser of the Swiss Federal Institute of Technology in Zürich. More than 100 graduate students and postdoctoral associates contributed to the work, which took more than a decade to complete.

Vitamin B₁₂

Why put such extraordinary effort into the laboratory synthesis of a molecule so easily obtained from natural sources? There are many reasons. On a basic human level, a chemist might be motivated primarily by the challenge, much as a climber might be challenged by the ascent of a difficult peak. Beyond the pure challenge, the completion of a difficult synthesis is also valuable in that it establishes new standards and raises the field to a new level. If vitamin B₁₂ can be made, then why can't any molecule found in nature be made? Indeed, the decades that have passed since the work of Woodward and Eschenmoser have seen the laboratory synthesis of many enormously complex and valuable substances. Sometimes these substances—for instance, the anticancer compound paclitaxel, trade named Taxol—are not easily available in nature, so laboratory synthesis is the only

method for obtaining larger quantities.

But perhaps the most important reason for undertaking a complex synthesis is that, in so doing, new reactions and new chemistry are discovered. It invariably happens in a complex synthesis that a point is reached at which the planned route fails. At such a time, the only alternatives are either to quit or to devise a way around the difficulty. New reactions and new principles come from such situations, and it is in this way that the science of organic chemistry grows richer. In the synthesis of vitamin B₁₂, for example, unexpected findings emerged that led to the understanding of an entire new class of reactions—the *pericyclic* reactions that are the subject of Chapter 30 in this book. From synthesizing vitamin B₁₂ to understanding pericyclic reactions—no one could have possibly predicted such a link at the beginning of the synthesis, but that is the way of science.

Key Terms

- **acetylide anion**
- **alkylation**
- **alkyne**
- **enol**
- **Lindlar Catalyst**
- **retrosynthetic**
- **tautomer**

Summary

Alkynes are less common than alkenes, both in the laboratory and in living organisms, so we haven't covered them in great detail. The real importance of this chapter is that alkyne chemistry is a useful vehicle for looking at the general strategies used in organic synthesis—the construction of complex molecules in the laboratory.

An **alkyne** is a hydrocarbon that contains a carbon–carbon triple bond. Alkyne carbon atoms are *sp*-hybridized, and the triple bond consists of one *sp*–*sp* σ bond and two *p*–*p* π bonds. There are relatively few general methods of alkyne synthesis. Two favorable ones are the alkylation of an acetylide anion with a primary alkyl halide and the twofold elimination of HX from a vicinal dihalide.

The chemistry of alkynes is dominated by electrophilic addition reactions, similar to those of alkenes. Alkynes react with HBr and HCl to yield vinylic halides and with Br₂ and Cl₂ to yield 1,2-dihalides (vicinal dihalides). Alkynes can be hydrated by reaction with aqueous sulfuric acid in the presence of mercury(II) catalyst. The reaction leads to an intermediate **enol** that immediately **tautomerizes** to yield a ketone. Because the addition reaction occurs with Markovnikov regiochemistry, a methyl ketone is produced from a terminal alkyne. Alternatively, hydroboration–oxidation of a terminal alkyne yields an aldehyde.

Alkynes can be reduced to yield alkenes and alkanes. Complete reduction of the triple bond over a palladium hydrogenation catalyst yields an alkane; partial reduction by catalytic hydrogenation over a **Lindlar catalyst** yields a *cis* alkene. Reduction of the alkyne with lithium in ammonia yields a *trans* alkene.

Terminal alkynes are weakly acidic. The alkyne hydrogen can be removed by a strong base such as Na⁺ [−]NH₂ to yield an **acetylide anion**. An acetylide anion acts as a nucleophile and can displace a halide ion from a primary alkyl halide in an **alkylation** reaction. Acetylide anions are more stable than either alkyl anions or vinylic anions because their negative charge is in a hybrid orbital with 50% *s* character, allowing the charge to be closer to the nucleus.

Summary of Reactions

No stereochemistry is implied unless specifically indicated with wedged, solid, and dashed lines.

1. Preparation of alkynes

a. Dehydrohalogenation of vicinal dihalides (Section 9.2)

b. Alkylation of acetylide anions (Section 9.8)

2. Reactions of alkynes

a. Addition of HCl and HBr (Section 9.3)

b. Addition of Cl₂ and Br₂ (Section 9.3)

c. Hydration (Section 9.4)

(1) Mercuric sulfate catalyzed

(2) Hydroboration–oxidation

d. Reduction (Section 9.5)

(1) Catalytic hydrogenation

(2) Lithium in liquid ammonia

e. Conversion into acetylide anions (Section 9.7)

Additional Problems

Visualizing Chemistry

PROBLEM 9-14 Name the following alkynes, and predict the products of their reaction with (1) H_2 in the presence of a Lindlar catalyst and (2) H_3O^+ in the presence of HgSO_4 :

(a)

(b)

PROBLEM 9-15 From what alkyne might each of the following substances have been made? (Green = Cl.)

(a)

(b)

PROBLEM 9-16 How would you prepare the following substances, starting from any compounds having four carbons or fewer?

PROBLEM The following cycloalkyne is too unstable to exist. Explain.

9-17

Mechanism Problems

PROBLEM Assuming that halogens add to alkynes in the same manner as they add to alkenes, propose a mechanism for and predict the product(s) of the reaction of phenylpropyne with Br_2 .

9-18

PROBLEM Assuming that strong acids add to alkynes in the same manner as they add to alkenes, propose a mechanism for each of the following reactions.

9-19

PROBLEM The mercury-catalyzed hydration of alkynes involves the formation of an organomercury enol intermediate. Draw the electron-pushing mechanism to show how each of the following intermediates is formed.

9-20

PROBLEM The final step in the hydration of an alkyne under acidic conditions is the tautomerization of an enol intermediate to give the corresponding ketone. The mechanism involves a protonation followed by a deprotonation. Show the mechanism for each of the following tautomerizations.

9-21

PROBLEM 9-22 Predict the product(s) and show the complete electron-pushing mechanism for each of the following dissolving metal reductions.

PROBLEM 9-23 Identify the mechanisms for the following reactions as *polar*, *radical*, or *both*.

PROBLEM 9-24 Predict the product and provide the complete electron-pushing mechanism for the following two-step synthetic processes.

PROBLEM 9-25 Reaction of acetone with D_3O^+ yields hexadeuterioacetone. That is, all the hydrogens in acetone are exchanged for deuterium. Review the mechanism of mercuric-ion-catalyzed alkyne hydration, and then propose a mechanism for this deuterium incorporation.

Naming Alkynes

PROBLEM 9-26 Give IUPAC names for the following compounds:

PROBLEM 9-27 Draw structures corresponding to the following names:

- (a) 3,3-Dimethyl-4-optyne (b) 3-Ethyl-5-methyl-1,6,8-decatriyne
(c) 2,2,5,5-Tetramethyl-3-hexyne (d) 3,4-Dimethylcyclodecyne (e) 3,5-Heptadien-1-yne

- (f) 3-Chloro-4,4-dimethyl-1-nonen-6-yne (g) 3-*sec*-Butyl-1-heptyne
 (h) 5-*tert*-Butyl-2-methyl-3-octyne

PROBLEM The following two hydrocarbons have been isolated from various plants in the sunflower family.

9-28 Name them according to IUPAC rules.

- (a) $\text{CH}_3\text{CH}=\text{CHC}\equiv\text{CC}\equiv\text{CCH}=\text{CHCH}=\text{CHCH}=\text{CH}_2$ (all trans)
 (b) $\text{CH}_3\text{C}\equiv\text{CC}\equiv\text{CC}\equiv\text{CC}\equiv\text{CC}\equiv\text{CCH}=\text{CH}_2$

Reactions of Alkynes

PROBLEM Terminal alkynes react with Br_2 and water to yield bromo ketones. For example:

9-29

Propose a mechanism for the reaction. To what reaction of alkenes is the process analogous?

PROBLEM Predict the products of the following reactions:

9-30

PROBLEM Predict the products from reaction of 1-hexyne with the following reagents:

- 9-31** (a) 1 equiv HBr (b) 1 equiv Cl_2 (c) H_2 , Lindlar catalyst (d) NaNH_2 in NH_3 , then CH_3Br
 (e) H_2O , H_2SO_4 , HgSO_4 (f) 2 equiv HCl

PROBLEM Predict the products from reaction of 5-decyne with the following reagents:

- 9-32** (a) H_2 , Lindlar catalyst (b) Li in NH_3 (c) 1 equiv Br_2 (d) BH_3 in THF , then H_2O_2 , OH^-
 (e) H_2O , H_2SO_4 , HgSO_4 (f) Excess H_2 , Pd/C catalyst

PROBLEM Predict the products from reaction of 2-hexyne with the following reagents:

- 9-33** (a) 2 equiv Br_2 (b) 1 equiv HBr (c) Excess HBr (d) Li in NH_3 (e) H_2O , H_2SO_4 , HgSO_4

PROBLEM Propose structures for hydrocarbons that give the following products on oxidative cleavage by

9-34 KMnO_4 or O_3 :

PROBLEM Identify the reagents **a–c** in the following scheme:

9-44

PROBLEM The sex attractant given off by the common housefly is an alkene named *muscalure*. Propose a synthesis of muscalure starting from acetylene and any alkyl halides needed. What is the IUPAC name for muscalure?

9-45

General Problems

PROBLEM A hydrocarbon of unknown structure has the formula C_8H_{10} . On catalytic hydrogenation over the

9-46 Lindlar catalyst, 1 equivalent of H_2 is absorbed. On hydrogenation over a palladium catalyst, 3 equivalents of H_2 are absorbed.

- (a) How many degrees of unsaturation are present in the unknown structure?
 (b) How many triple bonds are present? (c) How many double bonds are present?
 (d) How many rings are present? (e) Draw a structure that fits the data.

PROBLEM Compound **A** (C_9H_{12}) absorbed 3 equivalents of H_2 on catalytic reduction over a palladium catalyst

9-47 to give **B** (C_9H_{18}). On ozonolysis, compound **A** gave, among other things, a ketone that was identified as cyclohexanone. On treatment with NaNH_2 in NH_3 , followed by addition of iodomethane, compound **A** gave a new hydrocarbon, **C** ($\text{C}_{10}\text{H}_{14}$). What are the structures of **A**, **B**, and **C**?

PROBLEM Hydrocarbon **A** has the formula C_{12}H_8 . It absorbs 8 equivalents of H_2 on catalytic reduction over

9-48 a palladium catalyst. On ozonolysis, only two products are formed: oxalic acid ($\text{HO}_2\text{CCO}_2\text{H}$) and succinic acid ($\text{HO}_2\text{CCH}_2\text{CH}_2\text{CO}_2\text{H}$). Write the reactions, and propose a structure for **A**.

PROBLEM Occasionally, a chemist might need to *invert* the stereochemistry of an alkene—that is, to convert

9-49 a *cis* alkene to a *trans* alkene, or vice versa. There is no one-step method for doing an alkene inversion, but the transformation can be carried out by combining several reactions in the proper sequence. How would you carry out the following reactions?

PROBLEM Organometallic reagents such as sodium acetylide undergo an addition reaction with ketones,

9-50 giving alcohols:

How might you use this reaction to prepare 2-methyl-1,3-butadiene, the starting material used in the manufacture of synthetic rubber?

PROBLEM 9-51 The oral contraceptive agent Mestranol is synthesized using a carbonyl addition reaction like that shown in Problem 9-50. Draw the structure of the ketone needed.

PROBLEM 9-52 1-Octen-3-ol, a potent mosquito attractant commonly used in mosquito traps, can be prepared in two steps from hexanal, $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CHO}$. The first step is an acetylide-addition reaction like that described in Problem 9-50. What is the structure of the product from the first step, and how can it be converted into 1-octen-3-ol?

PROBLEM 9-53 Erythrogonic acid, $\text{C}_{18}\text{H}_{26}\text{O}_2$, is an acetylenic fatty acid that turns a vivid red on exposure to light. On catalytic hydrogenation over a palladium catalyst, 5 equivalents of H_2 are absorbed, and stearic acid, $\text{CH}_3(\text{CH}_2)_{16}\text{CO}_2\text{H}$, is produced. Ozonolysis of erythrogonic acid gives four products: formaldehyde, CH_2O ; oxalic acid, $\text{HO}_2\text{CCO}_2\text{H}$; azelaic acid, $\text{HO}_2\text{C}(\text{CH}_2)_7\text{CO}_2\text{H}$; and the aldehyde acid $\text{OHC}(\text{CH}_2)_4\text{CO}_2\text{H}$. Draw two possible structures for erythrogonic acid, and suggest a way to tell them apart by carrying out some simple reactions.

PROBLEM 9-54 Hydrocarbon **A** has the formula C_9H_{12} and absorbs 3 equivalents of H_2 to yield **B**, C_9H_{18} , when hydrogenated over a Pd/C catalyst. On treatment of **A** with aqueous H_2SO_4 in the presence of mercury(II), two isomeric ketones, **C** and **D**, are produced. Oxidation of **A** with KMnO_4 gives a mixture of acetic acid ($\text{CH}_3\text{CO}_2\text{H}$) and the tricarboxylic acid **E**. Propose structures for compounds **A–D**, and write the reactions.

PROBLEM 9-55 A *cumulene* is a compound with three adjacent double bonds. Draw an orbital picture of a cumulene. What kind of hybridization do the two central carbon atoms have? What is the geometric relationship of the substituents on one end to the substituents on the other end? What kind of isomerism is possible? Make a model to help see the answer.

PROBLEM 9-56 Which of the following bases could be used to deprotonate 1-butyne?

PROBLEM 9-57 Arrange the following carbocations in order of increasing stability.

CHAPTER 10

Organohalides

FIGURE 10.1 The gases released during volcanic eruptions contain large amounts of organohalides, including chloromethane, chloroform, dichlorodifluoromethane, and many others. (credit: modification of work “Tavurvur volcano” by Taro Taylor, Richard Bartz/Wikimedia Commons, CC BY 2.0)

- 10.7 Organometallic Coupling Reactions
- 10.8 Oxidation and Reduction in Organic Chemistry

WHY THIS CHAPTER? Alkyl halides are encountered less frequently than their oxygen-containing relatives and are not often involved in the biochemical pathways of terrestrial organisms, but some of the kinds of reactions they undergo—nucleophilic substitutions and eliminations—are encountered frequently. Thus, alkyl halide chemistry is a relatively simple model for many mechanistically similar but structurally more complex reactions found in biomolecules. We'll begin this chapter with a look at how to name and prepare alkyl halides, and we'll see several of their reactions. Then, in the next chapter, we'll make a detailed study of the substitution and elimination reactions of alkyl halides—two of the most important and well-studied reaction types in organic chemistry.

Now that we've covered the chemistry of hydrocarbons, it's time to start looking at more complex substances that contain elements in addition to C and H. We'll begin by discussing the chemistry of **organohalides**,

compounds that contain one or more halogen atoms.

Halogen-substituted organic compounds are widespread in nature, and more than 5000 organohalides have been found in algae and various other marine organisms. Chloromethane, for instance, is released in large amounts by ocean kelp, as well as by forest fires and volcanoes. Halogen-containing compounds also have an array of industrial applications, including their use as solvents, inhaled anesthetics in medicine, refrigerants, and pesticides.

Trichloroethylene
(a solvent)

Halothane
(an inhaled anesthetic)

Tetrafluoropropene
(a refrigerant)

Bromomethane
(a fumigant)

Still other halo-substituted compounds are used as medicines and food additives. The nonnutritive sweetener sucralose, marketed as Splenda, contains three chlorine atoms, for instance. Sucralose is about 600 times as sweet as sucrose, so only 1 mg is equivalent to an entire teaspoon of table sugar.

Sucralose

A large variety of organohalides are known. The halogen might be bonded to an alkynyl group ($\text{C}\equiv\text{C}-\text{X}$), a vinylic group ($\text{C}=\text{C}-\text{X}$), an aromatic ring ($\text{Ar}-\text{X}$), or an alkyl group. In this chapter, however, we'll be primarily concerned with **alkyl halides**, compounds with a halogen atom bonded to a saturated, sp^3 -hybridized carbon atom.

10.1 Names and Structures of Alkyl Halides

Although commonly called *alkyl halides*, halogen-substituted alkanes are named systematically as *haloalkanes* (Section 3.4), treating the halogen as a substituent on a parent alkane chain. There are three steps:

STEP 1

Find the longest chain, and name it as the parent. If a double or triple bond is present, the parent chain must contain it.

STEP 2

Number the carbons of the parent chain beginning at the end nearer the first substituent, whether alkyl or halo. Assign each substituent a number according to its position on the chain.

5-Bromo-2,4-dimethylheptane

2-Bromo-4,5-dimethylheptane

If different halogens are present, number each one and list them in alphabetical order when writing the name.

1-Bromo-3-chloro-4-methylpentane

STEP 3

If the parent chain can be properly numbered from either end by step 2, begin at the end nearer the

substituent that has alphabetical precedence.

2-Bromo-5-methylhexane
(Not 5-bromo-2-methylhexane)

In addition to their systematic names, many simple alkyl halides are also named by identifying first the alkyl group and then the halogen. For example, CH_3I can be called either iodomethane or methyl iodide. Such names are well entrenched in the chemical literature and in daily usage, but they won't be used in this book.

Halogens increase in size going down the periodic table, so the lengths of the corresponding carbon–halogen bonds increase accordingly (TABLE 10.1). In addition, C–X bond strengths decrease going down the periodic table. As we've been doing thus far, we'll continue using an X to represent any of the halogens F, Cl, Br, or I.

TABLE 10.1 A Comparison of the Halomethanes

Halomethane	Bond length (pm)	Bond strength		Dipole moment (<i>D</i>)
		(kJ/mol)	(kcal/mol)	
CH_3F	139	460	110	1.85
CH_3Cl	178	350	84	1.87
CH_3Br	193	294	70	1.81
CH_3I	214	239	57	1.62

In our discussion of bond polarity in functional groups in Section 6.3, we noted that halogens are more electronegative than carbon. The C–X bond is therefore polar, with the carbon atom bearing a slight positive charge (δ^+) and the halogen a slight negative charge (δ^-). This polarity results in a dipole moment for all the halomethanes (TABLE 10.1) and implies that the alkyl halide C–X carbon atom should behave as an electrophile in polar reactions. We'll soon see that this is indeed the case.

PROBLEM Give IUPAC names for the following alkyl halides:

As another example, 2-methylpropane yields 2-chloro-2-methylpropane and 1-chloro-2-methylpropane in a 35 : 65 ratio, along with more highly chlorinated products.

From these and similar reactions, it's possible to calculate a reactivity order toward chlorination for different kinds of hydrogen atoms in a molecule. Take the butane chlorination, for instance. Butane has six equivalent primary hydrogens ($-\text{CH}_3$) and four equivalent secondary hydrogens ($-\text{CH}_2-$). The fact that butane yields 30% of 1-chlorobutane product means that each one of the six primary hydrogens is responsible for $30\% \div 6 = 5\%$ of the product. Similarly, the fact that 70% of 2-chlorobutane is formed means that each of the four secondary hydrogens is responsible for $70\% \div 4 = 17.5\%$ of the product. Thus, a secondary hydrogen reacts $17.5\% \div 5\% = 3.5$ times as often as a primary hydrogen.

A similar calculation for the chlorination of 2-methylpropane indicates that each of the nine primary hydrogens accounts for $65\% \div 9 = 7.2\%$ of the product, while the single tertiary hydrogen (R_3CH) accounts for 35% of the product. Thus, a tertiary hydrogen is $35\% \div 7.2\% = 5$ times as reactive as a primary hydrogen toward chlorination.

The observed reactivity order of alkane hydrogens toward radical chlorination can be explained by looking at the bond dissociation energies given previously in [TABLE 6.3](#). The data show that a tertiary C–H bond (400 kJ/mol; 96 kcal/mol) is weaker than a secondary C–H bond (410 kJ/mol; 98 kcal/mol), which is in turn weaker than a primary C–H bond (421 kJ/mol; 101 kcal/mol). Since less energy is needed to break a tertiary C–H bond than to break a primary or secondary C–H bond, the resultant tertiary radical is more stable than a primary or secondary radical.

PROBLEM 10-3 Draw and name all monochloro products you would expect to obtain from radical chlorination of 2-methylpentane. Which, if any, are chiral?

PROBLEM 10-4 Taking the relative reactivities of 1° , 2° , and 3° hydrogen atoms into account, what product(s) would you expect to obtain from monochlorination of 2-methylbutane? What would the approximate percentage of each product be? (Don't forget to take into account the number of each kind of

hydrogen.)

10.3 Preparing Alkyl Halides from Alkenes: Allylic Bromination

We've already seen several methods for preparing alkyl halides from alkenes, including the reactions of HX and X_2 with alkenes in electrophilic addition reactions (Section 7.7 and Section 8.2). The hydrogen halides HCl , HBr , and HI react with alkenes by a polar mechanism to give the product of Markovnikov addition. Bromine and chlorine undergo anti addition through halonium ion intermediates to give 1,2-dihalogenated products.

Another laboratory method for preparing alkyl halides from alkenes is by reaction with *N*-bromosuccinimide (abbreviated NBS), in the presence of ultraviolet light, to give products resulting from substitution of hydrogen by bromine at the position next to the double bond—the **allylic** position. Cyclohexene, for example, gives 3-bromocyclohexene.

This allylic bromination with NBS is analogous to the alkane chlorination reaction discussed in the previous section and occurs by a radical chain-reaction pathway (FIGURE 10.3). As in alkane halogenation, a $\text{Br}\cdot$ radical abstracts an allylic hydrogen atom, forming an allylic radical plus HBr . The HBr then reacts with NBS to form Br_2 , which in turn reacts with the allylic radical to yield the brominated product and a $\text{Br}\cdot$ radical that cycles back into the first step and carries on the chain.

FIGURE 10.3 Mechanism of allylic bromination of an alkene with NBS. The process is a radical chain reaction in which (1) a $\text{Br}\cdot$ radical abstracts an allylic hydrogen atom of the alkene and gives an allylic radical plus HBr . (2) The HBr then reacts with NBS to form Br_2 , which (3) reacts with the allylic radical to yield the bromoalkene product and a $\text{Br}\cdot$ radical that continues the chain.

Why does bromination with NBS occur exclusively at an allylic position rather than elsewhere in the molecule? The answer, once again, is found by looking at bond dissociation energies to see the relative stabilities of various

kinds of radicals. Although a typical secondary alkyl C–H bond has a strength of about 410 kJ/mol (98 kcal/mol) and a typical vinylic C–H bond has a strength of 465 kJ/mol (111 kcal/mol), an allylic C–H bond has a strength of only about 370 kJ/mol (88 kcal/mol). An allylic radical is therefore more stable than a typical alkyl radical with the same substitution by about 40 kJ/mol (9 kcal/mol).

We can thus expand the stability ordering to include vinylic and allylic radicals.

10.4 Stability of the Allyl Radical: Resonance Revisited

To see why an allylic radical is so stable, look at the orbital picture in **FIGURE 10.4**. The radical carbon atom with an unpaired electron can adopt sp^2 hybridization, placing the unpaired electron in a p orbital and giving a structure that is electronically symmetrical. The p orbital on the central carbon can therefore overlap equally well with a p orbital on either of the two neighboring carbons.

FIGURE 10.4 An orbital view of the allyl radical. The p orbital on the central carbon can overlap equally well with a p orbital on either neighboring carbon, giving rise to two equivalent resonance structures.

Because the allyl radical is electronically symmetrical, it has two resonance forms—one with the unpaired electron on the left and the double bond on the right and another with the unpaired electron on the right and the double bond on the left. Neither structure is correct by itself; the true structure of the allyl radical is a resonance hybrid of the two. (You might want to review **Section 2.4** to **Section 2.6** to brush up on resonance.) As noted in **Section 2.5**, the greater the number of resonance forms, the greater the stability of a compound, because bonding electrons are attracted to more nuclei. An allyl radical, with two resonance forms, is therefore more stable than a typical alkyl radical, which has only a single structure.

In molecular orbital terms, the stability of the allyl radical is due to the fact that the unpaired electron is **delocalized**, or spread out, over an extended π -orbital network rather than localized at only one site, as shown

by the computer-generated MO in **FIGURE 10.4**. This delocalization is particularly apparent in the so-called spin-density surface in **FIGURE 10.5**, which shows the calculated location of the unpaired electron. The two terminal carbons share the unpaired electron equally.

FIGURE 10.5 The spin density surface of the allyl radical locates the position of the unpaired electron and shows that it is equally shared between the two terminal carbons.

In addition to its effect on stability, delocalization of the unpaired electron in the allyl radical has other chemical consequences. Because the unpaired electron is delocalized over both ends of the π orbital system, reaction with Br_2 can occur at either end. As a result, allylic bromination of an unsymmetrical alkene often leads to a mixture of products. For example, bromination of 1-octene gives a mixture of 3-bromo-1-octene and 1-bromo-2-octene. The two products are not formed in equal amounts, however, because the intermediate allylic radical is not symmetrical and reaction at the two ends is not equally likely. Reaction at the less hindered, primary end is favored.

The products of allylic bromination reactions are useful for conversion into dienes by dehydrohalogenation with base. Cyclohexene can be converted into 1,3-cyclohexadiene, for example.

WORKED EXAMPLE 10.1

Predicting the Product of an Allylic Bromination Reaction

What products would you expect from the reaction of 4,4-dimethylcyclohexene with NBS?

Strategy

Draw the alkene reactant, and identify the allylic positions. In this case, there are two different allylic positions; we'll label them **A** and **B**. Now abstract an allylic hydrogen from each position to generate the two corresponding allylic radicals. Each of the two allylic radicals can add a Br atom at either end (**A** or **A'**; **B** or **B'**), to give a mixture of up to four products. Draw and name the products. In the present instance, the “two” products from reaction at position **B** are identical, so only three products are formed in this reaction.

Solution

PROBLEM Draw three resonance forms for the cyclohexadienyl radical.

PROBLEM The major product of the reaction of methylenecyclohexane with *N*-bromosuccinimide is

10-6 1-(bromomethyl)cyclohexene. Explain.

PROBLEM What products would you expect from reaction of the following alkenes with NBS? If more than one product is formed, show the structures of all.

10.5 Preparing Alkyl Halides from Alcohols

The most generally useful method for preparing alkyl halides is to make them from alcohols, which themselves can be obtained from carbonyl compounds as we'll see in **Sections 17.4** and **17.5**. Because of the importance of this process, many different methods have been developed to transform alcohols into alkyl halides. The simplest method is to treat the alcohol with HCl, HBr, or HI. For reasons that will be discussed in **Section 11.5**, this reaction works best with tertiary alcohols, R_3COH . Primary and secondary alcohols react much more slowly and at higher temperatures.

10.7 Organometallic Coupling Reactions

Many other kinds of organometallic compounds can be prepared in a manner similar to that of Grignard reagents. For instance, alkyllithium reagents, RLi , can be prepared by the reaction of an alkyl halide with lithium metal. Alkyllithiums are both nucleophiles and strong bases, and their chemistry is similar in many respects to that of alkylmagnesium halides.

One particularly valuable reaction of alkyllithiums occurs when making lithium diorganocopper compounds, R_2CuLi , by reaction with copper(I) iodide in diethyl ether as solvent. Often called **Gilman reagents (LiR_2Cu)**, lithium diorganocopper compounds are useful because they undergo a *coupling* reaction with organochlorides, bromides, and iodides (but not fluorides). One of the alkyl groups from the lithium diorganocopper reagent replaces the halogen of the organohalide, forming a new carbon–carbon bond and yielding a hydrocarbon product. Lithium dimethylcopper, for instance, reacts with 1-iododecane to give undecane in a 90% yield.

This organometallic coupling reaction is useful in organic synthesis because it forms carbon–carbon bonds, thereby allowing the preparation of larger molecules from smaller ones. As the following examples indicate, the coupling reaction can be carried out on aryl and vinylic halides as well as on alkyl halides.

An organocopper coupling reaction is carried out commercially to synthesize muscalure, (9Z)-tricosene, the sex attractant secreted by the common housefly. Minute amounts of muscalure greatly increase the lure of insecticide-treated fly bait and provide an effective and species-specific means of insect control.

The mechanism of the coupling reaction involves initial formation of a triorganocopper intermediate, followed

by coupling and loss of a mono-organocopper, RCu . The coupling is not a typical polar nucleophilic substitution reaction of the sort considered in the next chapter.

In addition to the coupling reaction of diorganocopper reagents with organohalides, related processes also occur with other organometallic reagents, particularly organopalladium compounds. One of the most commonly used procedures is the coupling reaction of an aromatic or vinyl substituted boronic acid $[\text{R}-\text{B}(\text{OH})_2]$ with an aromatic or vinyl substituted organohalide in the presence of a base and a palladium catalyst. This reaction is less general than the diorganocopper reaction because it doesn't work with alkyl substrates, but it is preferred when possible because it uses only a catalytic amount of metal rather than a full equivalent and because palladium compounds are less toxic than copper compounds. For example:

Called the *Suzuki-Miyaura* reaction, this process is particularly useful for preparing so-called biaryl compounds, which have two linked aromatic rings. A large number of commonly used drugs fit this description, so the Suzuki-Miyaura reaction is much-used in the pharmaceutical industry. As an example, valsartan, marketed as Diovan, is widely prescribed to treat high blood pressure, heart failure, and diabetic kidney disease. Its synthesis begins with a Suzuki-Miyaura coupling of *ortho*-chlorobenzonitrile with *para*-methylbenzeneboronic acid.

Shown in a simplified form in **FIGURE 10.6**, the mechanism of the Suzuki-Miyaura reaction involves initial reaction of the aromatic halide with the palladium catalyst to form an organopalladium intermediate, followed by reaction of that intermediate with the aromatic boronic acid. The resultant diorganopalladium complex then decomposes to the coupled biaryl product plus regenerated catalyst.

FIGURE 10.6 Mechanism of the Suzuki–Miyaura coupling reaction of an aromatic boronic acid with an aromatic halide to give a biaryl. The reaction takes place by (1) reaction of the aromatic halide, ArX, with the catalyst to form an organopalladium intermediate, followed by (2) reaction with the aromatic boronic acid. (3) Subsequent decomposition of the diarylpalladium intermediate gives the biaryl product.

PROBLEM How would you carry out the following transformations using an organocopper coupling reaction?

10-11 More than one step is required in each case.

10.8 Oxidation and Reduction in Organic Chemistry

We’ve pointed out on several occasions that some of the reactions discussed in this and earlier chapters are either oxidations or reductions. As noted in [Section 8.7](#), an organic oxidation results in a loss of electron density by carbon, caused either by bond formation between carbon and a more electronegative atom (usually O, N, or a halogen) or by bond-breaking between carbon and a less electronegative atom (usually H). Conversely, an organic reduction results in a gain of electron density by carbon, caused either by bond formation between carbon and a less electronegative atom or by bond-breaking between carbon and a more electronegative atom ([Section 8.6](#)).

Oxidation Decreases electron density on carbon by:

- forming one of these: C–O C–N C–X
- or breaking this: C–H

Reduction Increases electron density on carbon by:

- forming this: C–H
- or breaking one of these: C–O C–N C–X

Based on these definitions, the chlorination reaction of methane to yield chloromethane is an oxidation because a C–H bond is broken and a C–Cl bond is formed. The conversion of an alkyl chloride to an alkane via a Grignard reagent followed by protonation is a reduction, however, because a C–Cl bond is broken and a C–H bond is formed.

As other examples, the reaction of an alkene with Br_2 to yield a 1,2-dibromide is an oxidation because two C–Br bonds are formed, but the reaction of an alkene with HBr to yield an alkyl bromide is neither an oxidation nor a reduction because both a C–H and a C–Br bond are formed.

A list of compounds of increasing oxidation level is shown in **FIGURE 10.7**. Alkanes are at the lowest oxidation level because they have the maximum possible number of C–H bonds per carbon, and CO_2 is at the highest level because it has the maximum possible number of C–O bonds per carbon. Any reaction that converts a compound from a lower level to a higher level is an oxidation, any reaction that converts a compound from a higher level to a lower level is a reduction, and any reaction that doesn't change the level is neither an oxidation nor a reduction.

FIGURE 10.7 Oxidation levels of some common compounds.

Worked Example 10.2 shows how to compare the oxidation levels of different compounds with the same number of carbon atoms.

WORKED EXAMPLE 10.2

Comparing Oxidation Levels

Rank the following compounds in order of increasing oxidation level:

Strategy

Compounds that have the same number of carbon atoms can be compared by adding the number of C–O, C–N, and C–X bonds in each and then subtracting the number of C–H bonds. The larger the resultant value, the higher the oxidation level.

Solution

The first compound (propene) has six C–H bonds, giving an oxidation level of -6 ; the second (2-propanol) has one C–O bond and seven C–H bonds, giving an oxidation level of -6 ; the third (acetone) has two C–O bonds and six C–H bonds, giving an oxidation level of -4 ; and the fourth (propane) has eight C–H bonds, giving an oxidation level of -8 . Thus, the order of increasing oxidation level is

PROBLEM Rank both sets of compounds in order of increasing oxidation level:

10-12 (a)

(b) CH_3CN $\text{CH}_3\text{CH}_2\text{NH}_2$ $\text{H}_2\text{NCH}_2\text{CH}_2\text{NH}_2$

PROBLEM Tell whether each of the following reactions is an oxidation, a reduction, or neither.

10-13 (a)

(b)

CHEMISTRY MATTERS

Naturally Occurring Organohalides

Just forty years ago in 1980, only about 30 naturally occurring organohalides were known. It was simply assumed that chloroform, halogenated phenols, chlorinated aromatic compounds called PCBs, and other such substances found in the environment were industrial pollutants. Now, less than half a century later, the situation is quite different. More than 5000 organohalides have been found to occur naturally, and tens of thousands more surely exist. From a simple compound like chloromethane to an extremely complex one like the antibiotic vancomycin, a remarkably diverse range of organohalides exists in plants, bacteria, and animals. Many even have valuable physiological activity. The pentahalogenated alkene halomon, for instance, has been isolated from the red alga *Portieria hornemannii* and found to have anticancer activity against several human tumor cell lines.

Halomon

Some naturally occurring organohalides are produced in massive quantities. Forest fires, volcanic eruptions, and marine kelp release up to 5 million tons of CH_3Cl per year, for example, while annual industrial emissions total about 26,000 tons. Termites are thought to release as much as 10^8 kg of chloroform per year. A detailed examination of the Okinawan acorn worm *Ptychodera flava* found that the 64 million worms living in a 1 km^2 study area excreted nearly 8000 pounds per year of bromophenols and bromoindoles, compounds previously thought to be non-natural pollutants.

Why do organisms produce organohalides, many of which are undoubtedly toxic? The answer seems to be that many organisms use organohalogen compounds for self-defense, either as feeding deterrents, irritants to predators, or natural pesticides. Marine sponges, coral, and sea hares, for example, release foul-tasting organohalides that deter fish, starfish, and other predators. Even humans appear to produce halogenated compounds as part of their defense against infection. The human immune system contains a peroxidase enzyme capable of carrying out halogenation reactions on fungi and bacteria, thereby killing the pathogen. And most remarkable of all, even free chlorine— Cl_2 —has been found to be present in humans.

FIGURE 10.8 Marine corals secrete organohalogen compounds that act as a feeding deterrent to fish. (credit: “Coral reef” by Qui Nguyen, United Nations Environment Programme/Flickr, Public Domain)

Much remains to be learned—only a few hundred of the more than 500,000 known species of marine organisms have been examined—but it's clear that organohalides are an integral part of the world around us.

Key Terms

- **alkyl halide**
- **allylic**
- **carbanion**
- **delocalized**
- **Gilman reagent (LiR_2Cu)**
- **Grignard reagent (RMgX)**
- **organohalide**
- **organometallic**

Summary

Alkyl halides are not often found in terrestrial organisms, but the kinds of reactions they undergo are among the most important and well-studied reaction types in organic chemistry. In this chapter, we saw how to name and prepare alkyl halides, and we'll soon make a detailed study of their substitution and elimination reactions.

Simple alkyl halides can be prepared by radical halogenation of alkanes, but mixtures of products usually result. The reactivity order of alkanes toward halogenation is identical to the stability order of radicals: $\text{R}_3\text{C}\cdot > \text{R}_2\text{CH}\cdot > \text{RCH}_2\cdot$. Alkyl halides can also be prepared from alkenes by reaction with *N*-bromosuccinimide (NBS) to give the product of **allylic** bromination. The NBS bromination of alkenes takes place through an intermediate allylic radical, which is stabilized by resonance.

Alcohols react with HX to form alkyl halides, but the reaction works well only for tertiary alcohols, R_3COH . Primary and secondary alkyl halides are normally prepared from alcohols using either SOCl_2 , PBr_3 , or HF in pyridine. Alkyl halides react with magnesium in ether solution to form organomagnesium halides, called **Grignard reagents (RMgX)**, which are both nucleophilic and strongly basic.

Alkyl halides also react with lithium metal to form organolithium reagents, RLi . In the presence of CuI , these form diorganocoppers, or **Gilman reagents (LiR_2Cu)**. Gilman reagents react with organohalides to yield coupled hydrocarbon products.

Summary of Reactions

No stereochemistry is implied unless specifically indicated with wedged, solid, and dashed lines.

1. Preparation of alkyl halides
 - a. From alkenes by allylic bromination (Section 10.3)

- b. From alcohols (Section 10.5)
 - (1) Reaction with HX

Reactivity order: $3^\circ > 2^\circ > 1^\circ$

- (2) Reaction of 1° and 2° alcohols with SOCl_2

- (3) Reaction of 1° and 2° alcohols with PBr_3

- (4) Reaction of 1° and 2° alcohols with HF–pyridine

2. Reactions of alkyl halides

- a. Formation of Grignard (organomagnesium) reagents (Section 10.6)

- b. Formation of Gilman (diorganocopper) reagents (Section 10.7)

- c. Organometallic coupling (Section 10.7)

(1) Diorganocopper reaction

(2) Palladium-catalyzed Suzuki–Miyaura reaction

Visualizing Chemistry

PROBLEM Give IUPAC names for the following alkyl halides (green = Cl):

10-14 (a)

(b)

**PROBLEM** Show the product(s) of reaction of the following alkenes with NBS:

10-15 (a)

(b)

**PROBLEM** The following alkyl bromide can be prepared by reaction of the alcohol (*S*)-2-pentanol with PBr_3 .10-16 Name the compound, assign (*R*) or (*S*) stereochemistry, and tell whether the reaction of the alcohol results in the same stereochemistry or a change in stereochemistry (reddish brown = Br).

Mechanism Problems

PROBLEM 10-17 In light of the fact that tertiary alkyl halides undergo spontaneous dissociation to yield a carbocation plus halide ion (see Problem 10-41), propose a mechanism for the following reaction.

Naming Alkyl Halides

PROBLEM 10-18 Name the following alkyl halides:

PROBLEM 10-19 Draw structures corresponding to the following IUPAC names:

- (a) 2,3-Dichloro-4-methylhexane (b) 4-Bromo-4-ethyl-2-methylhexane
(c) 3-Iodo-2,2,4,4-tetramethylpentane (d) *cis*-1-Bromo-2-ethylcyclopentane

PROBLEM 10-20 Draw and name all the monochlorination products you might obtain from radical chlorination of the following compounds. Which of the products are chiral? Are any of the products optically active?

- (a) 2-methylbutane (b) methylcyclopropane (c) 2,2-dimethylpentane

Synthesizing Alkyl Halides

PROBLEM 10-21 How would you prepare the following compounds, starting with cyclopentene and any other reagents needed?

- (a) Chlorocyclopentane (b) Methylcyclopentane (c) 3-Bromocyclopentene
(d) Cyclopentanol (e) Cyclopentylcyclopentane (f) 1,3-Cyclopentadiene

PROBLEM 10-22 Predict the product(s) of the following reactions:

PROBLEM A chemist requires a large amount of 1-bromo-2-pentene as starting material for a synthesis and
10-23 decides to carry out an NBS allylic bromination reaction. What is wrong with the following synthesis plan? What side products would form in addition to the desired product?

PROBLEM What product(s) would you expect from the reaction of 1-methylcyclohexene with NBS? Would you
10-24 use this reaction as part of a synthesis?

PROBLEM What product(s) would you expect from the reaction of 1,4-hexadiene with NBS? What is the
10-25 structure of the most stable radical intermediate?

PROBLEM What product would you expect from the reaction of 1-phenyl-2-butene with NBS? Explain.
10-26

Oxidation and Reduction

PROBLEM Rank the compounds in each of the following series in order of increasing oxidation level:

10-27 (a)

(b)

PROBLEM Which of the following compounds have the same oxidation level, and which have different levels?

10-28

PROBLEM Tell whether each of the following reactions is an oxidation, a reduction, or neither:

10-29 (a)

(c)

General Problems

PROBLEM Arrange the following radicals from most stable to least stable.

10-30 (a)

(b)

(c)

PROBLEM Alkylbenzenes such as toluene (methylbenzene) react with NBS to give products in which bromine
10-31

substitution has occurred at the position next to the aromatic ring (the *benzylic* position). Explain, based on the bond dissociation energies in Table 6.3.

PROBLEM 10-32 Draw resonance structures for the benzyl radical, $\text{C}_6\text{H}_5\text{CH}_2\cdot$, the intermediate produced in the NBS bromination reaction of toluene (Problem 10-31).

PROBLEM 10-33 Draw resonance structures for the following species:

PROBLEM 10-34 (*S*)-3-Methylhexane undergoes radical bromination to yield optically inactive 3-bromo-3-methylhexane as the major product. Is the product chiral? What conclusions can you draw about the radical intermediate?

PROBLEM 10-35 Assume that you have carried out a radical chlorination reaction on (*R*)-2-chloropentane and have isolated (in low yield) 2,4-dichloropentane. How many stereoisomers of the product are formed, and in what ratio? Are any of the isomers optically active? (See Problem 10-34.)

PROBLEM 10-36 How would you carry out the following syntheses?

PROBLEM 10-37 The syntheses shown here are unlikely to occur as written. What is wrong with each?

PROBLEM 10-38 Why do you suppose it's not possible to prepare a Grignard reagent from a bromo alcohol such as 4-bromo-1-pentanol? Give another example of a molecule that is unlikely to form a Grignard reagent.

PROBLEM 10-39 Addition of HBr to a double bond with an ether ($-\text{OR}$) substituent occurs regioselectively to give a product in which the $-\text{Br}$ and $-\text{OR}$ are bonded to the same carbon. Draw the two possible carbocation intermediates in this electrophilic addition reaction, and explain using resonance why the observed product is formed.

PROBLEM Identify the reagents **a–c** in the following scheme:

10-40

PROBLEM Tertiary alkyl halides, R_3CX , undergo spontaneous dissociation to yield a carbocation, R_3C^+ , plus

10-41 halide ion. Which do you think reacts faster, $(CH_3)_3CBr$ or $H_2C=CHC(CH_3)_2Br$? Explain.

PROBLEM Carboxylic acids (RCO_2H ; $pK_a \approx 5$) are approximately 10^{11} times more acidic than alcohols (ROH ;

10-42 $pK_a \approx 16$). In other words, a carboxylate ion (RCO_2^-) is more stable than an alkoxide ion (RO^-). Explain, using resonance.

PROBLEM How might you use a Suzuki–Miyaura reaction to prepare the biaryl compounds below? In each

10-43 case, show the two potential reaction partners.

PROBLEM The relative rate of radical bromination is 1 : 82 : 1640 for 1° : 2° : 3° hydrogens, respectively. Draw

10-44 all of the monobrominated products that you might obtain from the radical bromination of the compounds below. Calculate the relative percentage of each.

(a) methylcyclobutane (b) 3,3-dimethylpentane (c) 3-methylpentane

PROBLEM Choose the alcohol from each pair below that would react faster with HX to form the corresponding

10-45 alkyl halide.

PROBLEM Predict the product and provide the entire catalytic cycle for the following Suzuki–Miyaura

10-46 reactions.

WHY THIS CHAPTER? Nucleophilic substitution and base-induced elimination are two of the most widely occurring and versatile reactions in organic chemistry, both in the laboratory and in biological pathways. We’ll look at them closely in this chapter to see how they occur, what their characteristics are, and how they can be used. We’ll begin with substitution reactions.

We saw in the preceding chapter that the carbon–halogen bond in an alkyl halide is polar and that the carbon atom is electron-poor. Thus, alkyl halides are electrophiles, and much of their chemistry involves polar reactions with nucleophiles and bases. Alkyl halides do one of two things when they react with a nucleophile/base such as hydroxide ion: they either undergo *substitution* of the X group by the nucleophile, or they undergo

elimination of HX to yield an alkene.

11.1 The Discovery of Nucleophilic Substitution Reactions

Discovery of the nucleophilic substitution reaction of alkyl halides dates back to work carried out by the German chemist Paul Walden in 1896. Walden found that the pure enantiomeric (+)- and (-)-malic acids could be interconverted through a series of simple substitution reactions. When Walden treated (-)-malic acid with PCl_5 , he isolated (+)-chlorosuccinic acid. This, on treatment with wet Ag_2O , gave (+)-malic acid. Similarly, reaction of (+)-malic acid with PCl_5 gave (-)-chlorosuccinic acid, which was converted into (-)-malic acid when treated with wet Ag_2O . The full cycle of reactions is shown in **FIGURE 11.2**.

FIGURE 11.2 Walden's cycle of reactions interconverting (+)- and (-)-malic acids.

At the time, the results were astonishing. The eminent chemist Emil Fischer called Walden's discovery "the most remarkable observation made in the field of optical activity since the fundamental observations of Pasteur." Because (-)-malic acid was converted into (+)-malic acid, some reactions in the cycle must have occurred with a change, or inversion, of configuration at the chirality center. But which ones, and how? (Remember from **Section 5.5** that the direction of light rotation and the configuration of a chirality center aren't directly related. You can't tell by looking at the sign of rotation whether a change in configuration has occurred during a reaction.)

Today, we refer to the transformations taking place in Walden's cycle as **nucleophilic substitution reactions** because each step involves the substitution of one nucleophile (chloride ion, Cl^- , or hydroxide ion, HO^-) by another. Nucleophilic substitution reactions are one of the most common and versatile reaction types in organic chemistry.

Following the work of Walden, further investigations were undertaken during the 1920s and 1930s to clarify the mechanism of nucleophilic substitution reactions and to find out how inversions of configuration occur. Among the first series studied was one that interconverted the two enantiomers of 1-phenyl-2-propanol (**FIGURE 11.3**). Although this particular series of reactions involves nucleophilic substitution of an alkyl *para*-toluenesulfonate (called a **tosylate**) rather than an alkyl halide, exactly the same type of reaction is involved as that studied by Walden. For all practical purposes, the entire tosylate group acts as if it were simply a halogen substituent. (In fact, when you see a tosylate substituent in a molecule, do a mental substitution and tell yourself that you're

dealing with an alkyl halide.)

FIGURE 11.3 A Walden cycle interconverting (+) and (–) enantiomers of 1-phenyl-2-propanol. Chirality centers are marked by asterisks, and the bonds broken in each reaction are indicated by red wavy lines. The inversion of chirality occurs in step 2, where acetate ion substitutes for tosylate ion.

In the three-step reaction sequence shown in **FIGURE 11.3**, (+)-1-phenyl-2-propanol is interconverted with its (–) enantiomer, so at least one of the three steps must involve an inversion of configuration at the chirality center. Step 1, formation of a tosylate, occurs by breaking the O–H bond of the alcohol rather than the C–O bond to the chiral carbon, so the configuration around the carbon is unchanged. Similarly, step 3, hydroxide-ion cleavage of the acetate, takes place without breaking the C–O bond at the chirality center. Thus, the inversion of stereochemical configuration must take place in step 2, the nucleophilic substitution of tosylate ion by acetate ion.

From this and nearly a dozen other series of similar reactions, researchers concluded that the nucleophilic substitution reaction of a primary or secondary alkyl halide or tosylate always proceeds with inversion of configuration. (Tertiary alkyl halides and tosylates, as we'll see shortly, give different stereochemical results and react by a different mechanism than the primary and secondary ones.)

WORKED EXAMPLE 11.1

Predicting the Stereochemistry of a Nucleophilic Substitution Reaction

What product would you expect from a nucleophilic substitution reaction of (*R*)-1-bromo-1-phenylethane with cyanide ion, ${}^{-}\text{C}\equiv\text{N}$, as nucleophile? Show the stereochemistry of both reactant and product, assuming that inversion of configuration occurs.

Strategy

Draw the *R* enantiomer of the reactant, and then change the configuration of the chirality center while replacing the ${}^{-}\text{Br}$ with a ${}^{-}\text{CN}$.

Solution

PROBLEM 11-1 What product would you expect from a nucleophilic substitution reaction of (*S*)-2-bromohexane with acetate ion, $\text{CH}_3\text{CO}_2{}^{-}$? Assume that inversion of configuration occurs, and show the stereochemistry of both the reactant and product.

11.2 The $\text{S}_{\text{N}}2$ Reaction

In almost all chemical reactions, there is a direct relationship between the rate at which the reaction occurs and the concentrations of the reactants. When we measure this relationship, we measure the **kinetics** of the reaction. For example, let's look at the kinetics of a simple nucleophilic substitution—the reaction of CH_3Br with OH^{-} to yield CH_3OH plus Br^{-} .

With a given temperature, solvent, and concentration of reactants, the substitution occurs at a certain rate. If we double the concentration of OH^{-} , the frequency of encounters between reaction partners doubles and we find that the reaction rate also doubles. Similarly, if we double the concentration of CH_3Br , the reaction rate again doubles. We call such a reaction, in which the rate is linearly dependent on the concentrations of two species, a **second-order reaction**. Mathematically, we can express this second-order dependence of the nucleophilic substitution reaction by setting up a **rate equation**. As either $[\text{RX}]$ or $[\text{OH}^{-}]$ changes, the rate of the reaction changes proportionately.

$$\begin{aligned}\text{Reaction rate} &= \text{Rate of disappearance of reactant} \\ &= k \times [\text{RX}] \times [\text{OH}^{-}]\end{aligned}$$

where

$[\text{RX}]$ = CH_3Br concentration in molarity

$[\text{OH}^{-}]$ = ${}^{-}\text{OH}$ concentration in molarity

k = a constant value (the rate constant)

A mechanism that accounts for both the inversion of configuration and the second-order kinetics that are observed with nucleophilic substitution reactions was suggested in 1937 by the British chemists E. D. Hughes

and Christopher Ingold, who formulated what they called the **S_N2 reaction**—short for *substitution, nucleophilic, bimolecular*. (**Bimolecular** means that two molecules, nucleophile and alkyl halide, take part in the step whose kinetics are measured.)

The essential feature of the S_N2 mechanism is that it takes place in a single step, without intermediates, when the incoming nucleophile reacts with the alkyl halide or tosylate (the *substrate*) from a direction opposite the group that is displaced (the *leaving group*). As the nucleophile comes in on one side of the substrate and bonds to the carbon, the halide or tosylate departs from the other side, thereby inverting the stereochemical configuration. The process is shown in **FIGURE 11.4** for the reaction of (*S*)-2-bromobutane with HO[−] to give (*R*)-2-butanol.

FIGURE 11.4 MECHANISM

The mechanism of the S_N2 reaction. The reaction takes place in a single step when the incoming nucleophile approaches from a direction 180° away from the leaving halide ion, thereby inverting the stereochemistry at carbon.

- 1 The nucleophile [−]OH uses its lone-pair electrons to attack the alkyl halide carbon 180° away from the departing halogen. This leads to a transition state with a partially formed C–OH bond and a partially broken C–Br bond.

- 2 The stereochemistry at carbon is inverted as the C–OH bond forms fully and the bromide ion departs with the electron pair from the former C–Br bond.

As shown in **FIGURE 11.4**, the S_N2 reaction occurs when an electron pair on the nucleophile Nu:[−] forces out the group X:[−], which takes with it the electron pair from the former C–X bond. This occurs through a transition state in which the new Nu–C bond is partially formed at the same time that the old C–X bond is partially broken and in which the negative charge is shared by both the incoming nucleophile and the outgoing halide ion. The transition state for this inversion has the remaining three bonds to carbon in a planar arrangement (**FIGURE 11.5**).

FIGURE 11.5 The transition state of an S_N2 reaction has a planar arrangement of the carbon atom and the remaining three groups. Electrostatic potential maps show that **negative charge** is delocalized in the transition state.

The mechanism proposed by Hughes and Ingold is fully consistent with experimental results, explaining both stereochemical and kinetic data. Thus, the requirement for a backside approach of the entering nucleophile (180° away from the departing X group) causes the stereochemistry of the substrate to invert, much like an umbrella turning inside-out in the wind. The Hughes–Ingold mechanism also explains why second-order kinetics are observed: the S_N2 reaction occurs in a single step that involves both alkyl halide and nucleophile. Two molecules are involved in the step whose rate is measured.

PROBLEM 11-2 What product would you expect to obtain from S_N2 reaction of OH^- with (*R*)-2-bromobutane? Show the stereochemistry of both the reactant and product.

PROBLEM 11-3 Assign configuration to the following substance, and draw the structure of the product that would result from nucleophilic substitution reaction with HS^- (reddish brown = Br):

11.3 Characteristics of the S_N2 Reaction

Now that we know how S_N2 reactions occur, we need to see how they can be used and what variables affect them. Some S_N2 reactions are fast, and some are slow; some take place in high yield and others in low yield. Understanding the factors involved can be of tremendous value. Let's begin by recalling a few things about reaction rates in general.

The rate of a chemical reaction is determined by the activation energy ΔG^\ddagger , the energy difference between reactant ground state and transition state. A change in reaction conditions can affect ΔG^\ddagger either by changing the reactant energy level or by changing the transition-state energy level. Lowering the reactant energy or raising the transition-state energy increases ΔG^\ddagger and decreases the reaction rate; raising the reactant energy or

decreasing the transition-state energy decreases ΔG^\ddagger and increases the reaction rate (FIGURE 11.6). We'll see examples of all these effects as we look at S_N2 reaction variables.

FIGURE 11.6 The effects of changes in reactant and transition-state energy levels on reaction rate. (a) A higher reactant energy level (red curve) corresponds to a faster reaction (smaller ΔG^\ddagger). (b) A higher transition-state energy level (red curve) corresponds to a slower reaction (larger ΔG^\ddagger).

Steric Effects in the S_N2 Reaction

The first S_N2 reaction variable to look at is the structure of the substrate. Because the S_N2 transition state involves partial bond formation between the incoming nucleophile and the alkyl halide carbon atom, it seems reasonable that a hindered, bulky substrate should prevent easy approach of the nucleophile, making bond formation difficult. In other words, the transition state for reaction of a sterically hindered substrate, whose carbon atom is “shielded” from the approach of the incoming nucleophile, is higher in energy and forms more slowly than the corresponding transition state for a less hindered substrate (FIGURE 11.7).

FIGURE 11.7 Steric hindrance to the S_N2 reaction. As the models indicate, the carbon atom in (a) bromomethane is readily accessible, resulting in a fast S_N2 reaction. The carbon atoms in (b) bromoethane (primary), (c) 2-bromopropane (secondary), and (d) 2-bromo-2-methylpropane (tertiary) are successively more hindered, resulting in successively slower S_N2 reactions.

As FIGURE 11.7 shows, the difficulty of nucleophile approach increases as the three substituents bonded to the halo-substituted carbon atom increase in size. Methyl halides are by far the most reactive substrates in S_N2 reactions, followed by primary alkyl halides such as ethyl and propyl. Alkyl branching at the reacting center, as in isopropyl halides (2°), slows the reaction greatly, and further branching, as in *tert*-butyl halides (3°), effectively halts the reaction. Even branching one carbon away from the reacting center, as in 2,2-dimethylpropyl (*neopentyl*) halides, greatly hinders nucleophilic displacement. As a result, S_N2 reactions occur only at relatively unhindered sites and are normally useful only with methyl halides, primary halides, and a few simple secondary halides. Relative reactivities for some different substrates are as follows:

Vinyl halides ($R_2C=CRX$) and aryl halides are not shown on this reactivity list because they are unreactive toward S_N2 displacement. This lack of reactivity is due to steric factors: the incoming nucleophile would have to approach in the plane of the carbon-carbon double bond and burrow through part of the molecule to carry out a backside displacement.

The Nucleophile

Another variable that has a major effect on the S_N2 reaction is the nature of the nucleophile. Any species, either neutral or negatively charged, can act as a nucleophile as long as it has an unshared pair of electrons; that is, as long as it is a Lewis base. If the nucleophile is negatively charged, the product is neutral; if the nucleophile is neutral, the product is positively charged.

A wide array of substances can be prepared using nucleophilic substitution reactions. In fact, we've already seen examples in previous chapters. For instance, the reaction of an acetylide anion with an alkyl halide, discussed in [Section 9.8](#), is an S_N2 reaction in which the acetylide nucleophile displaces a halide leaving group.

An acetylide anion

TABLE 11.1 lists some nucleophiles in the order of their reactivity, shows the products of their reactions with bromomethane, and gives the relative rates of their reactions. There are large differences in the rates at which various nucleophiles react.

TABLE 11.1 Some S_N2 Reactions with Bromomethane
$$\text{Nu}^- + \text{CH}_3\text{Br} \rightarrow \text{CH}_3\text{Nu} + \text{Br}^-$$

Nucleophile		Product		Relative rate of reaction
Formula	Name	Formula	Name	
H ₂ O	Water	CH ₃ OH ₂ ⁺	Methylhydronium ion	1
CH ₃ CO ₂ ⁻	Acetate	CH ₃ CO ₂ CH ₃	Methyl acetate	500
NH ₃	Ammonia	CH ₃ NH ₃ ⁺	Methylammonium ion	700
Cl ⁻	Chloride	CH ₃ Cl	Chloromethane	1,000
HO ⁻	Hydroxide	CH ₃ OH	Methanol	10,000
CH ₃ O ⁻	Methoxide	CH ₃ OCH ₃	Dimethyl ether	25,000
I ⁻	Iodide	CH ₃ I	Iodomethane	100,000
⁻ CN	Cyanide	CH ₃ CN	Acetonitrile	125,000
HS ⁻	Hydrosulfide	CH ₃ SH	Methanethiol	125,000

What are the reasons for the reactivity differences observed in TABLE 11.1? Why do some reactants appear to be much more “nucleophilic” than others? The answers to these questions aren’t straightforward. Part of the problem is that the term *nucleophilicity* is imprecise. The term is usually taken to be a measure of the affinity of a nucleophile for a carbon atom in the S_N2 reaction, but the reactivity of a given nucleophile can change from one reaction to the next. The exact nucleophilicity of a species in a given reaction depends on the substrate, the solvent, and even the reactant concentrations. Detailed explanations for the observed nucleophilicities aren’t always simple, but some trends can be detected from the data of TABLE 11.1.

- **Nucleophilicity roughly parallels basicity** when comparing nucleophiles that have the same reacting atom. Thus, OH⁻ is both more basic and more nucleophilic than acetate ion, CH₃CO₂⁻, which in turn is more basic and more nucleophilic than H₂O. Since “nucleophilicity” is usually taken as the affinity of a Lewis base for a carbon atom in the S_N2 reaction and “basicity” is the affinity of a base for a proton, it’s easy to see why there might be a correlation between the two kinds of behavior.
- **Nucleophilicity usually increases going down a column of the periodic table.** Thus, HS⁻ is more nucleophilic than HO⁻, and the halide reactivity order is I⁻ > Br⁻ > Cl⁻. Going down the periodic table, elements have their valence electrons in successively larger shells where they are successively farther from the nucleus, less tightly held, and consequently more reactive. This matter is complex, though, and the nucleophilicity order can change depending on the solvent.
- **Negatively charged nucleophiles are usually more reactive than neutral ones.** As a result, S_N2 reactions are often carried out under basic conditions rather than neutral or acidic conditions.

PROBLEM What product would you expect from S_N2 reaction of 1-bromobutane with each of the following?

11-4 (a) NaI (b) KOH (c) H-C≡C-Li (d) NH₃

PROBLEM Which substance in each of the following pairs is more reactive as a nucleophile? Explain.

11-5 (a) (CH₃)₂N⁻ or (CH₃)₂NH (b) (CH₃)₃B or (CH₃)₃N (c) H₂O or H₂S

The Leaving Group

Still another variable that can affect the S_N2 reaction is the nature of the group displaced by the incoming

nucleophile, the **leaving group**. Because the leaving group is expelled with a negative charge in most S_N2 reactions, the best leaving groups are those that best stabilize the negative charge in the transition state. The greater the extent of charge stabilization by the leaving group, the lower the energy of the transition state and the more rapid the reaction. But as we saw in [Section 2.8](#), the groups that best stabilize a negative charge are also the weakest bases. Thus, weak bases such as Cl^- , Br^- , and tosylate ion make good leaving groups, while strong bases such as OH^- and NH_2^- make poor leaving groups.

Relative reactivity	$\text{OH}^-, \text{NH}_2^-, \text{OR}^-$	F^-	Cl^-	Br^-	I^-	TosO^-
	$\ll 1$	1	200	10,000	30,000	60,000
						

It's just as important to know which are poor leaving groups as to know which are good, and the preceding data clearly indicate that F^- , HO^- , RO^- , and H_2N^- are not displaced by nucleophiles. In other words, alkyl fluorides, alcohols, ethers, and amines do not typically undergo S_N2 reactions. To carry out an S_N2 reaction with an alcohol, it's necessary to convert the OH^- into a better leaving group. This, in fact, is just what happens when a primary or secondary alcohol is converted into either an alkyl chloride by reaction with SOCl_2 or an alkyl bromide by reaction with PBr_3 ([Section 10.5](#)).

Alternatively, an alcohol can be made more reactive toward nucleophilic substitution by treating it with *para*-toluenesulfonyl chloride to form a tosylate. As noted previously, tosylates are **even** more reactive than halides in nucleophilic substitutions. Note that tosylate formation does not change the configuration of the oxygen-bearing carbon because the C–O bond is not broken.

The one general exception to the rule that ethers don't typically undergo S_N2 reactions pertains to epoxides, the three-membered cyclic ethers that we saw in [Section 8.7](#). Because of the angle strain in their three-membered ring, epoxides are much more reactive than other ethers. They react with aqueous acid to give 1,2-diols, as we saw in [Section 8.7](#), and they react readily with many other nucleophiles as well. Propene oxide, for instance, reacts with HCl to give 1-chloro-2-propanol by an S_N2 backside attack on the less hindered primary carbon atom. We'll look at the process in more detail in [Section 18.5](#).

PROBLEM Rank the following compounds in order of their expected reactivity toward S_N2 reaction:

The Solvent

The rates of S_N2 reactions are strongly affected by the solvent. Protic solvents—those that contain an –OH or –NH group—are generally the worst for S_N2 reactions, while polar aprotic solvents, which are polar but don't have an –OH or –NH group, are the best.

Protic solvents, such as methanol and ethanol, slow down S_N2 reactions by **solvation** of the reactant nucleophile. The solvent molecules hydrogen-bond to the nucleophile and form a cage around it, thereby lowering its energy and reactivity.

In contrast with protic solvents—which decrease the rates of S_N2 reactions by lowering the ground-state energy of the nucleophile—polar aprotic solvents increase the rates of S_N2 reactions by raising the ground-state energy of the nucleophile. Acetonitrile (CH₃CN), dimethylformamide [(CH₃)₂NCHO, abbreviated DMF], and dimethyl sulfoxide [(CH₃)₂SO, abbreviated DMSO] are particularly useful. A solvent known as hexamethylphosphoramide {(CH₃)₆P=O, abbreviated HMPA} can also be useful but it should only be handled with great care and not be allowed to touch the eyes or skin. These solvents can dissolve many salts because of their high polarity, but they tend to solvate metal cations rather than nucleophilic anions. As a result, the bare, unsolvated anions have a greater nucleophilicity and S_N2 reactions take place at correspondingly increased rates. For instance, a rate increase of 200,000 has been observed on changing from methanol to HMPA for the reaction of azide ion with 1-bromobutane.

PROBLEM Organic solvents like benzene, ether, and chloroform are neither protic nor strongly polar. What effect would you expect these solvents to have on the reactivity of a nucleophile in S_N2 reactions?

11-7

A Summary of S_N2 Reaction Characteristics

The effects on S_N2 reactions of the four variables—substrate structure, nucleophile, leaving group, and solvent—are summarized in the following statements and in the energy diagrams of **FIGURE 11.8**:

Substrate Steric hindrance raises the energy of the S_N2 transition state, increasing ΔG^\ddagger and decreasing the reaction rate (**FIGURE 11.8a**). As a result, S_N2 reactions are best for methyl and primary substrates. Secondary substrates react slowly, and tertiary substrates do not react by an S_N2 mechanism.

Nucleophile Basic, negatively charged nucleophiles are less stable and have a higher ground-state energy than neutral ones, decreasing ΔG^\ddagger and increasing the S_N2 reaction rate (**FIGURE 11.8b**).

Leaving group
Solvent

Good leaving groups (more stable anions) lower the energy of the transition state, decreasing ΔG^\ddagger and increasing the S_N2 reaction rate (FIGURE 11.8c).

Protic solvents solvate the nucleophile, thereby lowering its ground-state energy, increasing ΔG^\ddagger , and decreasing the S_N2 reaction rate. Polar aprotic solvents surround the accompanying cation but not the nucleophilic anion, thereby raising the ground-state energy of the nucleophile, decreasing ΔG^\ddagger , and increasing the reaction rate (FIGURE 11.8d).

FIGURE 11.8 Energy diagrams showing the effects of (a) substrate, (b) nucleophile, (c) leaving group, and (d) solvent on S_N2 reaction rates. Substrate and leaving group effects are felt primarily in the transition state. Nucleophile and solvent effects are felt primarily in the reactant ground state.

11.4 The S_N1 Reaction

Most nucleophilic substitutions take place by the S_N2 pathway just discussed. The reaction is favored when carried out with an unhindered substrate and a negatively charged nucleophile in a polar aprotic solvent, but is disfavored when carried out with a hindered substrate and a neutral nucleophile in a protic solvent. You might therefore expect the reaction of a tertiary substrate (hindered) with water (neutral, protic) to be among the slowest of substitution reactions. Remarkably, however, the opposite is true. The reaction of the tertiary halide 2-bromo-2-methylpropane ($\text{CH}_3)_3\text{CBr}$ with H_2O to give the alcohol 2-methyl-2-propanol is more than *1 million times* faster than the corresponding reaction of CH_3Br to give methanol.

What's going on here? A nucleophilic substitution reaction is occurring—a hydroxyl group is replacing a halogen—yet the reactivity order seems backward. These reactions can't be taking place by the S_N2 mechanism we've been discussing, so we must therefore conclude that they are occurring by an alternative substitution

mechanism. This alternative mechanism is called the **S_N1 reaction**, for *substitution, nucleophilic, unimolecular*.

In contrast to the S_N2 reaction of CH₃Br with OH[−], the S_N1 reaction of (CH₃)₃CBr with H₂O has a rate that depends only on the alkyl halide concentration and is independent of the H₂O concentration. In other words, the process is a **first-order reaction**; the concentration of the nucleophile does not appear in the rate equation.

$$\begin{aligned}\text{Reaction rate} &= \text{Rate of disappearance of alkyl halide} \\ &= k \times [\text{RX}]\end{aligned}$$

To explain this result, we need to know more about kinetics measurements. Many organic reactions occur in several steps, one of which usually has a higher-energy transition state than the others and is therefore slower. We call this step with the highest transition-state energy the **rate-limiting step**, or **rate-determining step**. No reaction can proceed faster than its rate-limiting step, which acts as a kind of traffic jam, or bottleneck. In the S_N1 reaction of (CH₃)₃CBr with H₂O, the fact that the nucleophile concentration does not appear in the first-order rate equation means that it is not involved in the rate-limiting step and must therefore be involved in some other, non-rate-limiting step. The mechanism shown in **FIGURE 11.9** accounts for these observations.

FIGURE 11.9 MECHANISM

The mechanism of the S_N1 reaction of 2-bromo-2-methylpropane with H₂O involves three steps. Step **1**—the spontaneous, unimolecular dissociation of the alkyl bromide to yield a carbocation—is rate-limiting.

1 Spontaneous dissociation of the alkyl bromide occurs in a slow, rate-limiting step to generate a carbocation intermediate plus bromide ion.

2 The carbocation intermediate reacts with water as a nucleophile in a fast step to yield protonated alcohol as product.

3 Loss of a proton from the protonated alcohol intermediate then gives the neutral alcohol product.

Unlike what occurs in an S_N2 reaction, where the leaving group is displaced while the incoming nucleophile approaches, an S_N1 reaction takes place by loss of the leaving group *before* the nucleophile approaches. 2-Bromo-2-methylpropane spontaneously dissociates to the *tert*-butyl carbocation (CH₃)₃C⁺, plus Br[−] in a slow, rate-limiting step, and the intermediate carbocation is then immediately trapped by the nucleophile water in

a faster second step. Thus, water is not a reactant in the step whose rate is measured. The energy diagram is shown in **FIGURE 11.10**.

FIGURE 11.10 An energy diagram for an S_N1 reaction. The rate-limiting step is the spontaneous dissociation of the alkyl halide to give a carbocation intermediate. Reaction of the carbocation with a nucleophile then occurs in a second, faster step.

Because an S_N1 reaction occurs through a carbocation intermediate, its stereochemical outcome is different from that of an S_N2 reaction. Carbocations, as we've seen, are planar, sp^2 -hybridized, and achiral. Thus, if we carry out an S_N1 reaction on one enantiomer of a chiral reactant and go through an achiral carbocation intermediate, the product loses its optical activity (**Section 8.12**). That is, the symmetrical intermediate carbocation can react with a nucleophile equally well from either side, leading to a racemic, 50 : 50 mixture of enantiomers (**FIGURE 11.11**).

FIGURE 11.11 Stereochemistry of the S_N1 reaction. Because the reaction goes through an achiral intermediate, an enantiomerically pure reactant gives an optically inactive racemic product.

The conclusion that S_N1 reactions on enantiomerically pure substrates should give racemic products is nearly, but not exactly, what is found. In fact, few S_N1 displacements occur with complete racemization. Most give a minor (0–20%) excess of inversion. The reaction of (*R*)-6-chloro-2,6-dimethyloctane with H_2O , for example, leads to an alcohol product that is approximately 80% racemized and 20% inverted (80% *R,S* + 20% *S* is equivalent to 40% *R* + 60% *S*).

This lack of complete racemization in S_N1 reactions is due to the fact that **ion pairs** are involved. According to this explanation, first proposed by Saul Winstein at UCLA, dissociation of the substrate occurs to give a structure in which the two ions are still loosely associated and in which the carbocation is effectively shielded from reaction on one side by the departing anion. If a certain amount of substitution occurs before the two ions fully diffuse apart, then a net inversion of configuration will be observed (**FIGURE 11.12**).

FIGURE 11.12 Ion pairs in an S_N1 reaction. The leaving group shields one side of the carbocation intermediate from reaction with the nucleophile, thereby leading to some inversion of configuration rather than complete racemization.

PROBLEM What product(s) would you expect from reaction of (*S*)-3-chloro-3-methyloctane with acetic acid?

11-8 Show the stereochemistry of both reactant and product.

PROBLEM Among the many examples of S_N1 reactions that occur with incomplete racemization, the optically pure tosylate of 2,2-dimethyl-1-phenyl-1-propanol ($[\alpha]_D = -30.3$) gives the corresponding acetate ($[\alpha]_D = +5.3$) when heated in acetic acid. If complete inversion had occurred, the optically pure acetate would have had $[\alpha]_D = +53.6$. What percentage racemization and what percentage inversion occurred in this reaction?

11-9

PROBLEM Assign configuration to the following substrate, and show the stereochemistry and identity of the

11-10 product you would obtain by S_N1 reaction with water (reddish brown = Br):

11.5 Characteristics of the S_N1 Reaction

Just as the S_N2 reaction is strongly influenced by the structure of the substrate, the leaving group, the nucleophile, and the solvent, the S_N1 reaction is similarly influenced. Factors that lower ΔG^\ddagger , either by lowering the energy level of the transition state or by raising the energy level of the ground state, favor faster S_N1 reactions. Conversely, factors that raise ΔG^\ddagger , either by raising the energy level of the transition state or by lowering the energy level of the reactant, slow down the S_N1 reaction.

The Substrate

According to the Hammond postulate (Section 7.10), any factor that stabilizes a high-energy intermediate also stabilizes the transition state leading to that intermediate. Because the rate-limiting step in an S_N1 reaction is the spontaneous, unimolecular dissociation of the substrate to yield a carbocation, the reaction is favored whenever a stabilized carbocation intermediate is formed. The more stable the carbocation intermediate, the faster the S_N1 reaction.

We saw in Section 7.9 that the stability order of alkyl carbocations is 3° > 2° > 1° > methyl. To this list we should also add the resonance-stabilized allyl and benzyl cations. Just as allylic radicals are unusually stable because the unpaired electron can be delocalized over an extended π orbital system (Section 10.4), so allylic and benzylic carbocations are unusually stable. (The word **benzylic** means “next to an aromatic ring.”) As Figure 11.13 indicates, an allylic cation has two resonance forms. In one form, the double bond is on the “left”; in the other form it’s on the “right.” A benzylic cation has five resonance forms, all of which contribute to the overall resonance hybrid.

FIGURE 11.13 Resonance forms of allylic and benzylic carbocations. The positive charge is delocalized over the π system in both. **Electron-poor atoms** are indicated by blue arrows.

Because of resonance stabilization, a primary allylic or benzylic carbocation is about as stable as a secondary

alkyl carbocation, and a secondary allylic or benzylic carbocation is about as stable as a tertiary alkyl carbocation. This stability order of carbocations is the same as the order of S_N1 reactivity for alkyl halides and tosylates.

We should also note parenthetically that primary allylic and benzylic substrates are particularly reactive in S_N2 reactions as well as in S_N1 reactions. Allylic and benzylic C–X bonds are about 50 kJ/mol (12 kcal/mol) weaker than the corresponding saturated bonds and are therefore more easily broken.

PROBLEM Rank the following substances in order of their expected S_N1 reactivity:

11-11

PROBLEM 3-Bromo-1-butene and 1-bromo-2-butene undergo S_N1 reaction at nearly the same rate, even though one is a secondary halide and the other is primary. Explain.

11-12

The Leaving Group

We said during the discussion of S_N2 reactivity that the best leaving groups are those that are most stable; that is, those that are the conjugate bases of strong acids. An identical reactivity order is found for the S_N1 reaction because the leaving group is directly involved in the rate-limiting step. Thus, the S_N1 reactivity order is

Leaving group reactivity

Note that in the S_N1 reaction, which is often carried out under acidic conditions, neutral water is sometimes the leaving group. This occurs, for example, when an alkyl halide is prepared from a tertiary alcohol by reaction with HBr or HCl (Section 10.5). As shown in Figure 11.14, the alcohol is first protonated and then spontaneously loses H₂O to generate a carbocation, which reacts with halide ion to give the alkyl halide. Knowing that an S_N1 reaction is involved in the conversion of alcohols to alkyl halides explains why the reaction works well only for tertiary alcohols. Tertiary alcohols react fastest because they give the most stable carbocation intermediates.

FIGURE 11.14 MECHANISM

The mechanism of the S_N1 reaction of a tertiary alcohol with HBr to yield an alkyl halide. Neutral water is the leaving group (step 2).

1 The $-OH$ group is first protonated by HBr.

2 Spontaneous dissociation of the protonated alcohol occurs in a slow, rate-limiting step to yield a carbocation intermediate plus water.

Carbocation

3 The carbocation intermediate reacts with bromide ion in a fast step to yield the neutral substitution product.

The Nucleophile

The nature of the nucleophile plays a major role in the S_N2 reaction but does not affect an S_N1 reaction. Because the S_N1 reaction occurs through a rate-limiting step in which the added nucleophile has no part, the nucleophile can't affect the reaction rate. The reaction of 2-methyl-2-propanol with HX, for instance, occurs at the same rate regardless of whether X is Cl, Br, or I. Furthermore, neutral nucleophiles are just as effective as negatively charged ones, so S_N1 reactions frequently occur under neutral or acidic conditions.

The Solvent

What about the solvent? Do solvents have the same effect in S_N1 reactions that they have in S_N2 reactions? The answer is both yes and no. Yes, solvents have a large effect on S_N1 reactions, but no, the reasons for the effects on S_N1 and S_N2 reactions are not the same. Solvent effects in the S_N2 reaction are due largely to stabilization or destabilization of the nucleophile *reactant*, while solvent effects in the S_N1 reaction are due largely to stabilization or destabilization of the *transition state*.

The Hammond postulate says that any factor stabilizing the intermediate carbocation should increase the rate of an S_N1 reaction. Solvation of the carbocation—the interaction of the ion with solvent molecules—has such an

effect. Solvent molecules orient around the carbocation so that the electron-rich ends of the solvent dipoles face the positive charge (FIGURE 11.15), thereby lowering the energy of the ion and favoring its formation.

FIGURE 11.15 Solvation of a carbocation by water. The electron-rich oxygen atoms of solvent molecules orient around the positively charged carbocation and thereby stabilize it.

The properties of a solvent that contribute to its ability to stabilize ions by solvation are related to the solvent's polarity. S_N1 reactions take place much more rapidly in strongly polar solvents, such as water and methanol, than in less polar solvents, such as ether and chloroform. In the reaction of 2-chloro-2-methylpropane, for example, a rate increase of 100,000 is observed upon going from ethanol (less polar) to water (more polar). The rate increases when going from a hydrocarbon solvent to water are so large they can't be measured accurately.

It should be emphasized again that both the S_N1 and the S_N2 reaction show solvent effects, but that they do so for different reasons. S_N2 reactions are *disfavored* in protic solvents because the *ground-state energy* of the nucleophile is lowered by solvation. S_N1 reactions are *favored* in protic solvents because the *transition-state energy* leading to carbocation intermediate is lowered by solvation.

A Summary of S_N1 Reaction Characteristics

The effects on S_N1 reactions of the four variables—substrate, leaving group, nucleophile, and solvent—are summarized in the following statements:

- Substrate** The best substrates yield the most stable carbocations. As a result, S_N1 reactions are best for tertiary, allylic, and benzylic halides.
- Leaving group** Good leaving groups increase the reaction rate by lowering the energy level of the transition state for carbocation formation.
- Nucleophile** The nucleophile must be nonbasic to prevent a competitive elimination of HX (Section 11.7), but otherwise does not affect the reaction rate. Neutral nucleophiles work well.
- Solvent** Polar solvents stabilize the carbocation intermediate by solvation, thereby increasing the reaction rate.

WORKED EXAMPLE 11.2

Predicting the Mechanism of a Nucleophilic Substitution Reaction

Predict whether each of the following substitution reactions is likely to be S_N1 or S_N2:

**Strategy**

Look at the substrate, leaving group, nucleophile, and solvent. Then decide from the summaries at the ends of [Section 11.3](#) and [Section 11.5](#) whether an S_N1 or an S_N2 reaction is favored. S_N1 reactions are favored by tertiary, allylic, or benzylic substrates, by good leaving groups, by nonbasic nucleophiles, and by protic solvents. S_N2 reactions are favored by primary substrates, by good leaving groups, by good nucleophiles, and by polar aprotic solvents.

Solution

(a) This is likely to be an S_N1 reaction because the substrate is secondary and benzylic, the nucleophile is weakly basic, and the solvent is protic.

(b) This is likely to be an S_N2 reaction because the substrate is primary, the nucleophile is a good one, and the solvent is polar aprotic.

PROBLEM Predict whether each of the following substitution reactions is likely to be S_N1 or S_N2 :

11-13 (a)

(b)

**11.6 Biological Substitution Reactions**

Both S_N1 and S_N2 reactions are common in biological chemistry, particularly in the pathways for biosynthesis of the many thousands of plant-derived substances called terpenoids, which we saw briefly in the [Chapter 8 Chemistry Matters](#) and will discuss in [Section 27.5](#). Unlike what typically happens in the laboratory, however, the substrate in a biological substitution reaction is usually an organodiphosphate rather than an alkyl halide. Thus, the leaving group is the diphosphate ion, abbreviated PP_i , rather than a halide ion. In fact, it's useful to think of the diphosphate group as the “biological equivalent” of a halide. The dissociation of an organodiphosphate in a biological reaction is typically assisted by complexation to a divalent metal cation such as Mg^{2+} to help neutralize charge and make the diphosphate a better leaving group.

An organodiphosphate

Diphosphate ion

As an example, two S_N1 reactions occur during the biosynthesis of geraniol, a fragrant alcohol found in roses and used in perfumery. Geraniol biosynthesis begins with dissociation of dimethylallyl diphosphate to give an allylic carbocation, which reacts with isopentenyl diphosphate (FIGURE 11.16). From the viewpoint of isopentenyl diphosphate, the reaction is an electrophilic alkene addition, but from the viewpoint of dimethylallyl diphosphate, the process is an S_N1 reaction in which the carbocation intermediate reacts with a double bond as the nucleophile.

FIGURE 11.16 Biosynthesis of geraniol from dimethylallyl diphosphate. Two S_N1 reactions occur, both with diphosphate ion as the leaving group.

Following this initial S_N1 reaction, loss of the pro-*R* hydrogen gives geranyl diphosphate, itself an allylic diphosphate that dissociates a second time. Reaction of the geranyl carbocation with water in a second S_N1 reaction, followed by loss of a proton, then yields geraniol.

As another example, S_N2 reactions are involved in almost all biological methylations, which transfer a $-\text{CH}_3$ group from an electrophilic donor to a nucleophile. The donor is *S*-adenosylmethionine (abbreviated SAM), which contains a positively charged sulfur (a sulfonium ion, Section 5.12), and the leaving group is the neutral *S*-adenosylhomocysteine molecule. In the biosynthesis of epinephrine (adrenaline) from norepinephrine, for

instance, the nucleophilic nitrogen atom of norepinephrine attacks the electrophilic methyl carbon atom of *S*-adenosylmethionine in an S_N2 reaction, displacing *S*-adenosylhomocysteine (FIGURE 11.17). In effect, *S*-adenosylmethionine is simply a biological equivalent of CH_3Cl .

FIGURE 11.17 The biosynthesis of epinephrine from norepinephrine occurs by an S_N2 reaction with *S*-adenosylmethionine.

PROBLEM 11-14 Review the mechanism of geraniol biosynthesis shown in Figure 11.16, and propose a mechanism for the biosynthesis of limonene from linalyl diphosphate.

11.7 Elimination Reactions: Zaitsev's Rule

We said at the beginning of this chapter that two kinds of reactions can take place when a nucleophile/Lewis base reacts with an alkyl halide. The nucleophile can either substitute for the halide by reaction at carbon or can cause elimination of HX by reaction at a neighboring hydrogen:

Elimination reactions are more complex than substitution reactions for several reasons. One is the problem of regiochemistry. What product results by loss of HX from an unsymmetrical halide? In fact, elimination reactions almost always give mixtures of alkene products, and the best we can usually do is to predict which will be the major product.

According to **Zaitsev's rule**, formulated in 1875 by the Russian chemist Alexander Zaitsev, base-induced elimination reactions generally (although not always) give the more stable alkene product—that is, the alkene with more alkyl substituents on the double-bond carbons. In the following two cases, for example, the more highly substituted alkene product predominates.

ZAITSEV'S RULE

In the elimination of HX from an alkyl halide, the more highly substituted alkene product predominates.

Another factor that complicates a study of elimination reactions is that they can take place by different mechanisms, just as substitutions can. We'll consider three of the most common mechanisms—the E1, E2, and E1cB reactions—which differ in the timing of C–H and C–X bond-breaking.

In the E1 reaction, the C–X bond breaks first to give a carbocation intermediate, which undergoes subsequent base abstraction of H⁺ to yield the alkene. In the E2 reaction, base-induced C–H bond cleavage is simultaneous with C–X bond cleavage, giving the alkene in a single step. In the E1cB reaction (cB for “conjugate base”), base abstraction of the proton occurs first, giving a carbanion (R:[−]) intermediate. This anion, the conjugate base of the reactant “acid,” then undergoes loss of X[−] in a subsequent step to give the alkene. All three mechanisms occur frequently in the laboratory, but the E1cB mechanism predominates in biological pathways.

E1 Reaction: C–X bond breaks first to give a carbocation intermediate, followed by base removal of a proton to yield the alkene.

E2 Reaction: C–H and C–X bonds break simultaneously, giving the alkene in a single step without intermediates.

E1cB Reaction: C–H bond breaks first, giving a carbanion intermediate that loses X[−] to form the alkene.

WORKED EXAMPLE 11.3

Predicting the Product of an Elimination Reaction

What product would you expect from reaction of 1-chloro-1-methylcyclohexane with KOH in ethanol?

Strategy

Treatment of an alkyl halide with a strong base such as KOH yields an alkene. To find the products in a specific case, locate the hydrogen atoms on each carbon next to the leaving group, and then generate the potential alkene products by removing HX in as many ways as possible. The major product will be the one that has the most highly substituted double bond—in this case, 1-methylcyclohexene.

Solution

PROBLEM 11-15 Ignoring double-bond stereochemistry, what products would you expect from elimination reactions of the following alkyl halides? Which product will be the major product in each case?

PROBLEM 11-16 What alkyl halides might the following alkenes have been made from?

11.8 The E2 Reaction and the Deuterium Isotope Effect

The **E2 reaction** (for *elimination, bimolecular*) occurs when an alkyl halide is treated with a strong base, such as hydroxide ion or alkoxide ion (RO^-). It is the most commonly occurring pathway for elimination and can be formulated as shown in **FIGURE 11.18**.

FIGURE 11.18 MECHANISM

Mechanism of the E2 reaction of an alkyl halide. The reaction takes place in a single step through a transition state in which the double bond begins to form at the same time the H and X groups are leaving.

- 1 Base (B:) attacks a neighboring hydrogen and begins to remove the H at the same time as the alkene double bond starts to form and the X group starts to leave.

- 2 Neutral alkene is produced when the C–H bond is fully broken and the X group has departed with the C–X bond electron pair.

Like the S_N2 reaction, the E2 reaction takes place in one step without intermediates. As the base begins to abstract H⁺ from a carbon next to the leaving group, the C–H bond begins to break, a C=C bond begins to form, and the leaving group begins to depart, taking with it the electron pair from the C–X bond. Among the pieces of evidence supporting this mechanism is the fact that E2 reactions show second-order kinetics and follow the rate law: rate = $k \times [\text{RX}] \times [\text{Base}]$. That is, both the base and alkyl halide take part in the rate-limiting step.

A second piece of evidence in support of the E2 mechanism is provided by a phenomenon known as the **deuterium isotope effect**. For reasons that we won't go into, a carbon–hydrogen bond is weaker by about 5 kJ/mol (1.2 kcal/mol) than the corresponding carbon–deuterium bond. Thus, a C–H bond is more easily broken than an equivalent C–D bond, and the rate of C–H bond cleavage is faster. For instance, the base-induced elimination of HBr from 1-bromo-2-phenylethane proceeds 7.11 times faster than the corresponding elimination of DBr from 1-bromo-2, 2-dideuterio-2-phenylethane. This result tells us that the C–H (or C–D) bond is broken in the rate-limiting step, consistent with our picture of the E2 reaction as a one-step process. If it were otherwise, we wouldn't observe a rate difference.

Yet a third piece of mechanistic evidence involves the stereochemistry of E2 eliminations. As shown by a large number of experiments, E2 reactions occur with **periplanar** geometry, meaning that all four reacting atoms—the hydrogen, the two carbons, and the leaving group—lie in the same plane. Two such geometries are possible: **syn periplanar** geometry, in which the H and the X are on the same side of the molecule, and **anti periplanar** geometry, in which the H and the X are on opposite sides of the molecule. Of the two, anti periplanar geometry is energetically preferred because it allows the substituents on the two carbons to adopt a staggered relationship, whereas syn geometry requires that the substituents be eclipsed.

What's so special about periplanar geometry? Because the sp^3 σ orbitals in the reactant C–H and C–X bonds must overlap and become p π orbitals in the alkene product, there must also be some overlap in the transition state. This can occur most easily if all the orbitals are in the same plane to begin with—that is, if they're periplanar (FIGURE 11.19).

FIGURE 11.19 The transition state for the E2 reaction of an alkyl halide with base. Overlap of the developing p orbitals in the transition state requires periplanar geometry of the reactant.

You can think of E2 elimination reactions with periplanar geometry as being similar to S_N2 reactions with 180° geometry. In an S_N2 reaction, an electron pair from the incoming nucleophile pushes out the leaving group on the opposite side of the molecule. In an E2 reaction, an electron pair from a neighboring C–H bond also pushes out the leaving group on the opposite side of the molecule.

Anti periplanar geometry for E2 eliminations has specific stereochemical consequences that provide strong evidence for the proposed mechanism. To take just one example, *meso*-1,2-dibromo-1,2-diphenylethane undergoes E2 elimination on treatment with base to give only the *E* alkene. None of the isomeric *Z* alkene is formed because the transition state leading to the *Z* alkene would have to have syn periplanar geometry and

would thus be higher in energy.

WORKED EXAMPLE 11.4

Predicting the Double-Bond Stereochemistry of the Product in an E2 Reaction

What stereochemistry do you expect for the alkene obtained by E2 elimination of (1*S*,2*S*)-1,2-dibromo-1,2-diphenylethane?

Strategy

Draw (1*S*,2*S*)-1,2-dibromo-1,2-diphenylethane so that you can see its stereochemistry and so that the $-\text{H}$ and $-\text{Br}$ groups to be eliminated are anti periplanar. Then carry out the elimination while keeping all substituents in approximately the same positions, and see what alkene results.

Solution

Anti periplanar elimination of HBr gives (Z)-1-bromo-1,2-diphenylethylene.

PROBLEM 11-17 What stereochemistry do you expect for the alkene obtained by E2 elimination of (1*R*,2*R*)-1,2-dibromo-1,2-diphenylethane? Draw a Newman projection of the reacting conformation.

PROBLEM 11-18 What stereochemistry do you expect for the trisubstituted alkene obtained by E2 elimination of the following alkyl halide on treatment with KOH? (reddish brown = Br.)

11.9 The E2 Reaction and Cyclohexane Conformation

Anti periplanar geometry for E2 reactions is particularly important in cyclohexane rings, where chair geometry forces a rigid relationship between the substituents on neighboring carbon atoms (Section 4.8). The anti periplanar requirement for E2 reactions overrides Zaitsev's rule and can be met in cyclohexanes only if the hydrogen and the leaving group are trans diaxial (FIGURE 11.20). If either the leaving group or the hydrogen is

equatorial, E2 elimination can't occur.

FIGURE 11.20 The geometric requirement for an E2 reaction in a substituted cyclohexane. The leaving group and the hydrogen must both be axial for anti periplanar elimination to occur.

The elimination of HCl from the isomeric menthyl and neomenthyl chlorides shown in **FIGURE 11.21** gives a good illustration of this trans-diaxial requirement. Neomenthyl chloride undergoes elimination of HCl on reaction with ethoxide ion 200 times faster than menthyl chloride. Furthermore, neomenthyl chloride yields 3-menthene as the major alkene product, whereas menthyl chloride yields 2-menthene.

FIGURE 11.21 Dehydrochlorination of menthyl and neomenthyl chlorides. **(a)** Neomenthyl chloride loses HCl directly from its more stable conformation, but **(b)** menthyl chloride must first ring-flip to a higher energy conformation before HCl loss can occur. The abbreviation “Et” represents an ethyl group.

The difference in reactivity between the isomeric menthyl chlorides is due to the difference in their conformations. Neomenthyl chloride has the conformation shown in **FIGURE 11.21a**, with the methyl and isopropyl groups equatorial and the chlorine axial—a perfect geometry for E2 elimination. Loss of the hydrogen atom at C4 occurs easily to yield the more substituted alkene product, 3-menthene, as predicted by Zaitsev's rule.

Menthyl chloride, by contrast, has a conformation in which all three substituents are equatorial (**FIGURE 11.21b**). To achieve the necessary geometry for elimination, menthyl chloride must first ring-flip to a higher-energy chair conformation, in which all three substituents are axial. E2 elimination then occurs with loss of

the only trans-diaxial hydrogen available, leading to the non-Zaitsev product 2-menthene. The net effect of the simple change in chlorine stereochemistry is a 200-fold change in reaction rate and a complete change of product. The chemistry of the molecule is controlled by its conformation.

PROBLEM Which isomer would you expect to undergo E2 elimination faster, **11-19** *trans*-1-bromo-4-*tert*-butylcyclohexane or *cis*-1-bromo-4-*tert*-butylcyclohexane? Draw each molecule in its more stable chair conformation, and explain your answer.

11.10 The E1 and E1cB Reactions

The E1 Reaction

Just as the E2 reaction is analogous to the S_N2 reaction, the S_N1 reaction has a close analog called the **E1 reaction** (for elimination, unimolecular). The E1 reaction can be formulated as shown in **FIGURE 11.22**, with the elimination of HCl from 2-chloro-2-methylpropane.

FIGURE 11.22 MECHANISM

Mechanism of the E1 reaction. Two steps are involved, the first of which is rate-limiting, and a carbocation intermediate is present.

- 1** Spontaneous dissociation of the tertiary alkyl chloride yields an intermediate carbocation in a slow, rate-limiting step.

Carbocation

- 2** Loss of a neighboring H⁺ in a fast step yields the neutral alkene product. The electron pair from the C-H bond goes to form the alkene π bond.

E1 eliminations begin with the same unimolecular dissociation to give a carbocation that we saw in the S_N1 reaction, but the dissociation is followed by loss of H⁺ from the adjacent carbon rather than by substitution. In fact, the E1 and S_N1 reactions normally occur together whenever an alkyl halide is treated in a protic solvent with a nonbasic nucleophile. Thus, the best E1 substrates are also the best S_N1 substrates, and mixtures of substitution and elimination products are usually obtained. For example, when 2-chloro-2-methylpropane is warmed to 65 °C in 80% aqueous ethanol, a 64 : 36 mixture of 2-methyl-2-propanol (S_N1) and 2-methylpropene (E1) results.

Much evidence has been obtained in support of the E1 mechanism. For example, E1 reactions show first-order kinetics, consistent with a rate-limiting, unimolecular dissociation process. Furthermore, E1 reactions show no

deuterium isotope effect because rupture of the C–H (or C–D) bond occurs after the rate-limiting step rather than during it. Thus, we can't measure a rate difference between a deuterated and nondeuterated substrate.

A final piece of evidence involves the stereochemistry of elimination. Unlike the E2 reaction, where anti periplanar geometry is required, there is no geometric requirement on the E1 reaction because the halide and the hydrogen are lost in separate steps. We might therefore expect to obtain the more stable (Zaitsev's rule) product from E1 reaction, which is just what we find. To return to a familiar example, menthyl chloride loses HCl under E1 conditions in a polar solvent to give a mixture of alkenes in which the Zaitsev product, 3-menthene, predominates (FIGURE 11.23).

FIGURE 11.23 Elimination reactions of menthyl chloride. E2 conditions (1, strong base in 100% ethanol) lead to 2-menthene through an anti periplanar elimination, whereas E1 conditions (2, dilute base in 80% aqueous ethanol) lead to a mixture of 2-menthene and 3-menthene.

The E1cB Reaction

In contrast to the E1 reaction, which involves a carbocation intermediate, the **E1cB reaction** takes place through a carbanion intermediate. Base-induced abstraction of a proton in a slow, rate-limiting step gives an anion, which expels a leaving group on the adjacent carbon. The reaction is particularly common in substrates that have a poor leaving group, such as –OH, two carbons removed from a carbonyl group, as in HOC–CH–C=O. The poor leaving group disfavors the alternative E1 and E2 possibilities, and the carbonyl group makes the adjacent hydrogen unusually acidic by resonance stabilization of the anion intermediate. We'll look at this acidifying effect of a carbonyl group in **Section 22.5**.

11.11 Biological Elimination Reactions

All three elimination reactions—E2, E1, and E1cB—occur in biological pathways, but the E1cB mechanism is particularly common. The substrate is usually an alcohol rather than an alkyl halide, and the H atom removed is usually adjacent to a carbonyl group, just as in laboratory reactions. Thus, 3-hydroxy carbonyl compounds are frequently converted to unsaturated carbonyl compounds by elimination reactions. A typical example occurs during the biosynthesis of fats and oils when a 3-hydroxybutyryl thioester is dehydrated to the corresponding unsaturated (crotonyl) thioester. The base in this reaction is a histidine amino acid in the enzyme, and the loss of the –OH group is assisted by simultaneous protonation.

11.12 A Summary of Reactivity: S_N1, S_N2, E1, E1cB, and E2

S_N1, S_N2, E1, E1cB, E2—how can you keep it all straight and predict what will happen in any given case? Will substitution or elimination occur? Will the reaction be bimolecular or unimolecular? There are no rigid answers to these questions, but it's possible to recognize some trends and make some generalizations.

- **Primary alkyl halides** S_N2 substitution occurs if a good nucleophile is used, E2 elimination occurs if a strong, sterically hindered base is used, and E1cB elimination occurs if the leaving group is two carbons away from a carbonyl group.
- **Secondary alkyl halides** S_N2 substitution occurs if a weakly basic nucleophile is used in a polar aprotic solvent, E2 elimination predominates if a strong base is used, and E1cB elimination takes place if the leaving group is two carbons away from a carbonyl group. Secondary allylic and benzylic alkyl halides can also undergo S_N1 and E1 reactions if a weakly basic nucleophile is used in a protic solvent.
- **Tertiary alkyl halides** E2 elimination occurs when a base is used, but S_N1 substitution and E1 elimination occur together under neutral conditions, such as in pure ethanol or water. E1cB elimination takes place if the leaving group is two carbons away from a carbonyl group.

WORKED EXAMPLE 11.5

Predicting the Product and Mechanism of Reactions

Tell whether each of the following reactions is likely to be S_N1, S_N2, E1, E1cB, or E2, and predict the product of each:

Strategy

Look carefully in each reaction at the structure of the substrate, the leaving group, the nucleophile, and the solvent. Then decide from the preceding summary which kind of reaction is likely to be favored.

Solution

(a) A secondary, nonallylic substrate can undergo an S_N2 reaction with a good nucleophile in a polar aprotic solvent but will undergo an E2 reaction on treatment with a strong base in a protic solvent. In this case, E2 reaction is likely to predominate.

(b) A secondary benzylic substrate can undergo an S_N2 reaction on treatment with a nonbasic nucleophile in a polar aprotic solvent and will undergo an E2 reaction on treatment with a base. Under protic conditions, such as aqueous formic acid (HCO₂H), an S_N1 reaction is likely, along with some E1 reaction.

PROBLEM Tell whether each of the following reactions is likely to be S_N1, S_N2, E1, E1cB, or E2:

CHEMISTRY MATTERS

Green Chemistry

Organic chemistry in the 20th century changed the world, giving us new medicines, food preservatives, insecticides, adhesives, textiles, dyes, building materials, composites, and all manner of polymers. But these advances did not come without a cost: Almost every chemical process produces waste that must be dealt with, including reaction solvents and toxic by-products that might evaporate into the air or be leached into groundwater if not disposed of properly. Even apparently harmless by-products must be safely buried or otherwise sequestered. As always, there's no such thing as a free lunch. With the good also comes the bad.

It may never be possible to make organic chemistry completely benign, but awareness of the environmental problems caused by many chemical processes has grown dramatically in recent years, giving rise to a movement called *green chemistry*. Green chemistry is the design and implementation of chemical products and processes that reduce waste and attempt to eliminate the generation of hazardous substances. There are 12 principles of green chemistry:

Prevent waste – Waste should be prevented rather than treated or cleaned up after it has been created.

Maximize atom economy – Synthetic methods should maximize the incorporation of all materials used in a process into the final product so that waste is minimized.

Use less hazardous processes – Synthetic methods should use reactants and generate wastes with minimal toxicity to health and the environment.

Design safer chemicals – Chemical products should be designed to have minimal toxicity.

Use safer solvents – Minimal use should be made of solvents, separation agents, and other auxiliary substances in a reaction.

Design for energy efficiency – Energy requirements for chemical processes should be minimized, with reactions carried out at room temperature if possible.

Use renewable feedstocks – Raw materials should come from renewable sources when feasible.

Minimize derivatives – Syntheses should be designed with minimal use of protecting groups to avoid extra steps and reduce waste.

Use catalysis – Reactions should be catalytic rather than stoichiometric.

Design for degradation – Products should be designed to be biodegradable at the end of their useful lifetimes.

Monitor pollution in real time – Processes should be monitored in real time for the formation of hazardous substances.

Prevent accidents – Chemical substances and processes should minimize the potential for fires, explosions, or other accidents.

The foregoing 12 principles may not all be met in most real-world applications, but they provide a worthy goal and they can make chemists think more carefully about the environmental implications of their work. Real success stories have occurred, and more are in progress. Approximately 7 million pounds per year of ibuprofen (6 billion tablets!) are now made by a “green” process that produces approximately 99% less waste than the process it replaces. Only three steps are needed, the anhydrous HF solvent used in the first step is recovered and reused, and the second and third steps are catalytic.

- S_N1 reaction
- S_N2 reaction
- solvation
- syn periplanar
- tosylate
- unimolecular
- Zaitsev's rule

Summary

The reaction of an alkyl halide or tosylate with a nucleophile/base results either in *substitution* or in *elimination*. The resultant nucleophilic substitution and base-induced elimination reactions are two of the most widely occurring and versatile reaction types in organic chemistry, both in the laboratory and in biological pathways.

Nucleophilic substitutions are of two types: **S_N2 reactions** and **S_N1 reactions**. In the S_N2 reaction, the entering nucleophile approaches the halide from a direction 180° away from the leaving group, resulting in an umbrella-like inversion of configuration at the carbon atom. The reaction is kinetically **second-order** and is strongly inhibited by increasing steric bulk of the reactants. Thus, S_N2 reactions are favored for primary and secondary substrates.

In the S_N1 reaction, the substrate spontaneously dissociates to a carbocation in a slow **rate-limiting step**, followed by a rapid reaction with the nucleophile. As a result, S_N1 reactions are kinetically **first-order** and take place with substantial racemization of configuration at the carbon atom. They are most favored for tertiary substrates. Both S_N1 and S_N2 reactions occur in biological pathways, although the leaving group is typically a diphosphate ion rather than a halide.

Eliminations of alkyl halides to yield alkenes occur by three mechanisms: **E2 reactions**, **E1 reactions**, and **E1cB reactions**, which differ in the timing of C–H and C–X bond-breaking. In the E2 reaction, C–H and C–X bond-breaking occur simultaneously when a base abstracts H⁺ from one carbon while the leaving group departs from the neighboring carbon. The reaction takes place preferentially through an **anti periplanar** transition state in which the four reacting atoms—hydrogen, two carbons, and leaving group—are in the same plane. The reaction shows **second-order kinetics** and a **deuterium isotope effect**, and occurs when a secondary or tertiary substrate is treated with a strong base. These elimination reactions usually give a mixture of alkene products in which the more highly substituted alkene predominates (**Zaitsev's rule**).

In the E1 reaction, C–X bond-breaking occurs first. The substrate dissociates to yield a carbocation in the

slow rate-limiting step before losing H^+ from an adjacent carbon in a second step. The reaction shows **first-order kinetics** and no deuterium isotope effect and occurs when a tertiary substrate reacts in polar, nonbasic solution.

In the E1cB reaction, C-H bond-breaking occurs first. A base abstracts a proton to give a carbanion, followed by loss of the leaving group from the adjacent carbon in a second step. The reaction is favored when the leaving group is two carbons removed from a carbonyl, which stabilizes the intermediate anion by resonance. Biological elimination reactions typically occur by this E1cB mechanism.

In general, substrates react in the following way:

Summary of Reactions

1. Nucleophilic substitutions

- a. $\text{S}_{\text{N}}1$ reaction of 3° , allylic, and benzylic halides (Section 11.4 and Section 11.5)

- b. $\text{S}_{\text{N}}2$ reaction of 1° and simple 2° halides (Section 11.2 and Section 11.3)

2. Eliminations

- a. $\text{E}1$ reaction (Section 11.10)

- b. E1cB reaction (Section 11.10)

- c. $\text{E}2$ reaction (Section 11.8)

Additional Problems

Visualizing Chemistry

PROBLEM Write the product you would expect from reaction of each of the following alkyl halides with (1) $\text{Na}^+ \text{SCH}_3^-$ and (2) $\text{Na}^+ \text{OH}^-$ (green = Cl):

11-21

PROBLEM From what alkyl bromide was the following alkyl acetate made by S_N2 reaction? Write the reaction, 11-22 showing all stereochemistry.

PROBLEM Assign *R* or *S* configuration to the following molecule, write the product you would expect from S_N2 11-23 reaction with NaCN, and assign *R* or *S* configuration to the product (green = Cl):

PROBLEM Draw the structure and assign *Z* or *E* stereochemistry to the product you expect from E2 reaction of 11-24 the following molecule with NaOH (green = Cl):

Mechanism Problems

PROBLEM Predict the product(s) and show the mechanism for each of the following reactions. What do the 11-25 mechanisms have in common? Why?

PROBLEM Show the mechanism for each of the following reactions. What do the mechanisms have in 11-26 common? Why?

PROBLEM 11-27 Predict the product(s) for each of the following elimination reactions. In each case show the mechanism. What do the mechanisms have in common? Why?

PROBLEM 11-28 Predict the product(s) for each of the following elimination reactions. In each case show the mechanism. What do the mechanisms have in common? Why?

PROBLEM 11-29 Predict the product(s) for each of the following elimination reactions. In each case show the mechanism. What do the mechanisms have in common? Why?

PROBLEM 11-30 Predict the product of each of the following reactions, and indicate if the mechanism is likely to be S_N1 , S_N2 , E1, E2, or E1cB.

PROBLEM 11-31 We saw in Section 8.7 that bromohydrins are converted into epoxides when treated with base. Propose a mechanism, using curved arrows to show the electron flow.

PROBLEM 11-32 The following tertiary alkyl bromide does not undergo a nucleophilic substitution reaction by either S_N1 or S_N2 mechanisms. Explain.

PROBLEM 11-33 Metabolism of *S*-adenosylhomocysteine (Section 11.6) involves the following sequence. Propose a mechanism for the second step.

PROBLEM 11-34 Reaction of iodoethane with CN^- yields a small amount of *isonitrile*, $\text{CH}_3\text{CH}_2\text{N}\equiv\text{C}$, along with the nitrile $\text{CH}_3\text{CH}_2\text{C}\equiv\text{N}$ as the major product. Write electron-dot structures for both products, assign formal charges as necessary, and propose mechanisms to account for their formation.

PROBLEM 11-35 One step in the urea cycle for ridding the body of ammonia is the conversion of argininosuccinate to the amino acid arginine plus fumarate. Propose a mechanism for the reaction, and show the structure of arginine.

PROBLEM 11-36 Methyl esters (RCO_2CH_3) undergo a cleavage reaction to yield carboxylate ions plus iodomethane on heating with LiI in dimethylformamide:

The following evidence has been obtained: (1) The reaction occurs much faster in DMF than in ethanol. (2) The corresponding ethyl ester ($\text{RCO}_2\text{CH}_2\text{CH}_3$) cleaves approximately 10 times more slowly than the methyl ester. Propose a mechanism for the reaction. What other kinds of experimental evidence could you gather to support your hypothesis?

PROBLEM 11-37 $\text{S}_{\text{N}}2$ reactions take place with inversion of configuration, and $\text{S}_{\text{N}}1$ reactions take place with racemization. The following substitution reaction, however, occurs with complete *retention* of configuration. Propose a mechanism. (Hint: two inversions = retention.)

PROBLEM 11-38 Propose a mechanism for the following reaction, an important step in the laboratory synthesis of proteins:

Nucleophilic Substitution Reactions

PROBLEM 11-39 Draw all isomers of C_4H_9Br , name them, and arrange them in order of decreasing reactivity in the S_N2 reaction.

PROBLEM 11-40 The following Walden cycle has been carried out: Explain the results, and indicate where inversion occurs.

PROBLEM 11-41 Which compound in each of the following pairs will react faster in an S_N2 reaction with OH^- ?

- (a) CH_3Br or CH_3I (b) $\text{CH}_3\text{CH}_2\text{I}$ in ethanol or in dimethyl sulfoxide (c) $(\text{CH}_3)_3\text{CCl}$ or CH_3Cl
 (d) $\text{H}_2\text{C}=\text{CHBr}$ or $\text{H}_2\text{C}=\text{CHCH}_2\text{Br}$

PROBLEM 11-42 Which reactant in each of the following pairs is more nucleophilic? Explain.

- (a) NH_2^- or NH_3 (b) H_2O or CH_3CO_2^- (c) BF_3 or F^- (d) $(\text{CH}_3)_3\text{P}$ or $(\text{CH}_3)_3\text{N}$ (e) I^- or Cl^-
 (f) $\text{C}\equiv\text{N}^-$ or OCH_3^-

PROBLEM 11-43 What effect would you expect the following changes to have on the rate of the S_N2 reaction of 1-iodo-2-methylbutane with cyanide ion?

- (a) The CN^- concentration is halved, and the 1-iodo-2-methylbutane concentration is doubled.
 (b) Both the CN^- and the 1-iodo-2-methylbutane concentrations are tripled.

PROBLEM 11-44 What effect would you expect the following changes to have on the rate of the reaction of ethanol with 2-iodo-2-methylbutane?

- (a) The concentration of the halide is tripled.
 (b) The concentration of the ethanol is halved by adding diethyl ether as an inert solvent.

PROBLEM 11-45 How might you prepare each of the following using a nucleophilic substitution reaction at some step?

- (a) $\text{CH}_3\text{C}\equiv\text{CCH}(\text{CH}_3)_2$ (b) $\text{CH}_3\text{OCH}(\text{CH}_3)_2$ (c) $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CN}$ (d) $\text{CH}_3\text{CH}_2\text{CH}_2\text{NH}_2$

PROBLEM 11-46 Which reaction in each of the following pairs would you expect to be faster?

- (a) The S_N2 displacement by I^- on CH_3Cl or on CH_3OTos
 (b) The S_N2 displacement by CH_3CO_2^- on bromoethane or on bromocyclohexane
 (c) The S_N2 displacement on 2-bromopropane by $\text{CH}_3\text{CH}_2\text{O}^-$ or by CN^-
 (d) The S_N2 displacement by $\text{HC}\equiv\text{C}^-$ on bromomethane in benzene or in acetonitrile

PROBLEM 11-47 Predict the product and give the stereochemistry resulting from reaction of each of the following nucleophiles with (*R*)-2-bromooctane:

- (a) CN^- (b) CH_3CO_2^- (c) CH_3S^-

PROBLEM 11-48 (*R*)-2-Bromooctane undergoes racemization to give (\pm)-2-bromooctane when treated with NaBr in dimethyl sulfoxide. Explain.

Elimination Reactions

PROBLEM Propose structures for compounds that fit the following descriptions:

- 11-49** (a) An alkyl halide that gives a mixture of three alkenes on E2 reaction
 (b) An organohalide that will not undergo nucleophilic substitution
 (c) An alkyl halide that gives the non-Zaitsev product on E2 reaction
 (d) An alcohol that reacts rapidly with HCl at 0 °C

PROBLEM What products would you expect from the reaction of 1-bromopropane with each of the following?

- 11-50** (a) NaNH_2 (b) $\text{KOC}(\text{CH}_3)_3$ (c) NaI (d) NaCN (e) $\text{NaC}\equiv\text{CH}$ (f) Mg , then H_2O

PROBLEM 1-Chloro-1,2-diphenylethane can undergo E2 elimination to give either *cis*- or

- 11-51** *trans*-1,2-diphenylethylene (stilbene). Draw Newman projections of the reactive conformations leading to both possible products, and suggest a reason why the *trans* alkene is the major product.

PROBLEM Predict the major alkene product of the following E1 reaction:

PROBLEM There are eight diastereomers of 1,2,3,4,5,6-hexachlorocyclohexane. Draw each in its more stable

- 11-53** chair conformation. One isomer loses HCl in an E2 reaction nearly 1000 times more slowly than the others. Which isomer reacts so slowly, and why?

General Problems

PROBLEM The following reactions are unlikely to occur as written. Tell what is wrong with each, and predict

- 11-54** the actual product.

PROBLEM Arrange the following carbocations in order of increasing stability.

PROBLEM Order each of the following sets of compounds with respect to $\text{S}_{\text{N}}1$ reactivity:

PROBLEM Order each of the following sets of compounds with respect to $\text{S}_{\text{N}}2$ reactivity:

PROBLEM Predict the major product(s) of each of the following reactions. Identify those reactions where you would expect the product mixture to rotate plane-polarized light.

PROBLEM Reaction of the following *S* tosylate with cyanide ion yields a nitrile product that also has *S* stereochemistry. Explain.

PROBLEM Ethers can often be prepared by $\text{S}_{\text{N}}2$ reaction of alkoxide ions, RO^- , with alkyl halides. Suppose you wanted to prepare cyclohexyl methyl ether. Which of the following two possible routes would you choose? Explain.

PROBLEM How can you explain the fact that *trans*-1-bromo-2-methylcyclohexane yields the non-Zaitsev elimination product 3-methylcyclohexene on treatment with base?

trans-1-Bromo-2-methylcyclohexane **3-Methylcyclohexene**

PROBLEM Predict the product(s) of the following reaction, indicating stereochemistry where necessary:

11-62

PROBLEM Alkynes can be made by dehydrohalogenation of vinylic halides in a reaction that is essentially an E2 process. In studying the stereochemistry of this elimination, it was found that (*Z*)-2-chloro-2-butenedioic acid reacts 50 times as fast as the corresponding *E* isomer. What conclusion can you draw about the stereochemistry of eliminations in vinylic halides? How does this result compare with eliminations of alkyl halides?

11-63

PROBLEM Based on your answer to Problem 11-63, predict the product(s) and show the mechanism for each of the following reactions.

11-64

PROBLEM (*S*)-2-Butanol slowly racemizes on standing in dilute sulfuric acid. Explain.

11-65

PROBLEM Reaction of HBr with (*R*)-3-methyl-3-hexanol leads to racemic 3-bromo-3-methylhexane. Explain.

11-66

PROBLEM Treatment of 1-bromo-2-deuterio-2-phenylethane with strong base leads to a mixture of deuterated and nondeuterated phenylethylenes in an approximately 7 : 1 ratio. Explain.

11-67

PROBLEM Propose a structure for an alkyl halide that gives only (*E*)-3-methyl-2-phenyl-2-pentene on E2 elimination. Make sure you indicate the stereochemistry.

11-68

PROBLEM 11-69 Although anti periplanar geometry is preferred for E2 reactions, it isn't absolutely necessary. The following deuterated bromo compound reacts with strong base to yield an undeuterated alkene. A syn elimination has occurred. Make a molecular model of the reactant, and explain the result.

PROBLEM 11-70 The reaction of 1-chlorooctane with CH_3CO_2^- to give octyl acetate is greatly accelerated by adding a small quantity of iodide ion. Explain.

PROBLEM 11-71 Compound **X** is optically inactive and has the formula $\text{C}_{16}\text{H}_{16}\text{Br}_2$. On treatment with strong base, **X** gives hydrocarbon **Y**, $\text{C}_{16}\text{H}_{14}$. Compound **Y** absorbs 2 equivalents of hydrogen when reduced over a palladium catalyst and reacts with ozone to give two fragments. One fragment, **Z**, is an aldehyde with formula $\text{C}_7\text{H}_6\text{O}$. The other fragment is glyoxal, $(\text{CHO})_2$. Write the reactions involved, and suggest structures for **X**, **Y**, and **Z**. What is the stereochemistry of **X**?

PROBLEM 11-72 When a primary alcohol is treated with *p*-toluenesulfonyl chloride at room temperature in the presence of an organic base such as pyridine, a tosylate is formed. When the same reaction is carried out at higher temperature, an alkyl chloride is often formed. Explain.

PROBLEM 11-73 The amino acid methionine is formed by a methylation reaction of homocysteine with *N*-methyltetrahydrofolate. The stereochemistry of the reaction has been probed by carrying out the transformation using a donor with a "chiral methyl group," which contains protium (H), deuterium (D), and tritium (T) isotopes of hydrogen. Does the methylation reaction occur with inversion or retention of configuration?

PROBLEM 11-74 Amines are converted into alkenes by a two-step process called the Hofmann elimination. $\text{S}_{\text{N}}2$ reaction of the amine with an excess of CH_3I in the first step yields an intermediate that undergoes E2 reaction when treated with silver oxide as base. Pentylamine, for example, yields 1-pentene. Propose a structure for the intermediate, and explain why it readily undergoes elimination.

PROBLEM 11-75 The antipsychotic drug flupentixol is prepared by the following scheme:

- What alkyl chloride **B** reacts with amine **A** to form **C**?
- Compound **C** is treated with SOCl_2 , and the product is allowed to react with magnesium metal to give a Grignard reagent **D**. What is the structure of **D**?
- We'll see in Section 19.7 that Grignard reagents add to ketones, such as **E**, to give tertiary alcohols, such as **F**. Because of the newly formed chirality center, compound **F** exists as a pair of enantiomers. Draw both, and assign *R,S* configurations.
- Two stereoisomers of flupentixol are subsequently formed from **F**, but only one is shown. Draw the other isomer, and identify the type of stereoisomerism.

12.8 Infrared Spectra of Some Common Functional Groups

WHY THIS CHAPTER? Finding the structures of new molecules, whether small ones synthesized in the laboratory or large proteins and nucleic acids found in living organisms, is central to progress in chemistry and biochemistry. We can only scratch the surface of structure determination in this book, but after reading this and the following two chapters, you should have a good idea of the range of structural techniques available and of how and when each is used.

Every time a reaction is run, the products must be identified, and every time a new compound is found in nature, its structure must be determined. Determining the structure of an organic compound was a difficult and time-consuming process until the mid-20th century, but powerful techniques and specialized instruments are now routinely used to simplify the problem. In this and the next two chapters, we'll look at four such techniques—mass spectrometry (MS), infrared (IR) spectroscopy, ultraviolet spectroscopy (UV), and nuclear magnetic resonance spectroscopy (NMR)—and we'll see the kind of information that can be obtained from each.

Mass spectrometry

What is the size and formula?

Infrared spectroscopy

What functional groups are present?

Ultraviolet spectroscopy

Is a conjugated π electron system present?

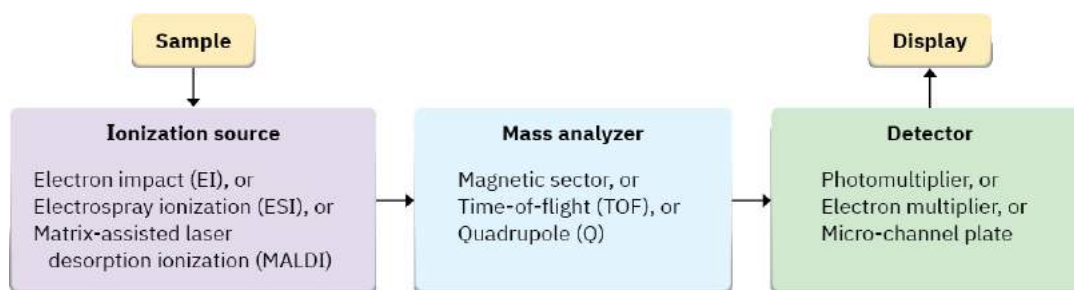

Nuclear magnetic resonance spectroscopy

What is the carbon–hydrogen framework?

12.1 Mass Spectrometry of Small Molecules: Magnetic-Sector Instruments

At its simplest, **mass spectrometry (MS)** is a technique for measuring the mass, and therefore the molecular weight (MW), of a molecule. In addition, it's often possible to gain structural information about a molecule by measuring the masses of the fragments produced when molecules are broken apart.

More than 20 different kinds of commercial mass spectrometers are available depending on the intended application, but all have three basic parts: an *ionization source* in which sample molecules are given an electrical charge, a *mass analyzer* in which ions are separated by their mass-to-charge ratio, and a *detector* in which the separated ions are observed and counted.

Among the most common mass spectrometers used for routine purposes in the laboratory is the electron-impact, magnetic-sector instrument shown schematically in **FIGURE 12.2**. A small amount of sample is vaporized into the ionization source, where it is bombarded by a stream of high-energy electrons. The energy of the electron beam can be varied but is commonly around 70 electron volts (eV), or 6700 kJ/mol. When a high-energy electron strikes an organic molecule, it dislodges a valence electron from the molecule, producing a **cation radical**—*cation* because the molecule has lost an electron and now has a positive charge; *radical* because the molecule now has an odd number of electrons.

Electron bombardment transfers so much energy that most of the cation radicals fragment after formation. They break apart into smaller pieces, some of which retain the positive charge and some of which are neutral. The fragments then flow through a curved pipe in a strong magnetic field, which deflects them into different paths according to their mass-to-charge ratio (m/z). Neutral fragments are not deflected by the magnetic field and are lost on the walls of the pipe, but positively charged fragments are sorted by the mass spectrometer onto a detector, which records them as peaks at the various m/z ratios. Since the number of charges z on each ion is usually 1, the value of m/z for each ion is simply its mass m . Masses up to approximately 2500 atomic mass units (amu) can be analyzed by this type of instrument.

FIGURE 12.2 Representation of an electron-ionization, magnetic-sector mass spectrometer. Molecules are ionized by collision with high-energy electrons, causing some of the molecules to fragment. Passage of the charged fragments through a magnetic field then sorts them according to their mass.

Another common type of mass spectrometer uses what is called a **quadrupole mass analyzer**, which has a set of four solid rods arranged parallel to the direction of the ion beam, with an oscillating electrostatic field generated in the space between the rods. For a given field, only one m/z value will make it through the quadrupole region. The others will crash into the rods or the walls of the instrument and never reach the detector **FIGURE 12.3**.

FIGURE 12.3 Representation of a quadrupole mass analyzer. Only ions of a certain m/z will reach the detector; other ions will collide with the rods.

The mass spectrum of a compound is typically presented as a bar graph, with masses (m/z values) on the x axis and intensity, or relative abundance of ions of a given m/z striking the detector, on the y axis. The tallest peak, assigned an intensity of 100%, is called the **base peak**, and the peak that corresponds to the unfragmented cation radical is called the **parent peak**, or the *molecular ion* (M^+ , or simply M). **FIGURE 12.4** shows the mass spectrum of propane.

FIGURE 12.4 Mass spectrum of propane (C_3H_8 ; MW = 44).

Mass spectral fragmentation patterns are usually complex, and the molecular ion is often not the base peak. The mass spectrum of propane in **FIGURE 12.4**, for instance, shows a molecular ion at $m/z = 44$ that is only about 30% as high as the base peak at $m/z = 29$. In addition, many other fragment ions are present.

12.2 Interpreting Mass Spectra

What kinds of information can we get from a mass spectrum? The most obvious information is the molecular weight of the sample, which in itself can be invaluable. If we were given samples of hexane (MW = 86), 1-hexene (MW = 84), and 1-hexyne (MW = 82), for example, mass spectrometry would easily distinguish them.

Some instruments, called *double-focusing mass spectrometers*, have two magnetic sectors in their mass analyzers, giving these spectrometers such high resolution that they provide mass measurements accurate to 5 ppm, or about 0.0005 amu, making it possible to distinguish between two formulas with the same nominal mass. For example, both C_5H_{12} and C_4H_8O have MW = 72, but they differ slightly beyond the decimal point: C_5H_{12} has an exact mass of 72.0939 amu, whereas C_4H_8O has an exact mass of 72.0575 amu. A high-resolution instrument can easily distinguish between them. Note, however, that exact mass measurements refer to molecules with specific isotopic compositions. Thus, the sum of the exact atomic masses of the specific isotopes in a molecule is measured—1.007 83 amu for 1H , 12.000 00 amu for ^{12}C , 14.003 07 amu for ^{14}N , 15.994 91 amu for ^{16}O , and so on—rather than the sum of the average atomic masses of elements, as found on a periodic table.

Unfortunately, not every compound shows a molecular ion in its electron-impact mass spectrum. Although M^+ is usually easy to identify if it's abundant, some compounds, such as 2,2-dimethylpropane, fragment so easily that no molecular ion is observed (**FIGURE 12.5**). In such cases, alternative “soft” ionization methods that don't use electron bombardment can prevent or minimize fragmentation (see Section 12.4).

FIGURE 12.5 Mass spectrum of 2,2-dimethylpropane (C_5H_{12} ; MW = 72). No molecular ion is observed when electron-impact ionization is used. What do you think is the formula and structure of the M^+ peak at $m/z = 57$?

Knowing the molecular weight makes it possible to narrow considerably the choices of molecular formula. For example, if the mass spectrum of an unknown compound shows a molecular ion at $m/z = 110$, the molecular formula is likely to be C_8H_{14} , $C_7H_{10}O$, $C_6H_6O_2$, or $C_6H_{10}N_2$. There are always a number of molecular formulas possible for all but the lowest molecular weights, and a computer can easily generate a list of the choices.

A further point about mass spectrometry, noticeable in the spectra of both propane (FIGURE 12.4) and 2,2-dimethylpropane (FIGURE 12.5), is that the peak for the molecular ion is not at the highest m/z value. There is also a small peak at $M + 1$ due to the presence of different isotopes in the molecules. Although ^{12}C is the most abundant carbon isotope, a small amount (1.10% natural abundance) of ^{13}C is also present. Thus, a certain percentage of the molecules analyzed in the mass spectrometer are likely to contain a ^{13}C atom, giving rise to the observed $M + 1$ peak. In addition, a small amount of ^2H (deuterium; 0.015% natural abundance) is present, making a further contribution to the $M + 1$ peak.

Mass spectrometry would be useful even if molecular weight and formula were the only information that could be obtained, but in fact it provides much more. For one thing, the mass spectrum of a compound serves as a kind of “molecular fingerprint.” Every organic compound fragments in a unique way depending on its structure, and the likelihood of two compounds having identical mass spectra is small. Thus, it’s sometimes possible to identify an unknown by computer-based matching of its mass spectrum to one of the more than 785,061 searchable spectra recorded in a database called the *Registry of Mass Spectral Data*.

It’s also possible to derive structural information about a molecule by interpreting its fragmentation pattern. Fragmentation occurs when the high-energy cation radical flies apart by spontaneous cleavage of a chemical bond. One of the two fragments retains the positive charge and is a carbocation, while the other fragment is a neutral radical.

Not surprisingly, the positive charge often remains with the fragment that is best able to stabilize it. In other words, a relatively stable carbocation is often formed during fragmentation. For example, 2,2-dimethylpropane tends to fragment in such a way that the positive charge remains with the *tert*-butyl group. 2,2-Dimethylpropane therefore has a base peak at $m/z = 57$, corresponding to C_4H_9^+ (FIGURE 12.5).

Because mass-spectral fragmentation patterns are usually complex, it’s often difficult to assign structures to fragment ions. Most hydrocarbons fragment in many ways, as demonstrated by the mass spectrum of hexane in FIGURE 12.6. The hexane spectrum shows a moderately abundant molecular ion at $m/z = 86$ and fragment ions at $m/z = 71$, 57, 43, and 29. Since all the carbon–carbon bonds of hexane are electronically similar, all break to a similar extent, giving rise to the observed mixture of ions.

FIGURE 12.6 Mass spectrum of hexane (C_6H_{14} ; MW = 86). The base peak is at $m/z = 57$, and numerous other ions are present.

FIGURE 12.7 shows how the hexane fragments might arise. The loss of a methyl radical (CH_3 , $M = 15$) from the hexane cation radical ($M^+ = 86$) gives rise to a fragment of mass $86 - 15 = 71$; the loss of an ethyl radical (C_2H_5 , $M = 29$) accounts for a fragment of mass $86 - 29 = 57$; the loss of a propyl radical (C_3H_7 , $M = 43$) accounts for a fragment of mass $86 - 43 = 43$; and the loss of a butyl radical accounts for a fragment of mass 29. With practice, it’s sometimes possible to analyze the fragmentation pattern of an unknown compound and work backward to a structure that is compatible with the data.

FIGURE 12.7 Fragmentation of hexane in a mass spectrometer.

We'll see in the next section and in later chapters that specific functional groups, such as alcohols, ketones, aldehydes, and amines, show specific kinds of mass spectral fragmentations that can be interpreted to provide structural information.

WORKED EXAMPLE 12.1

Using Mass Spectra to Identify Compounds

Assume that you have two unlabeled samples, one of methylcyclohexane and the other of ethylcyclopentane. How could you use mass spectrometry to tell them apart? The mass spectra of both are shown in **FIGURE 12.8**.

FIGURE 12.8 Mass spectra of unlabeled samples A and B for **Worked Example 12.1**.

Strategy

Look at the possible structures and decide on how they differ. Then think about how many of these differences in structure might give rise to differences in mass spectra. Methyl cyclohexane, for instance, has a $-\text{CH}_3$ group,

and ethylcyclopentane has a $-\text{CH}_2\text{CH}_3$ group, which should affect the fragmentation patterns.

Solution

Both mass spectra show molecular ions at $M^+ = 98$, corresponding to C_7H_{14} , but they differ in their fragmentation patterns. Sample **A** has its base peak at $m/z = 69$, corresponding to the loss of a CH_2CH_3 group (29 mass units), but **B** has a rather small peak at $m/z = 69$. Sample **B** shows a base peak at $m/z = 83$, corresponding to the loss of a CH_3 group (15 mass units), but sample **A** has only a small peak at $m/z = 83$. We can therefore be reasonably certain that **A** is ethylcyclopentane and **B** is methylcyclohexane.

PROBLEM 12-1 The sex hormone testosterone contains only C, H, and O and has a mass of 288.2089 amu, as determined by high-resolution mass spectrometry. What is the likely molecular formula of testosterone?

PROBLEM 12-2 Two mass spectra are shown in Figure 12.9. One spectrum is that of 2-methyl-2-pentene; the other is of 2-hexene. Which is which? Explain.

FIGURE 12.9 Mass spectra for Problem 12-2.

12.3 Mass Spectrometry of Some Common Functional Groups

As each functional group is discussed in future chapters, mass-spectral fragmentations characteristic of that group will be described. As a preview, though, we'll point out some distinguishing features of several common functional groups.

Alcohols

Alcohols undergo fragmentation in a mass spectrometer by two pathways: *alpha cleavage* and *dehydration*. In the α -cleavage pathway, a C–C bond nearest the hydroxyl group is broken, yielding a neutral radical plus a resonance-stabilized, oxygen-containing cation. This type of fragmentation is seen in the spectrum of 2-pentanol in **FIGURE 12.10**.

FIGURE 12.10 Mass spectrum of 2-pentanol.

In the dehydration pathway, water is eliminated, yielding an alkene radical cation with a mass 18 amu less than M^+ . For simplicity, we have drawn the dehydration below as an E2-type process. Often the hydrogen that is lost is not beta to the hydroxyl. Only a small peak from dehydration is observed in the spectrum of 2-pentanol (FIGURE 12.10).

Amines

The *nitrogen rule* of mass spectrometry says that a compound with an odd number of nitrogen atoms has an odd-numbered molecular weight. The logic behind the rule comes from the fact that nitrogen is trivalent, thus requiring an odd number of hydrogen atoms. The presence of nitrogen in a molecule is often detected simply by observing its mass spectrum. An odd-numbered molecular ion usually means that the unknown compound has one or three nitrogen atoms, and an even-numbered molecular ion usually means that a compound has either zero or two nitrogen atoms.

Aliphatic amines undergo a characteristic α cleavage in a mass spectrometer, similar to that observed for alcohols. A C–C bond nearest the nitrogen atom is broken, yielding an alkyl radical and a resonance-stabilized, nitrogen-containing cation.

The mass spectrum of triethylamine has a base peak at $m/z = 86$, which arises from an alpha cleavage resulting in the loss of a methyl group (FIGURE 12.11).

FIGURE 12.11 Mass spectrum of triethylamine.

Halides

The fact that some elements have two common isotopes gives their mass spectra a distinctive appearance. Chlorine, for example, exists as two isotopes, ^{35}Cl and ^{37}Cl , in roughly a 3 : 1 ratio. In a sample of chloroethane, three out of four molecules contain a ^{35}Cl atom and one out of four has a ^{37}Cl atom. In the mass spectrum of chloroethane (FIGURE 12.12 we see the molecular ion (M) at $m/z = 64$ for ions that contain a ^{35}Cl and another peak at $m/z = 66$, called the M + 2 peak, for ions containing a ^{37}Cl . The ratio of the relative abundance of M : M + 2 is about 3 : 1, a reflection of the isotopic abundances of chlorine.

FIGURE 12.12 Mass spectrum of chloroethane.

In the case of bromine, the isotopic distribution is 50.7% ^{79}Br and 49.3% ^{81}Br . In the mass spectrum of 1-bromohexane (FIGURE 12.13) the molecular ion appears at $m/z = 164$ for ^{79}Br -containing ions and the M + 2 peak is at $m/z = 166$ for ^{81}Br -containing ions. The ions at $m/z = 135$ and 137 are informative as well. The two nearly equally large peaks tell us that the ions at those m/z values still contain the bromine atom. The peak at $m/z = 85$, on the other hand, does not contain bromine because there is not a large peak at $m/z = 87$.

FIGURE 12.13 Mass spectrum of 1-bromohexane.

Carbonyl Compounds

Ketones and aldehydes that have a hydrogen on a carbon three atoms away from the carbonyl group undergo a characteristic mass-spectral cleavage called the **McLafferty rearrangement**. The hydrogen atom is transferred to the carbonyl oxygen, a C–C bond between the alpha and beta carbons is broken, and a neutral alkene fragment is produced. The charge remains with the oxygen-containing fragment.

In addition, ketones and aldehydes frequently undergo α cleavage of the bond between the carbonyl carbon and the neighboring carbon to yield a neutral radical and a resonance-stabilized acyl cation. Because the carbon neighboring the carbonyl carbon is called the alpha carbon, the reaction is called an alpha cleavage.

(To be more general about neighboring positions in carbonyl compounds, Greek letters are used in alphabetical order: alpha, beta, gamma, delta, and so on.)

The mass spectrum of butyrophenone illustrates both alpha cleavage and the McLafferty rearrangement (FIGURE 12.14). Alpha cleavage of the propyl substituent results in the loss of $\text{C}_3\text{H}_7 = 43$ mass units from the parent ion at $m/z = 148$ to give the fragment ion at $m/z = 105$. A McLafferty rearrangement of butyrophenone results in the loss of ethylene, $\text{C}_2\text{H}_4 = 28$ mass units, from the parent leaving the ion at $m/z = 120$.

FIGURE 12.14 Mass spectrum of butyrophenone.

WORKED EXAMPLE 12.2

Identifying Fragmentation Patterns in a Mass Spectrum

The mass spectrum of 2-methyl-3-pentanol is shown in FIGURE 12.15. What fragments can you identify?

FIGURE 12.15 Mass spectrum of 2-methyl-3-pentanol, for Worked Example 12.2.

Strategy

Calculate the mass of the molecular ion, and identify the functional groups in the molecule. Then write the fragmentation processes you might expect, and compare the masses of the resultant fragments with the peaks present in the spectrum.

Solution

2-Methyl-3-pentanol, an open-chain alcohol, has $M^+ = 102$ and might be expected to fragment by α cleavage and by dehydration. These processes would lead to fragment ions of $m/z = 84$, 73, and 59. Of the three expected fragments, dehydration is not observed (no $m/z = 84$ peak), but both α cleavages take place ($m/z = 73$, 59).

Loss of C_3H_7 ($M^+ - 43$)
by α cleavage gives
a peak of mass 59.

PROBLEM What are the masses of the charged fragments produced in the following cleavage pathways?

- 12-3** (a) Alpha cleavage of 2-pentanone ($\text{CH}_3\text{COCH}_2\text{CH}_2\text{CH}_3$)
 (b) Dehydration of cyclohexanol (hydroxycyclohexane)
 (c) McLafferty rearrangement of 4-methyl-2-pentanone [$\text{CH}_3\text{COCH}_2\text{CH}(\text{CH}_3)_2$]
 (d) Alpha cleavage of triethylamine [$(\text{CH}_3\text{CH}_2)_3\text{N}$]

PROBLEM List the masses of the parent ion and of several fragments you might expect to find in the mass

- 12-4** spectrum of the following molecule:

12.4 Mass Spectrometry in Biological Chemistry: Time-of-Flight (TOF) Instruments

MS analyses of sensitive biological samples rarely use magnetic sector ionization. Instead, they typically use either electrospray ionization (*ESI*) or matrix-assisted laser desorption ionization (*MALDI*), typically linked to a time-of-flight (*TOF*) mass analyzer. Both *ESI* and *MALDI* are soft ionization methods that produce charged molecules with little fragmentation, even with sensitive biological samples of very high molecular weight.

In an *ESI* source, as a sample solution exits the tube, it is subjected to a high voltage that causes the droplets to become charged. The sample molecules gain one or more protons from charged solvent molecules in the droplet. The volatile solvent quickly evaporates, giving variably protonated sample molecules ($\text{M} + \text{H}_n^{n+}$). In a *MALDI* source, the sample is adsorbed onto a suitable matrix compound, such as 2,5-dihydroxybenzoic acid, which is ionized by a short burst of laser light. The matrix compound then transfers the energy to the sample and protonates it, forming $\text{M} + \text{H}_n^{n+}$ ions.

Following ion formation, the variably protonated sample molecules are electrically focused into a small packet with a narrow spatial distribution, and the packet is given a sudden kick of energy by an accelerator electrode. As each molecule in the packet is given the same energy, $E = mv^2/2$, it begins moving with a velocity that depends on the square root of its mass, $v = \sqrt{2E/m}$. Lighter molecules move faster, and heavier molecules move slower. The analyzer itself—the *drift tube*—is simply an electrically grounded metal tube inside which the different charged molecules become separated as they move at different velocities and take different amounts of time to complete their flight.

The **Time of Flight** technique is considerably more sensitive than the magnetic sector alternative, and protein samples of up to 100 kilodaltons (100,000 amu) can be separated with a mass accuracy of 3 ppm. **FIGURE 12.16** shows a *MALDI*-*TOF* spectrum of chicken egg-white lysozyme, MW = 14,306.7578 daltons. Biochemists generally use the unit *dalton*, abbreviated Da, instead of amu, although the two are equivalent (1 dalton = 1 amu).

FIGURE 12.16 MALDI-TOF mass spectrum of chicken egg-white lysozyme. The peak at 14,306.7578 daltons (amu) is due to the monoprotonated protein, $M + H^+$, and the peak at 28,614.2188 daltons is due to an impurity formed by dimerization of the protein. Other peaks at lower m/z values are various protonated species, $M + H_n^{n+}$.

12.5 Spectroscopy and the Electromagnetic Spectrum

Infrared, ultraviolet, and nuclear magnetic resonance spectroscopies differ from mass spectrometry in that they are nondestructive and involve the interaction of molecules with electromagnetic energy rather than with an ionizing source. Before beginning a study of these techniques, however, let's briefly review the nature of radiant energy and the electromagnetic spectrum.

Visible light, X rays, microwaves, radio waves, and so forth are all different kinds of electromagnetic radiation. Collectively, they make up the **electromagnetic spectrum**, shown in **FIGURE 12.17**. The electromagnetic spectrum is arbitrarily divided into regions, with the familiar visible region accounting for only a small portion, from 3.8×10^{-7} m to 7.8×10^{-7} m in wavelength. The visible region is flanked by the infrared and ultraviolet regions.

FIGURE 12.17 The electromagnetic spectrum covers a continuous range of wavelengths and frequencies, from radio waves at the low-frequency end to gamma (γ) rays at the high-frequency end. The familiar visible region accounts for only a small portion near the middle of the spectrum.

Electromagnetic radiation is often said to have dual behavior. In some respects, it has the properties of a particle, called a **photon**, yet in other respects it behaves as an energy wave. Like all waves, electromagnetic radiation is characterized by a *wavelength*, a *frequency*, and an *amplitude* (**FIGURE 12.18**). The **wavelength**, λ (Greek lambda), is the distance from one wave maximum to the next. The **frequency**, ν (Greek nu), is the

number of waves that pass by a fixed point per unit time, usually given in reciprocal seconds (s^{-1}), or **hertz, Hz** ($1 \text{ Hz} = 1 \text{ s}^{-1}$). The **amplitude** is the height of a wave, measured from midpoint to peak. The intensity of radiant energy, whether a feeble glow or a blinding glare, is proportional to the square of the wave's amplitude.

FIGURE 12.18 Electromagnetic waves are characterized by a wavelength, a frequency, and an amplitude. (a) Wavelength (λ) is the distance between two successive wave maxima. Amplitude is the height of the wave measured from the center. (b)–(c) What we perceive as different kinds of electromagnetic radiation are simply waves with different wavelengths and frequencies.

Multiplying the wavelength of a wave in meters (m) by its frequency in reciprocal seconds (s^{-1}) gives the speed of the wave in meters per second (m/s). The rate of travel of all electromagnetic radiation in a vacuum is a constant value, commonly called the “speed of light” and abbreviated c . Its numerical value is defined as exactly $2.997\,924\,58 \times 10^8$ m/s, usually rounded off to 3.00×10^8 m/s.

$$\text{Wavelength} \times \text{Frequency} = \text{Speed}$$

$$\lambda \text{ (m)} \times \nu \text{ (s}^{-1}\text{)} = c \text{ (m/s)}$$

$$\lambda = \frac{c}{\nu} \text{ or } \nu = \frac{c}{\lambda}$$

Just as matter comes only in discrete units called atoms, electromagnetic energy is transmitted only in discrete amounts called *quanta*. The amount of energy ϵ corresponding to 1 quantum of energy (1 **photon**) of a given frequency ν is expressed by the Planck equation

$$\epsilon = h\nu = \frac{hc}{\lambda}$$

where h = Planck's constant ($6.62 \times 10^{-34} \text{ J} \cdot \text{s} = 1.58 \times 10^{-34} \text{ cal} \cdot \text{s}$).

The Planck equation says that the energy of a given photon varies directly with its frequency ν but inversely with its wavelength λ . High frequencies and short wavelengths correspond to high-energy radiation such as gamma rays; low frequencies and long wavelengths correspond to low-energy radiation such as radio waves. Multiplying ϵ by Avogadro's number N_A gives the same equation in more familiar units, where E represents the energy of Avogadro's number (one “mole”) of photons of wavelength λ :

$$E = \frac{N_A hc}{\lambda} = \frac{1.20 \times 10^{-4} \text{ kJ/mol}}{\lambda \text{ (m)}} \text{ or } \frac{2.86 \times 10^{-5} \text{ kcal/mol}}{\lambda \text{ (m)}}$$

When an organic compound is exposed to a beam of electromagnetic radiation, it absorbs energy of some wavelengths but passes, or transmits, energy of other wavelengths. If we irradiate the sample with energy of many different wavelengths and determine which are absorbed and which are transmitted, we can measure the **absorption spectrum** of the compound.

An example of an absorption spectrum—that of ethanol exposed to infrared radiation—is shown in **FIGURE**

12.19. The horizontal axis records the wavelength, and the vertical axis records the intensity of the various energy absorptions in percent transmittance. The baseline corresponding to 0% absorption (or 100% transmittance) runs along the top of the chart, so a downward spike means that energy absorption has occurred at that wavelength.

FIGURE 12.19 An infrared absorption spectrum for ethanol, $\text{CH}_3\text{CH}_2\text{OH}$. A transmittance of 100% means that all the energy is passing through the sample, whereas a lower transmittance means that some energy is being absorbed. Thus, each downward spike corresponds to an energy absorption.

The energy a molecule gains when it absorbs radiation must be distributed over the molecule in some way. With infrared radiation, the absorbed energy causes bonds to stretch and bend more vigorously. With ultraviolet radiation, the energy causes an electron to jump from a lower-energy orbital to a higher-energy one. Different radiation frequencies affect molecules in different ways, but each provides structural information when the results are interpreted.

There are many kinds of spectroscopies, which differ according to the region of the electromagnetic spectrum used. We'll look at three: infrared spectroscopy, ultraviolet spectroscopy, and nuclear magnetic resonance spectroscopy. Let's begin by seeing what happens when an organic sample absorbs infrared energy.

WORKED EXAMPLE 12.3

Correlating Energy and Frequency of Radiation

Which is higher in energy, FM radio waves with a frequency of 1.015×10^8 Hz (101.5 MHz) or visible green light with a frequency of 5×10^{14} Hz?

Strategy

Remember the equations $\varepsilon = h\nu$ and $\varepsilon = hc/\lambda$, which say that energy increases as frequency increases and as wavelength decreases.

Solution

Since visible light has a higher frequency than radio waves, it is higher in energy.

PROBLEM Which has higher energy, infrared radiation with $\lambda = 1.0 \times 10^{-6}$ m or an X ray with $\lambda = 3.0 \times 10^{-9}$ m?

12-5 Radiation with $\nu = 4.0 \times 10^9$ Hz or with $\lambda = 9.0 \times 10^{-6}$ m?

PROBLEM It's useful to develop a feeling for the amounts of energy that correspond to different parts of the electromagnetic spectrum. Calculate the energies in kJ/mol of each of the following kinds of radiation:

- 12-6**
- (a) A gamma ray with $\lambda = 5.0 \times 10^{-11}$ m
 - (b) An X ray with $\lambda = 3.0 \times 10^{-9}$ m
 - (c) Ultraviolet light with $\nu = 6.0 \times 10^{15}$ Hz
 - (d) Visible light with $\nu = 7.0 \times 10^{14}$ Hz
 - (e) Infrared radiation with $\lambda = 2.0 \times 10^{-5}$ m
 - (f) Microwave radiation with $\nu = 1.0 \times 10^{11}$ Hz

12.6 Infrared Spectroscopy

In **infrared (IR) spectroscopy**, the IR region of the electromagnetic spectrum covers the range from just above the visible (7.8×10^{-7} m) to approximately 10^{-4} m, but only the midportion from 2.5×10^{-6} m to 2.5×10^{-5} m

is used by organic chemists (FIGURE 12.20). Wavelengths within the IR region are usually given in micrometers ($1 \mu\text{m} = 10^{-6} \text{ m}$), and frequencies are given in wavenumbers rather than in hertz. The **wavenumber** $\tilde{\nu}$ is the reciprocal of wavelength in centimeters and is therefore expressed in units of cm^{-1} .

$$\text{Wavenumber: } \tilde{\nu} (\text{cm}^{-1}) = \frac{1}{\lambda (\text{cm})}$$

Thus, the useful IR region is from 4000 to 400 cm^{-1} , corresponding to energies of 48.0 kJ/mol to 4.80 kJ/mol (11.5 – 1.15 kcal/mol).

FIGURE 12.20 The infrared and adjacent regions of the electromagnetic spectrum.

Why does an organic molecule absorb some wavelengths of IR radiation but not others? All molecules have a certain amount of energy and are in constant motion. Their bonds stretch and contract, atoms wag back and forth, and other molecular vibrations occur. Some of the kinds of allowed vibrations are shown below:

The amount of energy a molecule contains is not continuously variable but is *quantized*. That is, a molecule can stretch or bend only at specific frequencies corresponding to specific energy levels. Take bond stretching, for example. Although we usually speak of bond lengths as if they were fixed, the numbers given are really averages. In fact, a typical C–H bond with an average bond length of 110 pm is actually vibrating at a specific frequency, alternately stretching and contracting as if there were a spring connecting the two atoms.

When a molecule is irradiated with electromagnetic radiation, energy is absorbed if the frequency of the radiation matches the frequency of the vibration. The result of this energy absorption is an increased amplitude for the vibration; in other words, the “spring” connecting the two atoms stretches and compresses a bit further. Since each frequency absorbed by a molecule corresponds to a specific molecular motion, we can find what kinds of motions a molecule has by measuring its IR spectrum. By interpreting these motions, we can find out what kinds of bonds (functional groups) are present in the molecule.

IR spectrum → What molecular motions? → What functional groups?

12.7 Interpreting Infrared Spectra

The complete interpretation of an IR spectrum is difficult because most organic molecules have dozens of different bond stretching and bending motions, and thus have dozens of absorptions. On the one hand, this complexity is a problem because it generally limits the laboratory use of IR spectroscopy to pure samples of fairly small molecules—little can be learned from IR spectroscopy about large, complex biomolecules. On the other hand, this complexity is useful because an IR spectrum acts as a unique fingerprint of a compound. In fact,

the complex region of the IR spectrum, from 1500 cm^{-1} to around 400 cm^{-1} , is called the *fingerprint region*. If two samples have identical IR spectra, they are almost certainly identical compounds.

Fortunately, we don't need to interpret an IR spectrum fully to get useful structural information. Most functional groups have characteristic IR absorption bands that don't change much from one compound to another. The C=O absorption of a ketone is almost always in the range 1680 to 1750 cm^{-1} ; the O–H absorption of an alcohol is almost always in the range 3400 to 3650 cm^{-1} ; the C=C absorption of an alkene is almost always in the range 1640 to 1680 cm^{-1} ; and so forth. By learning where characteristic functional-group absorptions occur, it's possible to get structural information from IR spectra. **TABLE 12.1** lists the characteristic IR bands of some common functional groups.

TABLE 12.1 Characteristic IR Absorptions of Some Functional Groups

Functional Group		Absorption (cm^{-1})	Intensity
Alkane	C–H	2850–2960	Medium
Alkene	=C–H	3020–3100	Medium
	C=C	1640–1680	Medium
Alkyne	$\equiv\text{C–H}$	3300	Strong
	$\text{C}\equiv\text{C}$	2100–2260	Medium
Alkyl halide	C–Cl	600–800	Strong
	C–Br	500–600	Strong
Alcohol	O–H	3400–3650	Strong, broad
	C–O	1050–1150	Strong
Arene	C–H	3030	Weak
Aromatic ring		1660–2000	Weak
		1450–1600	Medium
Amine	N–H	3300–3500	Medium
	C–N	1030–1230	Medium
Carbonyl compound	C=O	1670–1780	Strong
	Aldehyde	1730	Strong
	Ketone	1715	Strong
	Ester	1735	Strong
	Amide	1690	Strong
	Carboxylic acid	1710	Strong

TABLE 12.1 Characteristic IR Absorptions of Some Functional Groups

Functional Group		Absorption (cm^{-1})	Intensity
Carboxylic acid	O–H	2500–3100	Strong, broad
Nitrile	$\text{C}\equiv\text{N}$	2210–2260	Medium
Nitro	NO_2	1540	Strong

Look at the IR spectra of hexane, 1-hexene, and 1-hexyne in **FIGURE 12.21** to see an example of how IR spectroscopy can be used. Although all three IR spectra contain many peaks, there are characteristic absorptions of $\text{C}=\text{C}$ and $\text{C}\equiv\text{C}$ functional groups that allow the three compounds to be distinguished. Thus, 1-hexene shows a characteristic $\text{C}=\text{C}$ absorption at 1660 cm^{-1} and a vinylic $=\text{C}-\text{H}$ absorption at 3100 cm^{-1} , whereas 1-hexyne has a $\text{C}\equiv\text{C}$ absorption at 2100 cm^{-1} and a terminal alkyne $\equiv\text{C}-\text{H}$ absorption at 3300 cm^{-1} .

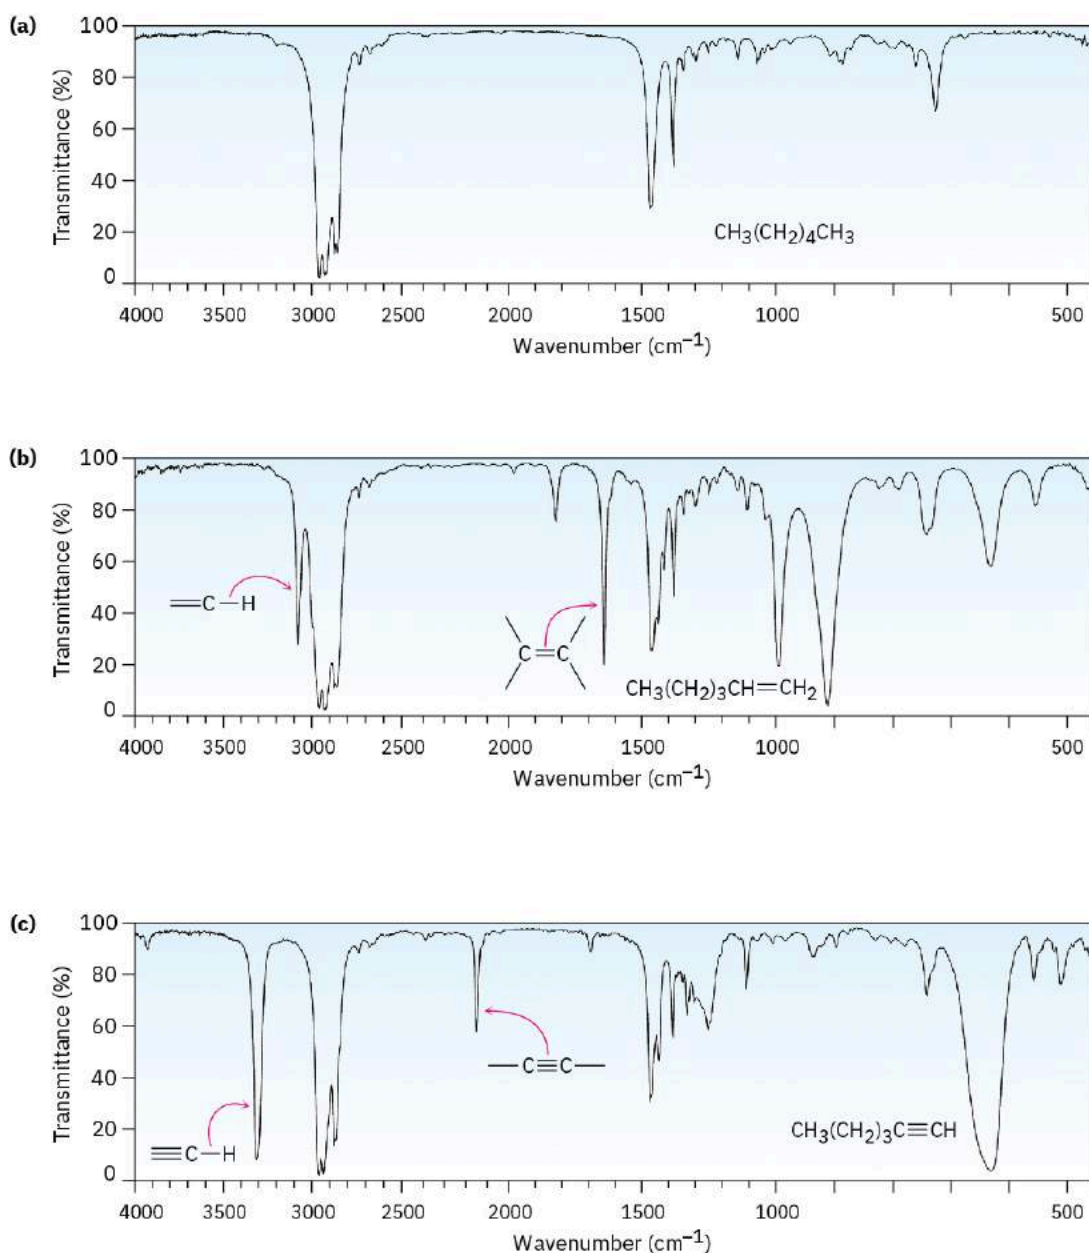

FIGURE 12.21 IR spectra of (a) hexane, (b) 1-hexene, and (c) 1-hexyne. Spectra like these are easily obtained from sub-milligram amounts of material in a few minutes using commercially available instruments.

It helps in remembering the position of specific IR absorptions to divide the IR region from 4000 cm^{-1} to 400 cm^{-1} into four parts, as shown in **FIGURE 12.22**.

FIGURE 12.22 The four regions of the infrared spectrum: single bonds to hydrogen, triple bonds, double bonds, and fingerprint.

- The region from 4000 to 2500 cm^{-1} corresponds to absorptions caused by N–H, C–H, and O–H single-bond stretching motions. N–H and O–H bonds absorb in the 3300 to 3600 cm^{-1} range; C–H bond stretching occurs near 3000 cm^{-1} .
- The region from 2500 to 2000 cm^{-1} is where triple-bond stretching occurs. Both $\text{C}\equiv\text{N}$ and $\text{C}\equiv\text{C}$ bonds absorb here.
- The region from 2000 to 1500 cm^{-1} is where double bonds ($\text{C}=\text{O}$, $\text{C}=\text{N}$, and $\text{C}=\text{C}$) absorb. Carbonyl groups generally absorb in the range 1680 to 1750 cm^{-1} , and alkene stretching normally occurs in the narrow range of 1640 to 1680 cm^{-1} .
- The region below 1500 cm^{-1} is the fingerprint portion of the IR spectrum. A large number of absorptions due to a variety of C–C, C–O, C–N, and C–X single-bond vibrations occur here.

Why do different functional groups absorb where they do? As noted previously, a good analogy is that of two weights (atoms) connected by a spring (a bond). Short, strong bonds vibrate at a higher energy and higher frequency than do long, weak bonds, just as a short, strong spring vibrates faster than a long, weak spring. Thus, triple bonds absorb at a higher frequency than double bonds, which in turn absorb at a higher frequency than single bonds. In addition, C–H, O–H, and N–H bonds vibrate at a higher frequency than bonds between heavier C, O, and N atoms.

WORKED EXAMPLE 12.4

Distinguishing Isomeric Compounds by IR Spectroscopy

Acetone (CH_3COCH_3) and 2-propen-1-ol ($\text{H}_2\text{C}=\text{CHCH}_2\text{OH}$) are isomers. How could you distinguish them by IR spectroscopy?

Strategy

Identify the functional groups in each molecule, and refer to **TABLE 12.1**.

Solution

Acetone has a strong $\text{C}=\text{O}$ absorption at 1715 cm^{-1} , while 2-propen-1-ol has an $-\text{OH}$ absorption at 3500 cm^{-1} and a $\text{C}=\text{C}$ absorption at 1660 cm^{-1} .

PROBLEM What functional groups might the following molecules contain?

- 12-7** (a) A compound with a strong absorption at 1710 cm^{-1}
 (b) A compound with a strong absorption at 1540 cm^{-1}
 (c) A compound with strong absorptions at 1720 cm^{-1} and 2500 to 3100 cm^{-1}

PROBLEM How might you use IR spectroscopy to distinguish between the following pairs of isomers?

- 12-8** (a) $\text{CH}_3\text{CH}_2\text{OH}$ and CH_3OCH_3 (b) Cyclohexane and 1-hexene
 (c) $\text{CH}_3\text{CH}_2\text{CO}_2\text{H}$ and $\text{HOCH}_2\text{CH}_2\text{CHO}$

12.8 Infrared Spectra of Some Common Functional Groups

As each functional group is discussed in future chapters, the spectroscopic properties of that group will be described. For the present, we'll point out some distinguishing features of the hydrocarbon functional groups already studied and briefly preview some other common functional groups. We should also point out, however, that in addition to interpreting absorptions that *are* present in an IR spectrum, it's also possible to get structural information by noticing which absorptions are *not* present. If the spectrum of a compound has no absorptions at 3300 and 2150 cm^{-1} , the compound is not a terminal alkyne; if the spectrum has no absorption near 3400 cm^{-1} , the compound is not an alcohol; and so on.

Alkanes

The IR spectrum of an alkane is fairly uninformative because no functional groups are present and all absorptions are due to C–H and C–C bonds. Alkane C–H bonds show a strong absorption from 2850 to 2960 cm^{-1} , and saturated C–C bonds show a number of bands in the 800 to 1300 cm^{-1} range. Since most organic compounds contain saturated alkane-like portions, most organic compounds have these characteristic IR absorptions. The C–H and C–C bands are clearly visible in the three spectra shown previously in **FIGURE 12.21**.

Alkenes

Alkenes show several characteristic stretching absorptions. Vinylic =C–H bonds absorb from 3020 to 3100 cm^{-1} , and alkene C=C bonds usually absorb near 1650 cm^{-1} , although in some cases their peaks can be rather small and difficult to see clearly when the alkene is symmetric, or nearly so. Both absorptions are visible in the 1-hexene spectrum in **FIGURE 12.21b**.

Alkenes have characteristic =C–H out-of-plane bending absorptions in the 700 to 1000 cm^{-1} range, thereby allowing the substitution pattern on a double bond to be determined (**FIGURE 12.23**). For example, monosubstituted alkenes such as 1-hexene show strong characteristic bands at 910 and 990 cm^{-1} , and 1,1-disubstituted alkenes ($\text{R}_2\text{C}=\text{CH}_2$) have an intense band at 890 cm^{-1} .

FIGURE 12.23 C–H out-of-plane bending vibrations for substituted alkenes.

Alkynes

Alkynes show a $\text{C}\equiv\text{C}$ stretching absorption at 2100 to 2260 cm^{-1} , an absorption that is much more intense for terminal alkynes than for internal alkynes. Terminal alkynes such as 1-hexyne also have a characteristic $\equiv\text{C}-\text{H}$ stretching absorption at 3300 cm^{-1} (FIGURE 12.21c). This band is diagnostic for terminal alkynes because it is fairly intense and quite sharp.

Aromatic Compounds

Aromatic compounds, such as benzene, have a weak $\text{C}-\text{H}$ stretching absorption at 3030 cm^{-1} , just to the left of a typical saturated $\text{C}-\text{H}$ band. In addition, they have a series of weak absorptions in the 1660 to 2000 cm^{-1} range and a series of medium-intensity absorptions in the 1450 to 1600 cm^{-1} region. These latter absorptions are due to complex molecular motions of the entire ring. The $\text{C}-\text{H}$ out-of-plane bending region for benzene derivatives, between 650 to 1000 cm^{-1} , gives valuable information about the ring's substitution pattern, as it does for the substitution pattern of alkenes (FIGURE 12.24).

FIGURE 12.24 C–H out-of-plane bending vibrations for substituted benzenes.

The IR spectrum of phenylacetylene, shown in Figure 12.29 at the end of this section, gives an example, clearly showing the following absorbances: $\equiv\text{C-H}$ stretch at 3300 cm^{-1} , C–H stretches from the benzene ring at 3000 to 3100 cm^{-1} , C=C stretches of the benzene ring between 1450 and 1600 cm^{-1} , and out-of-plane bending of the ring's C–H groups, indicating monosubstitution at 750 cm^{-1} .

Alcohols

The O–H functional group of alcohols is easy to spot. Alcohols have a characteristic band in the range 3400 to 3650 cm^{-1} that is usually broad and intense. Hydrogen bonding between O–H groups is responsible for making the absorbance so broad. If an O–H stretch is present, it's hard to miss this band or to confuse it with anything else.

Alcohols —O–H $3400\text{--}3650\text{ cm}^{-1}$ (broad, intense)

Cyclohexanol (FIGURE 12.25) is a good example.

FIGURE 12.25 IR spectrum of cyclohexanol.

Amines

The N–H functional group of amines is also easy to spot in the IR, with a characteristic absorption in the 3300 to 3500 cm^{-1} range. Although alcohols absorb in the same range, an N–H absorption band is much sharper and less intense than an O–H band.

Amines —N–H $3300\text{--}3500\text{ cm}^{-1}$ (sharp, medium intensity)

Primary amines (R-NH_2) have two absorbances—one for the symmetric stretching mode and one for the asymmetric mode (FIGURE 12.26). Secondary amines ($\text{R}_2\text{N-H}$) only have one N–H stretching absorbance in this

region.

FIGURE 12.26 IR spectrum of cyclohexylamine.

Carbonyl Compounds

Carbonyl functional groups are the easiest to identify of all IR absorptions because of their sharp, intense peak in the range 1670 to 1780 cm^{-1} . Most important, the exact position of absorption within this range can often be used to identify the exact kind of carbonyl functional group—aldehyde, ketone, ester, and so forth.

ALDEHYDES

Saturated aldehydes absorb at 1730 cm^{-1} ; aldehydes next to either a double bond or an aromatic ring absorb at 1705 cm^{-1} .

The C–H group attached to the carbonyl is responsible for the characteristic IR absorbance for aldehydes at 2750 and 2850 cm^{-1} (FIGURE 12.27). Although these are not very intense, the absorbance at 2750 cm^{-1} is helpful when trying to distinguish between an aldehyde and a ketone.

FIGURE 12.27 The IR spectrum of benzaldehyde.

KETONES

Saturated open-chain ketones and six-membered cyclic ketones absorb at 1715 cm^{-1} . Ring strain stiffens the C=O bond, making five-membered cyclic ketones absorb at 1750 cm^{-1} and four-membered cyclic ketones absorb at 1780 cm^{-1} , about 20 to 30 cm^{-1} lower than the corresponding saturated ketone.

ESTERS

Saturated esters have a C=O absorbance at 1735 cm^{-1} and two strong absorbances in the 1300 to 1000 cm^{-1} range from the C–O portion of the functional group. Like other carbonyl functional groups, esters next to either an aromatic ring or a double bond absorb at 1715 cm^{-1} , about 20 to 30 cm^{-1} lower than a saturated ester.

WORKED EXAMPLE 12.5

Predicting IR Absorptions of Compounds

Where might the following compounds have IR absorptions?

Strategy

Identify the functional groups in each molecule, and then check [TABLE 12.1](#) to see where those groups absorb.

Solution

(a) *Absorptions:* 3400 to 3650 cm^{-1} (O–H), 3020 to 3100 cm^{-1} (=C–H), 1640 to 1680 cm^{-1} (C=C). This molecule has an alcohol O–H group and an alkene double bond.

(b) *Absorptions:* 3300 cm^{-1} ($\equiv\text{C-H}$), 2100 to 2260 cm^{-1} ($\text{C}\equiv\text{C}$), 1735 cm^{-1} (C=O). This molecule has a terminal alkyne triple bond and a saturated ester carbonyl group.

WORKED EXAMPLE 12.6

Identifying Functional Groups from an IR Spectrum

The IR spectrum of an unknown compound is shown in [FIGURE 12.28](#). What functional groups does the compound contain?

FIGURE 12.28 IR spectrum for [Worked Example 12.6](#).

Strategy

All IR spectra have many absorptions, but those useful for identifying specific functional groups are usually found in the region from 1500 cm^{-1} to 3300 cm^{-1} . Pay particular attention to the carbonyl region (1670 to 1780

cm^{-1}), the aromatic region (1660 to 2000 cm^{-1}), the triple-bond region (2000 to 2500 cm^{-1}), and the C–H region (2500 to 3500 cm^{-1}).

Solution

The spectrum shows an intense absorption at 1725 cm^{-1} due to a carbonyl group (perhaps an aldehyde, $-\text{CHO}$), a series of weak absorptions from 1800 to 2000 cm^{-1} characteristic of aromatic compounds, and a C–H absorption near 3030 cm^{-1} , also characteristic of aromatic compounds. In fact, the compound is phenylacetaldehyde.

PROBLEM 12-9 The IR spectrum of phenylacetylene is shown in Figure 12.29. What absorption bands can you identify?

FIGURE 12.29 The IR spectrum of phenylacetylene, Problem 12-9.

PROBLEM 12-10 Where might the following compounds have IR absorptions?

(a)

(b)

(c)

PROBLEM 12-11 Where might the following compound have IR absorptions?

12-11

CHEMISTRY MATTERS

X-Ray Crystallography

The various spectroscopic techniques described in this and the next two chapters are enormously important in chemistry and have been fine-tuned to such a degree that the structure of almost any molecule can be found. Nevertheless, wouldn't it be nice if you could simply look at a molecule and "see" its structure with your eyes?

Determining the three-dimensional shape of an object around you is easy—you just look at it, let your eyes focus the light rays reflected from the object, and let your brain assemble the data into a recognizable image. If the object is small, you use a microscope and let the microscope lens focus the visible light. Unfortunately, there is a limit to what you can see, even with the best optical microscope. Called the diffraction limit, you can't see anything smaller than the wavelength of light you are using for the observation. Visible light has wavelengths of several hundred nanometers, but atoms in molecules have dimensions on the order of 0.1 nm. Thus, to see a molecule—whether a small one in the laboratory or a large, complex enzyme with a molecular weight in the tens of thousands—you need wavelengths in the 0.1 nm range, which corresponds to X rays.

Let's say that we want to determine the structure and shape of an enzyme or other biological molecule. The technique used is called **X-ray crystallography**. First, the molecule is crystallized (which often turns out to be the most difficult and time-consuming part of the entire process) and a small crystal of 0.4 to 0.5 mm on its longest axis is glued to the end of a glass fiber. The fiber and attached crystal are then mounted in an instrument called an X-ray diffractometer, which consists of a radiation source, a sample positioning and orienting device that can rotate the crystal in any direction, a detector, and a controlling computer.

Once mounted in the diffractometer, the crystal is irradiated with X rays, usually so-called $\text{CuK}\alpha$ radiation with a wavelength of 0.154 nm. When the X rays strike the enzyme crystal, they interact with electrons in the molecule and are scattered into a diffraction pattern which, when detected and visualized, appears as a series of intense spots against a null background.

FIGURE 12.30 The structure of human muscle fructose-1,6-bisphosphate aldolase, as determined by X-ray crystallography. (credit: modification of work Protein Data Bank, 1ALD. PDB ID: 1ALD, Gamblin, S.J. Davies, G.J. Grimes, J.M. Jackson, R.M. Littlechild, J.A. Watson, H.C. (1991) *J. Mol. Biol.* 219: 573-576, CC BY 1.0.)

Manipulation of the diffraction pattern to extract three-dimensional molecular data is a complex process, but the final result is an electron-density map of the molecule. Because electrons are largely localized around atoms, any two centers of electron density located within bonding distance of each other are assumed to represent bonded atoms, leading to a recognizable chemical structure. So important is this structural information for biochemistry that an online database of approximately 145,000 biological substances has been created. Operated by Rutgers University and funded by the U.S. National Science Foundation, the Protein Data Bank (PDB) is a worldwide repository for processing and distributing three-dimensional structural data for biological macromolecules. We'll see how to access the PDB in the Chapter 26 *Chemistry Matters*.

Summary

Finding the structure of a new molecule, whether a small one synthesized in the laboratory or a large protein found in living organisms, is central to the progression of chemistry and biochemistry. The structure of an organic molecule is usually determined using spectroscopic methods, including mass spectrometry and infrared spectroscopy. **Mass spectrometry (MS)** tells the molecular weight and formula of a molecule; **infrared (IR) spectroscopy** identifies the functional groups present in the molecule.

In small-molecule mass spectrometry, molecules are first ionized by collision with a high-energy electron beam. The ions then fragment into smaller pieces, which are magnetically sorted according to their mass-to-charge ratio (m/z). The ionized sample molecule is called the *molecular ion*, M^+ , and measurement of its mass gives the molecular weight of the sample. Structural clues about unknown samples can be obtained by interpreting the fragmentation pattern of the molecular ion. Mass-spectral fragmentations are usually complex, however, and interpretation is often difficult. In biological mass spectrometry, molecules are protonated using either electrospray ionization (ESI) or matrix-assisted laser desorption ionization (MALDI), and the protonated molecules are separated by time-of-flight (TOF) mass analysis.

Infrared spectroscopy involves the interaction of a molecule with **electromagnetic radiation**. When an organic molecule is irradiated with infrared energy, certain **frequencies** are absorbed by the molecule. The frequencies absorbed correspond to the amounts of energy needed to increase the amplitude of specific molecular vibrations such as bond stretching and bending. Since every functional group has a characteristic combination of bonds, every functional group has a characteristic set of infrared absorptions. For example, the terminal alkyne $\equiv\text{C}-\text{H}$ bond absorbs IR radiation of 3300 cm^{-1} , and the alkene $\text{C}=\text{C}$ bond absorbs in the range 1640 to 1680 cm^{-1} . By observing which frequencies of infrared radiation are absorbed by a molecule and which are not, it's possible to determine the functional groups a molecule contains.

Additional Problems

Visualizing Chemistry

PROBLEM Where in the IR spectrum would you expect each of the following molecules to absorb?

12-12

PROBLEM 12-13 Show the structures of the fragments you would expect in the mass spectra of the following molecules:

Mass Spectrometry

PROBLEM Propose structures for compounds that fit the following mass-spectral data:

- 12-14** (a) A hydrocarbon with $M^+ = 132$ (b) A hydrocarbon with $M^+ = 166$
 (c) A hydrocarbon with $M^+ = 84$

PROBLEM 12-15 Write molecular formulas for compounds that show the following molecular ions in their high-resolution mass spectra, assuming that C, H, N, and O might be present. The exact atomic masses are: 1.007 83 (^1H), 12.000 00 (^{12}C), 14.003 07 (^{14}N), 15.994 91 (^{16}O).

- (a) $M^+ = 98.0844$ (b) $M^+ = 123.0320$

PROBLEM 12-16 Camphor, a saturated monoketone from the Asian camphor tree, is used among other things as a moth repellent and as a constituent of embalming fluid. If camphor has $M^+ = 152.1201$ by high-resolution mass spectrometry, what is its molecular formula? How many rings does camphor have?

PROBLEM 12-17 The nitrogen rule of mass spectrometry says that a compound containing an odd number of nitrogens has an odd-numbered molecular ion. Conversely, a compound containing an even number of nitrogens has an even-numbered M^+ peak. Explain.

PROBLEM 12-18 In light of the nitrogen rule mentioned in Problem 12-17, what is the molecular formula of pyridine, $M^+ = 79$?

PROBLEM 12-19 Nicotine is a diamino compound isolated from dried tobacco leaves. Nicotine has two rings and $M^+ = 162.1157$ by high-resolution mass spectrometry. Give a molecular formula for nicotine, and calculate the number of double bonds.

PROBLEM 12-20 The hormone cortisone contains C, H, and O, and shows a molecular ion at $M^+ = 360.1937$ by high-resolution mass spectrometry. What is the molecular formula of cortisone? (The degree of unsaturation for cortisone is 8.)

PROBLEM 12-21 Halogenated compounds are particularly easy to identify by their mass spectra because both chlorine and bromine occur naturally as mixtures of two abundant isotopes. Recall that chlorine occurs as ^{35}Cl (75.8%) and ^{37}Cl (24.2%); and bromine occurs as ^{79}Br (50.7%) and ^{81}Br (49.3%). At what masses do the molecular ions occur for the following formulas? What are the relative percentages of each molecular ion?

- (a) Bromomethane, CH_3Br (b) 1-Chlorohexane, $\text{C}_6\text{H}_{13}\text{Cl}$

PROBLEM By knowing the natural abundances of minor isotopes, it's possible to calculate the relative heights of M^+ and $M + 1$ peaks. If ^{13}C has a natural abundance of 1.10%, what are the relative heights of the M^+ and $M + 1$ peaks in the mass spectrum of benzene, C_6H_6 ?

12-22

PROBLEM Propose structures for compounds that fit the following data:

12-23 (a) A ketone with $M^+ = 86$ and fragments at $m/z = 71$ and $m/z = 43$

(b) An alcohol with $M^+ = 88$ and fragments at $m/z = 73$, $m/z = 70$, and $m/z = 59$

PROBLEM 2-Methylpentane (C_6H_{14}) has the mass spectrum shown. Which peak represents M^+ ? Which is the base peak? Propose structures for fragment ions of $m/z = 71$, 57, 43, and 29. Why does the base peak have the mass it does?

12-24

PROBLEM Assume that you are in a laboratory carrying out the catalytic hydrogenation of cyclohexene to cyclohexane. How could you use a mass spectrometer to determine when the reaction is finished?

12-25

PROBLEM What fragments might you expect in the mass spectra of the following compounds?

12-26 (a)

(b)

(c)

Infrared Spectroscopy

PROBLEM How might you use IR spectroscopy to distinguish among the three isomers 1-butyne, 1,3-butadiene, and 2-butyne?

12-27

PROBLEM Would you expect two enantiomers such as (*R*)-2-bromobutane and (*S*)-2-bromobutane to have identical or different IR spectra? Explain.

12-28

PROBLEM Would you expect two diastereomers such as *meso*-2,3-dibromobutane and (*2R,3R*)-dibromobutane to have identical or different IR spectra? Explain.

12-29

PROBLEM Propose structures for compounds that meet the following descriptions:

- 12-30 (a)** C_5H_8 , with IR absorptions at 3300 and 2150 cm^{-1}
(b) $\text{C}_4\text{H}_8\text{O}$, with a strong IR absorption at 3400 cm^{-1}
(c) $\text{C}_4\text{H}_8\text{O}$, with a strong IR absorption at 1715 cm^{-1}
(d) C_8H_{10} , with IR absorptions at 1600 and 1500 cm^{-1}

PROBLEM How could you use infrared spectroscopy to distinguish between the following pairs of isomers?

- 12-31 (a)** $\text{HC}\equiv\text{CCH}_2\text{NH}_2$ and $\text{CH}_3\text{CH}_2\text{C}\equiv\text{N}$ **(b)** CH_3COCH_3 and $\text{CH}_3\text{CH}_2\text{CHO}$

PROBLEM Two infrared spectra are shown. One is the spectrum of cyclohexane, and the other is the spectrum of cyclohexene. Identify them, and explain your answer.

12-32

PROBLEM At what approximate positions might the following compounds show IR absorptions?

PROBLEM How would you use infrared spectroscopy to distinguish between the following pairs of constitutional isomers?

PROBLEM At what approximate positions might the following compounds show IR absorptions?

PROBLEM Assume that you are carrying out the dehydration of 1-methylcyclohexanol to yield 1-methylcyclohexene. How could you use infrared spectroscopy to determine when the reaction is complete?

12-36

PROBLEM 12-37 Assume that you are carrying out the base-induced dehydrobromination of 3-bromo-3-methylpentane (Section 11.7) to yield an alkene. How could you use IR spectroscopy to tell which of three possible elimination products is formed, if one includes *E/Z* isomers?

General Problems

PROBLEM 12-38 Which is stronger, the C=O bond in an ester (1735 cm^{-1}) or the C=O bond in a saturated ketone (1715 cm^{-1})? Explain.

PROBLEM 12-39 Carvone is an unsaturated ketone responsible for the odor of spearmint. If carvone has $M^+ = 150$ in its mass spectrum and contains three double bonds and one ring, what is its molecular formula?

PROBLEM 12-40 Carvone (Problem 12-39) has an intense infrared absorption at 1690 cm^{-1} . What kind of ketone does carvone contain?

PROBLEM 12-41 The mass spectrum (a) and the infrared spectrum (b) of an unknown hydrocarbon are shown. Propose as many structures as you can.

PROBLEM 12-42 The mass spectrum (a) and the infrared spectrum (b) of another unknown hydrocarbon are shown. Propose as many structures as you can.

PROBLEM Propose structures for compounds that meet the following descriptions:

- 12-43** (a) An optically active compound $C_5H_{10}O$ with an IR absorption at 1730 cm^{-1}
 (b) A non-optically active compound C_5H_9N with an IR absorption at 2215 cm^{-1}

PROBLEM 4-Methyl-2-pentanone and 3-methylpentanal are isomers. Explain how you could tell them apart,
12-44 both by mass spectrometry and by infrared spectroscopy.

4-Methyl-2-pentanone

3-Methylpentanal

PROBLEM Grignard reagents (alkylmagnesium halides) undergo a general and very useful reaction with
12-45 ketones. Methylmagnesium bromide, for example, reacts with cyclohexanone to yield a product with the formula $C_7H_{14}O$. What is the structure of this product if it has an IR absorption at 3400 cm^{-1} ?

Cyclohexanone

PROBLEM Ketones undergo a reduction when treated with sodium borohydride, $NaBH_4$. What is the structure
12-46 of the compound produced by reaction of 2-butanone with $NaBH_4$ if it has an IR absorption at 3400 cm^{-1} and $M^+ = 74$ in the mass spectrum?

2-Butanone

PROBLEM Nitriles, $R-C\equiv N$, undergo a hydrolysis reaction when heated with aqueous acid. What is the
12-47 structure of the compound produced by hydrolysis of propanenitrile, $CH_3CH_2C\equiv N$, if it has IR absorptions from $2500\text{--}3100\text{ cm}^{-1}$ and at 1710 cm^{-1} , and has $M^+ = 74$?

PROBLEM The infrared spectrum of the compound with the following mass spectrum lacks any significant
12-48 absorption above 3000 cm^{-1} . There is a prominent peak near 1740 cm^{-1} and another strong peak near 1200 cm^{-1} . Propose a structure.

PROBLEM 12-49 The infrared spectrum of the compound with the following mass spectrum has a medium-intensity peak at about 1650 cm^{-1} . There is also a C-H out-of-plane bending peak near 880 cm^{-1} . Propose a structure.

PROBLEM 12-50 The infrared spectrum of the compound with the following mass spectrum has strong absorbances at 1584 , 1478 , and 1446 cm^{-1} . Propose a structure.

WHY THIS CHAPTER? Nuclear magnetic resonance (NMR) spectroscopy has far-reaching applications in many scientific fields, particularly in chemical structure determination. Although we'll just give an overview of the subject in this chapter, focusing on NMR applications with small molecules, more advanced NMR techniques are also used in biological chemistry to study protein structure and folding.

Nuclear magnetic resonance (NMR) spectroscopy is the most valuable spectroscopic technique available to organic chemists. It's the method of structure determination that organic chemists usually turn to first.

We saw in the chapter on **Structure Determination: Mass Spectrometry and Infrared Spectroscopy** that mass spectrometry gives a molecule's formula and infrared spectroscopy identifies a molecule's functional groups. Nuclear magnetic resonance spectroscopy complements these other techniques by mapping a molecule's carbon–hydrogen framework. Taken together, MS, IR, and NMR make it possible to determine the structures of even very complex molecules.

Mass spectrometry	Molecular size and formula
Infrared spectroscopy	Functional groups present
NMR spectroscopy	Map of carbon–hydrogen framework

13.1 Nuclear Magnetic Resonance Spectroscopy

Many kinds of nuclei behave as if they were spinning about an axis, somewhat as the earth spins daily. Because they're positively charged, these spinning nuclei act like tiny magnets and can interact with an external magnetic field, denoted B_0 . Not all nuclei act this way, but fortunately for organic chemists, both the proton (^1H) and the ^{13}C nucleus do have spins. The more common ^{12}C isotope, however, does not have nuclear spin. (In speaking about NMR, the words *proton* and *hydrogen* are often used interchangeably, since a hydrogen nucleus is just a proton.) Let's see what the consequences of nuclear spin are and how we can use the results.

In the absence of an external magnetic field, the spins of magnetic nuclei are oriented randomly. When a sample containing these nuclei is placed between the poles of a strong magnet, however, the nuclei adopt specific orientations, much as a compass needle orients in the earth's magnetic field. A spinning ^1H or ^{13}C nucleus can orient so that its own tiny magnetic field is aligned either with (parallel to) or against (antiparallel to) the external field. The two orientations don't have the same energy, however, and aren't equally likely. The parallel orientation is slightly lower in energy by an amount that depends on the strength of the external field, making this spin state very slightly favored over the antiparallel orientation (**FIGURE 13.2**).

FIGURE 13.2 (a) Nuclear spins are oriented randomly in the absence of an external magnetic field but (b) have a specific orientation in the presence of an external field, B_0 . Some of the spins (red) are aligned parallel to the external field while others (blue) are antiparallel. The parallel spin state is slightly lower in energy and therefore favored.

If the oriented nuclei are irradiated with electromagnetic radiation of the proper frequency, energy absorption occurs and the lower-energy spin state “flips” to the higher-energy state. When this spin-flip occurs, the magnetic nuclei are said to be in resonance with the applied radiation—hence the name *nuclear magnetic resonance*.

The exact frequency necessary for resonance depends both on the strength of the external magnetic field, the identity of the nucleus, and the electronic environment of the nucleus. If a very strong magnetic field is applied, the energy difference between the two spin states is larger and higher-frequency (higher-energy) radiation is required for a spin-flip. If a weaker magnetic field is applied, less energy is required to effect the transition between nuclear spin states (**FIGURE 13.3**).

FIGURE 13.3 The energy difference ΔE between nuclear spin states depends on the strength of the applied magnetic field. Absorption of energy with frequency ν converts a nucleus from a lower spin state to a higher spin state. **(a)** Spin states have equal energies in the absence of an applied magnetic field but **(b)** have unequal energies in the presence of a magnetic field. At $\nu = 200$ MHz, $\Delta E = 8.0 \times 10^{-5}$ kJ/mol (1.9×10^{-5} kcal/mol). **(c)** The energy difference between spin states is greater at larger applied fields. At $\nu = 500$ MHz, $\Delta E = 2.0 \times 10^{-4}$ kJ/mol.

In practice, superconducting magnets that produce enormously powerful fields up to 23.5 tesla (T) are sometimes used, but field strengths in the range of 4.7 to 7.0 T are more common. At a magnetic field strength of 4.7 T, so-called radiofrequency (rf) energy in the 200 MHz range ($1 \text{ MHz} = 10^6 \text{ Hz}$) brings a ^1H nucleus into resonance, and rf energy of 50 MHz brings a ^{13}C nucleus into resonance. At the highest field strength currently available in commercial instruments (23.5 T), 1000 MHz energy is required for ^1H spectroscopy. These energies needed for NMR are much smaller than those required for IR spectroscopy; 200 MHz rf energy corresponds to only 8.0×10^{-5} kJ/mol versus the 4.8 to 48 kJ/mol needed for IR spectroscopy.

^1H and ^{13}C nuclei are not unique in their ability to exhibit the NMR phenomenon. All nuclei with an odd number of protons (^1H , ^2H , ^{14}N , ^{19}F , ^{31}P , for example) and all nuclei with an odd number of neutrons (^{13}C , for example) show magnetic properties. Only nuclei with even numbers of both protons and neutrons (^{12}C , ^{16}O , ^{32}S) do not give rise to magnetic phenomena (TABLE 13.1).

TABLE 13.1 The NMR Behavior of Some Common Nuclei

Magnetic nuclei	Nonmagnetic nuclei
^1H	^{12}C
^{13}C	^{16}O
^2H	^{32}S
^{14}N	
^{19}F	
^{31}P	

PROBLEM The amount of energy required to spin-flip a nucleus depends both on the strength of the external magnetic field and on the nucleus. At a field strength of 4.7 T, rf energy of 200 MHz is required to bring a ^1H nucleus into resonance, but energy of only 187 MHz will bring a ^{19}F nucleus into resonance. Calculate the amount of energy required to spin-flip a ^{19}F nucleus. Is this amount greater or less than that required to spin-flip a ^1H nucleus?

PROBLEM Calculate the amount of energy required to spin-flip a proton in a spectrometer operating at 300 MHz. Does increasing the spectrometer frequency from 200 to 300 MHz increase or decrease the amount of energy necessary for resonance?

13.2 The Nature of NMR Absorptions

From the description thus far, you might expect all ^1H nuclei in a molecule to absorb energy at the same frequency and all ^{13}C nuclei to absorb at the same frequency. If so, we would observe only a single NMR absorption signal in the ^1H or ^{13}C spectrum of a molecule, a situation that would be of little use. In fact, the absorption frequency is not the same for all ^1H or all ^{13}C nuclei.

All nuclei in molecules are surrounded by electrons. When an external magnetic field is applied to a molecule, the electrons moving around nuclei set up tiny local magnetic fields of their own. These local magnetic fields act in opposition to the applied field so that the effective field actually felt by the nucleus is a bit weaker than the applied field.

$$B_{\text{effective}} = B_{\text{applied}} - B_{\text{local}}$$

In describing this effect of local fields, we say that nuclei experience **shielding** from the full effect of the applied field by the surrounding electrons. Because each chemically distinct nucleus in a molecule is in a slightly different electronic environment, each nucleus is shielded to a slightly different extent and the effective magnetic field felt by each is slightly different. These tiny differences in the effective magnetic fields experienced by different nuclei can be detected, and we thus see a distinct NMR signal for each chemically distinct ^{13}C or ^1H nucleus in a molecule. As a result, an NMR spectrum effectively maps the carbon–hydrogen framework of an organic molecule. With practice, it's possible to read this map and derive structural information.

FIGURE 13.4 shows both the ^1H and the ^{13}C NMR spectra of methyl acetate, $\text{CH}_3\text{CO}_2\text{CH}_3$. The horizontal axis shows the effective field strength felt by the nuclei, and the vertical axis indicates the intensity of absorption of rf energy. Each peak in the NMR spectrum corresponds to a chemically distinct ^1H or ^{13}C nucleus in the molecule. Note that NMR spectra are formatted with the zero absorption line at the bottom, whereas IR spectra are formatted with the zero absorption line at the top; **Section 12.5**. Note also that ^1H and ^{13}C spectra can't be observed simultaneously on the same spectrometer because different amounts of energy are required to spin-flip the different kinds of nuclei. The two spectra must be recorded separately.

FIGURE 13.4 (a) The ^1H NMR spectrum and (b) the proton-decoupled ^{13}C NMR spectrum of methyl acetate, $\text{CH}_3\text{CO}_2\text{CH}_3$. The small peak

labeled “TMS” at the far right of each spectrum is a calibration peak, as explained in the next section.

The ^{13}C NMR spectrum of methyl acetate in **FIGURE 13.4b** shows three peaks, one for each of the three chemically distinct carbon atoms in the molecule. The ^1H NMR spectrum in **FIGURE 13.4a** shows only two peaks, however, even though methyl acetate has six hydrogens. One peak is due to the $\text{CH}_3\text{C}=\text{O}$ hydrogens, and the other to the $-\text{OCH}_3$ hydrogens. Because the three hydrogens in each methyl group have the same electronic environment, they are shielded to the same extent and are said to be equivalent. Chemically equivalent nuclei always show the same absorption. The two methyl groups themselves, however, are not equivalent, so the two sets of hydrogens absorb at different positions.

The operation of a basic NMR spectrometer is illustrated in **FIGURE 13.5**. An organic sample is dissolved in a suitable solvent (usually deuteriochloroform, CDCl_3 , which has no hydrogens) and placed in a thin glass tube between the poles of a magnet. The strong magnetic field causes the ^1H and ^{13}C nuclei in the molecule to align in one of the two possible orientations, and the sample is irradiated with rf energy. If the frequency of the rf irradiation is held constant and the strength of the applied magnetic field is varied, each nucleus comes into resonance at a slightly different field strength. A sensitive detector monitors the absorption of rf energy, and its electronic signal is then amplified and displayed as a peak.

FIGURE 13.5 Schematic operation of a basic NMR spectrometer. A thin glass tube containing the sample solution is placed between the poles of a strong magnet and irradiated with rf energy.

NMR spectroscopy differs from IR spectroscopy (**Section 12.6–Section 12.8**) in that the timescales of the two techniques are quite different. The absorption of infrared energy by a molecule giving rise to a change in vibrational amplitude is an essentially instantaneous process (about 10^{-13} s), but the NMR process is much slower (about 10^{-3} s). This difference in timescales between IR and NMR spectroscopy is analogous to the difference between cameras operating at very fast and very slow shutter speeds. The fast camera (IR) takes an instantaneous picture and freezes the action. If two rapidly interconverting species are present, IR spectroscopy records the spectrum of both. The slow camera (NMR), however, takes a blurred, time-averaged picture. If two species interconverting faster than 10^3 times per second are present in a sample, NMR records only a single, averaged spectrum, rather than separate spectra of the two discrete species.

Because of this blurring effect, NMR spectroscopy can be used to measure the rates and activation energies of very fast chemical processes. In cyclohexane, for example, a ring-flip (**Section 4.6**) occurs so rapidly at room temperature that axial and equatorial hydrogens can't be distinguished by NMR; only a single, averaged ^1H NMR absorption is seen for cyclohexane at 25 °C. At -90 °C, however, the ring-flip is slowed down enough that two absorption peaks are visible, one for the six axial hydrogens and one for the six equatorial hydrogens. Knowing the temperature and the rate at which signal blurring begins to occur, it's possible to calculate that the activation energy for the cyclohexane ring-flip is 45 kJ/mol (10.8 kcal/mol).

PROBLEM 2-Chloropropene shows signals for three kinds of protons in its $^1\text{H NMR}$ spectrum. Explain.

13-3

13.3 Chemical Shifts

NMR spectra are displayed on charts that show the applied field strength increasing from left to right (**FIGURE 13.6**). Thus, the left part of the chart is the low-field, or **downfield**, side, and the right part is the high-field, or **upfield**, side. Nuclei that absorb on the downfield side of the chart require a lower field strength for resonance, implying that they have less shielding. Nuclei that absorb on the upfield side require a higher field strength for resonance, implying that they have more shielding.

FIGURE 13.6 The NMR chart. The downfield, deshielded side is on the left, and the upfield, shielded side is on the right. The tetramethylsilane (TMS) absorption is used as reference point.

To define the position of an absorption, the NMR chart is calibrated and a reference point is used. In practice, a small amount of tetramethylsilane [TMS; $(\text{CH}_3)_4\text{Si}$] is added to the sample so that a reference absorption peak is produced when the spectrum is run. TMS is used as reference for both ^1H and ^{13}C measurements because in both cases it produces a single peak that occurs upfield of other absorptions normally found in organic compounds. The ^1H and ^{13}C spectra of methyl acetate in **FIGURE 13.4** have the TMS reference peak indicated.

The position on the chart at which a nucleus absorbs is called its **chemical shift**. The chemical shift of TMS is set as the zero point, and other absorptions normally occur downfield, to the left on the chart. NMR charts are calibrated using an arbitrary scale called the **delta (δ) scale**, where 1 δ equals 1 part-per-million (1 ppm) of the spectrometer operating frequency. For example, if we were measuring the ^1H NMR spectrum of a sample using an instrument operating at 200 MHz, 1 δ would be 1 part per million of 200,000,000 Hz, or 200 Hz. If we were measuring the spectrum using a 500 MHz instrument, 1 δ = 500 Hz. The following equation can be used for any absorption:

$$\delta = \frac{\text{Observed chemical shift (number of Hz away from TMS)}}{\text{Spectrometer frequency in MHz}}$$

Although this method of calibrating NMR charts may seem complex, there's a good reason for it. As we saw earlier, the rf frequency required to bring a given nucleus into resonance depends on the spectrometer's magnetic field strength. But because there are many different kinds of spectrometers with many different magnetic field strengths available, chemical shifts given in frequency units (Hz) vary from one instrument to another. Thus, a resonance that occurs at 120 Hz downfield from TMS on one spectrometer might occur at 600 Hz downfield from TMS on another spectrometer with a more powerful magnet.

By using a system of measurement in which NMR absorptions are expressed in relative terms (parts per million relative to spectrometer frequency) rather than absolute terms (Hz), it's possible to compare spectra obtained

on different instruments. *The chemical shift of an NMR absorption in δ units is constant, regardless of the operating frequency of the spectrometer.* A ^1H nucleus that absorbs at 2.0 δ on a 200 MHz instrument also absorbs at 2.0 δ on a 500 MHz instrument.

The range in which most NMR absorptions occur is quite narrow. Almost all ^1H NMR absorptions occur from 0 to 10 δ downfield from the proton absorption of TMS, and almost all ^{13}C absorptions occur from 1 to 220 δ downfield from the carbon absorption of TMS. Thus, there is a likelihood that accidental overlap of nonequivalent signals will occur. The advantage of using an instrument with higher field strength (say, 500 MHz) rather than lower field strength (200 MHz) is that different NMR absorptions are more widely separated at the higher field strength. The chances that two signals will accidentally overlap are therefore lessened, and interpretation of spectra becomes easier. For example, two signals that are only 20 Hz apart at 200 MHz (0.1 ppm) are 50 Hz apart at 500 MHz (still 0.1 ppm).

PROBLEM 13-4 The following ^1H NMR peaks were recorded on a spectrometer operating at 200 MHz. Convert each into δ units.

- (a) CHCl_3 ; 1454 Hz (b) CH_3Cl ; 610 Hz (c) CH_3OH ; 693 Hz (d) CH_2Cl_2 ; 1060 Hz

PROBLEM 13-5 When the ^1H NMR spectrum of acetone, CH_3COCH_3 , is recorded on an instrument operating at 200 MHz, a single sharp resonance at 2.1 δ is seen.

- (a) How many hertz downfield from TMS does the acetone resonance correspond to?
 (b) If the ^1H NMR spectrum of acetone is recorded at 500 MHz, what would the position of the absorption be in δ units?
 (c) How many hertz downfield from TMS does this 500 MHz resonance correspond to?

13.4 Chemical Shifts in ^1H NMR Spectroscopy

As mentioned previously, differences in chemical shifts are caused by the small local magnetic field of electrons surrounding different nuclei. Nuclei that are more strongly shielded by electrons require a higher applied field to bring them into resonance so they absorb on the right side of the NMR chart. Nuclei that are less strongly shielded need a lower applied field for resonance so they absorb on the left of the NMR chart.

Most ^1H chemical shifts fall within the range 0 to 10 δ , which can be divided into the five regions shown in **TABLE 13.2**. By remembering the positions of these regions, it's often possible to tell at a glance what kinds of protons a molecule contains.

TABLE 13.2 Regions of the ^1H NMR Spectrum

TABLE 13.3 shows the correlation of ^1H chemical shift with electronic environment in more detail. In general, protons bonded to saturated, sp^3 -hybridized carbons absorb at higher fields, whereas protons bonded to sp^2 -hybridized carbons absorb at lower fields. Protons on carbons that are bonded to electronegative atoms, such as N, O, or halogen, also absorb at lower fields.

TABLE 13.3 Correlation of ^1H Chemical Shifts with Environment

Type of hydrogen		Chemical shift (δ)
Reference	$\text{Si}(\text{CH}_3)_4$	0
Alkyl (primary)	$-\text{CH}_3$	0.7–1.3
Alkyl (secondary)	$-\text{CH}_2-$	1.2–1.6
Alkyl (tertiary)	$\begin{array}{c} \\ -\text{CH}- \\ \end{array}$	1.4–1.8
Allylic	$\begin{array}{c} \text{H} \\ \\ \text{C}=\text{C}-\text{C}- \\ \end{array}$	1.6–2.2
Methyl ketone	$\begin{array}{c} \text{O} \\ \\ -\text{C}-\text{CH}_3 \end{array}$	2.0–2.4
Aromatic methyl	$\text{Ar}-\text{CH}_3$	2.4–2.7
Alkynyl	$-\text{C} \equiv \text{C}-\text{H}$	2.5–3.0
Alkyl halide	$\begin{array}{c} \text{H} \\ \\ -\text{C}-\text{Hal} \\ \end{array}$	2.5–4.0
Alcohol	$\begin{array}{c} \\ -\text{C}-\text{O}-\text{H} \\ \end{array}$	2.5–5.0
Alcohol, ether	$\begin{array}{c} \text{H} \\ \\ -\text{C}-\text{O}- \\ \end{array}$	3.3–4.5
Vinylic	$\begin{array}{c} \text{H} \\ \\ \text{C}=\text{C} \\ / \quad \backslash \end{array}$	4.5–6.5
Aryl	$\text{Ar}-\text{H}$	6.5–8.0
Aldehyde	$\begin{array}{c} \text{O} \\ \\ -\text{C}-\text{H} \end{array}$	9.7–10.0
Carboxylic acid	$\begin{array}{c} \text{O} \\ \\ -\text{C}-\text{O}-\text{H} \end{array}$	11.0–12.0

WORKED EXAMPLE 13.1

Predicting Chemical Shifts in ^1H NMR Spectra

Methyl 2,2-dimethylpropanoate ($\text{CH}_3)_2\text{CCO}_2\text{CH}_3$ has two peaks in its ^1H NMR spectrum. What are their approximate chemical shifts?

Strategy

Identify the types of hydrogens in the molecule, and note whether each is alkyl, vinylic, or next to an electronegative atom. Then predict where each absorbs, using TABLE 13.3 if necessary.

Solution

The $-\text{OCH}_3$ protons absorb around 3.5 to 4.0 δ because they are on carbon bonded to oxygen. The $(\text{CH}_3)_3\text{C}-$ protons absorb near 1.0 δ because they are typical alkane-like protons.

PROBLEM 13-6 Each of the following compounds has a single ^1H NMR peak. Approximately where would you expect each compound to absorb?

PROBLEM 13-7 Identify the different types of protons in the following molecule, and tell where you would expect each to absorb:

13.5 Integration of ^1H NMR Absorptions: Proton Counting

Look at the ^1H NMR spectrum of methyl 2,2-dimethylpropanoate in FIGURE 13.7. There are two peaks, corresponding to the two kinds of protons, but the peaks aren't the same size. The peak at 1.2 δ , due to the $(\text{CH}_3)_3\text{C}-$ protons, is larger than the peak at 3.7 δ , due to the $-\text{OCH}_3$ protons.

FIGURE 13.7 The ^1H NMR spectrum of methyl 2,2-dimethylpropanoate. Integrating the peaks in a stair-step manner shows that they have a 1 : 3 ratio, corresponding to the ratio of the numbers of protons (3 : 9) responsible for each peak. Modern instruments give a direct digital readout of relative peak areas.

The area under each peak is proportional to the number of protons causing that peak. By electronically measuring, or **integrating**, the area under each peak, it's possible to measure the relative numbers of the different kinds of protons in a molecule.

Modern NMR instruments provide a digital readout of relative peak areas, but an older, more visual method displays the integrated peak areas as a stair-step line, with the height of each step proportional to the area under the peak, and therefore proportional to the relative number of protons causing the peak. For example, the two steps for the peaks in methyl 2,2-dimethylpropanoate have a 1 : 3 (or 3 : 9) height ratio when integrated—exactly what we expect because the three $-\text{OCH}_3$ protons are equivalent and the nine $(\text{CH}_3)_3\text{C}-$ protons are equivalent.

PROBLEM 13-8 How many peaks would you expect in the ^1H NMR spectrum of 1,4-dimethylbenzene (*para*-xylene, or *p*-xylene)? What ratio of peak areas would you expect on integration of the spectrum? Refer to Table 13.3 for approximate chemical shifts, and sketch what the spectrum would look like. (Remember from **Section 2.4** that aromatic rings have two resonance forms.)

13.6 Spin-Spin Splitting in ^1H NMR Spectra

In the ^1H NMR spectra we've seen thus far, each different kind of proton in a molecule has given rise to a single peak. It often happens, though, that the absorption of a proton splits into multiple peaks, called a **multiplet**. For example, in the ^1H NMR spectrum of bromoethane shown in **FIGURE 13.8**, the $-\text{CH}_2\text{Br}$ protons appear as four peaks (a *quartet*) centered at $3.42\ \delta$ and the $-\text{CH}_3$ protons appear as three peaks (a *triplet*) centered at $1.68\ \delta$.

FIGURE 13.8 The ^1H NMR spectrum of bromoethane, $\text{CH}_3\text{CH}_2\text{Br}$. The $-\text{CH}_2\text{Br}$ protons appear as a quartet at $3.42\ \delta$, and the $-\text{CH}_3$ protons appear as a triplet at $1.68\ \delta$.

Called **spin-spin splitting**, multiple absorptions of a nucleus are caused by the interaction, or **coupling**, of the spins of nearby nuclei. In other words, the tiny magnetic field produced by one nucleus affects the magnetic field felt by a neighboring nucleus. Look at the $-\text{CH}_3$ protons in bromoethane, for example. The three equivalent $-\text{CH}_3$ protons are neighbored by two other magnetic nuclei—the two protons on the adjacent $-\text{CH}_2\text{Br}$ group. Each of the neighboring $-\text{CH}_2\text{Br}$ protons has its own nuclear spin, which can align either with or against the applied field, producing a tiny effect that is felt by the $-\text{CH}_3$ protons.

There are three ways in which the spins of the two $-\text{CH}_2\text{Br}$ protons can align, as shown in **FIGURE 13.9**. If both proton spins align with the applied field, the total effective field felt by the neighboring $-\text{CH}_3$ protons is slightly larger than it would be otherwise. Consequently, the applied field necessary to cause resonance is slightly reduced. Alternatively, if one of the $-\text{CH}_2\text{Br}$ proton spins aligns with the field and one aligns against the field, there is no effect on the neighboring $-\text{CH}_3$ protons. (This arrangement can occur in two ways, depending on which of the two proton spins aligns which way.) Finally, if both $-\text{CH}_2\text{Br}$ proton spins align against the applied field, the effective field felt by the $-\text{CH}_3$ protons is slightly smaller than it would be otherwise, and the applied field needed for resonance is slightly increased.

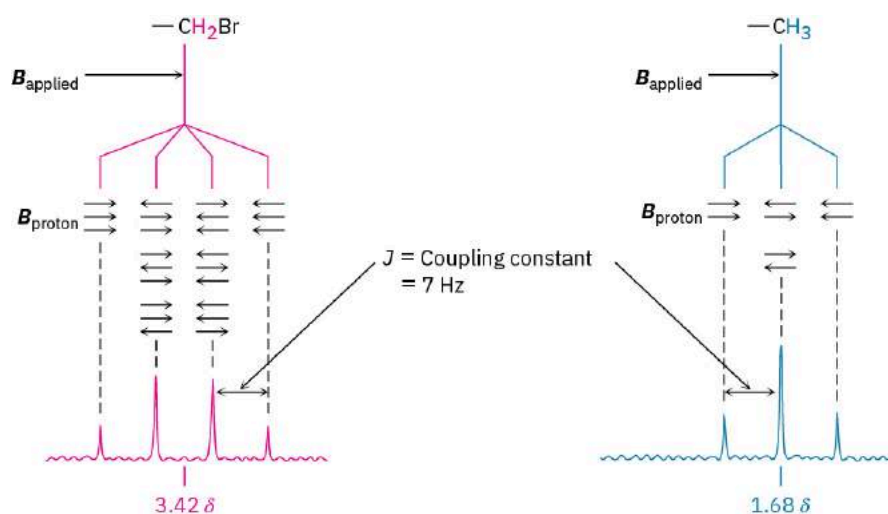

FIGURE 13.9 The origin of spin–spin splitting in bromoethane. The nuclear spins of neighboring protons, indicated by horizontal arrows, align either with or against the applied field, causing the splitting of absorptions into multiplets.

Any given molecule has only one of the three possible alignments of $-\text{CH}_2\text{Br}$ spins, but in a large collection of molecules, all three spin states are represented in a 1 : 2 : 1 statistical ratio. We therefore find that the neighboring $-\text{CH}_3$ protons come into resonance at three slightly different values of the applied field, and we see a 1 : 2 : 1 triplet in the NMR spectrum. One resonance is a little above where it would be without coupling, one is at the same place it would be without coupling, and the third resonance is a little below where it would be without coupling.

In the same way that the $-\text{CH}_3$ absorption of bromoethane is split into a triplet, the $-\text{CH}_2\text{Br}$ absorption is split into a quartet. The three spins of the neighboring $-\text{CH}_3$ protons can align in four possible combinations: all three with the applied field, two with and one against (three ways), one with and two against (three ways), or all three against. Thus, four peaks are produced for the $-\text{CH}_2\text{Br}$ protons in a 1 : 3 : 3 : 1 ratio.

As a general rule, called the **$n + 1$ rule**, protons that have n equivalent neighboring protons show $n + 1$ peaks in their NMR spectrum. For example, the spectrum of 2-bromopropane in **FIGURE 13.10** shows a *doublet* at 1.71 δ and a seven-line multiplet, or *septet*, at 4.28 δ . The septet is caused by splitting of the $-\text{CHBr}-$ proton signal by six equivalent neighboring protons on the two methyl groups ($n = 6$ leads to $6 + 1 = 7$ peaks). The doublet is due to signal splitting of the six equivalent methyl protons by the single $-\text{CHBr}-$ proton ($n = 1$ leads to 2 peaks). Integration confirms the expected 6 : 1 ratio.

FIGURE 13.10 The ^1H NMR spectrum of 2-bromopropane. The $-\text{CH}_3$ proton signal at 1.71 δ is split into a doublet, and the $-\text{CHBr}-$ proton signal at 4.28 δ is split into a septet. Note that the distance between peaks is the same in both multiplets. Note also that the two outer peaks of the septet are small enough to be nearly missed.

The distance between peaks in a multiplet is called the **coupling constant** and is denoted J . Coupling constants are measured in hertz and generally fall in the range 0 to 18 Hz. The exact value of the coupling constant between two neighboring protons depends on the geometry of the molecule, but a typical value for an open-chain alkane is $J = 6$ to 8 Hz. The same coupling constant is shared by both groups of hydrogens whose spins are coupled and is independent of spectrometer field strength. In bromoethane, for instance, the $-\text{CH}_2\text{Br}$ protons

are coupled to the $-\text{CH}_3$ protons and appear as a quartet with $J = 7$ Hz. The $-\text{CH}_3$ protons appear as a triplet with the same $J = 7$ Hz coupling constant.

Because coupling is a reciprocal interaction between two adjacent groups of protons, it's sometimes possible to tell which multiplets in a complex NMR spectrum are related to each other. If two multiplets have the same coupling constant, they are probably related, and the protons causing those multiplets are therefore adjacent in the molecule.

The most commonly observed coupling patterns and the relative intensities of lines in their multiplets are listed in **TABLE 13.4**. Note that it's not possible for a given proton to have five equivalent neighboring protons. (Why not?) A six-line multiplet, or sextet, is therefore found only when a proton has five nonequivalent neighboring protons that coincidentally happen to be coupled with an identical coupling constant J .

TABLE 13.4 Some Common Spin Multiplicities

Number of equivalent adjacent protons	Multiplet	Ratio of intensities
0	Singlet	1
1	Doublet	1 : 1
2	Triplet	1 : 2 : 1
3	Quartet	1 : 3 : 3 : 1
4	Quintet	1 : 4 : 6 : 4 : 1
6	Septet	1 : 6 : 15 : 20 : 15 : 6 : 1

Spin–spin splitting in ^1H NMR can be summarized by three rules.

RULE 1

Chemically equivalent protons don't show spin–spin splitting. Equivalent protons may be on the same carbon or on different carbons, but their signals don't split.

Three C–H protons are chemically equivalent; no splitting occurs.

Four C–H protons are chemically equivalent; no splitting occurs.

RULE 2

The signal of a proton with n equivalent neighboring protons is split into a multiplet of $n + 1$ peaks with coupling constant J . Protons that are farther than two carbon atoms apart don't usually couple, although they sometimes show weak coupling when they are separated by a π bond.

Splitting observed

Splitting not usually observed

RULE 3

Two groups of protons coupled to each other have the same coupling constant, J .

The spectrum of *para*-methoxypropiofenone in **FIGURE 13.11** further illustrates these three rules. The downfield absorptions at 6.91 and 7.93 δ are due to the four aromatic-ring protons. There are two kinds of aromatic protons, each of which gives a signal that is split into a doublet by its neighbor. The $-\text{OCH}_3$ signal is

unsplit and appears as a sharp singlet at 3.84δ . The $-\text{CH}_2-$ protons next to the carbonyl group appear at 2.93δ in the region expected for protons on carbon next to an unsaturated center, and their signal is split into a quartet by coupling with the protons of the neighboring methyl group. The methyl protons appear as a triplet at 1.20δ in the usual upfield region.

FIGURE 13.11 The ^1H NMR spectrum of *para*-methoxypropiophenone.

WORKED EXAMPLE 13.2

Assigning a Chemical Structure from a ^1H NMR Spectrum

Propose a structure for a compound, $\text{C}_5\text{H}_{12}\text{O}$, that fits the following ^1H NMR data: 0.92δ (3 H, triplet, $J = 7$ Hz), 1.20δ (6 H, singlet), 1.50δ (2 H, quartet, $J = 7$ Hz), 1.64δ (1 H, broad singlet).

Strategy

It's best to begin solving structural problems by calculating a molecule's degree of unsaturation (we'll see this again in Worked Example 13.4). In the present instance, a formula of $\text{C}_5\text{H}_{12}\text{O}$ corresponds to a saturated, open-chain molecule, either an alcohol or an ether.

To interpret the NMR information, let's look at each absorption individually. The three-proton absorption at 0.92δ is due to a methyl group in an alkane-like environment, and the triplet-splitting pattern implies that the CH_3 is next to a CH_2 . Thus, our molecule contains an ethyl group, CH_3CH_2- . The six-proton singlet at 1.20δ is due to two equivalent alkane-like methyl groups attached to a carbon with no hydrogens, $(\text{CH}_3)_2\text{C}$, and the two-proton quartet at 1.50δ is due to the CH_2 of the ethyl group. All 5 carbons and 11 of the 12 hydrogens in the molecule are now accounted for. The remaining hydrogen, which appears as a broad one-proton singlet at 1.64δ , is probably due to an OH group, since there is no other way to account for it. Putting the pieces together gives the structure: 2-methyl-2-butanol.

Solution

PROBLEM Predict the splitting patterns you would expect for each proton in the following molecules:

PROBLEM Draw structures for compounds that meet the following descriptions:

- 13-10** (a) C_2H_6O ; one singlet (b) C_3H_7Cl ; one doublet and one septet (c) $C_4H_8Cl_2O$; two triplets
 (d) $C_4H_8O_2$; one singlet, one triplet, and one quartet

PROBLEM The integrated 1H NMR spectrum of a compound of formula $C_4H_{10}O$ is shown in Figure 13.12.

- 13-11** Propose a structure.

FIGURE 13.12 An integrated 1H NMR spectrum for Problem 11.

13.7 1H NMR Spectroscopy and Proton Equivalence

Because each electronically distinct hydrogen in a molecule has its own unique absorption, one use of 1H NMR is to find out how many kinds of electronically nonequivalent hydrogens are present. In the 1H NMR spectrum of methyl acetate shown previously in **FIGURE 13.4a**, for instance, there are two signals, corresponding to the two kinds of nonequivalent protons present, $CH_3C=O$ protons and $-OCH_3$ protons.

For relatively small molecules, a quick look at the structure is often enough to decide how many kinds of protons are present and thus how many NMR absorptions might appear. If in doubt, though, the equivalence or nonequivalence of two protons can be determined by comparing the structures that would be formed if each hydrogen were replaced by an X group. There are four possibilities.

- One possibility is that the protons are chemically unrelated and thus nonequivalent. If so, the products formed on substitution of H by X would be different constitutional isomers. In butane, for instance, the $-CH_3$ protons are different from the $-CH_2-$ protons. They therefore give different products on substitution by X than the $-CH_2-$ protons and would likely show different NMR absorptions.

- A second possibility is that the protons are chemically identical and thus electronically equivalent. If so, the same product would be formed regardless of which H is substituted by X. In butane, for instance, the six $-CH_3$ hydrogens on C1 and C4 are identical, would give the identical structure on substitution by X, and would show an identical NMR absorption. Such protons are said to be **homotopic**.

The six $-\text{CH}_3$ hydrogens are **homotopic** and have the same NMR absorption.

Only one substitution product is possible.

- The third possibility is a bit more subtle. Although they might at first seem homotopic, the two $-\text{CH}_2-$ hydrogens on C2 in butane (and the two $-\text{CH}_2-$ hydrogens on C3) are in fact not identical. Substitution by X of a hydrogen at C2 (or C3) would form a new chirality center, so different enantiomers (Section 5.1) would result, depending on whether the *pro-R* or *pro-S* hydrogen had been substituted (Section 5.11). Such hydrogens, whose substitution by X would lead to different enantiomers, are said to be **enantiotopic**. Enantiotopic hydrogens, even though not identical, are nevertheless electronically equivalent and thus have the same NMR absorption.

The two hydrogens on C2 (and on C3) are **enantiotopic** and have the same NMR absorption.

The two possible substitution products are **enantiomers**.

- The fourth possibility arises in chiral molecules, such as (*R*)-2-butanol. The two $-\text{CH}_2-$ hydrogens at C3 are neither homotopic nor enantiotopic. Because substitution of a hydrogen at C3 would form a *second* chirality center, different diastereomers (Section 5.6) would result, depending on whether the *pro-R* or *pro-S* hydrogen had been substituted. Such hydrogens, whose substitution by X leads to different diastereomers, are said to be **diastereotopic**. Diastereotopic hydrogens are neither chemically nor electronically equivalent. They are completely different and would likely show different NMR absorptions.

The two hydrogens on C3 are **diastereotopic** and have different NMR absorptions.

The two possible substitution products are **diastereomers**.

PROBLEM Identify the indicated sets of protons as unrelated, homotopic, enantiotopic, or diastereotopic:

13-12 (a)

(b)

(c)

(d)

(e)

(f)

PROBLEM How many kinds of electronically nonequivalent protons are present in each of the following compounds, and thus how many NMR absorptions might you expect in each?

13-13

- (a) $\text{CH}_3\text{CH}_2\text{Br}$ (b) $\text{CH}_3\text{OCH}_2\text{CH}(\text{CH}_3)_2$ (c) $\text{CH}_3\text{CH}_2\text{CH}_2\text{NO}_2$ (d) Methylbenzene
 (e) 2-Methyl-1-butene (f) *cis*-3-Hexene

PROBLEM How many absorptions would you expect (*S*)-malate, an intermediate in carbohydrate metabolism, 13-14 to have in its ^1H NMR spectrum? Explain.

13.8 More Complex Spin–Spin Splitting Patterns

In the ^1H NMR spectra we've seen so far, the chemical shifts of different protons have been distinct and the spin–spin splitting patterns have been straightforward. It often happens, however, that different kinds of hydrogens in a molecule have accidentally overlapping signals. The spectrum of toluene (methylbenzene) in **FIGURE 13.13**, for example, shows that the five aromatic ring protons give a complex, overlapping pattern, even though they aren't all equivalent.

FIGURE 13.13 The ^1H NMR spectrum of toluene, showing the accidental overlap of the five nonequivalent aromatic ring protons.

Yet another complication in ^1H NMR spectroscopy arises when a signal is split by two or more *nonequivalent* kinds of protons, as is the case with *trans*-cinnamaldehyde, isolated from oil of cinnamon (**FIGURE 13.14**). Although the $n + 1$ rule predicts splitting caused by equivalent protons, splittings caused by nonequivalent protons are more complex.

FIGURE 13.14 The ^1H NMR spectrum of *trans*-cinnamaldehyde. The signal of the proton at C2 (blue) is split into four peaks—a doublet of doublets—by the two nonequivalent neighboring protons.

To understand the ^1H NMR spectrum of *trans*-cinnamaldehyde, we have to isolate the different parts and look at the signal of each proton individually.

- The five aromatic proton signals (black in **FIGURE 13.14**) overlap into a complex pattern with a large peak at 7.42 δ and a broad absorption at 7.57 δ .
- The aldehyde proton signal at C1 (red) appears in the normal downfield position at 9.69 δ and is split into a doublet with $J = 6$ Hz by the adjacent proton at C2.

- The vinylic proton at C3 (**green**) is next to the aromatic ring and is therefore shifted downfield from the normal vinylic region. This C3 proton signal appears as a doublet centered at $7.49\ \delta$. Because it has one neighbor proton at C2, its signal is split into a doublet, with $J = 12\ \text{Hz}$.
- The C2 vinylic proton signal (**blue**) appears at $6.73\ \delta$ and shows an interesting, four-line absorption pattern. It is coupled to the two nonequivalent protons at C1 and C3 with two different coupling constants: $J_{1-2} = 6\ \text{Hz}$ and $J_{2-3} = 12\ \text{Hz}$.

A good way to understand the effect of multiple coupling, such as that occurring for the C2 proton of *trans*-cinnamaldehyde, is to draw a *tree diagram*, like that in **FIGURE 13.15**. The diagram shows the individual effect of each coupling constant on the overall pattern. Coupling with the C3 proton splits the signal of the C2 proton in *trans*-cinnamaldehyde into a doublet with $J = 12\ \text{Hz}$. Further coupling with the aldehyde proton then splits each peak of the doublet into new doublets with $J = 6\ \text{Hz}$, and we therefore observe a four-line spectrum for the C2 proton.

FIGURE 13.15 A tree diagram for the C2 proton of *trans*-cinnamaldehyde shows how it is coupled to the C1 and C3 protons with different coupling constants.

One further trait evident in the cinnamaldehyde spectrum is that the four peaks of the C2 proton signal are not all the same size. The two left-hand peaks are somewhat larger than the two right-hand peaks. Such a size difference occurs whenever coupled nuclei have similar chemical shifts—in this case, $7.49\ \delta$ for the C3 proton and $6.73\ \delta$ for the C2 proton. The peaks nearer the signal of the coupled partner are always larger, and the peaks farther from the signal of the coupled partner are always smaller. Thus, the left-hand peaks of the C2 proton multiplet at $6.73\ \delta$ are closer to the C3 proton absorption at $7.49\ \delta$ and are larger than the right-hand peaks. At the same time, the right-hand peak of the C3 proton doublet at $7.49\ \delta$ is larger than the left-hand peak because it is closer to the C2 proton multiplet at $6.73\ \delta$. This skewing effect on multiplets can often be useful because it tells where to look in the spectrum to find the coupled partner: look in the direction of the larger peaks.

PROBLEM 13-15 3-Bromo-1-phenyl-1-propene shows a complex NMR spectrum in which the vinylic proton at C2 is coupled with both the C1 vinylic proton ($J = 16\ \text{Hz}$) and the C3 methylene protons ($J = 8\ \text{Hz}$). Draw a tree diagram for the C2 proton signal, and account for the fact that a five-line multiplet is observed.

13.9 Uses of ^1H NMR Spectroscopy

NMR is used to help identify the product of nearly every reaction run in the laboratory. For example, we said in **Section 8.5** that hydroboration–oxidation of alkenes occurs with non-Markovnikov regiochemistry to yield the less highly substituted alcohol. With the help of NMR, we can now prove this statement.

Does hydroboration–oxidation of methylenecyclohexane yield cyclohexylmethanol or 1-methylcyclohexanol?

The ^1H NMR spectrum of the reaction product is shown in **FIGURE 13.16a**. The spectrum shows a two-proton peak at 3.40 δ , indicating that the product has a $-\text{CH}_2-$ group bonded to an electronegative oxygen atom ($-\text{CH}_2\text{OH}$). Furthermore, the spectrum shows no large three-proton singlet absorption near 1 δ , where we would expect the signal of a quaternary $-\text{CH}_3$ group to appear. (**FIGURE 13.16b**) gives the spectrum of 1-methylcyclohexanol, the alternative product.) Thus, it's clear that cyclohexylmethanol is the reaction product.

FIGURE 13.16 (a) The ^1H NMR spectrum of cyclohexylmethanol, the product from hydroboration–oxidation of methylenecyclohexane, and (b) the ^1H NMR spectrum of 1-methylcyclohexanol, the possible alternative reaction product.

PROBLEM How could you use ^1H NMR to determine the regiochemistry of electrophilic addition to alkenes?

- 13-16** For example, does addition of HCl to 1-methylcyclohexene yield 1-chloro-1-methylcyclohexane or 1-chloro-2-methylcyclohexane?

13.10 ^{13}C NMR Spectroscopy: Signal Averaging and FT–NMR

In some ways, it's surprising that carbon NMR is even possible. After all, ^{12}C , the most abundant carbon isotope, has no nuclear spin and can't be seen by NMR. Carbon-13 is the only naturally occurring carbon isotope with a nuclear spin, but its natural abundance is only 1.1%. Thus, only about 1 of every 100 carbon atoms in an organic sample can be observed by NMR. The problem of low abundance has been overcome, however, by the use of *signal averaging* and *Fourier-transform NMR (FT–NMR)*. Signal averaging increases instrument sensitivity, and FT–NMR increases instrument speed.

The low natural abundance of ^{13}C means that any individual NMR spectrum is extremely “noisy.” That is, the signals are so weak that they are cluttered with random background electronic noise, as shown in **FIGURE 13.17a**. If, however, hundreds or thousands of individual runs are added together by a computer and then averaged, a greatly improved spectrum results (**FIGURE 13.17b**). Background noise, because of its random nature, increases very slowly as the runs are added, while the nonzero signals stand out clearly. Unfortunately,

the value of signal averaging is limited when using the method of NMR spectrometer operation described in Section 13.2, because it takes about 5 to 10 minutes to obtain a single spectrum. Thus, a faster way to obtain spectra is needed if signal averaging is to be used.

FIGURE 13.17 Carbon-13 NMR spectra of 1-pentanol, $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{OH}$. Spectrum (a) is a single run, showing the large amount of background noise. Spectrum (b) is an average of 200 runs.

In the method of NMR spectrometer operation described in Section 13.2, the rf frequency is held constant while the strength of the magnetic field is varied so that all signals in the spectrum are recorded sequentially. In the FT-NMR technique used by modern spectrometers, however, all the signals are recorded simultaneously. A sample is placed in a magnetic field of constant strength and is irradiated with a short pulse of rf energy that covers the entire range of useful frequencies. All ^1H or ^{13}C nuclei in the sample resonate at once, giving a complex, composite signal that is mathematically manipulated using so-called Fourier transforms and then displayed in the usual way. Because all resonance signals are collected at once, it takes only a few seconds rather than a few minutes to record an entire spectrum.

Combining the speed of FT-NMR with the sensitivity enhancement of signal averaging is what gives modern NMR spectrometers their power. Literally thousands of spectra can be taken and averaged in a few hours, resulting in sensitivity so high that a ^{13}C NMR spectrum can be obtained from less than 0.1 mg of sample and a ^1H spectrum can be recorded from only a few *micrograms*.

One further question needs to be answered before moving forward with our discussion of ^{13}C NMR. Why is spin-spin splitting seen only for ^1H NMR? Why is there no splitting of *carbon* signals into multiplets in ^{13}C NMR? After all, you might expect that the spin of a given ^{13}C nucleus would couple with the spin of an adjacent magnetic nucleus, either ^{13}C or ^1H .

No coupling of a ^{13}C nucleus with nearby carbons is seen because their low natural abundance makes it unlikely that two ^{13}C nuclei will be adjacent. No coupling of a ^{13}C nucleus with nearby hydrogens is seen because ^{13}C spectra are normally recorded using *broadband decoupling*. At the same time that the sample is irradiated with a pulse of rf energy to cover the carbon resonance frequencies, it is also irradiated by a second band of rf energy covering all the hydrogen resonance frequencies. This second irradiation makes the hydrogens spin-flip so rapidly that their local magnetic fields average to zero and no coupling with carbon spins occurs.

13.11 Characteristics of ^{13}C NMR Spectroscopy

At its simplest, ^{13}C NMR makes it possible to count the number of different carbon atoms in a molecule. Look at the ^{13}C NMR spectra of methyl acetate and 1-pentanol shown previously in **FIGURE 13.4b** and **FIGURE 13.17b**. In each case, a single sharp resonance line is observed for each different carbon atom.

Most ^{13}C resonances are between 0 and 220 ppm downfield from the TMS reference line, with the exact chemical shift of each ^{13}C resonance dependent on that carbon's electronic environment within the molecule.

FIGURE 13.18 shows the correlation of chemical shift with environment.

FIGURE 13.18 Chemical shift correlations for ^{13}C NMR.

The factors that determine chemical shifts are complex, but it's possible to make some generalizations from the data in **FIGURE 13.18**. One trend is that a carbon atom's chemical shift is affected by the electronegativity of nearby atoms. Carbons bonded to oxygen, nitrogen, or halogen absorb downfield (to the left) of typical alkane carbons. Because electronegative atoms attract electrons, they pull electrons away from neighboring carbon atoms, causing those carbons to be deshielded and to come into resonance at a lower field.

Another trend is that sp^3 -hybridized carbons generally absorb from 0 to 90 δ , while sp^2 carbons absorb from 110 to 220 δ . Carbonyl carbons ($\text{C}=\text{O}$) are particularly distinct in ^{13}C NMR and are always found at the low-field end of the spectrum, from 160 to 220 δ . **FIGURE 13.19** shows the ^{13}C NMR spectra of 2-butanone and *para*-bromoacetophenone and indicates the peak assignments. Note that the $\text{C}=\text{O}$ carbons are at the left edge of the spectrum in each case.

FIGURE 13.19 Carbon-13 NMR spectra of (a) 2-butanone and (b) *para*-bromoacetophenone.

The ^{13}C NMR spectrum of *para*-bromoacetophenone is interesting in several ways. Note particularly that only six carbon absorptions are observed, even though the molecule contains eight carbons. *para*-bromoacetophenone has a symmetry plane that makes ring carbons 4 and 4', and ring carbons 5 and 5' equivalent. (Remember from Section 2.4 that aromatic rings have two resonance forms.) Thus, the six ring carbons show only four absorptions in the range 128 to 137 δ .

A second interesting point about both spectra in FIGURE 13.19 is that the peaks aren't uniform in size. Some peaks are larger than others even though they are one-carbon resonances (except for the two 2-carbon peaks of *para*-bromoacetophenone). This difference in peak size is a general feature of broadband-decoupled ^{13}C NMR spectra, and explains why we can't integrate ^{13}C NMR spectra in the same way we integrate the resonances in a ^1H NMR spectrum. The local environment of each carbon atom determines not only its chemical shift but also the time it takes for the nuclei to return to their equilibrium state after receiving a pulse of rf radiation and flipping their spins. Quaternary carbons, regardless of their hybridization state or substituents, typically give smaller resonances than primary, secondary, or tertiary carbons.

WORKED EXAMPLE 13.3

Predicting Chemical Shifts in ^{13}C NMR Spectra

At what approximate positions would you expect ethyl acrylate, $\text{H}_2\text{C}=\text{CHCO}_2\text{CH}_2\text{CH}_3$, to show ^{13}C NMR absorptions?

Strategy

Identify the distinct carbons in the molecule, and note whether each is alkyl, vinylic, aromatic, or in a carbonyl group. Then predict where each absorbs, using **FIGURE 13.18** as necessary.

Solution

Ethyl acrylate has five chemically distinct carbons: two different C=C, one C=O, one O-C, and one alkyl C. From **FIGURE 13.18**, the likely absorptions are

The actual absorptions are at 14.1, 60.5, 128.5, 130.3, and 166.0 δ .

PROBLEM 13-17 Predict the number of carbon resonance lines you would expect in the ^{13}C NMR spectra of the following compounds:

(a) Methylcyclopentane (b) 1-Methylcyclohexene (c) 1,2-Dimethylbenzene

(d) 2-Methyl-2-butene (e)

(f)

PROBLEM 13-18 Propose structures for compounds that fit the following descriptions:

- (a) A hydrocarbon with seven lines in its ^{13}C NMR spectrum
 (b) A six-carbon compound with only five lines in its ^{13}C NMR spectrum
 (c) A four-carbon compound with three lines in its ^{13}C NMR spectrum

PROBLEM 13-19 Classify the resonances in the ^{13}C NMR spectrum of methyl propanoate, $\text{CH}_3\text{CH}_2\text{CO}_2\text{CH}_3$ (Figure 13.20).

FIGURE 13.20 ^{13}C NMR spectrum of methyl propanoate, Problem 19.

13.12 DEPT ^{13}C NMR Spectroscopy

Numerous techniques developed in recent years have made it possible to obtain enormous amounts of information from ^{13}C NMR spectra. Among these techniques is one called **DEPT-NMR**, for *distortionless enhancement by polarization transfer*, which makes it possible to distinguish between signals due to CH_3 , CH_2 , CH , and quaternary carbons. That is, the number of hydrogens attached to each carbon in a molecule can be determined.

A DEPT experiment is usually done in three stages, as shown in **FIGURE 13.21** for 6-methyl-5-hepten-2-ol. The first stage is to run an ordinary spectrum (called a broadband-decoupled spectrum) to locate the chemical shifts

of all carbons. Next, a second spectrum called a DEPT-90 is run, using special conditions under which only signals due to CH carbons appear. Signals due to CH_3 , CH_2 , and quaternary carbons are absent. Finally, a third spectrum called a DEPT-135 is run, using conditions under which CH_3 and CH resonances appear as positive signals, CH_2 resonances appear as negative signals—that is, as peaks below the baseline—and quaternary carbons are again absent.

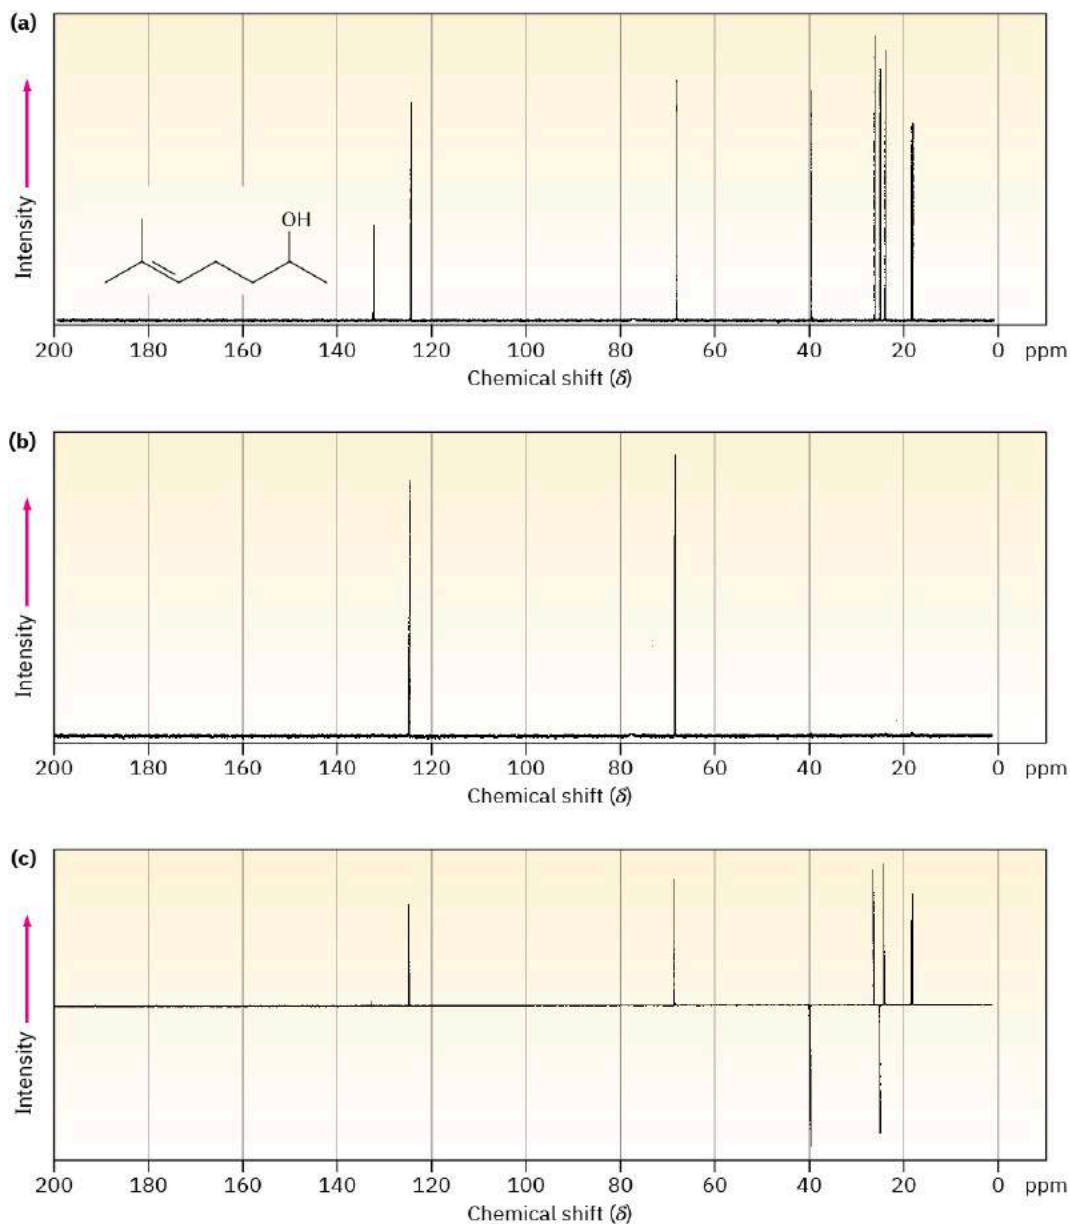

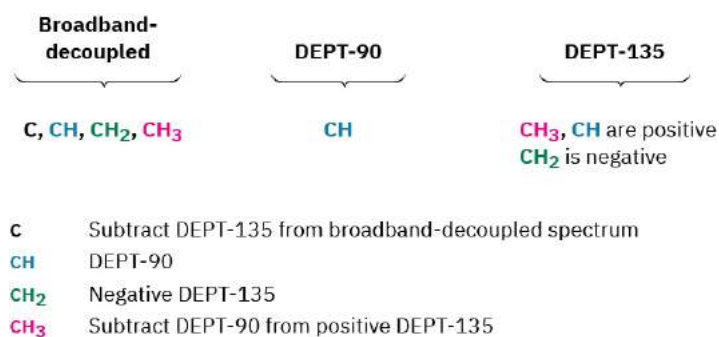

FIGURE 13.21 DEPT-NMR spectra for 6-methyl-5-hepten-2-ol. Part (a) is an ordinary broadband-decoupled spectrum, which shows signals for all eight carbons. Part (b) is a DEPT-90 spectrum, which shows only signals for the two CH carbons. Part (c) is a DEPT-135 spectrum, which shows positive signals for the two CH and three CH_3 carbons and negative signals for the two CH_2 carbons.

Putting together the information from all three spectra makes it possible to tell the number of hydrogens attached to each carbon. The CH carbons are identified in the DEPT-90 spectrum, the CH_2 carbons are identified as negative peaks in the DEPT-135 spectrum, the CH_3 carbons are identified by subtracting the CH peaks from the positive peaks in the DEPT-135 spectrum, and quaternary carbons are identified by subtracting all peaks in the DEPT-135 spectrum from the peaks in the broadband-decoupled spectrum.

WORKED EXAMPLE 13.4

Assigning a Chemical Structure from a ¹³C NMR Spectrum

Propose a structure for an alcohol, C₄H₁₀O, that has the following ¹³C NMR spectral data:

Broadband decoupled ¹³C NMR: 19.0, 31.7, 69.5 δ;

DEPT-90: 31.7 δ;

DEPT-135: positive peak at 19.0 δ, negative peak at 69.5 δ.

Strategy

As noted in Section 7.2, it usually helps with compounds of known formula but unknown structure to calculate the compound's degree of unsaturation. In the present instance, a formula of C₄H₁₀O corresponds to a saturated, open-chain molecule.

To gain information from the ¹³C data, let's begin by noting that the unknown alcohol has four carbon atoms, yet has only three NMR absorptions, which implies that two of the carbons must be equivalent. Looking at chemical shifts, two of the absorptions are in the typical alkane region (19.0 and 31.7 δ), while one is in the region of a carbon bonded to an electronegative atom (69.5 δ)—oxygen in this instance. The DEPT-90 spectrum tells us that the alkyl carbon at 31.7 δ is tertiary (CH); the DEPT-135 spectrum tells us that the alkyl carbon at 19.0 δ is a methyl (CH₃) and that the carbon bonded to oxygen (69.5 δ) is secondary (CH₂). The two equivalent carbons are probably both methyls bonded to the same tertiary carbon, (CH₃)₂CH-. We can now put the pieces together to propose a structure: 2-methyl-1-propanol.

Solution

PROBLEM 13-20 Assign a chemical shift to each carbon in 6-methyl-5-hepten-2-ol (Figure 13.21).

PROBLEM 13-21 Estimate the chemical shift of each carbon in the following molecule. Predict which carbons will appear in the DEPT-90 spectrum, which will give positive peaks in the DEPT-135 spectrum, and which will give negative peaks in the DEPT-135 spectrum.

PROBLEM 13-22 Propose a structure for an aromatic hydrocarbon, $\text{C}_{11}\text{H}_{16}$, that has the following ^{13}C NMR spectral data:

Broadband decoupled: 29.5, 31.8, 50.2, 125.5, 127.5, 130.3, 139.8 δ

DEPT-90: 125.5, 127.5, 130.3 δ

DEPT-135: positive peaks at 29.5, 125.5, 127.5, 130.3 δ ; negative peak at 50.2 δ

13.13 Uses of ^{13}C NMR Spectroscopy

The information derived from ^{13}C NMR spectroscopy is extraordinarily useful for structure determination. Not only can we count the number of nonequivalent carbon atoms in a molecule, we can also get information about the electronic environment of each carbon and find how many protons are attached to each. As a result, we can address many structural questions that go unanswered by IR spectroscopy or mass spectrometry.

Here's an example: how do we know that the E2 reaction of an alkyl halide follows Zaitsev's rule ([Section 11.7](#))? Does treatment of 1-chloro-1-methylcyclohexane with a strong base give predominantly the trisubstituted alkene 1-methylcyclohexene or the disubstituted alkene methylenecyclohexane?

1-Methylcyclohexene will have five sp^3 -carbon resonances in the 20 to 50 δ range and two sp^2 -carbon resonances in the 100 to 150 δ range. Methylenecyclohexane, however, because of its symmetry, will have only three sp^3 -carbon resonance peaks and two sp^2 -carbon peaks. The spectrum of the actual reaction product, shown in [FIGURE 13.22](#), clearly identifies 1-methylcyclohexene as the product of this E2 reaction.

FIGURE 13.22 The ^{13}C NMR spectrum of 1-methylcyclohexene, the E2 reaction product from treatment of 1-chloro-1-methylcyclohexane with base.

PROBLEM 13-23 We saw in [Section 9.3](#) that addition of HBr to a terminal alkyne leads to the Markovnikov addition product, with the Br bonding to the more highly substituted carbon. How could you use ^{13}C NMR to identify the product of the addition of 1 equivalent of HBr to 1-hexyne?

CHEMISTRY MATTERS

Magnetic Resonance Imaging (MRI)

As practiced by organic chemists, NMR spectroscopy is a powerful method of structure determination. A small amount of sample, typically a few milligrams or less, is dissolved in a small amount of solvent, the solution is placed in a thin glass tube, and the tube is placed into the narrow (1–2 cm) gap between the poles of a strong magnet. Imagine, though, that a much larger NMR instrument were available. Instead of a few milligrams, the sample size could be tens of kilograms; instead of a narrow gap between magnet poles, the gap could be large enough for a whole person to climb into so that an NMR spectrum of body parts could be obtained. That large instrument is exactly what's used for *magnetic resonance imaging (MRI)*, a diagnostic technique of enormous value to the medical community.

Like NMR spectroscopy, MRI takes advantage of the magnetic properties of certain nuclei, typically hydrogen, and of the signals emitted when those nuclei are stimulated by radiofrequency energy. Unlike what happens in NMR spectroscopy, though, MRI instruments use data manipulation techniques to look at the three-dimensional *location* of magnetic nuclei in the body rather than at the chemical nature of the nuclei. As noted, most MRI instruments currently look at hydrogen, present in abundance wherever there is water or fat in the body.

The signals detected by MRI vary with the density of hydrogen atoms and with the nature of their surroundings, allowing identification of different types of tissue and even allowing the visualization of motion. For example, the volume of blood leaving the heart in a single stroke can be measured, and heart motion can be observed. Soft tissues that don't show up well on X-ray images can be seen clearly, allowing diagnosis of brain tumors, strokes, and other conditions. This technique is also valuable in diagnosing damage to knees or other joints and is a noninvasive alternative to surgical explorations.

Several types of atoms in addition to hydrogen can be detected by MRI, and the applications of images based on ^{31}P atoms are being explored. This approach holds great promise for studies of metabolism.

FIGURE 13.23 If you're a runner, you really don't want this to happen to you. The MRI of this left knee shows bone formation in the tissue in a patient with osteochondroma. Summary

Nuclear magnetic resonance spectroscopy, or **NMR**, is the most valuable of the numerous spectroscopic techniques used for structure determination. Although we focused in this chapter on NMR applications with small molecules, more advanced NMR techniques are also used in biological chemistry to study protein structure and folding.

When magnetic nuclei, such as ^1H and ^{13}C , are placed in a strong magnetic field, their spins orient either with or against the field. On irradiation with radiofrequency (rf) waves, energy is absorbed and the nuclei “spin-flip” from the lower energy state to the higher energy state. This absorption of rf energy is detected, amplified, and displayed as an NMR spectrum.

Each electronically distinct ^1H or ^{13}C nucleus in a molecule comes into resonance at a slightly different value of the applied field, thereby producing a unique absorption signal. The exact position of each peak is called the **chemical shift**. Chemical shifts are caused by electrons setting up tiny local magnetic fields that **shield** a nearby nucleus from the applied field.

The NMR chart is calibrated in **delta units (δ)**, where $1 \delta = 1$ ppm of spectrometer frequency. Tetramethylsilane (TMS) is used as a reference point because it shows both ^1H and ^{13}C absorptions at unusually high values of applied magnetic field. The TMS absorption occurs on the right-hand (**upfield**) side of the chart and is arbitrarily assigned a value of 0δ .

^{13}C spectra are run on Fourier-transform NMR (**FT-NMR**) spectrometers using broadband decoupling of proton spins so that each chemically distinct carbon shows a single unsplit resonance line. As with ^1H NMR, the chemical shift of each ^{13}C signal provides information about a carbon’s chemical environment in the sample. In addition, the number of protons attached to each carbon can be determined using the DEPT-NMR technique.

In ^1H NMR spectra, the area under each absorption peak can be electronically **integrated** to determine the relative number of hydrogens responsible for each peak. In addition, neighboring nuclear spins can **couple**, causing the **spin-spin splitting** of NMR peaks into **multiplets**. The NMR signal of a hydrogen neighbored by n equivalent adjacent hydrogens splits into $n + 1$ peaks (the **$n + 1$ rule**) with **coupling constant J** .

Additional Problems

Visualizing Chemistry

PROBLEM Into how many peaks would you expect the ^1H NMR signals of the indicated protons to be split?
13-24 (Green = Cl.)

PROBLEM 13-25 How many absorptions would you expect the following compound to have in its ^1H and ^{13}C NMR spectra?

PROBLEM 13-26 Sketch what you might expect the ^1H and ^{13}C NMR spectra of the following compound to look like (green = Cl):

PROBLEM 13-27 How many electronically nonequivalent kinds of protons and how many kinds of carbons are present in the following compound? Don't forget that cyclohexane rings can ring-flip.

PROBLEM 13-28 Identify the indicated protons in the following molecules as unrelated, homotopic, enantiotopic, or diastereotopic.

Chemical Shifts and NMR Spectroscopy

PROBLEM The following ^1H NMR absorptions were obtained on a spectrometer operating at 200 MHz and are given in hertz downfield from the TMS standard. Convert the absorptions to δ units.

13-29 (a) 436 Hz (b) 956 Hz (c) 1504 Hz

PROBLEM The following ^1H NMR absorptions were obtained on a spectrometer operating at 300 MHz. Convert the chemical shifts from δ units to hertz downfield from TMS.

13-30 (a) 2.1 δ (b) 3.45 δ (c) 6.30 δ (d) 7.70 δ

PROBLEM When measured on a spectrometer operating at 200 MHz, chloroform (CHCl_3) shows a single sharp absorption at 7.3 δ .

13-31

- (a) How many parts per million downfield from TMS does chloroform absorb?
 (b) How many hertz downfield from TMS would chloroform absorb if the measurement were carried out on a spectrometer operating at 360 MHz?
 (c) What would be the position of the chloroform absorption in δ units when measured on a 360 MHz spectrometer?

PROBLEM Why do you suppose accidental overlap of signals is much more common in ^1H NMR than in ^{13}C NMR?

13-32

PROBLEM Is a nucleus that absorbs at 6.50 δ more shielded or less shielded than a nucleus that absorbs at 3.20 δ ? Does the nucleus that absorbs at 6.50 δ require a stronger applied field or a weaker applied field to come into resonance than the one that absorbs at 3.20 δ ?

13-33

^1H NMR Spectroscopy

PROBLEM How many types of nonequivalent protons are present in each of the following molecules?

13-34 (a)  (b) $\text{CH}_3\text{CH}_2\text{CH}_2\text{OCH}_3$ (c)  (d) 

Naphthalene

Styrene

Ethyl acrylate

PROBLEM The following compounds all show a single line in their ^1H NMR spectra. List them in order of expected increasing chemical shift:

13-35

CH_4 , CH_2Cl_2 , cyclohexane, CH_3COCH_3 , $\text{H}_2\text{C}=\text{CH}_2$, benzene

PROBLEM How many signals would you expect each of the following molecules to have in its ^1H and ^{13}C spectra?

13-36

PROBLEM Propose structures for compounds with the following formulas that show only one peak in their ^1H NMR spectra:
13-37 NMR spectra:

(a) C_5H_{12} (b) C_5H_{10} (c) $\text{C}_4\text{H}_8\text{O}_2$

PROBLEM Predict the splitting pattern for each kind of hydrogen in the following molecules:

13-38 (a) $(\text{CH}_3)_3\text{CH}$ (b) $\text{CH}_3\text{CH}_2\text{CO}_2\text{CH}_3$ (c) *trans*-2-Butene

PROBLEM Predict the splitting pattern for each kind of hydrogen in isopropyl propanoate,

13-39 $\text{CH}_3\text{CH}_2\text{CO}_2\text{CH}(\text{CH}_3)_2$.

PROBLEM Identify the indicated sets of protons as unrelated, homotopic, enantiotopic, or diastereotopic:

PROBLEM Identify the indicated sets of protons as unrelated, homotopic, enantiotopic, or diastereotopic:

PROBLEM The acid-catalyzed dehydration of 1-methylcyclohexanol yields a mixture of two alkenes. How

13-42 could you use ^1H NMR to help you decide which was which?

PROBLEM How could you use ^1H NMR to distinguish between the following pairs of isomers?

PROBLEM Propose structures for compounds that fit the following ^1H NMR data:

13-44 (a) $\text{C}_5\text{H}_{10}\text{O}$ (b) $\text{C}_3\text{H}_5\text{Br}$
 0.95 δ (6 H, doublet, $J = 7$ Hz) 2.32 δ (3 H, singlet)
 2.10 δ (3 H, singlet) 2.32 δ (3 H, singlet)
 2.43 δ (1 H, multiplet) 2.32 δ (3 H, singlet)

PROBLEM Propose structures for the two compounds whose ^1H NMR spectra are shown.

13-45

(a) C_4H_9Br (b) $C_4H_8Cl_2$  **^{13}C NMR Spectroscopy**

PROBLEM How many ^{13}C NMR absorptions would you expect for *cis*-1,3-dimethylcyclohexane? For **13-46** *trans*-1,3-dimethylcyclohexane? Explain.

PROBLEM How many absorptions would you expect to observe in the ^{13}C NMR spectra of the following **13-47** compounds?

- (a) 1,1-Dimethylcyclohexane (b) $CH_3CH_2OCH_3$ (c) *tert*-Butylcyclohexane
(d) 3-Methyl-1-pentyne (e) *cis*-1,2-Dimethylcyclohexane (f) Cyclohexanone

PROBLEM Suppose you ran a DEPT-135 spectrum for each substance in Problem 13.47. Which carbon atoms **13-48** in each molecule would show positive peaks, and which would show negative peaks?

PROBLEM How could you use 1H and ^{13}C NMR to help distinguish the following isomeric compounds of the **13-49** formula C_4H_8 ?

PROBLEM How could you use 1H NMR, ^{13}C NMR, and IR spectroscopy to help you distinguish between the **13-50** following structures?

**3-Methyl-2-cyclohexenone****3-Cyclopentenyl methyl ketone**

PROBLEM Assign as many resonances as you can to specific carbon atoms in the ^{13}C NMR spectrum of ethyl **13-51**

benzoate.

General Problems

PROBLEM Assume that you have a compound with the formula C_3H_6O .

- 13-52** (a) How many double bonds and/or rings does your compound contain?
 (b) Propose as many structures as you can that fit the molecular formula.
 (c) If your compound shows an infrared absorption peak at 1715 cm^{-1} , what functional group does it have?
 (d) If your compound shows a single ^1H NMR absorption peak at $2.1\ \delta$, what is its structure?

PROBLEM The compound whose ^1H NMR spectrum is shown has the molecular formula $C_3H_6Br_2$. Propose a structure.

13-53

PROBLEM The compound whose ^1H NMR spectrum is shown has the molecular formula $C_4H_7O_2Cl$ and has an infrared absorption peak at 1740 cm^{-1} . Propose a structure.

13-54

PROBLEM Propose structures for compounds that fit the following ^1H NMR data:

13-55

- (a) $C_4H_6Cl_2$
 2.18 δ (3 H, singlet)
 4.16 δ (2 H, doublet, $J = 7$ Hz)
 5.71 δ (1 H, triplet, $J = 7$ Hz)
- (b) $C_{10}H_{14}$
 1.30 δ (9 H, singlet)
 7.30 δ (5 H, singlet)
- (c) C_4H_7BrO
 2.11 δ (3 H, singlet)
 3.52 δ (2 H, triplet, $J = 6$ Hz)
 4.40 δ (2 H, triplet, $J = 6$ Hz)
- (d) $C_9H_{11}Br$
 2.15 δ (2 H, quintet, $J = 7$ Hz)
 2.75 δ (2 H, triplet, $J = 7$ Hz)
 3.38 δ (2 H, triplet, $J = 7$ Hz)
 7.22 δ (5 H, singlet)

PROBLEM 13-56 Long-range coupling between protons more than two carbon atoms apart is sometimes observed when π bonds intervene. An example is found in 1-methoxy-1-buten-3-yne. Not only does the acetylenic proton, H_a , couple with the vinylic proton H_b , it also couples with the vinylic proton H_c , four carbon atoms away. The data are:

1-Methoxy-1-buten-3-yne

Construct tree diagrams that account for the observed splitting patterns of H_a , H_b , and H_c .

PROBLEM 13-57 The 1H and ^{13}C NMR spectra of compound A, C_8H_9Br , are shown. Propose a structure for A, and assign peaks in the spectra to your structure.

PROBLEM 13-58 Propose structures for the three compounds whose 1H NMR spectra are shown.

(a) $C_5H_{10}O$ (b) C_7H_7Br (c) C_8H_9Br 

PROBLEM The mass spectrum and ^{13}C NMR spectrum of a hydrocarbon are shown. Propose a structure for **13-59** this hydrocarbon, and explain the spectral data.

PROBLEM 13-60 Compound **A**, a hydrocarbon with $M^+ = 96$ in its mass spectrum, has the following ¹³C spectral data. On reaction with BH_3 , followed by treatment with basic H_2O_2 , **A** is converted into **B**, whose ¹³C spectral data are also given. Propose structures for **A** and **B**.

Compound A

Broadband-decoupled ¹³C NMR: 26.8, 28.7, 35.7, 106.9, 149.7 δ

DEPT-90: no peaks

DEPT-135: no positive peaks; negative peaks at 26.8, 28.7, 35.7, 106.9 δ

Compound B

Broadband-decoupled ¹³C NMR: 26.1, 26.9, 29.9, 40.5, 68.2 δ

DEPT-90: 40.5 δ

DEPT-135: positive peak at 40.5 δ; negative peaks at 26.1, 26.9, 29.9, 68.2 δ

PROBLEM 13-61 Propose a structure for compound **C**, which has $M^+ = 86$ in its mass spectrum, an IR absorption at 3400 cm^{-1} , and the following ¹³C NMR spectral data:

Compound C

Broadband-decoupled ¹³C NMR: 30.2, 31.9, 61.8, 114.7, 138.4 δ

DEPT-90: 138.4 δ

DEPT-135: positive peak at 138.4 δ; negative peaks at 30.2, 31.9, 61.8, 114.7 δ

PROBLEM 13-62 Compound **D** is isomeric with compound **C** (Problem 13.61) and has the following ¹³C NMR spectral data. Propose a structure.

Compound D

Broadband-decoupled ¹³C NMR: 9.7, 29.9, 74.4, 114.4, 141.4 δ

DEPT-90: 74.4, 141.4 δ

DEPT-135: positive peaks at 9.7, 74.4, 141.4 δ; negative peaks at 29.9, 114.4 δ

PROBLEM Propose a structure for compound **E**, $C_7H_{12}O_2$, which has the following ^{13}C NMR spectral data:

13-63 Compound E

Broadband-decoupled ^{13}C NMR: 19.1, 28.0, 70.5, 129.0, 129.8, 165.8 δ

DEPT-90: 28.0, 129.8 δ

DEPT-135: positive peaks at 19.1, 28.0, 129.8 δ ; negative peaks at 70.5, 129.0 δ

PROBLEM Compound **F**, a hydrocarbon with $M^+ = 96$ in its mass spectrum, undergoes reaction with HBr to yield compound **G**. Propose structures for **F** and **G**, whose ^{13}C NMR spectral data are given below.

13-64

Compound F

Broadband-decoupled ^{13}C NMR: 27.6, 29.3, 32.2, 132.4 δ

DEPT-90: 132.4 δ

DEPT-135: positive peak at 132.4 δ ; negative peaks at 27.6, 29.3, 32.2 δ

Compound G

Broadband-decoupled ^{13}C NMR: 25.1, 27.7, 39.9, 56.0 δ

DEPT-90: 56.0 δ

DEPT-135: positive peak at 56.0 δ ; negative peaks at 25.1, 27.7, 39.9 δ

PROBLEM 3-Methyl-2-butanol has five signals in its ^{13}C NMR spectrum at 17.90, 18.15, 20.00, 35.05, and 72.75 δ . Why are the two methyl groups attached to C3 nonequivalent? Making a molecular model should be helpful.

13-65

PROBLEM A ^{13}C NMR spectrum of commercially available 2,4-pentanediol, shows *five* peaks at 23.3, 23.9, 46.5, 64.8, and 68.1 δ . Explain.

13-66

PROBLEM Carboxylic acids (RCO_2H) react with alcohols ($R'OH$) in the presence of an acid catalyst. The reaction product of propanoic acid with methanol has the following spectroscopic properties. Propose a structure.

13-67

Propanoic acid

MS: $M^+ = 88$

IR: 1735 cm^{-1}

^1H NMR: 1.11 δ (3 H, triplet, $J = 7$ Hz); 2.32 δ (2 H, quartet, $J = 7$ Hz);

3.65 δ (3 H, singlet)

^{13}C NMR: 9.3, 27.6, 51.4, 174.6 δ

PROBLEM Nitriles ($RC\equiv N$) react with Grignard reagents ($R'MgBr$). The reaction product from 2-methylpropanenitrile with methylmagnesium bromide has the following spectroscopic properties. Propose a structure. MS: $M^+ = 86$ IR: 1715 cm^{-1} ^1H NMR: 1.05 δ (6 H, doublet, $J = 7$ Hz); 2.12 δ (3 H, singlet); 2.67 δ (1 H, septet, $J = 7$ Hz) ^{13}C NMR: 18.2, 27.2, 41.6, 211.2 δ

13-68

PROBLEM 13-69 The proton NMR spectrum is shown for a compound with the formula $C_5H_9NO_4$. The infrared spectrum displays strong bands at 1750 and 1562 cm^{-1} and a medium-intensity band at 1320 cm^{-1} . The normal carbon-13 and the DEPT experimental results are tabulated. Draw the structure of this compound.

Normal Carbon	DEPT-135	DEPT-90
14 ppm	Positive	No peak
16	Positive	No peak
63	Negative	No peak
83	Positive	Positive
165	No peak	No peak

PROBLEM 13-70 The proton NMR spectrum of a compound with the formula $C_5H_{10}O$ is shown. The normal carbon-13 and the DEPT experimental results are tabulated. The infrared spectrum shows a broad peak at about 3340 cm^{-1} and a medium-sized peak at about 1651 cm^{-1} . Draw the structure of this compound.

Normal Carbon	DEPT-135	DEPT-90
22.2 ppm	Positive	No peak
40.9	Negative	No peak
60.2	Negative	No peak
112.5	Negative	No peak
142.3	No peak	No peak

PROBLEM 13-71 The proton NMR spectrum of a compound with the formula $C_7H_{12}O_2$ is shown. The infrared spectrum displays a strong band at 1738 cm^{-1} and a weak band at 1689 cm^{-1} . The normal carbon-13 and the DEPT experimental results are tabulated. Draw the structure of this compound.

Normal Carbon	DEPT-135	DEPT-90
18 ppm	Positive	No peak
21	Positive	No peak
26	Positive	No peak
61	Negative	No peak
119	Positive	Positive
139	No peak	No peak
171	No peak	No peak

CHAPTER 14

Conjugated Compounds and Ultraviolet Spectroscopy

FIGURE 14.1 Saffron, derived from stigmas of the saffron crocus, is the world's most expensive spice. Its color is caused by the presence of alternating single and double bonds. (credit: modification of work "Welcome to My World! ~ Huron River Watershed" by j van cise photos/ Flickr, CC BY 2.0)

14.8 Interpreting Ultraviolet Spectra: The Effect of Conjugation

14.9 Conjugation, Color, and the Chemistry of Vision

WHY THIS CHAPTER? Conjugated compounds of many different sorts are common in nature. Many of the pigments responsible for the brilliant colors of fruits, flowers, and even animals have numerous alternating single and double bonds. β -Carotene, for instance, the orange pigment responsible for the color of carrots and an important source of vitamin A, is a conjugated *polyene* with 11 double bonds. Conjugated *enones* (alkene + ketone) are common structural features of many biologically important molecules such as progesterone, the hormone that prepares the uterus for implantation of a fertilized ovum. Cyclic conjugated molecules such as benzene are a major field of study in themselves. In this chapter, we'll look at some of the distinctive properties

of conjugated molecules and at the reasons for those properties.

β -Carotene
(orange pigment and vitamin A precursor)

Progesterone, a conjugated enone

Benzene,
a cyclic conjugated molecule

Most of the unsaturated compounds we looked at in the chapters on **Alkenes: Structure and Reactivity** and **Alkenes: Reactions and Synthesis** had only one double bond, but many compounds have numerous sites of unsaturation. If the different unsaturations are well separated in a molecule, they react independently, but if they're close together, they may interact. In particular, compounds that have alternating single and double bonds—so-called **conjugated** compounds—have some distinctive characteristics. The conjugated diene 1,3-butadiene, for instance, has some properties quite different from those of the nonconjugated 1,4-pentadiene.

1,3-Butadiene
(conjugated; alternating
double and single bonds)

1,4-Pentadiene
(nonconjugated; nonalternating
double and single bonds)

14.1 Stability of Conjugated Dienes: Molecular Orbital Theory

Conjugated dienes can be prepared by some of the methods previously discussed for preparing alkenes (**Section 11.7–Section 11.11**). The base-induced elimination of HX from an allylic halide is one such reaction.

Cyclohexene **3-Bromocyclohexene** **1,3-Cyclohexadiene (76%)**

Simple conjugated dienes used in polymer synthesis include 1,3-butadiene, chloroprene (2-chloro-1,3-butadiene), and isoprene (2-methyl-1,3-butadiene). Isoprene has been prepared industrially by several methods, including the acid-catalyzed double dehydration of 3-methyl-1,3-butanediol.

3-Methyl-1,3-butanediol

Isoprene
2-Methyl-1,3-butadiene

One of the properties that distinguishes conjugated from nonconjugated dienes is that the central single bond is shorter than might be expected. The C2–C3 single bond in 1,3-butadiene, for instance, has a length of 147 pm, some 6 pm shorter than the C2–C3 bond in butane (153 pm).

Another distinctive property of conjugated dienes is their unusual stability, as evidenced by their heats of hydrogenation (TABLE 14.1). We saw in Section 7.6 that monosubstituted alkenes, such as 1-butene, have $\Delta H^\circ_{\text{hydrog}}$ near -126 kJ/mol (-30.1 kcal/mol), whereas disubstituted alkenes, such as 2-methylpropene, have $\Delta H^\circ_{\text{hydrog}}$ near -119 kJ/mol (-28.4 kcal/mol), which is approximately 7 kJ/mol less negative. We concluded from these data that more highly substituted alkenes are more stable than less substituted ones. That is, more highly substituted alkenes release less heat on hydrogenation because they contain less energy to start with. A similar conclusion can be drawn for conjugated dienes.

TABLE 14.1 Heats of Hydrogenation for Some Alkenes and Dienes

Alkene or diene	Product	$\Delta H^\circ_{\text{hydrog}}$	
		(kJ/mol)	(kcal/mol)
$\text{CH}_3\text{CH}_2\text{CH}=\text{CH}_2$	$\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_3$	-126	-30.1
$\begin{array}{c} \text{CH}_3 \\ \\ \text{CH}_3\text{C}=\text{CH}_2 \end{array}$	$\begin{array}{c} \text{CH}_3 \\ \\ \text{CH}_3\text{CHCH}_3 \end{array}$	-119	-28.4
$\text{H}_2\text{C}=\text{CHCH}_2\text{CH}=\text{CH}_2$	$\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$	-253	-60.5
$\text{H}_2\text{C}=\text{CH}-\text{CH}=\text{CH}_2$	$\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_3$	-236	-56.4
$\begin{array}{c} \text{CH}_3 \\ \\ \text{H}_2\text{C}=\text{CH}-\text{C}=\text{CH}_2 \end{array}$	$\begin{array}{c} \text{CH}_3 \\ \\ \text{CH}_3\text{CH}_2\text{CHCH}_3 \end{array}$	-229	-54.7

Because a monosubstituted alkene has a $\Delta H^\circ_{\text{hydrog}}$ of approximately -126 kJ/mol, we might expect that a compound with two monosubstituted double bonds would have a $\Delta H^\circ_{\text{hydrog}}$ approximately twice that value, or -252 kJ/mol. Nonconjugated dienes, such as 1,4-pentadiene ($\Delta H^\circ_{\text{hydrog}} = -253$ kJ/mol), meet this expectation, but the conjugated diene 1,3-butadiene ($\Delta H^\circ_{\text{hydrog}} = -236$ kJ/mol) does not. 1,3-Butadiene is approximately 16 kJ/mol (3.8 kcal/mol) more stable than expected.

	$\Delta H^\circ_{\text{hydrog}}$ (kJ/mol)		
$\text{H}_2\text{C}=\text{CHCH}_2\text{CH}=\text{CH}_2$	$-126 + (-126) = -252$	Expected	
1,4-Pentadiene	-253	Observed	
	1	Difference	
$\text{H}_2\text{C}=\text{CHCH}=\text{CH}_2$	$-126 + (-126) = -252$	Expected	
1,3-Butadiene	-236	Observed	
	-16	Difference	

What accounts for the stability of conjugated dienes? According to valence bond theory (Section 1.5 and Section 1.8), their stability is due to orbital hybridization. Typical C–C single bonds, like those in alkanes, result from σ overlap of sp^3 orbitals on both carbons, but in a conjugated diene, the central C–C single bond results from σ overlap of sp^2 orbitals on both carbons. Because sp^2 orbitals have more s character (33% s) than sp^3 orbitals (25% s), the electrons in sp^2 orbitals are closer to the nucleus and the bonds they form are somewhat shorter

The lowest-energy π molecular orbital (denoted ψ_1 , Greek psi) has no nodes between the nuclei and is therefore bonding. The π MO of next-lowest energy, ψ_2 , has one node between nuclei and is also bonding. Above ψ_1 and ψ_2 in energy are the two antibonding π MOs, ψ_3^* and ψ_4^* . (The asterisks indicate antibonding orbitals.) Note that the number of nodes between nuclei increases as the energy level of the orbital increases. The ψ_3^* orbital has two nodes between nuclei, and ψ_4^* , the highest-energy MO, has three nodes between nuclei.

Comparing the π molecular orbitals of 1,3-butadiene (two conjugated double bonds) with those of 1,4-pentadiene (two isolated double bonds) shows why the conjugated diene is more stable. In a conjugated diene, the lowest-energy π MO (ψ_1) has a favorable bonding interaction between C2 and C3 that is absent in a nonconjugated diene. As a result, there is a certain amount of double-bond character to the C2–C3 single bond, making that bond both stronger and shorter than a typical single bond. Electrostatic potential maps show clearly the additional electron density in the central single bond (FIGURE 14.4).

FIGURE 14.4 Electrostatic potential maps of 1,3-butadiene (conjugated) and 1,4-pentadiene (nonconjugated). Additional electron density is present in the central C–C bond of 1,3-butadiene, corresponding to partial double-bond character.

In describing 1,3-butadiene, we say that the π electrons are spread out, or *delocalized*, over the entire π framework, rather than localized between two specific nuclei. Delocalization allows the bonding electrons to be closer to more nuclei, thus leading to lower energy and greater stability.

PROBLEM Allene, $\text{H}_2\text{C}=\text{C}=\text{CH}_2$, has a heat of hydrogenation of -298 kJ/mol (-71.3 kcal/mol). Rank a 14-1 conjugated diene, a nonconjugated diene, and an allene in order of stability.

14.2 Electrophilic Additions to Conjugated Dienes: Allylic Carbocations

One of the most striking differences between conjugated dienes and typical alkenes is their behavior in electrophilic addition reactions. To review briefly, the addition of an electrophile to a carbon–carbon double bond is a general reaction of alkenes (Section 7.7). Markovnikov regiochemistry is observed because the more stable carbocation is formed as an intermediate. Thus, addition of HCl to 2-methylpropene yields 2-chloro-2-methylpropane rather than 1-chloro-2-methylpropane, and addition of 2 equivalents of HCl to the nonconjugated diene 1,4-pentadiene yields 2,4-dichloropentane.

Conjugated dienes also undergo electrophilic addition reactions readily, but mixtures of products are invariably obtained. Addition of HBr to 1,3-butadiene, for instance, yields a mixture of two products (not counting cis–trans isomers). 3-Bromo-1-butene is the typical Markovnikov product of **1,2-addition** to a double bond, but 1-bromo-2-butene seems unusual. The double bond in this product has moved to a position between carbons 2 and 3, and HBr has added to carbons 1 and 4, a result described as **1,4-addition**.

Many other electrophiles besides HBr add to conjugated dienes, and mixtures of products are usually formed. For example, Br₂ adds to 1,3-butadiene to give a mixture of 3,4-dibromo-1-butene and 1,4-dibromo-2-butene.

How can we account for the formation of 1,4-addition products? The answer is that allylic carbocations are involved as intermediates (recall that the word *allylic* means “next to a double bond”). When 1,3-butadiene reacts with an electrophile such as H⁺, two carbocation intermediates are possible—a primary nonallylic carbocation and a secondary allylic cation. Because an allylic cation is stabilized by resonance between two forms (Section 11.5), it is more stable and forms faster than a nonallylic carbocation.

When the allylic cation reacts with Br^- to complete the electrophilic addition, the reaction can occur either at C1 or at C3 because both carbons share the positive charge (FIGURE 14.5). Thus, a mixture of 1,2- and 1,4-addition products results. You might recall that a similar product mixture was seen for NBS bromination of alkenes in Section 10.3, a reaction that proceeds through an allylic radical.

FIGURE 14.5 An electrostatic potential map of the allylic carbocation produced by protonation of 1,3-butadiene shows that the positive charge is shared by carbons 1 and 3. Reaction of Br^- with the more positive carbon (C3) predominantly yields the 1,2-addition product.

WORKED EXAMPLE 14.1

Predicting the Product of an Electrophilic Addition Reaction of a Conjugated Diene

Give the structures of the likely products from reaction of 1 equivalent of HCl with 2-methyl-1,3-cyclohexadiene. Show both 1,2 and 1,4 adducts.

Strategy

Electrophilic addition of HCl to a conjugated diene involves the formation of allylic carbocation intermediate. Thus, the first step is to protonate the two ends of the diene and draw the resonance forms of the two allylic carbocations that result. Then, allow each resonance form to react with Cl^- , generating a maximum of four possible products.

In the present instance, protonation of the C1–C2 double bond gives a carbocation that can react further to give the 1,2 adduct 3-chloro-3-methylcyclohexene and the 1,4 adduct 3-chloro-1-methylcyclohexene. Protonation of the C3–C4 double bond gives a symmetrical carbocation, whose two resonance forms are equivalent. Thus, the 1,2 adduct and the 1,4 adduct have the same structure: 6-chloro-1-methylcyclohexene. Of the two possible modes of protonation, the first is more likely because it yields a more stable, tertiary allylic cation rather than a less-stable, secondary allylic cation.

Solution

PROBLEM 14-2 Give the structures of both 1,2 and 1,4 adducts resulting from reaction of 1 equivalent of HCl with 1,3-pentadiene.

PROBLEM 14-3 Look at the possible carbocation intermediates produced during addition of HCl to 1,3-pentadiene (Problem 14-2), and predict which 1,2 adduct predominates. Which 1,4 adduct predominates?

PROBLEM 14-4 Give the structures of both 1,2 and 1,4 adducts resulting from reaction of 1 equivalent of HBr with the following compound:

14.3 Kinetic versus Thermodynamic Control of Reactions

Electrophilic addition to a conjugated diene at or below room temperature normally leads to a mixture of products in which the 1,2 adduct predominates over the 1,4 adduct. When the same reaction is carried out at higher temperatures, however, the product ratio often changes and the 1,4 adduct predominates. For example, addition of HBr to 1,3-butadiene at 0 °C yields a 71 : 29 mixture of 1,2 and 1,4 adducts, but the same reaction carried out at 40 °C yields a 15 : 85 mixture. Furthermore, when the product mixture formed at 0 °C is heated to 40 °C in the presence of HBr, the ratio of adducts slowly changes from 71 : 29 to 15 : 85. Why?

To understand the effect of temperature on product distribution, let's briefly review what we said in [Section 6.7](#) about rates and equilibria. Imagine a reaction that can give either or both of two products, **B** and **C**.

Let's assume that **B** forms faster than **C** (in other words, $\Delta G_{\ddagger}^{\ddagger}_{\text{B}} < \Delta G_{\ddagger}^{\ddagger}_{\text{C}}$) but that **C** is more stable than **B** (in other words, $\Delta G^{\circ}_{\text{C}} > \Delta G^{\circ}_{\text{B}}$). An energy diagram for the two processes might look like that shown in **FIGURE 14.6**.

FIGURE 14.6 An energy diagram for two competing reactions in which the less stable product **B** forms faster than the more stable product **C**.

Let's first carry out the reaction at a lower temperature so that both processes are irreversible and no equilibrium is reached. Because **B** forms faster than **C**, **B** is the major product. It doesn't matter that **C** is more stable than **B**, because the two are not in equilibrium. *The product of an irreversible reaction depends only on relative rates, not on stability.* Such reactions are said to be under **kinetic control**.

Now let's carry out the same reaction at some higher temperature so that both processes are readily reversible and an equilibrium is reached. Because **C** is more stable than **B**, **C** is the major product obtained. It doesn't matter that **C** forms more slowly than **B**, because the two are in equilibrium. *The product of a readily reversible reaction depends only on stability, not on relative rates.* Such reactions are said to be under equilibrium control, or **thermodynamic control**.

We can now explain the effect of temperature on the electrophilic addition reactions of conjugated dienes. At low temperature (0 °C), HBr adds to 1,3-butadiene under kinetic control to give a 71 : 29 mixture of products, with the more rapidly formed 1,2 adduct predominating. Because these low-temperature conditions don't allow the reaction to reach equilibrium, the product that forms faster predominates. At higher temperature (40 °C), however, the reaction occurs under thermodynamic control to give a 15 : 85 mixture of products, with the more stable 1,4 adduct predominating. The higher temperature allows the addition process to become reversible, so an equilibrium mixture of products results. **FIGURE 14.7** shows this situation in an energy diagram.

FIGURE 14.7 Energy diagram for the electrophilic addition of HBr to 1,3-butadiene. The 1,2 adduct is the kinetic product because it forms faster, but the 1,4 adduct is the thermodynamic product because it is more stable.

The electrophilic addition of HBr to 1,3-butadiene is a good example of how a change in experimental conditions can change the product of a reaction. The concept of thermodynamic control versus kinetic control is a useful one that we can sometimes take advantage of in the laboratory.

PROBLEM 14-5 The 1,2 adduct and the 1,4 adduct formed by reaction of HBr with 1,3-butadiene are in equilibrium at 40 °C. Propose a mechanism by which the interconversion of products takes place.

PROBLEM 14-6 Why do you suppose 1,4 adducts of 1,3-butadiene are generally more stable than 1,2 adducts?

14.4 The Diels–Alder Cycloaddition Reaction

Perhaps the most striking difference between conjugated and nonconjugated dienes is that conjugated dienes undergo an addition reaction with alkenes to yield substituted cyclohexene products. For example, 1,3-butadiene and 3-buten-2-one give 3-cyclohexenyl methyl ketone.

This process, named the **Diels–Alder cycloaddition reaction** after its discoverers, is extremely useful in the laboratory because it forms two carbon–carbon bonds in a single step and is one of the few general methods available for making cyclic molecules. (As the name implies, a *cycloaddition* reaction is one in which two reactants add together to give a cyclic product.) The 1950 Nobel Prize in Chemistry was awarded to Otto Diels and Kurt Alder in recognition of the importance of their discovery.

The mechanism of Diels–Alder cycloaddition is different from that of other reactions we’ve studied because it is neither polar nor radical. Rather, the Diels–Alder reaction is a *pericyclic* process. Pericyclic reactions, which we’ll discuss in more detail in Chapter 30, take place in a single step by a cyclic redistribution of bonding electrons. The two reactants simply join together through a cyclic transition state in which the two new C–C bonds form at the same time.

We can picture a Diels–Alder addition as occurring by head-on (σ) overlap of the two alkene *p* orbitals with the two *p* orbitals on carbons 1 and 4 of the diene (**FIGURE 14.8**). This is, of course, a cyclic orientation of the reactants.

FIGURE 14.8 Mechanism of the Diels–Alder cycloaddition reaction. The reaction occurs in a single step through a cyclic transition state in which the two new C–C bonds form simultaneously.

In the Diels–Alder transition state, the two alkene carbons and carbons 1 and 4 of the diene rehybridize from sp^2 to sp^3 to form two new single bonds, while carbons 2 and 3 of the diene remain sp^2 -hybridized to form the new double bond in the cyclohexene product. We'll study this mechanism in more detail in **Section 30.5** but will concentrate for the present on learning about the characteristics and uses of the Diels–Alder reaction.

14.5 Characteristics of the Diels–Alder Reaction

The Dienophile

The Diels–Alder cycloaddition reaction occurs most rapidly if the alkene component, called the **dienophile** (“diene lover”), has an electron-withdrawing substituent group. Thus, ethylene itself reacts sluggishly, but propenal, ethyl propenoate, maleic anhydride, benzoquinone, propenenitrile, and similar compounds are highly reactive. Note also that alkynes, such as methyl propynoate, can act as Diels–Alder dienophiles.

In all cases, the double or triple bond of the dienophile is adjacent to the positively polarized carbon of an electron-withdrawing substituent. As a result, the double-bond carbons in these substances are substantially less electron-rich than the carbons in ethylene, as indicated by the electrostatic potential maps in **FIGURE 14.9**.

FIGURE 14.9 Electrostatic potential maps of ethylene, propenal, and propenenitrile show that electron-withdrawing groups make the double-bond carbons **less electron-rich**.

One of the most useful features of the Diels–Alder reaction is that it is **stereospecific**, meaning that a single product stereoisomer is formed. Furthermore, the stereochemistry of the dienophile is retained. If we carry out cycloaddition with methyl *cis*-2-butenate, only the *cis*-substituted cyclohexene product is formed. With methyl *trans*-2-butenate, only the *trans*-substituted cyclohexene product is formed.

Another stereochemical feature of the Diels–Alder reaction is that the diene and dienophile partners orient so that the *endo* product, rather than the alternative *exo* product, is formed. The words *endo* and *exo* are used to indicate relative stereochemistry when referring to bicyclic structures like substituted norbornanes ([Section 4.9](#)). A substituent on one bridge is said to be **endo** if it is *syn* (*cis*) to the larger of the other two bridges and is said to be **exo** if it is *anti* (*trans*) to the larger of the other two.

Endo products result from Diels–Alder reactions because the amount of orbital overlap between diene and dienophile is greater when the reactants lie directly on top of one another, so that the electron-withdrawing substituent on the dienophile is underneath the diene double bonds. In the reaction of 1,3-cyclopentadiene with maleic anhydride, for instance, the following result is obtained:

WORKED EXAMPLE 14.2

Predicting the Product of a Diels–Alder Reaction

Predict the product of the following Diels–Alder reaction:

Strategy

Draw the diene so that the ends of its two double bonds are near the dienophile double bond. Then form two single bonds between the partners, convert the three double bonds into single bonds, and convert the former single bond of the diene into a double bond. Because the dienophile double bond is *cis* to begin with, the two attached hydrogens must remain *cis* in the product.

Solution

PROBLEM Predict the product of the following Diels–Alder reaction:

14-7

The Diene

Just as the dienophile component has certain constraints that affect its reactivity, so too does the conjugated diene component. The diene must adopt what is called an ***s-cis* conformation**, meaning “*cis*-like” about the single bond, to undergo a Diels–Alder reaction. Only in the *s-cis* conformation are carbons 1 and 4 of the diene close enough to react through a cyclic transition state.

**s-Cis conformation****s-Trans conformation**

In the alternative *s-trans* conformation, the ends of the diene partner are too far apart to overlap with the dienophile *p* orbitals.

**Successful reaction****No reaction (ends too far apart)**

Two examples of dienes that can't adopt an *s-cis* conformation, and thus don't undergo Diels–Alder reactions, are shown in **FIGURE 14.10**. In the bicyclic diene, the double bonds are rigidly fixed in an *s-trans* arrangement by geometric constraints of the rings. In (2*Z*,4*Z*)-2,4-hexadiene, steric strain between the two methyl groups prevents the molecule from adopting *s-cis* geometry.

**A bicyclic diene
(rigid *s-trans* diene)****Severe steric strain
in *s-cis* form****(2*Z*,4*Z*)-2,4-Hexadiene
(*s-trans*, more stable)**

FIGURE 14.10 Two dienes that can't achieve an *s-cis* conformation and thus can't undergo Diels–Alder reactions.

In contrast to these unreactive dienes that can't achieve an *s-cis* conformation, other dienes are fixed only in the correct *s-cis* geometry and are therefore highly reactive in Diels–Alder cycloaddition. 1,3-Cyclopentadiene, for example, is so reactive that it reacts with itself. At room temperature, 1,3-cyclopentadiene *dimerizes*. One molecule acts as diene and a second molecule acts as dienophile in a self-Diels–Alder reaction.

**1,3-Cyclopentadiene
(*s-cis*)****Bicyclopentadiene**

Biological Diels–Alder reactions are also known but are uncommon. One example occurs in the biosynthesis of the cholesterol-lowering drug lovastatin (trade name Mevacor) isolated from the bacterium *Aspergillus terreus*. The key step is the *intramolecular* Diels–Alder reaction of a triene, in which the diene and dienophile components are within the same molecule.

PROBLEM Which of the following alkenes would you expect to be good Diels–Alder dienophiles?

14-8

PROBLEM Which of the following dienes have an *s-cis* conformation, and which have an *s-trans* conformation?

14-9 Of the *s-trans* dienes, which can readily rotate to *s-cis*?

PROBLEM Predict the product of the following Diels–Alder reaction:

14-10

14.6 Diene Polymers: Natural and Synthetic Rubbers

Conjugated dienes can be polymerized just as simple alkenes can ([Section 8.10](#)). Diene polymers are structurally more complex than simple alkene polymers, however, because double bonds occur every four carbon atoms along the chain, leading to the possibility of *cis*–*trans* isomers. The initiator (In) for the reaction can be either a radical, as occurs in ethylene polymerization, or an acid. Note that the polymerization is a 1,4 addition of the growing chain to a conjugated diene monomer.

Rubber is a naturally occurring diene polymer of isoprene (2-methyl-1,3-butadiene) and is produced by more than 400 different plants. The major source is the so-called rubber tree, *Hevea brasiliensis*, from which the crude material, called *latex*, is harvested as it drips from a slice made through the bark. The double bonds of rubber have *Z* stereochemistry, but gutta-percha, the *E* isomer of rubber, also occurs naturally. Harder and more brittle than rubber, gutta-percha has a variety of applications, including use in dental endodontics and as the covering on some golf balls.

A number of different synthetic rubbers are produced commercially by diene polymerization. Both *cis*- and *trans*-polyisoprene can be made, and the synthetic rubber thus produced is similar to the natural material. Chloroprene (2-chloro-1,3-butadiene) is polymerized to yield neoprene, an excellent, although expensive, synthetic rubber with good weather resistance. Neoprene is used in the production of industrial hoses and gloves, among other things.

Both natural and synthetic rubbers are too soft and tacky to be useful until they are hardened by heating with elemental sulfur, a process called *vulcanization*. Vulcanization cross-links the rubber chains by forming carbon–sulfur bonds between them, thereby hardening and stiffening the polymer. The exact degree of hardening can be varied, yielding material soft enough for automobile tires or hard enough for bowling balls (*ebonite*).

The unusual ability of rubber to stretch and then contract to its original shape is due to the irregular structure of the polymer chains caused by the double bonds. These double bonds introduce bends and kinks into the polymer chains, thereby preventing neighboring chains from nestling together. When stretched, the randomly coiled chains straighten out and orient along the direction of the pull but are kept from sliding over one another by the cross-links. When the tension is released, the polymer reverts to its original random state.

PROBLEM Draw a segment of the polymer that might be prepared from 2-phenyl-1,3-butadiene.

14-11

PROBLEM Show the mechanism of the acid-catalyzed polymerization of 1,3-butadiene.

14-12

14.7 Ultraviolet Spectroscopy

As we've seen, mass spectrometry, infrared spectroscopy, and nuclear magnetic resonance spectroscopy are techniques of structure determination applicable to all organic molecules. In addition to these three generally useful methods, there is a fourth—**ultraviolet (UV) spectroscopy**—that is applicable only to conjugated compounds. UV is less commonly used than the other three spectroscopic techniques because of the specialized information it gives, so we'll only discuss it briefly.

Mass spectrometry	Molecular size and formula
IR spectroscopy	Functional groups present
NMR spectroscopy	Carbon–hydrogen framework
UV spectroscopy	Conjugated π electron systems

The ultraviolet region of the electromagnetic spectrum extends from the short-wavelength end of the visible region (4×10^{-7} m) to the long-wavelength end of the X-ray region (10^{-8} m), but the narrow range from 2×10^{-7} m to 4×10^{-7} m is the part of greatest interest to organic chemists. Absorptions in this region are usually measured in nanometers (nm), where $1 \text{ nm} = 10^{-9}$ m. Thus, the ultraviolet range of interest is from 200 to 400 nm (**FIGURE 14.11**).

FIGURE 14.11 The ultraviolet (UV) and neighboring regions of the electromagnetic spectrum.

We saw in **Section 12.5** that when an organic molecule is irradiated with electromagnetic energy, the radiation either passes through the sample or is absorbed, depending on its energy. With IR irradiation, the energy absorbed corresponds to the amount needed to increase molecular vibrations. With UV radiation, the energy absorbed corresponds to the amount needed to promote an electron from a lower-energy orbital to a higher-energy one in a conjugated molecule. The conjugated diene 1,3-butadiene, for instance, has four π molecular orbitals, as shown previously in **FIGURE 14.3**. The two lower-energy, bonding MOs are occupied in the ground state, and the two higher-energy, antibonding MOs are unoccupied.

On irradiation with ultraviolet light ($h\nu$), 1,3-butadiene absorbs energy and a π electron is promoted from the **highest occupied molecular orbital (HOMO)** to the **lowest unoccupied molecular orbital (LUMO)**. Because the electron is promoted from a bonding π molecular orbital to an antibonding π^* molecular orbital, we call this a $\pi \rightarrow \pi^*$ excitation (read as “pi to pi star”). The energy gap between the HOMO and the LUMO of 1,3-butadiene is such that UV light of 217 nm wavelength is required to effect the $\pi \rightarrow \pi^*$ electronic transition (**FIGURE 14.12**).

FIGURE 14.12 Ultraviolet excitation of 1,3-butadiene results in the promotion of an electron from ψ_2 , the highest occupied molecular orbital (HOMO), to ψ_3^* , the lowest unoccupied molecular orbital (LUMO).

An ultraviolet spectrum is recorded by irradiating a sample with UV light of continuously changing wavelength. When the wavelength corresponds to the energy level required to excite an electron to a higher level, energy is absorbed. This absorption is detected and displayed on a chart that plots wavelength versus *absorbance* (A), defined as

$$A = \log \frac{I_0}{I}$$

where I_0 is the intensity of the incident light and I is the intensity of the light transmitted through the sample.

Note that UV spectra differ from IR spectra in how they are presented. For historical reasons, IR spectra are usually displayed so that the baseline corresponding to zero absorption runs across the top of the chart and a valley indicates an absorption, whereas UV spectra are displayed with the baseline at the bottom of the chart so that a peak indicates an absorption (**FIGURE 14.13**).

FIGURE 14.13 The ultraviolet spectrum of 1,3-butadiene, $\lambda_{\text{max}} = 217 \text{ nm}$.

The amount of UV light absorbed is expressed as the sample's **molar absorptivity** (ϵ), defined by the equation

$$\epsilon = \frac{A}{c \times l}$$

where

A = Absorbance

c = Concentration in mol/L

l = Sample pathlength in cm

Molar absorptivity is a physical constant, characteristic of the particular substance being observed and thus characteristic of the particular π electron system in the molecule. Typical values for conjugated dienes are in

the range $\epsilon = 10,000$ to $25,000$. The units for molar absorptivity, $L/(\text{mol} \cdot \text{cm})$, are usually dropped.

A particularly important use of this equation comes from rearranging it to the form $c = A/(\epsilon \cdot l)$, which lets us measure the concentration of a sample in solution when A , ϵ , and l are known. As an example, β -carotene, the pigment responsible for the orange color of carrots, has $\epsilon = 138,000 L/(\text{mol} \cdot \text{cm})$. If a sample of β -carotene is placed in a cell with a pathlength of 1.0 cm and the UV absorbance reads 0.37 , then the concentration of β -carotene in the sample is

$$c = \frac{A}{\epsilon l} = \frac{0.37}{\left(1.38 \times 10^5 \frac{\text{L}}{\text{mol} \cdot \text{cm}}\right)(1.00 \text{ cm})}$$

$$= 2.7 \times 10^{-6} \text{ mol/L}$$

Unlike IR and NMR spectra, which show many absorptions for a given molecule, UV spectra are usually quite simple—often only a single peak. The peak is usually broad, and we identify its position by noting the wavelength at the top of the peak— λ_{max} , read as “lambda max.”

PROBLEM Calculate the energy range of electromagnetic radiation in the UV region of the spectrum from **200 14-13** to 400 nm (see **Section 12.5**). How does this value compare with the values calculated previously for IR and NMR spectroscopy?

PROBLEM If pure vitamin A has $\lambda_{\text{max}} = 325$ ($\epsilon = 50,100$), what is the vitamin A concentration in a sample whose **14-14** absorbance at 325 nm is $A = 0.735$ in a cell with a pathlength of 1.00 cm ?

14.8 Interpreting Ultraviolet Spectra: The Effect of Conjugation

The wavelength necessary to effect the $\pi \rightarrow \pi^*$ transition in a conjugated molecule depends on the energy gap between HOMO and LUMO, which in turn depends on the nature of the conjugated system. Thus, by measuring the UV spectrum of an unknown, we can derive structural information about the nature of any conjugated π electron system present in a molecule.

One of the most important factors affecting the wavelength of UV absorption by a molecule is the extent of conjugation. Molecular orbital calculations show that the energy difference between HOMO and LUMO decreases as the extent of conjugation increases. Thus, 1,3-butadiene absorbs at $\lambda_{\text{max}} = 217 \text{ nm}$, 1,3,5-hexatriene absorbs at $\lambda_{\text{max}} = 258 \text{ nm}$, and 1,3,5,7-octatetraene absorbs at $\lambda_{\text{max}} = 290 \text{ nm}$. (Remember: longer wavelength means lower energy.)

Other kinds of conjugated systems, such as conjugated enones and aromatic rings, also have characteristic UV absorptions that are useful in structure determination. The UV absorption maxima of some representative conjugated molecules are given in **TABLE 14.2**.

TABLE 14.2 Ultraviolet Absorptions of Some Conjugated Molecules

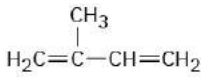

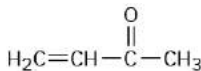

Name	Structure	λ_{max} (nm)
2-Methyl-1,3-butadiene		220
1,3-Cyclohexadiene		256
1,3,5-Hexatriene	$\text{H}_2\text{C}=\text{CH}-\text{CH}=\text{CH}-\text{CH}=\text{CH}_2$	258
1,3,5,7-Octatetraene	$\text{H}_2\text{C}=\text{CH}-\text{CH}=\text{CH}-\text{CH}=\text{CH}-\text{CH}=\text{CH}_2$	290

TABLE 14.2 Ultraviolet Absorptions of Some Conjugated Molecules

Name	Structure	λ_{max} (nm)
3-Buten-2-one		219
Benzene		203

PROBLEM 14-15 Which of the following compounds would you expect to show ultraviolet absorptions in the 200 to 400 nm range?

14.9 Conjugation, Color, and the Chemistry of Vision

Why are some organic compounds colored while others are not? β -Carotene, the pigment in carrots, is yellow-orange, for instance, while cholesterol is colorless. The answer involves both the chemical structures of colored molecules and the way we perceive light.

The visible region of the electromagnetic spectrum is adjacent to the ultraviolet region, extending from approximately 400 to 800 nm. Colored compounds have such elaborate systems of conjugation that their “UV” absorptions extend into the visible region. β -Carotene, for instance, has 11 double bonds in conjugation, and its absorption occurs at $\lambda_{\text{max}} = 455$ nm (FIGURE 14.14).

FIGURE 14.14 Ultraviolet spectrum of β -carotene, a conjugated molecule with 11 double bonds. The absorption occurs in the visible region.

“White” light from the sun or from a lamp consists of all wavelengths in the visible region. When white light strikes β -carotene, the wavelengths from 400 to 500 nm (blue) are absorbed while all other wavelengths are transmitted and can reach our eyes. We therefore see the white light with the blue removed, which we perceive as a yellow-orange color for β -carotene.

Conjugation is crucial not only for the colors we see in organic molecules but also for the light-sensitive molecules on which our visual system is based. The key substance for vision is dietary β -carotene, which is converted to vitamin A by enzymes in the liver, oxidized to an aldehyde called 11-*trans*-retinal, and then isomerized by a change in geometry of the C11–C12 double bond to produce 11-*cis*-retinal.

There are two main types of light-sensitive receptor cells in the retina of the human eye: *rod* cells and *cone* cells. The 3 million or so rod cells are primarily responsible for seeing dim light and shades of gray, whereas the 100 million cone cells are responsible for seeing bright light and colors. In the rod cells of the eye, 11-*cis*-retinal is converted into rhodopsin, a light-sensitive substance formed from the protein opsin and 11-*cis*-retinal. When light strikes the rod cells, isomerization of the C11–C12 double bond occurs and *trans*-rhodopsin, called metarhodopsin II, is produced. In the absence of light, this *cis*–*trans* isomerization takes approximately 1100 years, but in the presence of light, it occurs within 2×10^{-13} seconds! Isomerization of rhodopsin is accompanied by a change in molecular geometry, which in turn causes a nerve impulse to be sent through the optic nerve to the brain, where it is perceived as vision.

Metarhodopsin II is then recycled back into rhodopsin by a multistep sequence involving cleavage to all-*trans*-retinal and *cis*-*trans* isomerization back to 11-*cis*-retinal.

CHEMISTRY MATTERS

Photolithography

Fifty years ago, someone interested in owning a computer would have paid approximately \$150,000 for 16 megabytes of random-access memory that would have occupied a volume the size of a small desk. Today, anyone can buy 60 times as much computer memory for \$10 and fit the small chip into their shirt pocket. The difference between then and now is due to improvements in *photolithography*, the process by which integrated-circuit chips are made.

Photolithography begins by coating a layer of SiO_2 onto a silicon wafer and further coating with a thin (0.5–1.0 μm) film of a light-sensitive organic polymer called a *resist*. A *mask* is then used to cover those parts of the chip that will become a circuit, and the wafer is irradiated with UV light. The nonmasked sections of the polymer undergo a chemical change when irradiated, which makes them more soluble than the masked, unirradiated sections. On washing the irradiated chip with solvent, solubilized polymer is selectively removed from the irradiated areas, exposing the SiO_2 underneath. This SiO_2 is then chemically etched away by reaction with hydrofluoric acid, leaving behind a pattern of polymer-coated SiO_2 . Further washing removes the remaining polymer, leaving a positive image of the mask in the form of exposed ridges of SiO_2 (FIGURE 14.16). Additional cycles of coating, masking, and etching then produce the completed chips.

FIGURE 14.15 Manufacturing the ultrathin circuitry on this computer chip depends on the organic chemical reactions of special polymers. (credit: “Integrated circuit on microchip” by Jon Sullivan/Wikimedia Commons, Public Domain)

FIGURE 14.16 Outline of the photolithography process for producing integrated circuit chips.

The polymer resist currently used in chip manufacturing is based on the two-component *diazoquinone–novolac system*. Novolac resin is a soft, relatively low-molecular-weight polymer made from methylphenol and formaldehyde, while the diazoquinone is a bicyclic (two-ring) molecule containing a diazo

group =N=N) adjacent to a ketone carbonyl (C=O). The diazoquinone–novolac mix is relatively insoluble when fresh, but on exposure to ultraviolet light and water vapor, the diazoquinone component undergoes reaction to yield N_2 and a carboxylic acid, which can be washed away with dilute base. Novolac–diazoquinone technology is capable of producing features as small as $0.5 \mu\text{m}$ ($5 \times 10^{-7} \text{ m}$), but further improvements in miniaturization are still being developed.

Summary

The unsaturated compounds we've looked at previously have had only one double bond, but many compounds have numerous sites of unsaturation, which gives them some distinctive properties. Many such compounds are common in nature, including pigments and hormones.

A **conjugated** diene or other compound is one that contains alternating double and single bonds. One characteristic of conjugated dienes is that they are more stable than their nonconjugated counterparts. This stability can be explained by a molecular orbital description in which four *p* atomic orbitals combine to form four π molecular orbitals. Only the two bonding orbitals are occupied; the two antibonding orbitals are unoccupied. A π bonding interaction in the lowest-energy MO introduces some partial double-bond character between carbons 2 and 3, thereby strengthening the C2–C3 bond and stabilizing the molecule.

Conjugated dienes undergo several reactions not observed for nonconjugated dienes. One is the 1,4-addition of electrophiles. When a conjugated diene is treated with an electrophile such as HCl, **1,2-** and **1,4-addition** products are formed. Both result from the same resonance-stabilized allylic carbocation intermediate and are produced in varying amounts depending on the reaction conditions. The 1,2 adduct is usually formed faster and is said to be the product of **kinetic control**. The 1,4 adduct is usually more stable and is said to be the product of **thermodynamic control**.

Another reaction unique to conjugated dienes is **Diels–Alder cycloaddition**. Conjugated dienes react with electron-poor alkenes (**dienophiles**) in a single step through a cyclic transition state to yield a cyclohexene product. The reaction is stereospecific, meaning that only a single product stereoisomer is formed, and can occur only if the diene is able to adopt an *s-cis* conformation.

Ultraviolet (UV) spectroscopy is a method of structure determination applicable specifically to conjugated π -electron systems. When a conjugated molecule is irradiated with ultraviolet light, energy absorption occurs and a π electron is promoted from the **highest occupied molecular orbital (HOMO)** to the **lowest unoccupied molecular orbital (LUMO)**. For 1,3-butadiene, radiation of $\lambda_{\text{max}} = 217 \text{ nm}$ is required. The greater the extent of conjugation, the less the energy needed and the longer the wavelength of radiation required.

Summary of Reactions

1. Electrophilic addition reactions (Section 14.2 and Section 14.3)

2. Diels–Alder cycloaddition reaction (Section 14.4 and Section 14.5)

Additional Problems

Visualizing Chemistry

PROBLEM Show the structures of all possible adducts of the following diene with 1 equivalent of HCl:
14-16

PROBLEM Show the product of the Diels–Alder reaction of the following diene with 3-buten-2-one,
14-17 $\text{H}_2\text{C}=\text{CHCOCH}_3$. Make sure you show the full stereochemistry of the reaction product.

PROBLEM The following diene does not undergo Diels–Alder reactions. Explain.

14-18

PROBLEM The following model is that of an allylic carbocation intermediate formed by protonation of a conjugated diene with HBr. Show the structure of the diene and the structures of the final reaction products.

14-19

Mechanism Problems

PROBLEM Predict the major product(s) from the addition of 1 equivalent of HX and show the mechanism for each of the following reactions.

14-20

PROBLEM We've seen that the Diels–Alder cycloaddition reaction is a one-step, pericyclic process that occurs through a cyclic transition state. Propose a mechanism for the following reaction:

14-21

PROBLEM In light of your answer to Problem 14-21 propose mechanisms for the following reactions.

14-22 (a)

PROBLEM 14-23 Luminol, which is used by forensic scientists to find blood, fluoresces as a result of Diels–Alder-like process. The dianion of luminol reacts with O₂ to form an unstable peroxide intermediate that then loses nitrogen to form a dicarboxylate and emit light. The process is similar to that in Problems 14-21 and 14-22. Propose a mechanism for this process.

Luminol dianion

PROBLEM 14-24 A useful diene in the synthesis of many naturally occurring substances is known as Danishefsky's diene. It's useful because after the Diels–Alder reaction it can be converted into a product that can't be accessed by a typical Diels–Alder reaction. Show the Diels–Alder adduct and propose a mechanism that accounts for the final products.

Conjugated Dienes

PROBLEM 14-25 Name the following compounds:

PROBLEM 14-26 Draw and name the six possible diene isomers of formula C₅H₈. Which of the six are conjugated dienes?

PROBLEM 14-27 What product(s) would you expect to obtain from reaction of 1,3-cyclohexadiene with each of the following?

PROBLEM 14-28 Electrophilic addition of Br_2 to isoprene (2-methyl-1,3-butadiene) yields the following product mixture:

Of the 1,2-addition products, explain why 3,4-dibromo-3-methyl-1-butene (21%) predominates over 3,4-dibromo-2-methyl-1-butene (3%).

PROBLEM 14-29 Propose a structure for a conjugated diene that gives the same product from both 1,2 and 1,4-addition of HBr.

PROBLEM 14-30 Draw the possible products resulting from addition of 1 equivalent of HCl to 1-phenyl-1,3-butadiene. Which would you expect to predominate, and why?

Diels–Alder Reactions

PROBLEM 14-31 Predict the products of the following Diels–Alder reactions:

PROBLEM 14-32 2,3-Di-*tert*-butyl-1,3-butadiene does not undergo Diels–Alder reactions. Explain.

PROBLEM 14-33 Show the structure, including stereochemistry, of the product from the following Diels–Alder reaction:

PROBLEM 14-34 How can you account for the fact that *cis*-1,3-pentadiene is much less reactive than *trans*-1,3-pentadiene in the Diels–Alder reaction?

PROBLEM 14-35 Would you expect a conjugated diyne such as 1,3-butadiyne to undergo Diels–Alder reaction with a dienophile? Explain.

PROBLEM 14-36 Reaction of isoprene (2-methyl-1,3-butadiene) with ethyl propenoate gives a mixture of two Diels–Alder adducts. Show the structure of both, and explain why a mixture is formed.

PROBLEM Rank the following dienophiles in order of their expected reactivity in the Diels–Alder reaction.

14-37

PROBLEM 1,3-Cyclopentadiene is very reactive in Diels–Alder cycloaddition reactions, but

14-38 1,3-cyclohexadiene is less reactive and 1,3-cycloheptadiene is nearly inert. Explain. (Molecular models are helpful.)

PROBLEM 1,3-Pentadiene is much more reactive in Diels–Alder reactions than 2,4-pentadienal. Why might

14-39 this be?

1,3-Pentadiene

2,4-Pentadienal

PROBLEM How could you use Diels–Alder reactions to prepare the following products? Show the starting diene

14-40 and dienophile in each case.

PROBLEM Show the product of the following reaction.

14-41

Diene Polymers

PROBLEM Tires whose sidewalls are made of natural rubber tend to crack and weather rapidly in areas around

14-42 cities where high levels of ozone and other industrial pollutants are found. Explain.

PROBLEM 1,3-Cyclopentadiene polymerizes slowly at room temperature to yield a polymer that has no double

14-43 bonds except on the ends. On heating, the polymer breaks down to regenerate 1,3-cyclopentadiene. Propose a structure for the product.

UV Spectroscopy

PROBLEM Arrange the molecules in each of the following sets according to where you would expect to find

14-44 their wavelength of maximum absorption in UV spectroscopy, from shortest to longest wavelength.

PROBLEM 14-45 Which of the following compounds would you expect to have a $\pi \rightarrow \pi^*$ UV absorption in the 200 to 400 nm range?

PROBLEM 14-46 Would you expect allene, $\text{H}_2\text{C}=\text{C}=\text{CH}_2$, to show a UV absorption in the 200 to 400 nm range? Explain.

PROBLEM 14-47 The following ultraviolet absorption maxima have been measured:

1,3-Butadiene	217 nm
2-Methyl-1,3-butadiene	220 nm
1,3-Pentadiene	223 nm
2,3-Dimethyl-1,3-butadiene	226 nm
2,4-Hexadiene	227 nm
2,4-Dimethyl-1,3-pentadiene	232 nm
2,5-Dimethyl-2,4-hexadiene	240 nm

What conclusion can you draw about the effect of alkyl substitution on UV absorption maxima? Approximately what effect does each added alkyl group have?

PROBLEM 14-48 1,3,5-Hexatriene has $\lambda_{\text{max}} = 258$ nm. In light of your answer to Problem 14-47, approximately where would you expect 2,3-dimethyl-1,3,5-hexatriene to absorb?

PROBLEM 14-49 β -Ocimene is a pleasant-smelling hydrocarbon found in the leaves of certain herbs. It has the molecular formula $\text{C}_{10}\text{H}_{16}$ and a UV absorption maximum at 232 nm. On hydrogenation with a palladium catalyst, 2,6-dimethyloctane is obtained. Ozonolysis of β -ocimene, followed by treatment with zinc and acetic acid, produces the following four fragments:

- (a) How many double bonds does β -ocimene have?
 (b) Is β -ocimene conjugated or nonconjugated? (c) Propose a structure for β -ocimene.
 (d) Write the reactions, showing starting material and products.

General Problems

PROBLEM Draw the resonance forms that result when the following dienes are protonated. If the resonance forms differ in energy, identify the most stable one.

PROBLEM Answer the following questions for 1,3,5-cycloheptatriene.

- 14-51** (a) How many *p* atomic orbitals are in the conjugated system?
 (b) How many molecular orbitals describe the conjugated system?
 (c) How many molecular orbitals are bonding molecular orbitals?
 (d) How many molecular orbitals are anti-bonding molecular orbitals?
 (e) Which molecular orbitals are filled with electrons?
 (f) If this molecule were to absorb a photon of UV light an electron would move between which two molecular orbitals (be specific)?

PROBLEM Treatment of 3,4-dibromohexane with strong base leads to loss of 2 equivalents of HBr and

- 14-52** formation of a product with formula C_6H_{10} . Three products are possible. Name each of the three, and tell how you would use 1H and ^{13}C NMR spectroscopy to help identify them. How would you use UV spectroscopy?

PROBLEM Addition of HCl to 1-methoxycyclohexene yields 1-chloro-1-methoxycyclohexane as a sole product.

- 14-53** Use resonance structures to explain why none of the other regioisomer is formed.

PROBLEM Aldrin, a chlorinated insecticide now banned from use in most countries since 1990, can be made

- 14-54** by Diels–Alder reaction of hexachloro-1,3-cyclopentadiene with norbornadiene. What is the structure of aldrin?

PROBLEM Norbornadiene (Problem 14-54) can be prepared by reaction of chloroethylene with

- 14-55** 1,3-cyclopentadiene, followed by treatment of the product with sodium ethoxide. Write the overall scheme, and identify the two kinds of reactions.

PROBLEM The triene shown here reacts with 2 equivalents of maleic anhydride to yield a product with the

- 14-56** formula $C_{17}H_{16}O_6$. Predict a structure for the product.

PROBLEM Myrcene, $C_{10}H_{16}$, is found in oil of bay leaves and is isomeric with β -ocimene (Problem 14-49).

- 14-57** It has an ultraviolet absorption at 226 nm and can be hydrogenated to yield 2,6-dimethyloctane. On ozonolysis followed by zinc/acetic acid treatment, myrcene yields formaldehyde, acetone, and 2-oxopentanedial:

Propose a structure for myrcene, and write the reactions, showing starting material and products.

PROBLEM 14-58 Hydrocarbon **A**, $\text{C}_{10}\text{H}_{14}$, has a UV absorption at $\lambda_{\text{max}} = 236 \text{ nm}$ and gives hydrocarbon **B**, $\text{C}_{10}\text{H}_{18}$, on hydrogenation. Ozonolysis of **A**, followed by zinc/acetic acid treatment, yields the following diketo dialdehyde:

An illustration shows the structure of diketo dialdehyde. It shows two carbonyl groups single bonded to each other. Each carbonyl group is bonded to a chain of three methylene groups and then to an aldehyde group.

- Propose two possible structures for **A**.
- Hydrocarbon **A** reacts with maleic anhydride to yield a Diels–Alder adduct. Which of your structures for **A** is correct?
- Write the reactions, showing the starting material and products.

PROBLEM 14-59 Adiponitrile, a starting material used in the manufacture of nylon, can be prepared in three steps from 1,3-butadiene. How would you carry out this synthesis?

PROBLEM 14-60 Ergosterol, a precursor of vitamin D, has $\lambda_{\text{max}} = 282 \text{ nm}$ and molar absorptivity $\epsilon = 11,900$. What is the concentration of ergosterol in a solution whose absorbance $A = 0.065$ with a sample pathlength $l = 1.00 \text{ cm}$?

PROBLEM 14-61 Dimethyl butynedioate undergoes a Diels–Alder reaction with (2*E*,4*E*)-2,4-hexadiene. Show the structure and stereochemistry of the product.

PROBLEM 14-62 Dimethyl butynedioate also undergoes a Diels–Alder reaction with (2*E*,4*Z*)-2,4-hexadiene, but the stereochemistry of the product is different from that of the (2*E*,4*E*) isomer (Problem 14-61). Explain.

PROBLEM 14-63 How would you carry out the following synthesis (more than one step is required)? What stereochemical relationship between the $-\text{CO}_2\text{CH}_3$ group attached to the cyclohexane ring and the $-\text{CHO}$ groups would your synthesis produce?

PROBLEM The double bond of an *enamine* (alkene + *amine*) is much more nucleophilic than a typical alkene double bond. Assuming that the nitrogen atom in an enamine is sp^2 -hybridized, draw an orbital picture of an enamine, and explain why the double bond is electron-rich.

14-64

PROBLEM Benzene has an ultraviolet absorption at $\lambda_{\text{max}} = 204$ nm, and *para*-toluidine has $\lambda_{\text{max}} = 235$ nm.

14-65

CHAPTER 15

Benzene and Aromaticity

FIGURE 15.1 A fennel plant is an aromatic herb used in cooking. A phenyl group—pronounced exactly the same way—is the characteristic structural unit of “aromatic” organic compounds. (credit: modification of work “Fennel” by Ruth Hartnup/Flickr, CC BY 2.0)

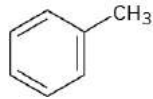

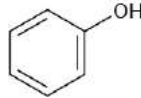

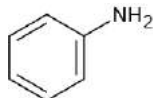

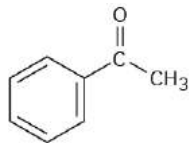

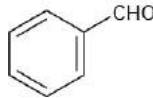

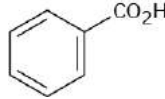

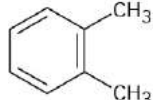

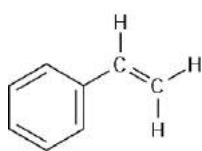

CHAPTER CONTENTS

- 15.1 Naming Aromatic Compounds
- 15.2 Structure and Stability of Benzene
- 15.3 Aromaticity and the Hückel $4n + 2$ Rule
- 15.4 Aromatic Ions
- 15.5 Aromatic Heterocycles: Pyridine and Pyrrole
- 15.6 Polycyclic Aromatic Compounds
- 15.7 Spectroscopy of Aromatic Compounds

WHY THIS CHAPTER? The reactivity of substituted aromatic compounds, more than that of any other class of substances, is intimately tied to their exact structure. As a result, aromatic compounds provide an extraordinarily sensitive probe for studying the relationship between structure and reactivity. We’ll examine this relationship here and in the following chapter, and we’ll find that the lessons learned are applicable to all other organic compounds, including important substances such as the nucleic acids that control our genetic makeup.

In the early days of organic chemistry, the word *aromatic* was used to describe such fragrant substances as benzaldehyde (from cherries, peaches, and almonds), toluene (from Tolu balsam), and benzene (from coal distillate). It was soon realized, however, that substances grouped as aromatic differed from most other organic compounds in their chemical behavior.

TABLE 15.1 Common Names of Some Aromatic Compounds

Structure	Name
	Toluene (bp 111 °C)
	Phenol (mp 43 °C)
	Aniline (bp 184 °C)
	Acetophenone (mp 21 °C)
	Benzaldehyde (bp 178 °C)
	Benzoic acid (mp 122 °C)
	<i>ortho</i> -Xylene (bp 144 °C)
	Styrene (bp 145 °C)

Monosubstituted benzenes are named systematically in the same manner as other hydrocarbons, with *-benzene* as the parent name. Thus, C_6H_5Br is bromobenzene, $C_6H_5NO_2$ is nitrobenzene, and $C_6H_5CH_2CH_2CH_3$ is propylbenzene.

Alkyl-substituted benzenes are sometimes referred to as **arenes** and are named in different ways depending on the size of the alkyl group. If the alkyl substituent is smaller than the ring (six or fewer carbons), the arene is referred to as an alkyl-substituted benzene. If the alkyl substituent is larger than the ring (seven or more carbons), the compound is referred to as a phenyl-substituted alkane. The name **phenyl**, pronounced **fen**-nil and sometimes abbreviated as Ph or Φ (Greek *phi*), is used for the $-C_6H_5$ unit when the benzene ring

is considered a substituent. The word is derived from the Greek *pheno* (“I bear light”), commemorating the discovery of benzene by Michael Faraday in 1825 from the oily residue left by the illuminating gas used in London street lamps. In addition, the name **benzyl** is used for the $C_6H_5CH_2-$ group.

Disubstituted benzenes are named using the prefixes **ortho** (*o*), **meta** (*m*), or **para** (*p*). An ortho-disubstituted benzene has its two substituents in a 1,2 relationship on the ring, a meta-disubstituted benzene has its two substituents in a 1,3 relationship, and a para-disubstituted benzene has its substituents in a 1,4 relationship.

The ortho, meta, para system of nomenclature is also useful when discussing reactions. For example, we might describe the reaction of bromine with toluene by saying, “Reaction occurs at the para position,” meaning at the position para to the methyl group already present on the ring.

As with cycloalkanes (Section 4.1), benzenes with more than two substituents are named by choosing a point of attachment as carbon 1 and numbering the substituents on the ring so that the second substituent has as low a number as possible. If ambiguity still exists, number so that the third or fourth substituent has as low a number as possible, until a point of difference is found. The substituents are listed alphabetically when writing the name.

Note in the second and third examples shown that *-phenol* and *-toluene* are used as the parent names rather than *-benzene*. Any of the monosubstituted aromatic compounds shown in TABLE 15.1 can serve as a parent name, with the principal substituent ($-OH$ in phenol or $-CH_3$ in toluene) attached to C1 on the ring.

PROBLEM Tell whether the following compounds are ortho-, meta-, or para-disubstituted:

PROBLEM Give IUPAC names for the following compounds:

PROBLEM Draw structures corresponding to the following IUPAC names:

- 15-3 (a) *p*-Bromochlorobenzene (b) *p*-Bromotoluene (c) *m*-Chloroaniline
(d) 1-Chloro-3,5-dimethylbenzene

15.2 Structure and Stability of Benzene

Benzene (C_6H_6) has six fewer hydrogens than the six-carbon cycloalkane cyclohexane (C_6H_{12}) and is clearly unsaturated, usually being represented as a six-membered ring with alternating double and single bonds. Yet it has been known since the mid-1800s that benzene is much less reactive than typical alkenes and fails to undergo typical alkene addition reactions. Cyclohexene, for instance, reacts rapidly with Br_2 and gives the addition product 1,2-dibromocyclohexane, but benzene reacts slowly with Br_2 and gives the substitution product C_6H_5Br rather than the addition product.

We can get a quantitative idea of benzene's stability by measuring heats of hydrogenation (Section 7.6). Cyclohexene, an isolated alkene, has $\Delta H^\circ_{\text{hydrog}} = -118 \text{ kJ/mol}$ (-28.2 kcal/mol), and 1,3-cyclohexadiene, a conjugated diene, has $\Delta H^\circ_{\text{hydrog}} = -230 \text{ kJ/mol}$ (-55.0 kcal/mol). As noted in Section 14.1, this value for 1,3-cyclohexadiene is a bit less than twice that for cyclohexene because conjugated dienes are more stable than isolated dienes.

Carrying the process one step further, we might expect $\Delta H^\circ_{\text{hydrog}}$ for "cyclohexatriene" (benzene) to be a bit less than $3 \times 118 = 354 \text{ kJ/mol}$, or three times the cyclohexene value. The actual value, however, is -206 kJ/mol , some 148 kJ/mol (35.4 kcal/mol) less than expected. Because of this difference in actual and expected energy released during hydrogenation, benzene must have 148 kJ/mol less energy to begin with. In other words, benzene is more stable than expected by 148 kJ/mol (FIGURE 15.3).

FIGURE 15.3 A comparison of the heats of hydrogenation for cyclohexene, 1,3-cyclohexadiene, and benzene. Benzene is 148 kJ/mol (35.4 kcal/mol) more stable than might be expected for “cyclohexatriene.”

Further evidence for the unusual nature of benzene is that all its carbon–carbon bonds have the same length—139 pm, which is intermediate between typical single (154 pm) and double (134 pm) bonds. In addition, an electrostatic potential map shows that the electron density in all six C–C bonds is identical. Thus, benzene is a planar molecule with the shape of a regular hexagon. All C–C–C bond angles are 120° , all six carbon atoms are sp^2 -hybridized, and each carbon has a p orbital perpendicular to the plane of the six-membered ring.

Because all six carbon atoms and all six p orbitals in benzene are equivalent, it’s impossible to define three localized π bonds in which a given p orbital overlaps only one neighboring p orbital. Rather, each p orbital overlaps equally well with both neighboring p orbitals, leading to a picture of benzene in which all six π electrons are free to move about the entire ring (FIGURE 15.4b). In resonance terms (Section 2.4 and Section 2.5), benzene is a hybrid of two equivalent forms. Neither form is correct by itself; the true structure of benzene is somewhere in between the two resonance forms but is impossible to draw with our usual conventions. Because of this resonance, benzene is more stable and less reactive than a typical alkene.

FIGURE 15.4 (a) An electrostatic potential map of benzene and (b) an orbital picture. Each of the six carbon atoms has a p orbital that can overlap equally well with neighboring p orbitals on both sides. As a result, all C–C bonds are equivalent and benzene must be represented as a hybrid of two resonance forms.

Chemists sometimes represent the two benzene resonance forms by using a circle to indicate the equivalence of the carbon–carbon bonds, but this representation has to be used carefully because it doesn’t indicate the number of π electrons in the ring. (How many electrons does a circle represent?) In this book, benzene and

other aromatic compounds will be represented by single line-bond structures. We'll be able to keep count of π electrons this way but must be aware of the limitations of the drawings.

Having just seen a resonance description of benzene, let's now look at the alternative molecular orbital description. We can construct π molecular orbitals for benzene just as we did for 1,3-butadiene in [Section 14.1](#). If six p atomic orbitals combine in a cyclic manner, six benzene molecular orbitals result, as shown in [FIGURE 15.5](#). The three low-energy molecular orbitals, denoted ψ_1 , ψ_2 , and ψ_3 , are bonding combinations, and the three high-energy orbitals are antibonding.

FIGURE 15.5 The six benzene π molecular orbitals. The bonding orbitals ψ_2 and ψ_3 have the same energy and are said to be degenerate, as are the antibonding orbitals ψ_4^* and ψ_5^* . The orbitals ψ_3 and ψ_4^* have no π electron density on two carbons because of a node passing through these atoms.

Note that the two bonding orbitals ψ_2 and ψ_3 have the same energy, as do the two antibonding orbitals ψ_4^* and ψ_5^* . Such orbitals with the same energy are said to be **degenerate**. Note also that the two orbitals ψ_3 and ψ_4^* have nodes passing through ring carbon atoms, thereby leaving no π electron density on these carbons. The six p electrons of benzene occupy the three bonding molecular orbitals and are delocalized over the entire conjugated system, leading to the observed 150 kJ/mol stabilization of benzene.

PROBLEM Pyridine is a flat, hexagonal molecule with bond angles of 120° . It undergoes substitution rather than addition and generally behaves like benzene. Draw a picture of the π orbitals of pyridine to explain its properties. Check your answer by looking ahead to [Section 15.5](#).

15.3 Aromaticity and the Hückel $4n + 2$ Rule

Let's list what we've said thus far about benzene and, by extension, about other benzene-like aromatic molecules.

- Benzene is cyclic and conjugated.
- Benzene is unusually stable, having a heat of hydrogenation 150 kJ/mol less negative than we might expect for a conjugated cyclic triene.

- Benzene is planar and has the shape of a regular hexagon. All bond angles are 120° , all carbon atoms are sp^2 -hybridized, and all carbon–carbon bond lengths are 139 pm.
- Benzene undergoes substitution reactions that retain the cyclic conjugation rather than electrophilic addition reactions that would destroy it.
- Benzene can be described as a resonance hybrid whose structure is intermediate between two line-bond structures.

This list might seem to be a good description of benzene and other aromatic molecules, but it isn't enough. Something else, called the **Hückel $4n + 2$ rule**, is needed to complete a description of aromaticity. According to a theory devised in 1931 by the German physicist Erich Hückel, a molecule is aromatic only if it has a planar, monocyclic system of conjugation and contains a total of $4n + 2$ π electrons, where n is an integer ($n = 0, 1, 2, 3$). In other words, only molecules with 2, 6, 10, 14, 18, π electrons can be aromatic. Molecules with $4n$ π electrons (4, 8, 12, 16,) can't be aromatic, even though they may be cyclic, planar, and apparently conjugated. In fact, planar, conjugated molecules with $4n$ π electrons are said to be **antiaromatic** because delocalization of their π electrons would lead to their destabilization.

Let's look at several examples to see how the Hückel $4n + 2$ rule works.

- **Cyclobutadiene** has four π electrons and is antiaromatic. As indicated by the electrostatic potential map, the π electrons are localized in two double bonds rather than delocalized around the ring.

Cyclobutadiene is highly reactive and shows none of the properties associated with aromaticity. In fact, it was not even prepared until 1965, when Rowland Pettit at the University of Texas was able to make it at low temperature. Even at -78°C , however, cyclobutadiene is so reactive that it dimerizes by a Diels–Alder reaction. One molecule behaves as a diene and the other as a dienophile.

- **Benzene** has six π electrons ($4n + 2 = 6$ when $n = 1$) and is aromatic.

- **Cyclooctatetraene** has eight π electrons, but when it was first prepared in 1911 by the German chemist Richard Willstätter, it was found not to be particularly stable. In fact, its π electrons are localized into four double bonds rather than delocalized around the ring, and the molecule is tub-shaped rather than planar. It has no cyclic conjugation because neighboring p orbitals don't have the necessary parallel alignment for overlap, and it resembles an open-chain polyene in its reactivity.

X-ray studies show that the C–C single bonds in cyclooctatetraene are 147 pm long and the double bonds are 134 pm long. In addition, the ^1H NMR spectrum shows a single sharp resonance line at 5.78 δ , a value characteristic of an alkene rather than an aromatic molecule.

What's so special about $4n + 2 \pi$ electrons? Why do 2, 6, 10, 14 π electrons lead to aromatic stability, while other numbers of electrons do not? The answer comes from molecular orbital theory. When the energy levels of molecular orbitals for cyclic conjugated molecules are calculated, it turns out that there is always a single lowest-lying MO, above which the MOs come in degenerate pairs. Thus, when electrons fill the various molecular orbitals, it takes two electrons, or one pair, to fill the lowest-lying orbital and four electrons, or two pairs, to fill each of n succeeding energy levels—a total of $4n + 2$. Any other number would leave an energy level partially filled.

The six π molecular orbitals of benzene were shown previously in **FIGURE 15.5**, and their relative energies are shown again in **FIGURE 15.6**. The lowest-energy MO, ψ_1 , occurs singly and contains two electrons. The next two lowest-energy orbitals, ψ_2 and ψ_3 , are degenerate, and it therefore takes four electrons to fill both. The result is a stable six- π -electron aromatic molecule with filled bonding orbitals.

FIGURE 15.6 Energy levels of the six benzene π molecular orbitals. There is a single, lowest-energy orbital, above which the orbitals come in degenerate pairs.

PROBLEM 15-5 To be aromatic, a molecule must have $4n + 2 \pi$ electrons and must have a planar, monocyclic system of conjugation. Cyclodecapentaene fulfills one of these criteria but not the other and has resisted all attempts at synthesis. Explain.

15.4 Aromatic Ions

According to the Hückel criteria for aromaticity, a molecule must be cyclic, conjugated (nearly planar with a p orbital on each atom), and have $4n + 2 \pi$ electrons. Nothing in this definition says that the number of π electrons must be the same as the number of atoms in the ring or that the substance must be neutral. In fact, the numbers can differ and the substance can be an ion. Thus, both the cyclopentadienyl anion and the cycloheptatrienyl cation are aromatic even though both are ions and neither contains a six-membered ring.

To understand why the cyclopentadienyl anion and the cycloheptatrienyl cation are aromatic, imagine starting from the related neutral hydrocarbons, 1,3-cyclopentadiene and 1,3,5-cycloheptatriene, and removing one hydrogen from the saturated CH_2 carbon in each. If that carbon then rehybridizes from sp^3 to sp^2 , the resultant products would be fully conjugated, with a p orbital on every carbon. There are three ways in which the hydrogen might be removed.

- The hydrogen can be removed with *both* electrons (H^-) from the C–H bond, leaving a carbocation as product.
- The hydrogen can be removed with *one* electron ($\text{H}\cdot$) from the C–H bond, leaving a carbon radical as product.
- The hydrogen can be removed with *no* electrons (H^+) from the C–H bond, leaving a carbanion as product.

All the potential products formed by removing a hydrogen from 1,3-cyclopentadiene and from 1,3,5-cycloheptatriene can be drawn with numerous resonance structures, but Hückel's rule predicts that only the six- π -electron cyclopentadienyl anion and cycloheptatrienyl cation can be aromatic. The other products are predicted by the $4n + 2$ rule to be unstable and antiaromatic (FIGURE 15.7).

FIGURE 15.7 The aromatic six- π -electron cyclopentadienyl anion and the six- π -electron cycloheptatrienyl cation. The anion can be formed by removing a hydrogen ion (H^+) from the CH_2 group of 1,3-cyclopentadiene. The cation can be generated by removing a hydride ion (H^-) from the CH_2 group of 1,3,5-cycloheptatriene.

In practice, both the four- π -electron cyclopentadienyl cation and the five- π -electron cyclopentadienyl radical are highly reactive and difficult to prepare. Neither shows any sign of the stability expected for an aromatic system. The six- π -electron cyclopentadienyl anion, by contrast, is easily prepared and remarkably stable (FIGURE 15.8a). In fact, the anion is so stable and easily formed that 1,3-cyclopentadiene is one of the most acidic hydrocarbons known, with $\text{p}K_a = 16$, a value comparable to that of water!

In the same way, the seven- π -electron cycloheptatrienyl radical and eight- π -electron anion are reactive and difficult to prepare, while the six- π -electron cycloheptatrienyl cation is extraordinarily stable (FIGURE 15.8b).

In fact, the cycloheptatrienyl cation was first prepared more than a century ago by reaction of 1,3,5-cycloheptatriene with Br_2 , although its structure was not recognized at the time.

FIGURE 15.8 (a) The aromatic cyclopentadienyl anion, showing cyclic conjugation and six π electrons in five p orbitals, and (b) the aromatic cycloheptatrienyl cation, showing cyclic conjugation and six π electrons in seven p orbitals. Electrostatic potential maps indicate that both ions are symmetrical, with the charge equally shared among all atoms in each ring.

PROBLEM Draw the five resonance structures of the cyclopentadienyl anion. Are all carbon–carbon bonds equivalent? **15-6** How many absorption lines would you expect to see in the ^1H NMR and ^{13}C NMR spectra of the anion?

PROBLEM Cyclooctatetraene readily reacts with potassium metal to form the stable cyclooctatetraene dianion, $\text{C}_8\text{H}_8^{2-}$. Why do you suppose this reaction occurs so easily? What geometry do you expect for the cyclooctatetraene dianion? **15-7**

PROBLEM The relative energy levels of the five π molecular orbitals of the cyclopentadienyl system are similar **15-8** to those in benzene. That is, there is a single lowest-energy MO, above which the orbitals come in degenerate pairs. Draw a diagram like that in Figure 15.6, and tell which of the five orbitals are occupied in the cation, radical, and anion.

15.5 Aromatic Heterocycles: Pyridine and Pyrrole

Look back once again at the definition of aromaticity in **Section 15.3**: a cyclic, conjugated molecule containing $4n + 2$ π electrons. Nothing in this definition says that the atoms in the ring must be *carbon*. In fact, *heterocyclic* compounds can also be aromatic. A **heterocycle** is a cyclic compound that contains atoms of more than one element in its ring, usually carbon along with nitrogen, oxygen, or sulfur. Pyridine and pyrimidine, for example, are six-membered heterocycles with carbon and nitrogen in their rings (**FIGURE 15.9**).

FIGURE 15.9 Pyridine and pyrimidine are nitrogen-containing aromatic heterocycles with π electron arrangements like that of benzene. Both have a lone pair of electrons on nitrogen in an sp^2 orbital in the plane of the ring.

Pyridine is much like benzene in its π electron structure. Each of the five sp^2 -hybridized carbons has a p orbital perpendicular to the plane of the ring, and each p orbital contains one π electron. The nitrogen atom is also sp^2 -hybridized and has one electron in a p orbital, bringing the total to six π electrons. The nitrogen lone-pair electrons (red in an electrostatic potential map) are in a sp^2 orbital in the plane of the ring and are not part of the aromatic π system. Pyrimidine, also shown in **FIGURE 15.9**, is a benzene analog that has two nitrogen atoms in a six-membered, unsaturated ring. Both nitrogens are sp^2 -hybridized, and each contributes one electron to the aromatic π system.

Pyrrole (spelled with two *r*'s and one *l*) and imidazole are five-membered heterocycles, yet both have six π electrons and are aromatic. In pyrrole, each of the four sp^2 -hybridized carbons contributes one π electron and the sp^2 -hybridized nitrogen atom contributes the two from its lone pair, which occupies a p orbital (**FIGURE 15.10**). Imidazole, also shown in (**FIGURE 15.10**), is an analog of pyrrole that has two nitrogen atoms in a five-membered, unsaturated ring. Both nitrogens are sp^2 -hybridized, but one is in a double bond and contributes only one electron to the aromatic π system whereas the other is not in a double bond and contributes two from its lone pair.

FIGURE 15.10 Pyrrole and imidazole are five-membered, nitrogen-containing heterocycles but have six- π -electron arrangements like that of the cyclopentadienyl anion. Both have a lone pair of electrons on nitrogen in a p orbital perpendicular to the ring.

Note that nitrogen atoms have different roles depending on the structure of the molecule. The nitrogen atoms in pyridine and pyrimidine are both in double bonds and contribute only one π electron to the aromatic sextet, just as a carbon atom in benzene does. The nitrogen atom in pyrrole, however, is not in a double bond and contributes two π electrons (its lone pair) to the aromatic sextet. In imidazole, both kinds of nitrogen are present in the same molecule—a double-bonded “pyridine-like” nitrogen that contributes one π electron and a “pyrrole-like” nitrogen that contributes two.

Pyrimidine and imidazole rings are particularly important in biological chemistry. Pyrimidine, for instance, is the parent ring system in cytosine, thymine, and uracil, three of the five heterocyclic amine bases found in nucleic acids. An aromatic imidazole ring is present in histidine, one of the 20 amino acids found in proteins.

WORKED EXAMPLE 15.1

Accounting for the Aromaticity of a Heterocycle

Thiophene, a sulfur-containing heterocycle, undergoes typical aromatic substitution reactions rather than addition reactions. Why is thiophene aromatic?

Strategy

Recall the requirements for aromaticity—a planar, cyclic, conjugated molecule with $4n + 2$ π electrons—and see how these requirements apply to thiophene.

Solution

Thiophene is the sulfur analog of pyrrole. The sulfur atom is sp^2 -hybridized and has a lone pair of electrons in a p orbital perpendicular to the plane of the ring. Sulfur also has a second lone pair of electrons in the ring plane.

PROBLEM Draw an orbital picture of furan to show how the molecule is aromatic.

PROBLEM Thiamin, or vitamin B₁, contains a positively charged five-membered nitrogen–sulfur heterocycle called a *thiazolium* ring. Explain why the thiazolium ring is aromatic.

15-10

15.6 Polycyclic Aromatic Compounds

The Hückel rule is strictly applicable only to monocyclic compounds, but the general concept of aromaticity can be extended to include *polycyclic* aromatic compounds. Naphthalene, with two benzene-like rings fused together; anthracene, with three rings; benzo[a]pyrene, with five rings; and coronene, with six rings, are all well-known aromatic hydrocarbons. Benzo[a]pyrene is particularly interesting because it is one of the cancer-causing substances found in tobacco smoke.

All polycyclic aromatic hydrocarbons can be represented by a number of different resonance forms. Naphthalene, for instance, has three.

Naphthalene and other polycyclic aromatic hydrocarbons show many of the chemical properties associated with aromaticity. Thus, measurement of its heat of hydrogenation shows an aromatic stabilization energy of approximately 250 kJ/mol (60 kcal/mol). Furthermore, naphthalene reacts slowly with electrophiles such as Br₂ to give substitution products rather than double-bond addition products.

The aromaticity of naphthalene is explained by the orbital picture in **FIGURE 15.11**. Naphthalene has a cyclic, conjugated π electron system, with p orbital overlap both along the ten-carbon periphery of the molecule and across the central bond. Because ten π electrons is a Hückel number, there is π electron delocalization and consequent aromaticity in naphthalene.

FIGURE 15.11 An orbital picture and electrostatic potential map of naphthalene, showing that the ten π electrons are fully delocalized

throughout both rings.

Just as there are heterocyclic analogs of benzene, there are also many heterocyclic analogs of naphthalene. Among the most common are quinoline, isoquinoline, indole, and purine. Quinoline, isoquinoline, and purine all contain pyridine-like nitrogens that are part of a double bond and contribute one electron to the aromatic π system. Indole and purine both contain pyrrole-like nitrogens that contribute two π electrons.

Among the many biological molecules that contain polycyclic aromatic rings, the amino acid tryptophan contains an indole ring and the antimalarial drug quinine contains a quinoline ring. Adenine and guanine, two of the five heterocyclic amine bases found in nucleic acids, have rings based on purine.

PROBLEM 15-11 Azulene, a beautiful blue hydrocarbon, is an isomer of naphthalene. Is azulene aromatic? Draw a second resonance form of azulene in addition to that shown.

PROBLEM 15-12 How many electrons does each of the four nitrogen atoms in purine contribute to the aromatic π system?

15.7 Spectroscopy of Aromatic Compounds

Infrared Spectroscopy

As we saw in the brief introduction to infrared spectroscopy (Section 12.8), aromatic rings show a characteristic C–H stretching absorption at 3030 cm^{-1} and a series of peaks in the 1450 to 1600 cm^{-1} range of the infrared spectrum. The aromatic C–H band at 3030 cm^{-1} generally has low intensity and occurs just to the left of a typical saturated C–H band.

As many as four absorptions are sometimes observed in the 1450 to 1600 cm^{-1} region because of the complex molecular motions of the ring itself. Two bands, one at 1500 cm^{-1} and one at 1600 cm^{-1} , are usually the most intense. In addition, aromatic compounds show weak absorptions in the 1660 to 2000 cm^{-1} region and strong absorptions in the 690 to 900 cm^{-1} range due to C–H out-of-plane bending. The exact position of both sets of absorptions is diagnostic of the substitution pattern of the aromatic ring (FIGURE 12.24 in Section 12.8).

Monosubstituted:	690–710 cm^{-1}	1,2,4-Trisubstituted:	780–830 cm^{-1}
	730–770 cm^{-1}		870–900 cm^{-1}
<i>o</i>-Disubstituted:	735–770 cm^{-1}	1,2,3-Trisubstituted:	670–720 cm^{-1}
<i>m</i>-Disubstituted:	690–710 cm^{-1}		750–790 cm^{-1}
	810–850 cm^{-1}	1,3,5-Trisubstituted:	660–700 cm^{-1}
<i>p</i>-Disubstituted:	810–840 cm^{-1}		830–900 cm^{-1}

The IR spectrum of toluene in FIGURE 15.12 shows these characteristic absorptions.

FIGURE 15.12 The infrared spectrum of toluene.

Ultraviolet Spectroscopy

Aromatic rings are detectable by ultraviolet spectroscopy because they contain a conjugated π electron system. In general, aromatic compounds show a series of bands, with a fairly intense absorption near 205 nm and a less intense absorption in the 255 to 275 nm range. The presence of these bands in the ultraviolet spectrum of a molecule is a sure indication of an aromatic ring. FIGURE 15.13 shows the ultraviolet spectrum of benzene.

FIGURE 15.13 Ultraviolet spectrum of benzene. There are primary bands at 184 and 202 nm and secondary (fine-structure) bands at 255 nm.

Nuclear Magnetic Resonance Spectroscopy

Aromatic hydrogens are strongly deshielded by the ring and absorb between 6.5 and 8.0 δ . The spins of nonequivalent aromatic protons on substituted rings often couple with each other, giving rise to spin–spin splitting patterns that can identify the substitution of the ring.

Much of the difference in chemical shift between aromatic protons (6.5–8.0 δ) and vinylic protons (4.5–6.5 δ) is due to a property of aromatic rings called **ring-current**. When an aromatic ring is oriented perpendicular to a strong magnetic field, the electrons circulate around the ring, producing a small local magnetic field. This induced field opposes the applied field in the middle of the ring but reinforces the applied field outside the ring (**FIGURE 15.14**). Aromatic protons therefore experience an effective magnetic field greater than the applied field and come into resonance at a lower applied field.

FIGURE 15.14 The origin of aromatic ring-current. Aromatic protons are deshielded by the induced magnetic field caused by delocalized π electrons circulating around the aromatic ring.

Note that the aromatic ring-current produces different effects inside and outside the ring. If a ring were large enough to have both “inside” and “outside” protons, the protons on the outside would be deshielded and absorb

at a field lower than normal but those on the inside would be shielded and absorb at a field higher than normal. This prediction has been strikingly confirmed by studies on [18]annulene, an 18- π -electron cyclic conjugated polyene that contains a Hückel number of electrons ($4n + 2 = 18$ when $n = 4$). The six inside protons of [18]annulene are strongly shielded by the aromatic ring-current and absorb at -3.0δ (that is, 3.0 ppm *upfield* from TMS, off the normal chart), while the 12 outside protons are strongly deshielded and absorb in the typical aromatic region at 9.3 ppm downfield from TMS.

The presence of a ring-current is characteristic of all Hückel aromatic molecules and is a good test of aromaticity. For example, benzene, a six- π -electron aromatic molecule, absorbs at 7.37δ because of its ring-current, but cyclooctatetraene, an eight- π -electron nonaromatic molecule, absorbs at 5.78δ .

Hydrogens on carbon next to aromatic rings—*benzylic* hydrogens—also show distinctive absorptions in the NMR spectrum. Benzylic protons normally absorb downfield from other alkane protons in the region from 2.3 to 3.0 δ .

The ^1H NMR spectrum of *p*-bromotoluene, shown in **FIGURE 15.15**, displays many of the features just discussed. The aromatic protons appear as two doublets at 7.04 and 7.37δ , and the benzylic methyl protons absorb as a sharp singlet at 2.26δ . Integration of the spectrum shows the expected 2 : 2 : 3 ratio of peak areas.

FIGURE 15.15 The ^1H NMR spectrum of *p*-bromotoluene.

The carbon atoms in an aromatic ring typically absorb in the range 110 to 140 δ in the ^{13}C NMR spectrum, as

indicated by the examples in **FIGURE 15.16**. These resonances are easily distinguished from those of alkane carbons but occur in the same range as alkene carbons. Thus, the presence of ^{13}C absorptions at 110 to 140 δ does not by itself establish the presence of an aromatic ring. Supporting evidence from infrared, ultraviolet, or ^1H NMR spectra is needed.

FIGURE 15.16 Some ^{13}C NMR absorptions of aromatic compounds (δ units).

CHEMISTRY MATTERS

Aspirin, NSAIDs, and COX-2 Inhibitors

Whatever the cause—whether tennis elbow, a sprained ankle, or a wrenched knee—pain and inflammation seem to go together. They are, however, different in their origin, and powerful drugs are available for treating each separately. Codeine, for example, is a powerful *analgesic*, or pain reliever, used in the management of debilitating pain, while cortisone and related steroids are potent *anti-inflammatory* agents, used for treating arthritis and other crippling inflammations. For minor pains and inflammation, both problems are often treated together by using a common over-the-counter medication called an *NSAID*, or *nonsteroidal anti-inflammatory drug*.

One of the most common NSAIDs is aspirin, or acetylsalicylic acid, whose use goes back to the late 1800s. It had been known from before the time of Hippocrates in 400 BC that fevers could be lowered by chewing the bark of willow trees. The active agent in willow bark was found in 1827 to be an aromatic compound called *salicin*, which could be converted by reaction with water into salicyl alcohol and then oxidized to give salicylic acid. Salicylic acid turned out to be even more effective than salicin for reducing fevers and to have analgesic and anti-inflammatory action as well. Unfortunately, it also turned out to be too corrosive to the walls of the stomach for everyday use. Conversion of the phenol $-OH$ group into an acetate ester, however, yielded acetylsalicylic acid, which proved just as potent as salicylic acid but less corrosive to the stomach.

FIGURE 15.17 Many athletes rely on NSAIDs to help with pain and soreness. (credit: “Dillon Gee delivers a pitch” by Arturo Pardavila III/Wikimedia Commons, CC BY 2.0)

Although extraordinary in its effect, aspirin is also more dangerous than commonly believed. 15 g of aspirin would be fatal to a child of 9–10 years, and 10 g would be lethal for a 6-year-old, and aspirin can cause stomach bleeding and allergic reactions in long-term users. Even more serious is a condition called *Reye's syndrome*, a potentially fatal reaction to aspirin sometimes seen in children recovering from the flu. As a result of these problems, numerous other NSAIDs have been developed in the last several decades, most notably ibuprofen and naproxen.

Like aspirin, both ibuprofen and naproxen are relatively simple aromatic compounds containing a side-chain carboxylic acid group. Ibuprofen, sold under the brand names Advil, Nuprin, Motrin, and others, has roughly the same potency as aspirin but is less prone to causing an upset stomach. Naproxen, sold under the names Aleve and Naprosyn, also has about the same potency as aspirin but remains active in the body six times longer.

Aspirin and other NSAIDs function by blocking the cyclooxygenase (COX) enzymes that carry out the body's synthesis of prostaglandins (Section 8.11 and Section 27.4). There are two forms of the enzyme: COX-1, which carries out the normal physiological production of prostaglandins, and COX-2, which mediates the body's response to arthritis and other inflammatory conditions. Unfortunately, both COX-1 and COX-2 enzymes are blocked by aspirin, ibuprofen, and other NSAIDs, thereby shutting down not only the response to inflammation but also various protective functions, including the control mechanism for production of acid in the stomach.

Medicinal chemists have therefore devised a number of drugs that act as selective inhibitors of only the COX-2 enzyme. Inflammation is thereby controlled without blocking protective functions. Originally heralded as a breakthrough in arthritis treatment, the first generation of COX-2 inhibitors, including rofecoxib, (marketed as Vioxx), celecoxib, (marketed as Celebrex), and Valdecoxib (marketed as Bextra), turned out to cause potentially serious heart problems, particularly in elderly or compromised patients. As a result, all three Cox-2 inhibitors were removed from the U.S. and other markets. Further studies, however, concluded that in proper doses the Cox-2 inhibitors were little different from other NSAIDs, and Vioxx returned to the market in 2017 for topical treatment of osteoarthritis.

Key Terms

- antiaromatic
- arene
- aromatic
- benzyl group
- degenerate orbitals
- heterocycle
- Hückel $4n + 2$ rule
- meta (*m*)
- ortho (*o*)
- para (*p*)
- phenyl group
- ring-current

Summary

Aromatic rings are a common part of many biological structures and are particularly important in nucleic acid chemistry and in the chemistry of several amino acids. In this chapter, we've seen how and why aromatic compounds are different from such apparently related compounds as cycloalkenes.

The word **aromatic** is used for historical reasons to refer to the class of compounds related structurally to benzene. Aromatic compounds are systematically named according to IUPAC rules, but many common names

are also used. Disubstituted benzenes are referred to as **ortho** (1,2 disubstituted), **meta** (1,3 disubstituted), or **para** (1,4 disubstituted) derivatives. The C_6H_5- unit itself is referred to as a **phenyl** group, and the $C_6H_5CH_2-$ unit is a **benzyl** group.

Benzene is described by valence-bond theory as a resonance hybrid of two equivalent structures and is described by molecular orbital theory as a planar, cyclic, conjugated molecule with six π electrons. According to the **Hückel rule**, a molecule must have $4n + 2 \pi$ electrons, where $n = 0, 1, 2, 3$, and so on, to be aromatic. Planar, cyclic, conjugated molecules with other numbers of π electrons are **antiaromatic**.

Other substances besides benzene-like compounds are also aromatic. The cyclopentadienyl anion and the cycloheptatrienyl cation, for instance, are aromatic ions. Pyridine and pyrimidine are six-membered, nitrogen-containing, aromatic **heterocycles**. Pyrrole and imidazole are five-membered, nitrogen-containing heterocycles. Naphthalene, quinoline, indole, and many others are polycyclic aromatic compounds.

Aromatic compounds have the following characteristics:

- Aromatic compounds are cyclic, planar, and conjugated.
- Aromatic compounds are unusually stable. Benzene, for instance, has a heat of hydrogenation 150 kJ/mol less than we might expect for a cyclic triene.
- Aromatic compounds react with electrophiles to give substitution products, in which cyclic conjugation is retained, rather than addition products, in which conjugation is destroyed.
- Aromatic compounds have $4n + 2 \pi$ electrons, which are delocalized over the ring.

Additional Problems

Visualizing Chemistry

PROBLEM Give IUPAC names for the following substances (red = O, blue = N):

15-13 (a)

(b)

PROBLEM All-cis cyclodecapentaene is a stable molecule that shows a single absorption in its 1H NMR

15-14 spectrum at 5.67 δ . Tell whether it is aromatic, and explain its NMR spectrum.

PROBLEM 1,6-Methanonaphthalene has an interesting 1H NMR spectrum in which the eight hydrogens

15-15 around the perimeter absorb at 6.9 to 7.3 δ , while the two CH_2 protons absorb at -0.5δ . Tell whether it is aromatic, and explain its NMR spectrum.

1,6-Methanonaphthalene

PROBLEM The following molecular model is that of a carbocation. Draw two resonance structures for the carbocation, indicating the positions of the double bonds.

15-16

PROBLEM Azulene, an isomer of naphthalene, has a remarkably large dipole moment for a hydrocarbon ($\mu = 1.0$ D). Explain, using resonance structures.

15-17

Azulene

Naming Aromatic Compounds

PROBLEM Give IUPAC names for the following compounds:

15-18 (a)

(b)

(c)

(d)

(e)

(f)

PROBLEM Draw structures corresponding to the following names:

15-19 (a) 3-Methyl-1,2-benzenediamine (b) 1,3,5-Benzenetriol (c) 3-Methyl-2-phenylhexane
(d) *o*-Aminobenzoic acid (e) *m*-Bromophenol (f) 2,4,6-Trinitrophenol (picric acid)

PROBLEM Draw and name all possible isomers of the following:

15-20 (a) Dinitrobenzene **(b)** Bromodimethylbenzene **(c)** Trinitrophenol

PROBLEM Draw and name all possible aromatic compounds with the formula C_7H_7Cl .

15-21

PROBLEM Draw and name all possible aromatic compounds with the formula C_8H_9Br . (There are 14.)

15-22

Structure of Aromatic Compounds

PROBLEM Propose structures for aromatic hydrocarbons that meet the following descriptions:

15-23 (a) C_9H_{12} ; gives only one $C_9H_{11}Br$ product on substitution of a hydrogen on the aromatic ring with bromine

(b) $C_{10}H_{14}$; gives only one $C_{10}H_{13}Cl$ product on substitution of a hydrogen on the aromatic ring with chlorine

(c) C_8H_{10} ; gives three C_8H_9Br products on substitution of a hydrogen on the aromatic ring with bromine

(d) $C_{10}H_{14}$; gives two $C_{10}H_{13}Cl$ products on substitution of a hydrogen on the aromatic ring with chlorine

PROBLEM Look at the three resonance structures of naphthalene shown in Section 15.6, and account for the

15-24 fact that not all carbon-carbon bonds have the same length. The C1-C2 bond is 136 pm long, whereas the C2-C3 bond is 139 pm long.

PROBLEM Anthracene has four resonance structures, one of which is shown. Draw the other three.

15-25

PROBLEM Phenanthrene has five resonance structures, one of which is shown. Draw the other four.

15-26

PROBLEM Look at the five resonance structures for phenanthrene (Problem 26), and predict which of its

15-27 carbon-carbon bonds is shortest.

PROBLEM In 1932, A. A. Levine and A. G. Cole studied the ozonolysis of *o*-xylene and isolated three products:

15-28 glyoxal, 2,3-butanedione, and pyruvaldehyde:

In what ratio would you expect the three products to be formed if *o*-xylene is a resonance hybrid of two structures? The actual ratio found was 3 parts glyoxal, 1 part 2,3-butanedione, and 2 parts pyruvaldehyde. What conclusions can you draw about the structure of *o*-xylene?

Aromaticity and Hückel's Rule

PROBLEM 3-Chlorocyclopropene, on treatment with $AgBF_4$, gives a precipitate of $AgCl$ and a stable solution

15-29 of a product that shows a single 1H NMR absorption at 11.04 δ . What is a likely structure for the product, and what is its relation to Hückel's rule?

PROBLEM Draw an energy diagram for the three molecular orbitals of the cyclopropenyl system (C_3H_3). How
15-30 are these three molecular orbitals occupied in the cyclopropenyl anion, cation, and radical? Which of the three substances is aromatic according to Hückel's rule?

PROBLEM Cyclopropanone is highly reactive because of its large amount of angle strain.
15-31 Methylcyclopropenone, although even more strained than cyclopropanone, is nevertheless quite stable and can even be distilled. Explain, taking the polarity of the carbonyl group into account.

Cyclopropanone

Methylcyclopropenone

PROBLEM Cycloheptatrienone is stable, but cyclopentadienone is so reactive that it can't be isolated. Explain,
15-32 taking the polarity of the carbonyl group into account.

Cycloheptatrienone

Cyclopentadienone

PROBLEM Which would you expect to be most stable, cyclononatetraenyl radical, cation, or anion?
15-33 (Cyclononatetraene has a ring of nine carbons and four double bonds.)

PROBLEM How might you convert 1,3,5,7-cyclononatetraene to an aromatic substance?
15-34

PROBLEM Calicene, like azulene (Problem 17), has an unusually large dipole moment for a hydrocarbon.
15-35 Explain, using resonance structures.

PROBLEM Pentalene is a most elusive molecule that has been isolated only at liquid-nitrogen temperature.
15-36 The pentalene dianion, however, is well known and quite stable. Explain.

Pentalene

Pentalene dianion

PROBLEM Indole is an aromatic heterocycle that has a benzene ring fused to a pyrrole ring. Draw an orbital
15-37 picture of indole.

(a) How many π electrons does indole have?

(b) What is the electronic relationship of indole to naphthalene?

PROBLEM 15-38 Ribavirin, an antiviral agent used against hepatitis C and viral pneumonia, contains a 1,2,4-triazole ring. Why is the ring aromatic?

Spectroscopy

PROBLEM 15-39 Compound **A**, C_8H_{10} , yields three substitution products, C_8H_9Br , on reaction with Br_2 . Propose two possible structures for **A**. The 1H NMR spectrum of **A** shows a complex four-proton multiplet at 7.0δ and a six-proton singlet at 2.30δ . What is the structure of **A**?

PROBLEM 15-40 What is the structure of a hydrocarbon that has $M^+ = 120$ in its mass spectrum and has the following 1H NMR spectrum?

7.25δ (5 H, broad singlet); 2.90δ (1 H, septet, $J = 7$ Hz); 1.22δ (6 H, doublet, $J = 7$ Hz)

PROBLEM 15-41 Propose structures for compounds that fit the following descriptions:

(a) $C_{10}H_{14}$

1H NMR: 7.18δ (4 H, broad singlet); 2.70δ (4 H, quartet, $J = 7$ Hz); 1.20δ (6 H, triplet, $J = 7$ Hz)

IR absorption at 745 cm^{-1}

(b) $C_{10}H_{14}$

1H NMR: 7.0δ (4 H, broad singlet); 2.85δ (1 H, septet, $J = 8$ Hz); 2.28δ (3 H, singlet); 1.20δ (6 H, doublet, $J = 8$ Hz)

IR absorption at 825 cm^{-1}

General Problems

PROBLEM 15-42 On reaction with acid, 4-pyrone is protonated on the carbonyl-group oxygen to give a stable cationic product. Using resonance structures and the Hückel $4n + 2$ rule, explain why the protonated product is so stable.

4-Pyrone

PROBLEM 15-43 Bextra, a COX-2 inhibitor once used in the treatment of arthritis, contains an isoxazole ring. Why is the ring aromatic?

PROBLEM 15-44 *N*-Phenylsydnone, so-named because it was first studied at the University of Sydney, Australia, behaves like a typical aromatic molecule. Explain, using the Hückel $4n + 2$ rule.

PROBLEM 15-45 Show the relative energy levels of the seven π molecular orbitals of the cycloheptatrienyl system. Tell which of the seven orbitals are filled in the cation, radical, and anion, and account for the aromaticity of the cycloheptatrienyl cation.

PROBLEM 15-46 1-Phenyl-2-butene has an ultraviolet absorption at $\lambda_{\text{max}} = 208 \text{ nm}$ ($\epsilon = 8000$). On treatment with a small amount of strong acid, isomerization occurs and a new substance with $\lambda_{\text{max}} = 250 \text{ nm}$ ($\epsilon = 15,800$) is formed. Propose a structure for this isomer, and suggest a mechanism for its formation.

PROBLEM 15-47 (a) Propose structures for aromatic compounds that have the following ^1H NMR spectra:
15-47 (a) $\text{C}_8\text{H}_9\text{Br}$

IR absorption at 820 cm^{-1}

(b) C_9H_{12} IR absorption at 750 cm^{-1} (c) $C_{11}H_{16}$ IR absorption at 820 cm^{-1} 

PROBLEM 15-48 Propose a structure for a molecule $C_{14}H_{12}$ that has the following 1H NMR spectrum and has IR absorptions at 700 , 740 , and 890 cm^{-1} :

PROBLEM 15-49 The proton NMR spectrum for a compound with formula $C_{10}H_{12}O_2$ is shown. The infrared spectrum has a strong band at 1711 cm^{-1} . The normal carbon-13 NMR spectral results are tabulated along with the DEPT-135 and DEPT-90 information. Draw the structure of this compound.

Normal Carbon	DEPT-135	DEPT-90
29 ppm	Positive	No peak
50	Negative	No peak
55	Positive	No peak
114	Positive	Positive
126	No peak	No peak
130	Positive	Positive
159	No peak	No peak
207	No peak	No peak

PROBLEM 15-50 The proton NMR spectrum of a compound with formula $C_6H_5NCl_2$ is shown. The normal carbon-13 and DEPT experimental results are tabulated. The infrared spectrum shows peaks at 3432 and 3313 cm^{-1} and a series of medium-sized peaks between 1618 and 1466 cm^{-1} . Draw the structure of this compound.

Normal Carbon	DEPT-135	DEPT-90
118.0 ppm	Positive	Positive
119.5	No peak	No peak
128.0	Positive	Positive
140.0	No peak	No peak

PROBLEM Aromatic substitution reactions occur by addition of an electrophile such as Br^+ to an aromatic ring to yield an allylic carbocation intermediate, followed by loss of H^+ . Show the structure of the intermediate formed by reaction of benzene with Br^+ .

15-51

PROBLEM The substitution reaction of toluene with Br_2 can, in principle, lead to the formation of three isomeric bromotoluene products. In practice, however, only *o*- and *p*-bromotoluene are formed in substantial amounts. The meta isomer is not formed. Draw the structures of the three possible carbocation intermediates (Problem 51), and explain why ortho and para products predominate over meta products.

15-52

PROBLEM Look at the following aromatic anions and their linear counterparts, and draw all of the resonance forms for each. What patterns emerge?

15-53

PROBLEM After the following reaction, the chemical shift of H_a moves downfield from 6.98 ppm to 7.30 ppm. Explain.

15-54

PROBLEM The following compound is the product initially formed in a Claisen rearrangement, which we'll see in Section 18.4. This product is not isolated, but tautomerizes to its enol form. Give the structure of the enol and provide an explanation as to why the enol tautomer is favored.

15-55

PROBLEM 15-56 Compounds called azo dyes are the major source of artificial color in textiles and food. Part of the reason for their intense coloring is the conjugation from an electron-donating group through the diazo bridge ($-N=N-$) to an electron-withdrawing group on the other side. For the following azo dyes, draw a resonance form that shows how the electron-donating group is related to the electron-withdrawing group on the other side of the diazo bridge. Used curved arrows to show how the electrons are reorganized.

WHY THIS CHAPTER? This chapter continues the coverage of aromatic molecules begun in the preceding chapter, but we'll shift focus to concentrate on reactions, looking at the relationship between aromatic structure and reactivity. This relationship is critical in understanding how many biological molecules and pharmaceutical agents are synthesized and why they behave as they do.

In the preceding chapter, we looked at aromaticity—the stability associated with benzene and related compounds that contain a cyclic conjugated system of $4n + 2 \pi$ electrons. In this chapter, we'll look at some of the unique reactions that aromatic molecules undergo.

The most common reaction of aromatic compounds is **electrophilic aromatic substitution**, in which an electrophile (E^+) reacts with an aromatic ring and substitutes for one of the hydrogens. The reaction is characteristic of all aromatic rings, not just benzene and substituted benzenes. In fact, the ability of a compound to undergo electrophilic substitution is a good test of aromaticity.

Many different substituents can be introduced onto an aromatic ring through electrophilic substitution. To list some possibilities, an aromatic ring can be substituted by a halogen ($-Cl$, $-Br$, $-I$), a nitro group ($-NO_2$), a sulfonic acid group ($-SO_3H$), a hydroxyl group ($-OH$), an alkyl group ($-R$), or an acyl group ($-COR$). Starting from only a few simple materials, it's possible to prepare many thousands of substituted aromatic compounds.

16.1 Electrophilic Aromatic Substitution Reactions: Bromination

Before seeing how electrophilic aromatic substitutions occur, let's briefly recall what we said in the chapter on **Alkenes: Structure and Reactivity** about electrophilic alkene additions. When a reagent such as HCl adds to an alkene, the electrophilic hydrogen ion approaches the π electrons of the double bond and forms a bond to one carbon, leaving a positive charge at the other carbon. This carbocation intermediate then reacts with the nucleophilic Cl^- ion to yield the addition product.

An electrophilic aromatic substitution reaction begins in a similar way, but there are a number of differences. One difference is that aromatic rings are less reactive toward electrophiles than alkenes. For example, Br_2 in CH_2Cl_2 solution reacts instantly with most alkenes but does not react with benzene at room temperature. For bromination of benzene to take place, a catalyst such as $FeBr_3$ is needed. The catalyst makes the Br_2 molecule more electrophilic by polarizing it to give a $FeBr_4^-Br^+$ species that reacts as if it were Br^+ . The polarized Br_2 molecule then reacts with the nucleophilic benzene ring to yield a nonaromatic carbocation intermediate that is doubly allylic (**Section 11.5**) and has three resonance forms.

Although more stable than a typical alkyl carbocation because of resonance, the intermediate in electrophilic aromatic substitution is nevertheless much less stable than the starting benzene ring itself, with its 150 kJ/mol (36 kcal/mol) of aromatic stability. Thus, the reaction of an electrophile with a benzene ring is endergonic, has a substantial activation energy, and is rather slow. **FIGURE 16.2** shows an energy diagram comparing the reaction of an electrophile with an alkene and with benzene. The benzene reaction is slower (higher ΔG^\ddagger) because the starting material is more stable.

FIGURE 16.2 A comparison of the reactions of an electrophile (E^+) with an alkene and with benzene: $\Delta G^\ddagger_{\text{alkene}} < \Delta G^\ddagger_{\text{benzene}}$. The benzene reaction is slower than the alkene reaction because of the stability of the aromatic ring.

Another difference between alkene addition and aromatic substitution occurs after the carbocation intermediate has formed. Instead of adding Br^- to give an addition product, the carbocation intermediate loses H^+ from the bromine-bearing carbon to give a substitution product. Note that this loss of H^+ is similar to what occurs in the second step of an E1 reaction (**Section 11.10**). The net effect of reaction of Br_2 with benzene is the substitution of H^+ by Br^+ by the overall mechanism shown in **FIGURE 16.3**.

FIGURE 16.3 MECHANISM

The mechanism for the electrophilic bromination of benzene. The reaction occurs in two steps and involves a resonance-stabilized carbocation intermediate.

Why does the reaction of Br_2 with benzene take a different course than its reaction with an alkene? The answer is straightforward. If addition occurred, the 150 kJ/mol stabilization energy of the aromatic ring would be lost and the overall reaction would be endergonic. When substitution occurs, though, the stability of the aromatic ring is retained and the reaction is exergonic. An energy diagram for the overall process is shown in **FIGURE 16.4**.

FIGURE 16.4 An energy diagram for the electrophilic bromination of benzene. Because the stability of the aromatic ring is retained, the overall process is exergonic.

PROBLEM Monobromination of toluene gives a mixture of three bromotoluene products. Draw and name **16-1** them.

16.2 Other Aromatic Substitutions

There are many other kinds of electrophilic aromatic substitutions besides bromination, and all occur by the same general mechanism. Let's look at some of these other reactions briefly.

Aromatic Halogenation

Chlorine and iodine can be introduced into aromatic rings by electrophilic substitution reactions just as bromine can, but fluorine is too reactive and only poor yields of monofluoroaromatic products are obtained by direct fluorination. Instead, other sources of "F⁺" are used, in which a fluorine atom is bonded to a positively charged nitrogen. One of the most common such reagents goes by the acronym F-TEDA-BF₄ in the presence of trifluoromethanesulfonic acid (TfOH). (You don't need to know the full name of F-TEDA, which is sold under the name Selectfluor.)

More than 20% of all pharmaceutical agents sold contain fluorine, including 30% of the top 100 drugs sold. Sitagliptin (Januvia), used to treat type 2 diabetes, fluoxetine (Prozac), an antidepressant, and atorvastatin (Lipitor), a statin used to lower cholesterol, are examples.

Aromatic rings react with Cl₂ in the presence of FeCl₃ catalyst to yield chlorobenzenes, just as they react with Br₂ and FeBr₃. This kind of reaction is used in the synthesis of numerous pharmaceutical agents, including the antiallergy medication loratadine, marketed as Claritin.

Iodine itself is unreactive toward aromatic rings, so an oxidizing agent such as hydrogen peroxide or a copper salt such as CuCl₂ must be added to the reaction. These substances accelerate the iodination reaction by oxidizing I₂ to a more powerful electrophilic species that reacts as if it were I⁺. The aromatic ring then reacts with I⁺ in the typical way, yielding a substitution product.

Electrophilic aromatic halogenations also occur in the biosynthesis of many naturally occurring molecules, particularly those produced by marine organisms. In humans, the best-known example occurs in the thyroid gland during the biosynthesis of thyroxine, a hormone involved in regulating growth and metabolism. The amino acid tyrosine is first iodinated by thyroid peroxidase, and two of the iodinated tyrosine molecules then couple. The electrophilic iodinating agent is an I^+ species, perhaps hypoiodous acid (HIO), that is formed from iodide ion by oxidation with H_2O_2 .

Aromatic Nitration

Aromatic rings are nitrated by reaction with a mixture of concentrated nitric and sulfuric acids. The electrophile is the nitronium ion, NO_2^+ , which is formed from HNO_3 by protonation and loss of water. The nitronium ion reacts with benzene to yield a carbocation intermediate, and loss of H^+ from this intermediate gives the neutral substitution product, nitrobenzene (FIGURE 16.5).

FIGURE 16.5 The mechanism for electrophilic nitration of an aromatic ring. An electrostatic potential map of the reactive electrophile NO_2^+ shows that the **nitrogen atom is most positive**.

Electrophilic nitration of an aromatic ring does not occur in nature but is particularly important in the laboratory because the nitro-substituted product can be reduced by reagents such as iron, tin, or SnCl_2 to yield the corresponding *arylamine*, ArNH_2 . Attachment of an amino group ($-\text{NH}_2$) to an aromatic ring by the two-step nitration/reduction sequence is a key part of the industrial synthesis of many dyes and pharmaceutical agents. We'll discuss this reduction and other reactions of aromatic nitrogen compounds in Chapter 24.

Aromatic Sulfonation

Aromatic rings can be sulfonated by reaction with so-called fuming sulfuric acid, a mixture of H_2SO_4 and SO_3 . The reactive electrophile is either HSO_3^+ or neutral SO_3 , depending on reaction conditions, and substitution occurs by the same two-step mechanism seen previously for bromination and nitration (FIGURE 16.6). Note, however, that the sulfonation reaction is readily reversible. It can occur either forward or backward, depending on the reaction conditions. Sulfonation is favored in strong acid, but desulfonation is favored in hot, dilute aqueous acid.

FIGURE 16.6 The mechanism for electrophilic sulfonation of an aromatic ring. An electrostatic potential map of the reactive electrophile HSO_3^+ shows that **sulfur and hydrogen are the most positive atoms**.

Aromatic sulfonation does not occur naturally but is widely used in the preparation of dyes and pharmaceutical agents. For example, the sulfa drugs, such as sulfanilamide, were among the first clinically useful antibiotics. Although largely replaced today by more effective agents, sulfa drugs are still used in the treatment of meningitis and urinary tract infections. These drugs are prepared commercially by a process that involves aromatic sulfonation as its key step.

Aromatic Hydroxylation

Direct hydroxylation of an aromatic ring to yield a hydroxybenzene (a *phenol*) is difficult and rarely done in the laboratory but occurs much more frequently in biological pathways. An example is the hydroxylation of *p*-hydroxyphenylacetate to give 3,4-dihydroxyphenylacetate. The reaction is catalyzed by *p*-hydroxyphenylacetate-3-hydroxylase and requires molecular oxygen plus the coenzyme reduced flavin adenine dinucleotide, abbreviated FADH_2 .

By analogy with other electrophilic aromatic substitutions, you might expect that an electrophilic oxygen species acting as an “ OH^+ equivalent” is needed for the hydroxylation reaction. That is just what happens, with the electrophilic oxygen arising by protonation of FAD hydroperoxide, RO-OH (FIGURE 16.7); that is, $\text{RO-OH} + \text{H}^+ \rightarrow \text{ROH} + \text{OH}^+$. The FAD hydroperoxide itself is formed by reaction of FADH_2 with O_2 .

FIGURE 16.7 MECHANISM

Mechanism for the electrophilic hydroxylation of *p*-hydroxyphenylacetate, by reaction with FAD hydroperoxide. The hydroxylating species is an “OH⁺ equivalent” that arises by protonation of FAD hydroperoxide, $\text{RO-OH} + \text{H}^+ \rightarrow \text{ROH} + \text{OH}^+$. The FAD hydroperoxide itself is formed by reaction of FADH_2 with O_2 .

16.3 Alkylation and Acylation of Aromatic Rings: The Friedel–Crafts Reaction

Among the most useful electrophilic aromatic substitution reactions in the laboratory is **alkylation**—the introduction of an alkyl group onto the benzene ring. Called the **Friedel–Crafts reaction** after its founders in 1877, Charles Friedel and James Crafts, the reaction is carried out by treating an aromatic compound with an alkyl chloride, RCl , in the presence of AlCl_3 to generate a carbocation electrophile, R^+ . Aluminum chloride catalyzes the reaction by helping the alkyl halide to generate a carbocation in much the same way that FeBr_3 catalyzes aromatic brominations by polarizing Br_2 (Section 16.1). Loss of H^+ then completes the reaction (Figure 16.8).

FIGURE 16.8 MECHANISM

Mechanism for the Friedel–Crafts alkylation reaction of benzene with 2-chloropropane to yield isopropylbenzene (cumene). The electrophile is a carbocation, generated by AlCl_3 -assisted dissociation of an alkyl halide.

Despite its utility, the Friedel–Crafts alkylation has several limitations. For one thing, only alkyl halides can be used. Aromatic (aryl) halides and vinylic halides don't react because aryl and vinylic carbocations are too high in energy to form under Friedel–Crafts conditions.

Another limitation is that Friedel–Crafts reactions don't succeed on aromatic rings that are substituted either by a strongly electron-withdrawing group such as carbonyl ($\text{C}=\text{O}$) or by a basic amino group that can be protonated. We'll see in the next section that the presence of a substituent group already on a ring can have a dramatic effect on that ring's reactivity to further electrophilic substitution. Rings that contain any of the substituents listed in Figure 16.9 do not undergo Friedel–Crafts alkylation.

FIGURE 16.9 Limitations on the aromatic substrate in Friedel–Crafts reactions. No reaction occurs if the substrate has either an electron-withdrawing substituent or a basic amino group.

A third limitation to the Friedel–Crafts alkylation is that it's often difficult to stop the reaction after a single substitution. Once the first alkyl group is on the ring, a second substitution reaction is facilitated for reasons we'll discuss in the next section. Thus, we often observe *polyalkylation*. Reaction of benzene with 1 mol equivalent of 2-chloro-2-methylpropane, for example, yields *p*-di-*tert*-butylbenzene as the major product, along with small amounts of *tert*-butylbenzene and unreacted benzene. A high yield of mono-alkylation product is obtained only when a large excess of benzene is used.

A final limitation to the Friedel–Crafts reaction is that a skeletal rearrangement of the alkyl carbocation electrophile sometimes occurs during reaction, particularly when a primary alkyl halide is used. Treatment of benzene with 1-chlorobutane at 0 °C, for instance, gives an approximately 2 : 1 ratio of rearranged (*sec*-butyl) to unrearranged (butyl) products.

The carbocation rearrangements that accompany Friedel–Crafts reactions are like those that accompany electrophilic additions to alkenes (**Section 7.11**) and occur either by hydride shift or alkyl shift. For example, the relatively unstable primary butyl carbocation produced by reaction of 1-chlorobutane with AlCl_3 rearranges to the more stable secondary butyl carbocation by the shift of a hydrogen atom and its electron pair (a hydride ion, H^-) from C2 to C1. Similarly, alkylation of benzene with 1-chloro-2,2-dimethylpropane yields (1,1-dimethylpropyl)benzene. The initially formed primary carbocation rearranges to a tertiary carbocation by shift of a methyl group and its electron pair from C2 to C1.

Just as an aromatic ring is alkylated by reaction with an alkyl chloride, it is **acylated** by reaction with a carboxylic acid chloride, RCOCl , in the presence of AlCl_3 . That is, an **acyl group** ($-\text{COR}$; pronounced **a-sil**) is substituted onto the aromatic ring. For example, reaction of benzene with acetyl chloride yields the ketone acetophenone.

The mechanism of Friedel–Crafts **acylation** is similar to that of Friedel–Crafts alkylation, and the same limitations on the aromatic substrate noted previously in **FIGURE 16.9** for alkylation also apply to acylation. The reactive electrophile is a resonance-stabilized acyl cation, generated by reaction between the acyl chloride and AlCl_3 (**FIGURE 16.10**). As the resonance structures in the figure indicate, an acyl cation is stabilized by interaction of the vacant orbital on carbon with lone-pair electrons on the neighboring oxygen. Because of this stabilization, no carbocation rearrangement occurs during acylation.

FIGURE 16.10 Mechanism of the Friedel–Crafts acylation reaction. The electrophile is a resonance-stabilized acyl cation, whose electrostatic potential map indicates that **carbon is the most positive atom**.

Unlike the multiple substitutions that often occur in Friedel–Crafts alkylations, acylations never occur more than once on a ring because the product acylbenzene is less reactive than the nonacylated starting material. We'll account for this reactivity difference in the next section.

Aromatic alkylations occur in numerous biological pathways, although there is of course no AlCl_3 present in living systems to catalyze the reaction. Instead, the carbocation electrophile is typically formed by dissociation of an organodiphosphate, as we saw in Section 11.6. The dissociation is usually assisted by complexation to a divalent metal cation such as Mg^{2+} , just as dissociation of an alkyl chloride is assisted by AlCl_3 .

An example of a biological Friedel–Crafts reaction occurs during the biosynthesis of phylloquinone, or vitamin K_1 , the human blood-clotting factor. Phylloquinone is formed by reaction of 1,4-dihydroxynaphthoic acid with phytol diphosphate. Phytol diphosphate first dissociates to a resonance-stabilized allylic carbocation, which then substitutes onto the aromatic ring in the typical way. Several further transformations lead to phylloquinone (FIGURE 16.11).

FIGURE 16.11 Biosynthesis of phylloquinone (vitamin K_1) from 1,4-dihydroxynaphthoic acid. The key step that joins the 20-carbon phytol side chain to the aromatic ring is a Friedel–Crafts-like electrophilic substitution reaction with a diphosphate ion as the leaving group.

WORKED EXAMPLE 16.1

Predicting the Product of a Carbocation Rearrangement

The Friedel–Crafts reaction of benzene with 2-chloro-3-methylbutane in the presence of AlCl_3 occurs with a carbocation rearrangement. What is the structure of the product?

Strategy

A Friedel–Crafts reaction involves initial formation of a carbocation, which can rearrange by either a hydride shift or an alkyl shift to give a more stable carbocation. Draw the initial carbocation, assess its stability, and see if the shift of a hydride ion or an alkyl group from a neighboring carbon will result in increased stability. In the present instance, the initial carbocation is a secondary one that can rearrange to a more stable tertiary one by a hydride shift.

Use this more stable tertiary carbocation to complete the Friedel–Crafts reaction.

Solution

PROBLEM 16-5 Which of the following alkyl halides would you expect to undergo Friedel–Crafts reaction with rearrangement and which without? Explain.

- (a) $\text{CH}_3\text{CH}_2\text{Cl}$ (b) $\text{CH}_3\text{CH}_2\text{CH}(\text{Cl})\text{CH}_3$ (c) $\text{CH}_3\text{CH}_2\text{CH}_2\text{Cl}$ (d) $(\text{CH}_3)_3\text{CCH}_2\text{Cl}$
 (e) Chlorocyclohexane

PROBLEM 16-6 What is the major monosubstitution product from the Friedel–Crafts reaction of benzene with 1-chloro-2-methylpropane in the presence of AlCl_3 ?

PROBLEM 16-7 Identify the carboxylic acid chloride that might be used in a Friedel–Crafts acylation reaction to prepare each of the following acylbenzenes:

16.4 Substituent Effects in Electrophilic Substitutions

Only one product can form when an electrophilic substitution occurs on benzene, but what would happen if we were to carry out a reaction on an aromatic ring that already has a substituent? The initial presence of a substituent on the ring has two effects.

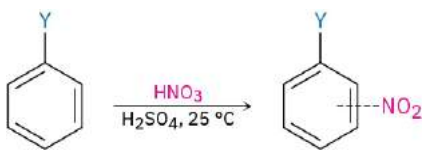

- **Substituents affect the reactivity of the aromatic ring.** Some substituents activate the ring, making it more reactive than benzene, and some deactivate the ring, making it less reactive than benzene. In aromatic nitration, for instance, an $-\text{OH}$ substituent makes the ring 1000 times more reactive than benzene, while an $-\text{NO}_2$ substituent makes the ring more than 10 million times less reactive.

- **Substituents affect the orientation of the reaction.** The three possible disubstituted products—ortho, meta, and para—are usually not formed in equal amounts. Instead, the nature of the substituent initially present on the benzene ring determines the position of the second substitution. An –OH group directs substitution toward the ortho and para positions, for instance, while a carbonyl group such as –CHO directs substitution primarily toward the meta position. **TABLE 16.1** lists experimental results for the nitration of some substituted benzenes.

TABLE 16.1 Orientation of Nitration in Substituted Benzenes

	Product (%)		
	Ortho	Meta	Para
Meta-directing deactivators			
$-\text{N}^+(\text{CH}_3)_3$	2	87	11
$-\text{NO}_2$	7	91	2
$-\text{CO}_2\text{H}$	22	76	2
$-\text{CN}$	17	81	2
$-\text{CO}_2\text{CH}_3$	28	66	6

$-\text{CHO}$	19	72	9
Ortho- and para-directing deactivators			
$-\text{F}$	13	1	86
$-\text{Cl}$	35	1	64
$-\text{Br}$	43	1	56
$-\text{I}$	45	1	54

TABLE 16.1 Orientation of Nitration in Substituted Benzenes

Product (%)			
	Ortho	Meta	Para
Ortho- and para-directing activators			
-CH ₃	63	3	34
-OH	50	0	50
-NHCOCH ₃	19	2	79

Substituents can be classified into three groups, as shown in **FIGURE 16.12**: *ortho*- and *para*-directing activators, *ortho*- and *para*-directing deactivators, and *meta*-directing deactivators. There are no *meta*-directing activators. Notice how the directing effect of a group correlates with its reactivity. All *meta*-directing groups are strongly deactivating, and most *ortho*- and *para*-directing groups are activating. The halogens are unique in being *ortho*- and *para*-directing but weakly deactivating.

FIGURE 16.12 Classification of substituent effects in electrophilic aromatic substitution. All activating groups are *ortho*- and *para*-directing, and all deactivating groups other than halogen are *meta*-directing. Halogens are unique in being deactivating but *ortho*- and *para*-directing.

WORKED EXAMPLE 16.2

Predicting the Product of an Electrophilic Aromatic Substitution Reaction

Predict the major product of the sulfonation of toluene.

Strategy

Identify the substituent present on the ring, and decide whether it is *ortho*- and *para*-directing or *meta*-directing. According to **FIGURE 16.12**, an alkyl substituent is *ortho*- and *para*-directing, so sulfonation of toluene will primarily give a mixture of *o*-toluenesulfonic acid and *p*-toluenesulfonic acid.

Solution

PROBLEM Rank the compounds in each of the following groups in order of their reactivity to electrophilic substitution:

16-8 substitution:

- (a) Nitrobenzene, phenol, toluene, benzene (b) Phenol, benzene, chlorobenzene, benzoic acid
 (c) Benzene, bromobenzene, benzaldehyde, aniline

PROBLEM Predict the major products of the following reactions:

- 16-9** (a) Nitration of bromobenzene (b) Bromination of nitrobenzene (c) Chlorination of phenol
 (d) Bromination of aniline

Activating and Deactivating Effects

What makes a group either activating or deactivating? The common characteristic of all activating groups is that they donate electrons to the ring, thereby making the ring more electron-rich, stabilizing the carbocation intermediate, and lowering the activation energy for its formation. Conversely, the common characteristic of all deactivating groups is that they withdraw electrons from the ring, thereby making the ring more electron-poor, destabilizing the carbocation intermediate, and raising the activation energy for its formation.

Compare the electrostatic potential maps of benzaldehyde (deactivated), chlorobenzene (weakly deactivated), and phenol (activated) with that of benzene. As shown in **FIGURE 16.13**, the ring is more positive (yellow-green) when an electron-withdrawing group such as $-\text{CHO}$ or $-\text{Cl}$ is present and more negative (red) when an electron-donating group such as $-\text{OH}$ is present.

FIGURE 16.13 Electrostatic potential maps of benzene and several substituted benzenes show that an electron-withdrawing group ($-\text{CHO}$ or $-\text{Cl}$) makes the ring more **electron-poor**, while an electron-donating group ($-\text{OH}$) makes the ring more **electron-rich**.

The withdrawal or donation of electrons by a substituent group is controlled by an interplay of *inductive effects* and *resonance effects*. As we saw in [Section 2.1](#), an **inductive effect** is the withdrawal or donation of electrons through a σ bond due to electronegativity. Halogens, hydroxyl groups, carbonyl groups, cyano groups, and nitro groups inductively withdraw electrons through the σ bond linking the substituent to a benzene ring. This effect is most pronounced in halobenzenes and phenols, in which the electronegative atom is directly attached to the ring, but is also significant in carbonyl compounds, nitriles, and nitro compounds, in which the electronegative atom is farther removed. Alkyl groups, on the other hand, inductively donate electrons. This is the same hyperconjugative donating effect that causes alkyl substituents to stabilize alkenes ([Section 7.6](#)) and carbocations ([Section 7.9](#)).

A **resonance effect** is the withdrawal or donation of electrons through a π bond due to the overlap of a p orbital on the substituent with a p orbital on the aromatic ring. Carbonyl, cyano, and nitro substituents, for example, withdraw electrons from the aromatic ring by resonance. The π electrons flow from the ring to the substituent, leaving a positive charge in the ring. Note that substituents with an electron-withdrawing resonance effect have the general structure $-\text{Y}=\text{Z}$, where the Z atom is more electronegative than Y.

Conversely, halogen, hydroxyl, alkoxy ($-\text{OR}$), and amino substituents donate electrons to the aromatic ring by resonance. Lone-pair electrons flow from the substituents to the ring, placing a negative charge on the ring. Substituents with an electron-donating resonance effect have the general structure $-\ddot{\text{Y}}$, where the Y atom has a lone pair of electrons available for donation to the ring.

One further point: inductive effects and resonance effects don't necessarily act in the same direction. Halogen, hydroxyl, alkoxy, and amino substituents, for instance, have electron-withdrawing inductive effects because of the electronegativity of the $-X$, $-O$, or $-N$ atom bonded to the aromatic ring but have electron-donating resonance effects because of the lone-pair electrons on those $-X$, $-O$, or $-N$ atoms. When the two effects act in opposite directions, the stronger effect dominates. Thus, hydroxyl, alkoxy, and amino substituents are activators because their stronger electron-donating resonance effect outweighs their weaker electron-withdrawing inductive effect. Halogens, however, are deactivators because their stronger electron-withdrawing inductive effect outweighs their weaker electron-donating resonance effect.

PROBLEM Use Figure 16.12 to explain why Friedel–Crafts alkylations often give polysubstitution but
16-10 Friedel–Crafts acylations do not.

PROBLEM An electrostatic potential map of (trifluoromethyl)benzene, $C_6H_5CF_3$, is shown. Would you expect
16-11 (trifluoromethyl)benzene to be more reactive or less reactive than toluene toward electrophilic substitution? Explain.

Ortho- and Para-Directing Activators: Alkyl Groups

Inductive and resonance effects account not only for reactivity but also for the orientation of electrophilic aromatic substitutions. Take alkyl groups, for instance, which have an electron-donating inductive effect and are ortho and para directors. The results of toluene nitration are shown in **FIGURE 16.14**.

FIGURE 16.14 Carbocation intermediates in the nitration of toluene. Ortho and para intermediates are more stable than the meta intermediate because the positive charge is on a tertiary carbon rather than a secondary carbon.

Nitration of toluene might occur either ortho, meta, or para to the methyl group, giving the three carbocation intermediates shown in **FIGURE 16.14**. Although all three intermediates are resonance-stabilized, the ortho and para intermediates are more stabilized than the meta intermediate. For both the ortho and para reactions, but not for the meta reaction, a resonance form places the positive charge directly on the methyl-substituted carbon, where it is in a tertiary position and can be stabilized by the electron-donating inductive effect of the methyl group. The ortho and para intermediates are thus lower in energy than the meta intermediate and form faster.

Ortho- and Para-Directing Activators: OH and NH₂

Hydroxyl, alkoxy, and amino groups are also ortho–para activators, but for a different reason than for alkyl groups. As described earlier in this section, hydroxyl, alkoxy, and amino groups have a strong, electron-donating resonance effect that outweighs a weaker electron-withdrawing inductive effect. When phenol is nitrated, for instance, reaction can occur either ortho, meta, or para to the –OH group, giving the carbocation intermediates shown in **FIGURE 16.15**. The ortho and para intermediates are more stable than the meta intermediate because they have more resonance forms, including one particularly favorable form that allows the positive charge to be stabilized by electron donation from the substituent oxygen atom. The intermediate from the meta reaction has no such stabilization.

FIGURE 16.15 Carbocation intermediates in the nitration of phenol. The ortho and para intermediates are more stable than the meta intermediate because they have more resonance forms, including one particularly favorable form that involves electron donation from the oxygen atom.

PROBLEM Acetanilide is less reactive than aniline toward electrophilic substitution. Explain.

16-12

Ortho- and Para-Directing Deactivators: Halogens

Halogens are deactivating because their stronger electron-withdrawing inductive effect outweighs their weaker electron-donating resonance effect. Although weak, that electron-donating resonance effect is nevertheless felt only at the ortho and para positions and not at the meta position (**FIGURE 16.16**). Thus, a halogen substituent can stabilize the positive charge of the carbocation intermediates from ortho and para reaction in the same way that hydroxyl and amino substituents can. The meta intermediate, however, has no such stabilization and is therefore formed more slowly.

FIGURE 16.16 Carbocation intermediates in the nitration of chlorobenzene. The ortho and para intermediates are more stable than the meta intermediate because of electron donation of the halogen lone-pair electrons.

Note again that halogens, hydroxyl, alkoxy, and amino groups all withdraw electrons inductively but donate electrons by resonance. Halogens have a stronger electron-withdrawing inductive effect but a weaker electron-donating resonance effect and are thus deactivators. Hydroxyl, alkoxy, and amino groups have a weaker electron-withdrawing inductive effect but a stronger electron-donating resonance effect and are thus activators. All are ortho and para directors, however, because of the lone pair of electrons on the atom bonded to the aromatic ring.

Meta-Directing Deactivators

The influence of meta-directing substituents can be explained using the same kinds of arguments used for ortho and para directors. Look at the nitration of benzaldehyde, for instance (FIGURE 16.17). Of the three possible carbocation intermediates, the meta intermediate has three favorable resonance forms, whereas the ortho and para intermediates have only two. In both ortho and para intermediates, the third resonance form is unfavorable because it places the positive charge directly on the carbon that bears the aldehyde group, where it is disfavored by a repulsive interaction with the positively polarized carbon atom of the $\text{C}=\text{O}$ group. Hence, the meta intermediate is more favored and is formed faster than the ortho and para intermediates.

FIGURE 16.17 Carbocation intermediates in the nitration of benzaldehyde. The ortho and para intermediates are less stable than the meta intermediate. The meta intermediate is more favorable than ortho and para intermediates because it has three favorable resonance forms rather than two.

In general, any substituent that has a positively polarized atom (δ^+) directly attached to the ring will make one of the resonance forms of the ortho and para intermediates unfavorable and will thus act as a meta director.

PROBLEM Draw resonance structures for the intermediates from the reaction of an electrophile at the ortho, meta, and para positions of nitrobenzene. Which intermediates are most stable?

A Summary of Substituent Effects in Electrophilic Aromatic Substitution

A summary of the activating and directing effects of substituents in electrophilic aromatic substitution is shown in **TABLE 16.2**.

TABLE 16.2 Substituent Effects in Electrophilic Aromatic Substitution

Substituent	Reactivity	Orienting effect	Inductive effect	Resonance effect
$-\text{CH}_3$	Activating	Ortho, para	Weak donating	—
$-\text{OH}, -\text{NH}_2$	Activating	Ortho, para	Weak withdrawing	Strong donating
$-\text{F}, -\text{Cl}$	Deactivating	Ortho, para	Strong withdrawing	Weak donating
$-\text{Br}, -\text{I}$				
$-\text{NO}_2, -\text{CN},$	Deactivating	Meta	Strong withdrawing	Strong withdrawing
$-\text{CHO}, -\text{CO}_2\text{R}$				
$-\text{COR}, -\text{CO}_2\text{H}$				

16.5 Trisubstituted Benzenes: Additivity of Effects

Electrophilic substitution of a disubstituted benzene ring is governed by the same resonance and inductive effects that influence monosubstituted rings. The only difference is that it's necessary to consider the additive effects of two different groups. In practice, this isn't as difficult as it sounds; three rules are usually sufficient.

RULE 1

If the directing effects of the two groups reinforce each other, the situation is straightforward. In *p*-nitrotoluene, for example, both the methyl and the nitro group direct further substitution to the same position (ortho to the methyl = meta to the nitro). A single product is thus formed on electrophilic substitution.

RULE 2

If the directing effects of the two groups oppose each other, the more powerful activating group has the dominant influence, but mixtures of products are often formed. For example, bromination of *p*-methylphenol yields primarily 2-bromo-4-methylphenol because $-\text{OH}$ is a more powerful activator than $-\text{CH}_3$.

RULE 3

Further substitution rarely occurs between the two groups in a meta-disubstituted compound because this site is too hindered. Aromatic rings with three adjacent substituents must therefore be prepared by some other route, such as by substitution of an ortho-disubstituted compound.

WORKED EXAMPLE 16.3

Predicting the Product of Substitution on a Disubstituted Benzene

What product would you expect from bromination of *p*-methylbenzoic acid?

Strategy

Identify the two substituents present on the ring, decide the directing effect of each and, if necessary, decide which substituent is the stronger activator. In the present case, the carboxyl group ($-\text{CO}_2\text{H}$) is a meta director and the methyl group is an ortho and para director. Both groups direct bromination to the position next to the methyl group, yielding 3-bromo-4-methylbenzoic acid.

Solution

PROBLEM 16-14 At what position would you expect electrophilic substitution to occur in each of the following substances:

PROBLEM 16-15 Show the major product(s) from reaction of the following substances with (1) $\text{CH}_3\text{CH}_2\text{Cl}$, AlCl_3 and (2) HNO_3 , H_2SO_4 :

**16.6 Nucleophilic Aromatic Substitution**

Although aromatic substitution reactions usually occur by an *electrophilic* mechanism, aryl halides that have electron-withdrawing substituents can also undergo a *nucleophilic* substitution reaction. For example, 2,4,6-trinitrochlorobenzene reacts with aqueous NaOH at room temperature to give 2,4,6-trinitrophenol. Here, the nucleophile OH^- substitutes for Cl^- .

Nucleophilic aromatic substitution is much less common than electrophilic substitution but nevertheless does have certain uses. One such use is the reaction of proteins with 2,4-dinitrofluorobenzene, known as *Sanger's reagent*, to attach a "label" to the terminal NH_2 group of the amino acid at one end of the protein chain.

Although the reaction appears superficially similar to the S_N1 and S_N2 nucleophilic substitutions of alkyl halides discussed in the chapter on **Reactions of Alkyl Halides: Nucleophilic Substitutions and Eliminations**, it must be different because aryl halides are inert to both S_N1 and S_N2 conditions. S_N1 reactions don't occur with aryl halides because dissociation of the halide is energetically unfavorable, due to the instability of the potential aryl cation product. S_N2 reactions don't occur with aryl halides because the halo-substituted carbon of the aromatic ring is sterically shielded from a backside approach. For a nucleophile to react with an aryl halide, it would have to approach directly through the aromatic ring and invert the stereochemistry of the aromatic ring carbon—a geometric impossibility.

Dissociation reaction does not occur because the aryl cation is unstable; therefore, no S_N1 reaction.

Backside displacement is sterically blocked; therefore, no S_N2 reaction.

Instead, nucleophilic substitutions on an aromatic ring proceed by the mechanism shown in **FIGURE 16.18**. The nucleophile first adds to the electron-deficient aryl halide, forming a resonance-stabilized, negatively charged intermediate called a *Meisenheimer complex* after its discoverer. Halide ion is then eliminated.

FIGURE 16.18 MECHANISM

Mechanism of nucleophilic aromatic substitution. The reaction occurs in two steps and involves a resonance-stabilized carbanion intermediate.

1 Nucleophilic addition of hydroxide ion to the electron-poor aromatic ring takes place, yielding a stabilized carbanion intermediate.

2 The carbanion intermediate undergoes elimination of chloride ion in a second step to give the substitution product.

Nucleophilic aromatic substitution occurs only if the aromatic ring has an electron-withdrawing substituent in a position ortho or para to the leaving group to stabilize the anion intermediate through resonance (FIGURE 16.19). A meta substituent offers no such resonance stabilization. Thus, *p*-chloronitrobenzene and *o*-chloronitrobenzene react with hydroxide ion at 130 °C to yield substitution products, but *m*-chloronitrobenzene is inert to OH^- .

FIGURE 16.19 Nucleophilic aromatic substitution on nitrochlorobenzenes. Only in the ortho and para intermediates is the negative charge stabilized by a resonance interaction with the nitro group, so only the ortho and para isomers undergo reaction.

Note the differences between electrophilic and nucleophilic aromatic substitutions. Electrophilic substitutions are favored by electron-donating substituents, which stabilize a carbocation intermediate, while nucleophilic substitutions are favored by electron-withdrawing substituents, which stabilize a carbanion intermediate. Thus, the electron-withdrawing groups that deactivate rings for electrophilic substitution (nitro, carbonyl, cyano, and so forth) activate them for nucleophilic substitution. What's more, these functional groups are meta directors in electrophilic substitution but are ortho–para directors in nucleophilic substitution. And finally, electrophilic substitutions replace hydrogen on the ring, while nucleophilic substitutions replace a leaving group, usually halide ion.

PROBLEM The herbicide oxyfluorfen can be prepared by reaction between a phenol and an aryl fluoride.
16-16 Propose a mechanism.

16.7 Benzyne

Halobenzenes without electron-withdrawing substituents don't react with nucleophiles under most conditions. At high temperature and pressure, however, even chlorobenzene can be forced to react. Chemists at the Dow Chemical Company discovered in 1928 that phenol could be prepared on an industrial scale by treatment of chlorobenzene with dilute aqueous NaOH at 340 °C under 170 atm pressure.

A similar substitution reaction occurs with other strong bases. Treatment of bromobenzene with potassium amide (KNH₂) in liquid NH₃ solvent, for instance, gives aniline. Curiously, though, when using bromobenzene labeled with radioactive ¹⁴C at the C1 position, the substitution product has equal amounts of the label at both C1 and C2, implying the presence of a symmetrical reaction intermediate in which C1 and C2 are equivalent.

Further mechanistic evidence comes from trapping experiments. When bromobenzene is treated with KNH₂ in the presence of a conjugated diene, such as furan, a Diels–Alder reaction (Section 14.4) occurs, implying that the symmetrical intermediate is a **benzyne**, formed by elimination of HBr from bromobenzene. Benzyne is too reactive to be isolated as a pure compound but, in the presence of water, addition occurs to give phenol. In the presence of a diene, Diels–Alder cycloaddition takes place.

The electronic structure of benzyne, shown in FIGURE 16.20, is that of a highly distorted alkyne. Although a typical alkyne triple bond uses *sp*-hybridized carbon atoms, the benzyne triple bond uses *sp*²-hybridized carbons. Furthermore, a typical alkyne triple bond has two mutually perpendicular π bonds formed by *p*–*p* overlap, but the benzyne triple bond has one π bond formed by *p*–*p* overlap and one π bond formed by *sp*²–*sp*² overlap. The latter π bond is in the plane of the ring and is very weak.

FIGURE 16.20 An orbital picture and electrostatic potential map of benzyne. The benzyne carbons are *sp*²-hybridized, and the “third” bond results from weak overlap of two adjacent *sp*² orbitals.

PROBLEM Treatment of *p*-bromotoluene with NaOH at 300 °C yields a mixture of two products, but treatment **16-17** of *m*-bromotoluene with NaOH yields a mixture of three products. Explain.

16.8 Oxidation of Aromatic Compounds

Oxidation of Alkyl Side Chains

Despite its unsaturation, the benzene ring is inert to strong oxidizing agents such as KMnO_4 , which will cleave alkene carbon-carbon bonds (Section 8.8). It turns out, however, that the presence of the aromatic ring has a dramatic effect on the reactivity of alkyl side chains. These side chains react rapidly with oxidizing agents and are converted into carboxyl groups, $-\text{CO}_2\text{H}$. The net effect is conversion of an alkylbenzene into a benzoic acid, $\text{Ar-R} \rightarrow \text{Ar-CO}_2\text{H}$. Butylbenzene is oxidized by aqueous KMnO_4 to give benzoic acid, for instance.

A similar oxidation is employed industrially for the preparation of the terephthalic acid used in the production of polyester fibers. Worldwide, approximately 118 million tons per year of terephthalic acid is produced by oxidation of *p*-xylene, using air as the oxidant and Co(III) salts as catalyst.

The mechanism of side-chain oxidation is complex and involves reaction of C-H bonds at the position next to the aromatic ring to form intermediate benzylic radicals. *tert*-Butylbenzene has no benzylic hydrogens, however, and is therefore inert.

Analogous side-chain oxidations occur in various biosynthetic pathways. The neurotransmitter norepinephrine, for instance, is biosynthesized from dopamine by a benzylic hydroxylation reaction. The process is catalyzed by the copper-containing enzyme dopamine β -monooxygenase and occurs by a radical mechanism. A copper-oxygen species in the enzyme first abstracts the pro-R benzylic hydrogen to give a radical, and a hydroxyl is then transferred from copper to carbon.

PROBLEM What aromatic products would you obtain from the KMnO_4 oxidation of the following substances?
16-18

Bromination of Alkylbenzene Side Chains

Side-chain bromination at the benzylic position occurs when an alkylbenzene is treated with *N*-bromosuccinimide (NBS). For example, propylbenzene gives (1-bromopropyl)benzene in 97% yield on reaction with NBS in the presence of benzoyl peroxide, $(\text{PhCO}_2)_2$, as a radical initiator. Bromination occurs exclusively in the benzylic position next to the aromatic ring and does not give a mixture of products.

The mechanism of benzylic bromination is similar to that discussed in [Section 10.3](#) for allylic bromination of alkenes. Abstraction of a benzylic hydrogen atom first generates an intermediate benzylic radical, which then reacts with Br_2 in step 2 to yield product and a $\text{Br}\cdot$ radical, which cycles back into the reaction to carry on the chain shown below as a summary. The Br_2 needed for reaction with the benzylic radical is produced in step 3 by a concurrent reaction of HBr with NBS.

Reaction occurs exclusively at the benzylic position because the benzylic radical intermediate is stabilized by resonance. [FIGURE 16.21](#) shows how the benzyl radical is stabilized by overlap of its *p* orbital with the ringed π electron system.

FIGURE 16.21 A resonance-stabilized benzylic radical. The spin-density surface shows that the unpaired electron is shared by the ortho

and para carbons of the ring.

PROBLEM Refer to Table 6.3 for a quantitative idea of the stability of a benzyl radical. How much more stable
16-19 (in kJ/mol) is the benzyl radical than a primary alkyl radical? How does a benzyl radical compare in stability to an allyl radical?

PROBLEM Styrene, the simplest alkenylbenzene, is prepared commercially for use in plastics manufacture
16-20 by catalytic dehydrogenation of ethylbenzene. How might you prepare styrene from benzene using reactions you've studied?

Styrene

16.9 Reduction of Aromatic Compounds

Catalytic Hydrogenation of Aromatic Rings

Just as aromatic rings are generally inert to oxidation, they're also inert to catalytic hydrogenation under conditions that reduce typical alkene double bonds. As a result, it's possible to reduce an alkene double bond selectively in the presence of an aromatic ring. For example, 4-phenyl-3-buten-2-one is reduced to 4-phenyl-2-butanone using a palladium catalyst at room temperature and atmospheric pressure. Neither the benzene ring nor the ketone carbonyl group is affected.

To hydrogenate an aromatic ring, it's necessary either to use a platinum catalyst with hydrogen gas at a pressure of several hundred atmospheres or to use a more effective catalyst such as rhodium on carbon. Under these conditions, aromatic rings are converted into cyclohexanes. For example, *o*-xylene yields 1,2-dimethylcyclohexane, and 4-*tert*-butylphenol gives 4-*tert*-butylcyclohexanol.

Reduction of Aryl Alkyl Ketones

In the same way that an aromatic ring activates a neighboring (benzylic) C–H toward oxidation, it also activates a benzylic carbonyl group toward reduction. Thus, an aryl alkyl ketone prepared by Friedel–Crafts acylation of an aromatic ring can be converted into an alkylbenzene by catalytic hydrogenation over a palladium catalyst.

Propiophenone, for instance, is reduced to propylbenzene by catalytic hydrogenation. Because the net effect of Friedel–Crafts acylation followed by reduction is the preparation of a primary alkylbenzene, this two-step sequence of reactions makes it possible to circumvent the carbocation rearrangement problems associated with direct Friedel–Crafts alkylation using a primary alkyl halide (Section 16.3).

The conversion of a carbonyl group into a methylene group ($\text{C}=\text{O} \rightarrow \text{CH}_2$) by catalytic hydrogenation is limited to *aryl* alkyl ketones; dialkyl ketones are not reduced under these conditions. Furthermore, the catalytic reduction of aryl alkyl ketones is not compatible with the presence of a nitro substituent on the aromatic ring because a nitro group is reduced to an amino group under reaction conditions. We'll see a more general method for reducing ketone carbonyl groups to yield alkanes in Section 19.9.

PROBLEM 16-21 How would you prepare diphenylmethane, $(\text{Ph})_2\text{CH}_2$, from benzene and an acid chloride?

16.10 Synthesis of Polysubstituted Benzenes

As discussed in the **Introduction to Organic Synthesis** in Section 9.9, one of the surest ways to learn organic chemistry is to work synthesis problems. The ability to plan a successful multistep synthesis of a complex molecule requires a working knowledge of the uses and limitations of a great many organic reactions. Not only must you know which reactions to use, you must also know when to use them because the order in which reactions are carried out is often critical to the success of the overall scheme.

The ability to plan a sequence of reactions in the right order is particularly important in the synthesis of substituted aromatic rings, where the introduction of a new substituent is strongly affected by the directing effects of other substituents. Planning syntheses of substituted aromatic compounds is therefore a good way to gain confidence in using the many reactions discussed in the past few chapters.

As we said in Section 9.9, it's usually best to work a synthesis problem backward, or *retrosynthetically*. Look at the target molecule and ask yourself, "What is an immediate precursor of this compound?" Choose a likely answer and continue working backward, one step at a time, until you arrive at a simple starting material. Let's try some examples.

WORKED EXAMPLE 16.4

Synthesizing a Polysubstituted Benzene

How would you synthesize 4-bromo-2-nitrotoluene from benzene?

Strategy

Draw the target molecule, identify the substituents, and recall how each group can be introduced separately. Then plan retrosynthetically.

The three substituents on the ring are a bromine, a methyl group, and a nitro group. A bromine can be introduced by bromination with $\text{Br}_2/\text{FeBr}_3$, a methyl group can be introduced by Friedel–Crafts alkylation with $\text{CH}_3\text{Cl}/\text{AlCl}_3$, and a nitro group can be introduced by nitration with $\text{HNO}_3/\text{H}_2\text{SO}_4$.

Solution

Ask yourself, “What is an immediate precursor of the target?” The final step will involve introduction of one of three groups—bromine, methyl, or nitro—so we have to consider three possibilities. Of the three, the bromination of *o*-nitrotoluene could be used because the activating methyl group would dominate the deactivating nitro group and direct bromination to the correct position. Unfortunately, a mixture of product isomers would be formed. A Friedel–Crafts reaction can’t be used as the final step because this reaction doesn’t work on a nitro-substituted (strongly deactivated) benzene. The best precursor of the desired product is probably *p*-bromotoluene, which can be nitrated ortho to the activating methyl group to give a single product.

Next ask, “What is an immediate precursor of *p*-bromotoluene?” Perhaps toluene is an immediate precursor because the methyl group would direct bromination to the ortho and para positions. Alternatively, bromobenzene might be an immediate precursor because we could carry out a Friedel–Crafts methylation and obtain a mixture of ortho and para products. Both answers are satisfactory, although both would also lead unavoidably to a mixture of products that would have to be separated.

“What is an immediate precursor of toluene?” Benzene, which could be methylated in a Friedel–Crafts reaction. Alternatively, “What is an immediate precursor of bromobenzene?” Benzene, which could be brominated.

The retrosynthetic analysis has provided two valid routes from benzene to 4-bromo-2-nitrotoluene.

WORKED EXAMPLE 16.5

Synthesizing a Polysubstituted Benzene

Synthesize 4-chloro-2-propylbenzenesulfonic acid from benzene.

Strategy

Draw the target molecule, identify its substituents, and recall how each of the three can be introduced. Then plan retrosynthetically.

The three substituents on the ring are a chlorine, a propyl group, and a sulfonic acid group. A chlorine can be introduced by chlorination with $\text{Cl}_2/\text{FeCl}_3$, a propyl group can be introduced by Friedel–Crafts acylation with $\text{CH}_3\text{CH}_2\text{COCl}/\text{AlCl}_3$ followed by reduction with H_2/Pd , and a sulfonic acid group can be introduced by sulfonation with $\text{SO}_3/\text{H}_2\text{SO}_4$.

Solution

“What is an immediate precursor of the target?” The final step will involve introduction of one of three groups—chlorine, propyl, or sulfonic acid—so we have to consider three possibilities. Of the three, the chlorination of *o*-propylbenzenesulfonic acid can’t be used because the reaction would occur at the wrong position. Similarly, a Friedel–Crafts reaction can’t be used as the final step because this reaction doesn’t work on sulfonic-acid-substituted (strongly deactivated) benzenes. Thus, the immediate precursor of the desired product is probably *m*-chloropropylbenzene, which can be sulfonated to give a mixture of product isomers that must then be separated.

“What is an immediate precursor of *m*-chloropropylbenzene?” Because the two substituents have a meta relationship, the first substituent placed on the ring must be a meta director so that the second substitution will take place at the proper position. Furthermore, because primary alkyl groups such as propyl can’t be introduced directly by Friedel–Crafts alkylation, the precursor of *m*-chloropropylbenzene is probably *m*-chloropropiophenone, which could be catalytically reduced.

“What is an immediate precursor of *m*-chloropropiophenone?” Propiophenone, which could be chlorinated in the meta position.

“What is an immediate precursor of propiophenone?” Benzene, which could undergo Friedel–Crafts acylation with propanoyl chloride and AlCl_3 .

The final synthesis is a four-step route from benzene:

Planning an organic synthesis has been compared with playing chess. There are no tricks; all that's required is a knowledge of the allowable moves (the organic reactions) and the discipline to plan ahead, carefully evaluating the consequences of each move. Practicing may not be easy, but it's a great way to learn organic chemistry.

PROBLEM How might you synthesize the following substances from benzene?

- 16-22** (a) *m*-Chloronitrobenzene (b) *m*-Chloroethylbenzene (c) 4-Chloro-1-nitro-2-propylbenzene
(d) 3-Bromo-2-methylbenzenesulfonic acid

PROBLEM In planning a synthesis, it's as important to know what not to do as to know what to do. As written, **16-23** the following reaction schemes have flaws in them. What is wrong with each?

CHEMISTRY MATTERS

Combinatorial Chemistry

Traditionally, organic compounds have been synthesized one at a time. This works well for preparing large amounts of a few substances, but it doesn't work so well for preparing small amounts of a great many substances. This latter goal is particularly important in the pharmaceutical industry, where vast numbers of structurally similar compounds must be synthesized and screened to find an optimum drug candidate.

To speed the process of drug discovery, **combinatorial chemistry** has been developed to prepare what are called *combinatorial libraries*, in which anywhere from a few dozen to several hundred thousand substances are prepared simultaneously. Among the early successes of combinatorial chemistry is the development of a benzodiazepine library, a class of aromatic compounds commonly used as antianxiety agents.

Benzodiazepine library
(R₁–R₄ are various organic substituents)

Two main approaches to combinatorial chemistry are used—*parallel synthesis* and *split synthesis*. In parallel synthesis, each compound is prepared independently. Typically, a reactant is first linked to the surface of polymer beads, which are then placed into small wells on a 96-well glass plate. Programmable robotic instruments add different sequences of building blocks to the different wells, thereby making 96 different products. When the reaction sequences are complete, the polymer beads are washed and their products are released.

In split synthesis, the initial reactant is again linked to the surface of polymer beads, which are then divided into several groups. A different building block is added to each group of beads, the different groups are combined, and the reassembled mix is again split to form new groups. Another building block is added to each group, the groups are again combined and redivided, and the process continues. If, for example, the beads are divided into four groups at each step, the number of compounds increases in the progression $4 \rightarrow 16 \rightarrow 64 \rightarrow 256$. After 10 steps, more than 1 million compounds have been prepared (FIGURE 16.23).

Of course, with so many different final products mixed together, the problem is to identify them. What structure is linked to what bead? Several approaches to this problem have been developed, all of which involve the attachment of encoding labels to each polymer bead to keep track of the chemistry each has undergone. Encoding labels used thus far have included proteins, nucleic acids, halogenated aromatic compounds, and even computer chips.

FIGURE 16.22 Organic chemistry by robot means no spilled flasks!

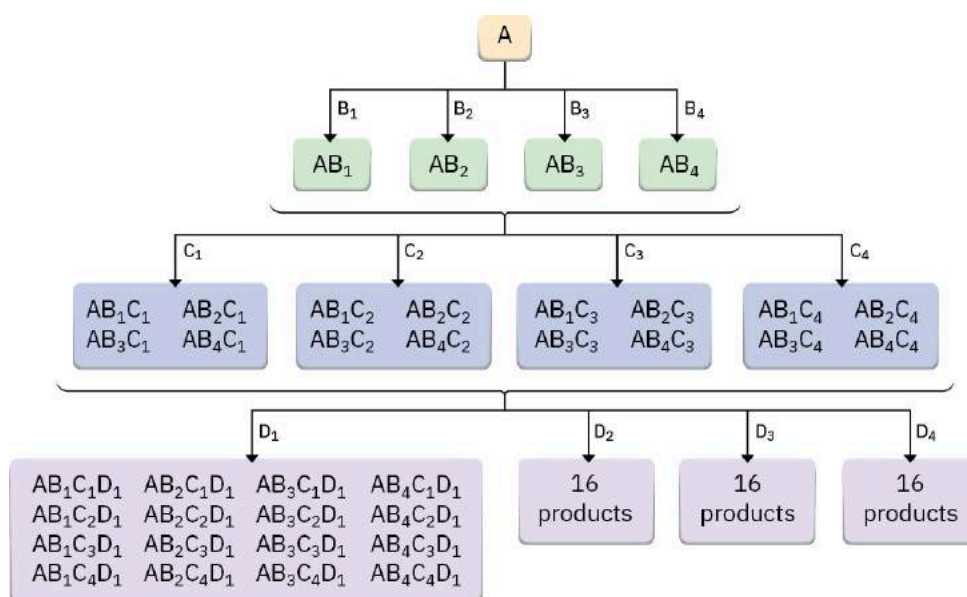

FIGURE 16.23 The results of split combinatorial synthesis. Assuming that 4 different building blocks are used at each step, 64 compounds result after 3 steps, and more than one million compounds result after 10 steps.

- alkylation
- benzyne
- combinatorial chemistry
- electrophilic aromatic substitution
- Friedel–Crafts reaction
- inductive effect
- nucleophilic aromatic substitution
- resonance effect

Summary

We've continued the coverage of aromatic molecules in this chapter, shifting focus to concentrate on reactions. In particular, we've looked at the relationship between aromatic structure and reactivity, a relationship critical to understanding how numerous biological molecules and pharmaceutical agents are synthesized and why they behave as they do.

An **electrophilic aromatic substitution reaction** takes place in two steps—initial reaction of an electrophile, E^+ , with the aromatic ring, followed by loss of H^+ from the resonance-stabilized carbocation intermediate to regenerate the aromatic ring.

Many variations of the reaction can be carried out, including halogenation, nitration, and sulfonation. **Friedel–Crafts alkylation** and **acylation** reactions, which involve reaction of an aromatic ring with carbocation electrophiles, are particularly useful. They are limited, however, by the fact that the aromatic ring must be at least as reactive as a halobenzene. In addition, polyalkylation and carbocation rearrangements often occur in Friedel–Crafts alkylation.

Substituents on the benzene ring affect both the reactivity of the ring toward further substitution and the orientation of that substitution. Groups can be classified as ortho- and para-directing activators, ortho- and para-directing deactivators, or meta-directing deactivators. Substituents influence aromatic rings by a combination of resonance and inductive effects. **Resonance effects** are transmitted through π bonds; **inductive effects** are transmitted through σ bonds.

Halobenzenes undergo **nucleophilic aromatic substitution** through either of two mechanisms. If the halobenzene has a strongly electron-withdrawing substituent in the ortho or para position, substitution occurs by addition of a nucleophile to the ring, followed by elimination of halide from the intermediate anion. If the halobenzene is not activated by an electron-withdrawing substituent, substitution can occur by elimination of HX to give a **benzyne**, followed by addition of a nucleophile.

The benzylic position of an alkylbenzene can be brominated by reaction with *N*-bromosuccinimide, and the entire side chain can be degraded to a carboxyl group by oxidation with aqueous KMnO_4 . Aromatic rings can also be reduced to cyclohexanes by hydrogenation over a platinum or rhodium catalyst, and aryl alkyl ketones are reduced to alkylbenzenes by hydrogenation over a platinum catalyst.

Summary of Reactions

1. Electrophilic aromatic substitution

a. Fluorination (Section 16.2)

b. Bromination (Section 16.1)

c. Chlorination (Section 16.2)

d. Iodination (Section 16.2)

e. Nitration (Section 16.2)

f. Sulfonation (Section 16.2)

g. Friedel–Crafts alkylation (Section 16.3)

h. Friedel–Crafts acylation (Section 16.3)

2. Reduction of aromatic nitro groups (Section 16.2)

3. Nucleophilic aromatic substitution

a. By addition to activated aryl halides (Section 16.6)

b. By formation of benzyne intermediate from unactivated aryl halide (Section 16.7)

4. Oxidation of alkylbenzene side chain (Section 16.8)

5. Benzylic bromination of alkylbenzene side chain (Section 16.8)

6. Catalytic hydrogenation of aromatic ring (Section 16.9)

7. Reduction of aryl alkyl ketones (Section 16.9)

Additional Problems

Visualizing Chemistry

PROBLEM Draw the product from reaction of each of the following substances with (1) Br₂, FeBr₃ and (2)**16-24** CH₃COCl, AlCl₃.

(a)

(b)

**PROBLEM** The following molecular model of a dimethyl-substituted biphenyl represents the lowest-energy conformation of the molecule. Why are the two benzene rings tilted at a 63° angle to each other**16-25**

rather than being in the same plane so that their p orbitals overlap? Why doesn't complete rotation around the single bond joining the two rings occur?

PROBLEM How would you synthesize the following compound starting from benzene? More than one step is needed.
16-26

PROBLEM The following compound can't be synthesized using the methods discussed in this chapter. Why not?
16-27

Mechanism Problems

Mechanisms of Electrophilic Substitutions

PROBLEM Aromatic iodination can be carried out with a number of reagents, including iodine monochloride,
16-28 ICl. What is the direction of polarization of ICl? Propose a mechanism for the iodination of an aromatic ring with ICl.

PROBLEM The sulfonation of an aromatic ring with SO_3 and H_2SO_4 is reversible. That is, heating
16-29 benzenesulfonic acid with H_2SO_4 yields benzene. Show the mechanism of the desulfonation reaction. What is the electrophile?

PROBLEM The carbocation electrophile in a Friedel–Crafts reaction can be generated by an alternate means
16-30 than reaction of an alkyl chloride with AlCl_3 . For example, reaction of benzene with 2-methylpropene in the presence of H_3PO_4 yields *tert*-butylbenzene. Propose a mechanism for this reaction.

PROBLEM The N,N,N -trimethylammonium group, $-\overset{+}{\text{N}}(\text{CH}_3)_3$, is one of the few groups that is a meta-directing
16-31 deactivator yet has no electron-withdrawing resonance effect. Explain.

PROBLEM 16-32 The nitroso group, $-N=O$, is one of the few nonhalogens that is an ortho- and para-directing deactivator. Explain this behavior by drawing resonance structures of the carbocation intermediates in ortho, meta, and para electrophilic reaction on nitrosobenzene, $C_6H_5N=O$.

PROBLEM 16-33 Triphenylmethane can be prepared by reaction of benzene and chloroform in the presence of $AlCl_3$. Propose a mechanism for the reaction.

PROBLEM 16-34 Using resonance structures of the intermediates, explain why bromination of biphenyl occurs at ortho and para positions rather than at meta.

PROBLEM 16-35 Benzene and alkyl-substituted benzenes can be hydroxylated by reaction with H_2O_2 in the presence of an acidic catalyst. What is the structure of the reactive electrophile? Propose a mechanism for the reaction.

Additional Mechanism Practice

PROBLEM 16-36 Addition of HBr to 1-phenylpropene yields only (1-bromopropyl)benzene. Propose a mechanism for the reaction, and explain why none of the other regioisomer is produced.

PROBLEM 16-37 Hexachlorophene, a substance used in the manufacture of germicidal soaps, is prepared by reaction of 2,4,5-trichlorophenol with formaldehyde in the presence of concentrated sulfuric acid. Propose a mechanism for the reaction.

PROBLEM 16-38 Benzenediazonium carboxylate decomposes when heated to yield N_2 , CO_2 , and a reactive substance that can't be isolated. When benzene-diazonium carboxylate is heated in the presence of furan, the following reaction is observed:

What intermediate is involved in this reaction? Propose a mechanism for its formation.

PROBLEM 4-Chloropyridine undergoes reaction with dimethylamine to yield 4-dimethylaminopyridine.

16-39 Propose a mechanism for the reaction.

PROBLEM Propose a mechanism to account for the following reaction:

16-40

PROBLEM In the *Gatterman-Koch reaction*, a formyl group ($-CHO$) is introduced directly onto a benzene ring.

16-41 For example, reaction of toluene with CO and HCl in the presence of mixed $CuCl/AlCl_3$ gives *p*-methylbenzaldehyde. Propose a mechanism.

PROBLEM Treatment of *p*-*tert*-butylphenol with a strong acid such as H_2SO_4 yields phenol and

16-42 2-methylpropene. Propose a mechanism.

PROBLEM Benzyl bromide is converted into benzaldehyde by heating in dimethyl sulfoxide. Propose a

16-43 structure for the intermediate, and show the mechanisms of the two steps in the reaction.

PROBLEM Propose a mechanism for the *Smiles rearrangement* below.

16-44

PROBLEM Because of their conjugation, azo dyes are highly colored compounds and the major artificial color

16-45 source for textiles and food. Azo dyes are produced by the reaction of aryl diazonium salts with a second aromatic compound. In the product, the aromatic rings are linked by a diazo bridge ($-N=N-$). From the reactants provided, propose a structure for each azo dye and draw the electron-pushing mechanism.

Reactivity and Orientation of Electrophilic Substitutions

PROBLEM Identify each of the following groups as an activator or deactivator and as an *o,p*-director or *m*-director:

16-46

PROBLEM Predict the major product(s) of nitration of the following substances. Which react faster than benzene, and which slower?

16-47

- (a) Bromobenzene (b) Benzonitrile (c) Benzoic acid (d) Nitrobenzene
(e) Benzenesulfonic acid (f) ethoxybenzene

PROBLEM Rank the compounds in each group according to their reactivity toward electrophilic substitution.

16-48

- (a) Chlorobenzene, *o*-dichlorobenzene, benzene
(b) *p*-Bromonitrobenzene, nitrobenzene, phenol (c) Fluorobenzene, benzaldehyde, *o*-xylene
(d) Benzonitrile, *p*-methylbenzonitrile, *p*-methoxybenzonitrile

PROBLEM Predict the major monoalkylation products you would expect to obtain from reaction of the following substances with chloromethane and AlCl_3 :

16-49

- (a) Bromobenzene (b) *m*-Bromophenol (c) *p*-Chloroaniline (d) 2,4-Dichloronitrobenzene
(e) 2,4-Dichlorophenol (f) Benzoic acid (g) *p*-Methylbenzenesulfonic acid
(h) 2,5-Dibromotoluene

PROBLEM Name and draw the major product(s) of electrophilic chlorination of the following compounds:

16-50

- (a) *m*-Nitrophenol (b) *o*-Xylene (c) *p*-Nitrobenzoic acid (d) *p*-Bromobenzenesulfonic acid

PROBLEM Predict the major product(s) you would obtain from sulfonation of the following compounds:

16-51

- (a) Fluorobenzene (b) *m*-Bromophenol (c) *m*-Dichlorobenzene (d) 2,4-Dibromophenol

PROBLEM Rank the following aromatic compounds in the expected order of their reactivity toward Friedel–Crafts alkylation. Which compounds are unreactive?

16-52

- (a) Bromobenzene (b) Toluene (c) Phenol (d) Aniline (e) Nitrobenzene
(f) *p*-Bromotoluene

PROBLEM What product(s) would you expect to obtain from the following reactions:

16-53

PROBLEM Predict the major product(s) of the following reactions:

Organic Synthesis

PROBLEM How would you synthesize the following substances starting from benzene or phenol? Assume that

16-55 ortho- and para-substitution products can be separated.

- (a) *o*-Bromobenzoic acid (b) *p*-Methoxytoluene (c) 2,4,6-Trinitrobenzoic acid
(d) *m*-Bromoaniline

PROBLEM Starting with benzene as your only source of aromatic compounds, how would you synthesize the following substances? Assume that you can separate ortho and para isomers if necessary.

- 16-56 (a) *p*-Chloroacetophenone (b) *m*-Bromonitrobenzene (c) *o*-Bromobenzenesulfonic acid
(d) *m*-Chlorobenzenesulfonic acid

PROBLEM Starting with either benzene or toluene, how would you synthesize the following substances:

16-57 Assume that ortho and para isomers can be separated.

- (a) 2-Bromo-4-nitrotoluene (b) 1,3,5-Trinitrobenzene (c) 2,4,6-Tribromoaniline
(d) *m*-Fluorobenzoic acid

PROBLEM As written, the following syntheses have flaws. What is wrong with each?

General Problems

PROBLEM At what position and on what ring do you expect nitration of 4-bromo-biphenyl to occur? Explain, using resonance structures of the potential intermediates.

16-59

PROBLEM 16-60 Electrophilic substitution on 3-phenylpropanenitrile occurs at the ortho and para positions, but reaction with 3-phenylpropenenitrile occurs at the meta position. Explain, using resonance structures of the intermediates.

PROBLEM 16-61 At what position, and on what ring, would you expect the following substances to undergo electrophilic substitution?

PROBLEM 16-62 At what position, and on what ring, would you expect bromination of benzanilide to occur? Explain by drawing resonance structures of the intermediates.

PROBLEM 16-63 Would you expect the Friedel–Crafts reaction of benzene with (*R*)-2-chlorobutane to yield optically active or racemic product? Explain.

PROBLEM 16-64 How would you synthesize the following substances starting from benzene?

PROBLEM 16-65 The compound MON-0585 is a nontoxic, biodegradable larvicide that is highly selective against mosquito larvae. Synthesize MON-0585 using either benzene or phenol as a source of the aromatic rings.

PROBLEM 16-66 Phenylboronic acid, $C_6H_5B(OH)_2$, is nitrated to give 15% ortho-substitution product and 85% meta. Explain the meta-directing effect of the $-B(OH)_2$ group.

PROBLEM 16-67 Draw resonance structures of the intermediate carbocations in the bromination of naphthalene, and account for the fact that naphthalene undergoes electrophilic substitution at C1 rather than C2.

PROBLEM 16-68 Propose a mechanism for the reaction of 1-chloroanthraquinone with methoxide ion to give the substitution product 1-methoxyanthraquinone. Use curved arrows to show the electron flow in each step.

PROBLEM 16-69 *p*-Bromotoluene reacts with potassium amide to give a mixture of *m*- and *p*-methylaniline. Explain.

PROBLEM 16-70 Propose a mechanism to account for the reaction of benzene with 2,2,5,5-tetramethyltetrahydrofuran.

PROBLEM 16-71 How would you synthesize the following compounds from benzene? Assume that ortho and para isomers can be separated.

PROBLEM 16-72 You know the mechanism of HBr addition to alkenes, and you know the effects of various substituent groups on aromatic substitution. Use this knowledge to predict which of the following two alkenes reacts faster with HBr. Explain your answer by drawing resonance structures of the carbocation intermediates.

PROBLEM 16-73 Use your knowledge of directing effects, along with the following data, to deduce the directions of the dipole moments in aniline, bromobenzene, and bromoaniline.

PROBLEM Identify the reagents represented by the letters **a–e** in the following scheme:

16-74

PROBLEM Phenols (ArOH) are relatively acidic, and the presence of a substituent group on the aromatic ring

16-75 has a large effect. The pK_a of unsubstituted phenol, for example, is 9.89, while that of *p*-nitrophenol is 7.15. Draw resonance structures of the corresponding phenoxide anions and explain the data.

PROBLEM Would you expect *p*-methylphenol to be more acidic or less acidic than unsubstituted phenol?

16-76 Explain. (See Problem 16-75.)

PROBLEM Predict the product(s) for each of the following reactions. In each case, draw the resonance forms of

16-77 the intermediate to explain the observed regiochemistry.

CHAPTER 17

Alcohols and Phenols

FIGURE 17.1 The phenol resveratrol, found in the skin of red grapes, continues to be studied for its potential anti-cancer, antiarthritic, and hypoglycemic properties. (credit: modification of work “Weinreben-Ötlingen” by Pierre Likissas/Wikimedia Commons, CC BY 3.0)

WHY THIS CHAPTER? Up to this point, we’ve focused on developing some general ideas of organic reactivity, looking at the chemistry of hydrocarbons and alkyl halides, and examining some of the tools used in structural studies. With that background, it’s now time to begin a study of the oxygen-containing functional groups that lie at the heart of organic and biological chemistry. We’ll look at alcohols in this chapter and move on to carbonyl compounds in Chapters 19 through 23.

Alcohols and **phenols** can be thought of as organic derivatives of water in which one of water’s hydrogens is replaced by an organic group: H-O-H versus R-O-H and Ar-O-H . In practice, the name *alcohol* is restricted to

compounds that have their -OH group bonded to a saturated, sp^3 -hybridized carbon atom, while compounds with their -OH group bonded to a vinylic, sp^2 -hybridized carbon are called *enols*. We'll look at enols in Chapter 22.

Alcohols occur widely in nature and have many industrial and pharmaceutical applications. Methanol, for instance, is one of the most important of all industrial chemicals. Historically, methanol was prepared by heating wood in the absence of air and thus came to be called *wood alcohol*. Today, approximately 173 million tons (50 billion gallons) of methanol is manufactured worldwide each year, most of it by catalytic reduction of carbon monoxide with hydrogen gas. Methanol is toxic to humans, causing blindness in small doses (15 mL) and death in larger amounts (100–250 mL). Industrially, it is used both as a solvent and as a starting material for production of formaldehyde (CH_2O) and acetic acid ($\text{CH}_3\text{CO}_2\text{H}$).

Ethanol was one of the first organic chemicals to be prepared and purified. Its production by fermentation of grains and sugars has been carried out for perhaps 9000 years, and its purification by distillation goes back at least as far as the 12th century. Today, approximately 88 million tons (26 billion gallons) of ethanol are produced worldwide each year, most of it by fermentation of corn, barley, sorghum, and other plant sources. Almost all of this ethanol is used for bus and automobile fuel.

Ethanol for industrial use as a solvent or chemical intermediate is largely obtained by acid-catalyzed hydration of ethylene at high temperature.

Phenols occur widely throughout nature and also serve as intermediates in the industrial synthesis of products as diverse as adhesives and antiseptics. Phenol itself is a general disinfectant found in coal tar; methyl salicylate is a flavoring agent found in oil of wintergreen; and urushiols are the allergenic constituents of poison oak and poison ivy. Note that the word *phenol* is the name both of the specific compound (hydroxybenzene) and of the class of compounds.

17.1 Naming Alcohols and Phenols

Alcohols are classified as primary (1°), secondary (2°), or tertiary (3°), depending on the number of organic groups bonded to the hydroxyl-bearing carbon.

A primary (1°) alcohol A secondary (2°) alcohol A tertiary (3°) alcohol

Simple alcohols are named in the IUPAC system as derivatives of the parent alkane, using the suffix *-ol*.

RULE 1

Select the longest carbon chain containing the hydroxyl group, and derive the parent name by replacing the *-e* ending of the corresponding alkane with *-ol*. The *-e* is deleted to prevent the occurrence of two adjacent vowels: propanol rather than propanol, for example.

RULE 2

Number the alkane chain beginning at the end nearer the hydroxyl group.

RULE 3

Number the substituents according to their position on the chain, and write the name, listing the substituents in alphabetical order and identifying the position to which the $-OH$ is bonded. Note that in naming *cis*-1,4-cyclohexanediol, the final *-e* of cyclohexane is not deleted because the next letter, *d*, is not a vowel; that is, cyclohexanediol rather than cyclohexandiol. Also, as with alkenes (Section 7.3), newer IUPAC naming recommendations place the locant immediately before the suffix rather than before the parent.

2-Methyl-2-pentanol
(New: **2-Methylpentan-2-ol**)

***cis*-1,4-Cyclohexanediol**
(New: ***cis*-Cyclohexane-1,4-diol**)

3-Phenyl-2-butanol
(New: **3-Phenylbutan-2-ol**)

Some simple and widely occurring alcohols have common names that are accepted by IUPAC. For example:

Benzyl alcohol
(phenylmethanol)

Allyl alcohol
(2-propen-1-ol)

***tert*-Butyl alcohol**
(2-methyl-2-propanol)

Ethylene glycol
(1,2-ethanediol)

Glycerol
(1,2,3-propanetriol)

Phenols are named as described previously for aromatic compounds according to the rules discussed in Section 15.1, with *-phenol* used as the parent name rather than *-benzene*.

***m*-Methylphenol**
(*m*-Cresol)

2,4-Dinitrophenol

PROBLEM Give IUPAC names for the following compounds:

PROBLEM Draw structures corresponding to the following IUPAC names:

- 17-2** (a) (*Z*)-2-Ethyl-2-buten-1-ol (b) 3-Cyclohexen-1-ol (c) *trans*-3-Chlorocycloheptanol
 (d) 1,4-Pentanediol (e) 2,6-Dimethylphenol (f) *o*-(2-Hydroxyethyl)phenol

17.2 Properties of Alcohols and Phenols

Alcohols and phenols have nearly the same geometry around the oxygen atom as water. The R–O–H bond angle has an approximately tetrahedral value (108.5° in methanol, for instance), and the oxygen atom is sp^3 -hybridized.

Also like water, alcohols and phenols have higher boiling points than might be expected, because of hydrogen-bonding (Section 2.12). A positively polarized –OH hydrogen atom from one molecule is attracted to a lone pair of electrons on the electronegative oxygen atom of another molecule, resulting in a weak force that holds the molecules together (Figure 17.2). These intermolecular attractions must be overcome for a molecule to break free from the liquid and enter the vapor state, so the boiling temperature is raised. For example, 1-propanol (MW = 60), butane (MW = 58), and chloroethane (MW = 65) have similar molecular weights, yet 1-propanol boils at 97 °C, compared with –0.5 °C for the alkane and 12.5 °C for the chloroalkane.

FIGURE 17.2 Hydrogen-bonding in alcohols and phenols. Attraction between a positively polarized –OH hydrogen and a negatively polarized oxygen holds molecules together. The electrostatic potential map of methanol shows the positively polarized –OH hydrogen and the negatively polarized oxygen.

Another similarity with water is that alcohols and phenols are both weakly basic and weakly acidic. As weak bases, they are reversibly protonated by strong acids to yield oxonium ions, ROH_2^+ .

As weak acids, they dissociate slightly in dilute aqueous solution by donating a proton to water, generating H_3O^+ and an **alkoxide ion**, RO^- , or a **phenoxide ion**, ArO^- .

Recall from the earlier discussion of acidity in [Section 2.7](#) to [Section 2.11](#) that the strength of any acid HA in water can be expressed by an acidity constant, K_a .

$$K_a = \frac{[A^-][H_3O^+]}{[HA]} \quad pK_a = -\log K_a$$

Compounds with a smaller K_a and larger pK_a are less acidic, whereas compounds with a larger K_a and smaller pK_a are more acidic. As shown in [TABLE 17.1](#), simple alcohols like methanol and ethanol are about as acidic as water, but the more highly substituted *tert*-butyl alcohol is somewhat weaker. Substituent groups also have a significant effect: 2,2,2-trifluoroethanol is approximately 3700 times stronger than ethanol, for instance. Phenols and *thiols*, the sulfur analogs of alcohols, are substantially more acidic than water.

TABLE 17.1 Acidity Constants of Some Alcohols and Phenols

Compound	pK_a

<i>p</i> -Aminophenol	10.46	
CH_3SH	10.3	
<i>p</i> -Methylphenol	10.17	
Phenol	9.89	
<i>p</i> -Chlorophenol	9.38	
<i>p</i> -Nitrophenol	7.15	

The effect of alkyl substitution on alcohol acidity is due primarily to solvation of the alkoxide ion formed on acid dissociation. The more readily the alkoxide ion is solvated by water, the more stable it is, the more its formation is energetically favored, and the greater the acidity of the parent alcohol. For example, the oxygen atom of an unhindered alkoxide ion, such as that from methanol, is sterically accessible and is easily solvated by water. The oxygen atom of a hindered alkoxide ion, however, such as that from *tert*-butyl alcohol, is less easily solvated and is therefore less stable.

Inductive effects (Section 16.4) are also important in determining alcohol acidities. Electron-withdrawing halogen substituents, for instance, stabilize an alkoxide ion by spreading the charge over a larger volume, thus making the alcohol more acidic. Compare, for instance, the acidities of ethanol ($pK_a = 16$) and 2,2,2-trifluoroethanol ($pK_a = 12.43$), or of *tert*-butyl alcohol ($pK_a = 18$) and nonafluoro-*tert*-butyl alcohol ($pK_a = 5.4$).

Because alcohols are weak acids, they don't react with weak bases, such as amines or bicarbonate ion, and they only react to a limited extent with metal hydroxides such as NaOH. Alcohols do, however, react with alkali metals and with strong bases such as sodium hydride (NaH), sodium amide (NaNH_2), and Grignard reagents (RMgX). Alkoxides are themselves bases that are frequently used as reagents in organic chemistry. They are named systematically by adding the *-ate* suffix to the name of the alcohol. Methanol becomes methanolate, for instance.

Phenols are about a million times more acidic than alcohols (TABLE 17.1). They are therefore soluble in dilute aqueous NaOH and can often be separated from a mixture simply by basic extraction into aqueous solution, followed by reacidification.

Phenols are more acidic than alcohols because the phenoxide anion is resonance-stabilized. Delocalization of the negative charge over the ortho and para positions of the aromatic ring results in increased stability of the phenoxide anion relative to undissociated phenol and in a consequently lower ΔG° for dissociation. **FIGURE 17.3** compares electrostatic potential maps of an alkoxide ion (CH_3O^-) with phenoxide ion to show how the negative charge in phenoxide ion is delocalized from oxygen to the ring.

FIGURE 17.3 The resonance-stabilized phenoxide ion is more stable than an alkoxide ion. Electrostatic potential maps show how the negative charge is concentrated on oxygen in the methoxide ion but is spread over the aromatic ring in the phenoxide ion.

Substituted phenols can be either more acidic or less acidic than phenol itself, depending on whether the substituent is electron-withdrawing or electron-donating (**Section 16.4**). Phenols with an electron-withdrawing substituent are more acidic because these substituents delocalize the negative charge; phenols with an electron-donating substituent are less acidic because these substituents concentrate the charge. The acidifying effect of an electron-withdrawing substituent is particularly noticeable in phenols with a nitro group at the ortho or para position.

WORKED EXAMPLE 17.1

Predicting the Relative Acidity of a Substituted Phenol

Is *p*-hydroxybenzaldehyde more acidic or less acidic than phenol?

Strategy

Identify the substituent on the aromatic ring, and decide whether it is electron-donating or electron-withdrawing. Electron-withdrawing substituents make the phenol more acidic by stabilizing the phenoxide anion, and electron-donating substituents make the phenol less acidic by destabilizing the anion.

Solution

We saw in **Section 16.4** that a carbonyl group is electron-withdrawing. Thus, *p*-hydroxybenzaldehyde is more

acidic ($pK_a = 7.9$) than phenol ($pK_a = 9.89$).

PROBLEM The following data for isomeric four-carbon alcohols show that there is a decrease in boiling point
17-3 with increasing substitution of the OH-bearing carbon. How might you account for this trend?

- 1-Butanol, bp 117.5 °C
 2-Butanol, bp 99.5 °C
 2-Methyl-2-propanol, bp 82.2 °C

PROBLEM Rank the following substances in order of increasing acidity:

- 17-4** (a) $(CH_3)_2CHOH$, $HC\equiv CH$, $(CF_3)_2CHOH$, CH_3OH
 (b) Phenol, *p*-methylphenol, *p*-(trifluoromethyl)phenol
 (c) Benzyl alcohol, phenol, *p*-hydroxybenzoic acid

PROBLEM *p*-Nitrobenzyl alcohol is more acidic than benzyl alcohol, but *p*-methoxybenzyl alcohol is less
17-5 acidic. Explain.

17.3 Preparation of Alcohols: A Review

Alcohols occupy a central position in organic chemistry. They can be prepared from many other kinds of compounds (alkenes, alkyl halides, ketones, esters, and aldehydes, among others), and they can be transformed into an equally wide assortment of compounds (**FIGURE 17.4**).

FIGURE 17.4 The central position of alcohols in organic chemistry. Alcohols can be prepared from, and converted into, many other kinds of compounds.

We've already seen several methods of alcohol synthesis:

- Alcohols can be prepared by hydration of alkenes. Because the direct hydration of alkenes with aqueous acid is generally a poor reaction in the laboratory, two indirect methods are commonly used. Hydroboration–oxidation yields the syn, non-Markovnikov hydration product (**Section 8.5**), whereas oxymercuration–demercuration yields the Markovnikov hydration product (**Section 8.4**).

- 1,2-Diols can be prepared either by direct hydroxylation of an alkene with OsO_4 followed by reduction with NaHSO_3 or by acid-catalyzed hydrolysis of an epoxide (Section 8.7). The OsO_4 reaction occurs with syn stereochemistry to give a cis diol, and epoxide opening occurs with anti stereochemistry to give a trans diol.

PROBLEM Predict the products of the following reactions:

17-6 (a)

(b)

(c)

17.4 Alcohols from Carbonyl Compounds: Reduction

The most general method for preparing alcohols, both in the laboratory and in living organisms, is by reduction of a carbonyl compound. Just as reduction of an alkene adds hydrogen to a $\text{C}=\text{C}$ bond to give an alkane (Section 8.6), reduction of a carbonyl compound adds hydrogen to a $\text{C}=\text{O}$ bond to give an alcohol. All kinds of carbonyl compounds can be reduced, including aldehydes, ketones, carboxylic acids, and esters.

Reduction of Aldehydes and Ketones

Aldehydes are easily reduced to give primary alcohols, and ketones are reduced to give secondary alcohols.

Dozens of reagents are used in the laboratory to reduce aldehydes and ketones, depending on the circumstances, but sodium borohydride, NaBH_4 , is usually chosen because of its safety and ease of handling. Sodium borohydride is a white, crystalline solid that can be weighed in the open atmosphere and used in either water or alcohol solution.

Aldehyde reduction

Ketone reduction

Lithium aluminum hydride, LiAlH_4 , is another reducing agent often used for reduction of aldehydes and ketones. A grayish powder that is soluble in ether and tetrahydrofuran, LiAlH_4 is much more reactive than NaBH_4 but also much more dangerous. It reacts violently with water and decomposes explosively when heated above 120°C .

We'll defer a detailed discussion of these reductions until Chapter 19. For the moment, we'll simply note that they involve the addition of a nucleophilic hydride ion ($:\text{H}^-$) to the positively polarized, electrophilic carbon atom of the carbonyl group. The initial product is an alkoxide ion, which is protonated by addition of H_3O^+ in a second step to yield the alcohol product.

In living organisms, aldehyde and ketone reductions are carried out by either of the coenzymes NADH (reduced nicotinamide adenine dinucleotide) or NADPH (reduced nicotinamide adenine dinucleotide phosphate). Although these biological “reagents” are much more complex structurally than NaBH_4 or LiAlH_4 , the mechanisms of laboratory and biological reactions are similar. The coenzyme acts as a hydride-ion donor to give an alkoxide anion, and the intermediate anion is then protonated by acid. An example is the reduction of acetoacetyl ACP to β -hydroxybutyryl ACP, a step in the biological synthesis of fats (FIGURE 17.5). Note that the *pro-R* hydrogen of NADPH is the one transferred in this example. Enzyme-catalyzed reactions usually occur with high specificity, although it’s not usually possible to predict the stereochemical result before the fact.

FIGURE 17.5 The biological reduction of a ketone (acetoacetyl ACP) to an alcohol (β -hydroxybutyryl ACP) by NADPH.

Reduction of Carboxylic Acids and Esters

Carboxylic acids and esters are reduced to give primary alcohols.

These reactions aren’t as rapid as the reductions of aldehydes and ketones. NaBH_4 reduces esters very slowly and does not reduce carboxylic acids at all. Instead, carboxylic acid and ester reductions are usually carried out with the more reactive reducing agent LiAlH_4 . All carbonyl groups, including acids, esters, ketones, and aldehydes, are reduced by LiAlH_4 . Note that one hydrogen atom is delivered to the carbonyl carbon atom during aldehyde and ketone reductions but that two hydrogens become bonded to the former carbonyl carbon during carboxylic acid and ester reductions. We’ll defer a discussion of the mechanisms of these reactions until Chapter 21.

Carboxylic acid reduction**Ester reduction**

✿ WORKED EXAMPLE 17.2

Identifying a Reactant, Given the Product

What carbonyl compounds would you reduce to obtain the following alcohols?

**Strategy**

Identify the target alcohol as primary, secondary, or tertiary. A primary alcohol can be prepared by reduction of an aldehyde, an ester, or a carboxylic acid; a secondary alcohol can be prepared by reduction of a ketone; and a tertiary alcohol can't be prepared by reduction.

Solution

(a) The target molecule is a secondary alcohol, which can be prepared only by reduction of a ketone. Either NaBH_4 or LiAlH_4 can be used.

(b) The target molecule is a primary alcohol, which can be prepared by reduction of an aldehyde, an ester, or a carboxylic acid. LiAlH_4 is needed for the ester and carboxylic acid reductions.

PROBLEM What reagent would you use to accomplish each of the following reactions?

PROBLEM 17-8 What carbonyl compounds give the following alcohols on reduction with LiAlH_4 ? Show all possibilities.

17.5 Alcohols from Carbonyl Compounds: Grignard Reaction

Grignard reagents (RMgX), prepared by reaction of organohalides with magnesium (Section 10.6), react with carbonyl compounds to yield alcohols in much the same way that hydride reducing agents do. Just as carbonyl reduction involves addition of a hydride ion nucleophile to the $\text{C}=\text{O}$ bond, Grignard reaction involves addition of a carbanion nucleophile (R^- MgX).

The nucleophilic addition reaction of Grignard reagents to carbonyl compounds has no direct counterpart in biological chemistry because organomagnesium compounds are too strongly basic to exist in an aqueous medium. Nevertheless, the reaction is worth understanding for two reasons. First, the reaction is an unusually broad and useful method of alcohol synthesis and demonstrates again the relative freedom with which chemists can operate in the laboratory. Second, the reaction does have an indirect biological counterpart, for we'll see in Chapter 23 that the addition of stabilized carbon nucleophiles to carbonyl compounds is used in almost all metabolic pathways as the major process for forming carbon-carbon bonds.

As examples of their addition to carbonyl compounds, Grignard reagents react with formaldehyde, $\text{H}_2\text{C}=\text{O}$, to give primary alcohols, with aldehydes to give secondary alcohols, and with ketones to give tertiary alcohols.

Formaldehyde reaction**Aldehyde reaction****Ketone reaction**

Esters react with Grignard reagents to yield tertiary alcohols in which two of the substituents bonded to the hydroxyl-bearing carbon have come from the Grignard reagent, just as LiAlH_4 reduction of an ester adds two hydrogens.

Carboxylic acids don't give addition products when treated directly with Grignard reagents because the acidic carboxyl hydrogen reacts with the basic Grignard reagent to yield a hydrocarbon and the magnesium salt of the acid.

Carboxylic acids do, however, react with Grignard reagents to give ketones if they are first treated with $i\text{-Pr}_2\text{NMgCl-LiCl}$, called the *turbo*-Hauser base, to form a complex and increase the electrophilicity of the carboxylate anion toward nucleophilic addition with a Grignard reagent.

The Grignard reaction, although useful, does have limitations. One major problem is that a Grignard reagent can't be prepared from an organohalide if other reactive functional groups are present in the same molecule. For example, a compound that is both an alkyl halide and a ketone can't form a Grignard reagent because it would react with itself. Similarly, a compound that is both an alkyl halide and a carboxylic acid, alcohol, or amine can't form a Grignard reagent because the acidic RCO_2H , ROH , or RNH_2 hydrogen present in the same molecule would react with the basic Grignard reagent as rapidly as it forms. In general, Grignard reagents can't be prepared from alkyl halides that contain the following functional groups (FG):

As with the reduction of carbonyl compounds discussed in the previous section, we'll defer a detailed treatment of the Grignard reactions until Chapter 19. For the moment, it's sufficient to note that Grignard reagents act as nucleophilic carbanions ($:R^-$) and that their addition to a carbonyl compound is analogous to the addition of hydride ion. The intermediate is an alkoxide ion, which is protonated by addition of H_3O^+ in a second step.

WORKED EXAMPLE 17.3

Using a Grignard Reaction to Synthesize an Alcohol

How could you use the addition of a Grignard reagent to a ketone to synthesize 2-phenyl-2-butanol?

Strategy

Draw the product, and identify the three groups bonded to the alcohol carbon atom. One of the three will have come from the Grignard reagent, and the remaining two will have come from the ketone.

Solution

2-Phenyl-2-butanol has a methyl group, an ethyl group, and a phenyl group ($-C_6H_5$) attached to the alcohol carbon atom. Thus, the possibilities are addition of ethylmagnesium bromide to acetophenone, addition of methylmagnesium bromide to propiophenone, and addition of phenylmagnesium bromide to 2-butanone.

WORKED EXAMPLE 17.4

Using a Grignard Reaction to Synthesize an Alcohol

How could you use the reaction of a Grignard reagent with a carbonyl compound to synthesize 2-methyl-2-pentanol?

Strategy

Draw the product, and identify the three groups bonded to the alcohol carbon atom. If the three groups are all different, the starting carbonyl compound must be a ketone. If two of the three groups are identical, the starting carbonyl compound could be either a ketone or an ester.

Solution

In the present instance, the product is a tertiary alcohol with two methyl groups and one propyl group. Starting from a ketone, the possibilities are addition of methylmagnesium bromide to 2-pentanone and addition of propylmagnesium bromide to acetone.

Starting from an ester, the only possibility is addition of methylmagnesium bromide to an ester of butanoic acid, such as methyl butanoate.

PROBLEM 17-9 Show the products obtained from addition of methylmagnesium bromide to the following compounds:

- (a) Cyclopentanone (b) Benzophenone (diphenyl ketone) (c) 3-Hexanone

PROBLEM 17-10 Use a Grignard reaction to prepare the following alcohols:

- (a) 2-Methyl-2-propanol (b) 1-Methylcyclohexanol (c) 3-Methyl-3-pentanol

(d) 2-Phenyl-2-butanol (e) Benzyl alcohol (f) 4-Methyl-1-pentanol

PROBLEM 17-11 Use the reaction of a Grignard reagent with a carbonyl compound to synthesize the following compound:

17.6 Reactions of Alcohols

We've already seen several reactions of alcohols—their conversion into alkyl halides and tosylates in [Section 10.5](#) and their dehydration to give alkenes in [Section 8.1](#)—albeit without mechanistic details. Let's now look at those details.

Conversion of Alcohols into Alkyl Halides

Tertiary alcohols react with either HCl or HBr at 0 °C by an S_N1 mechanism through a carbocation intermediate. Primary and secondary alcohols are much more resistant to acid, however, and are best converted into halides by treatment with either SOCl_2 or PBr_3 through an S_N2 mechanism.

The reaction of a tertiary alcohol with HX takes place by an S_N1 mechanism when acid protonates the hydroxyl oxygen atom. Water is expelled to generate a carbocation, and the cation reacts with nucleophilic halide ion to give the alkyl halide product.

The reactions of primary and secondary alcohols with SOCl_2 and PBr_3 take place by S_N2 mechanisms. Hydroxide ion itself is too poor a leaving group to be displaced by nucleophiles in S_N2 reactions, but reaction of an alcohol with SOCl_2 or PBr_3 converts the $-\text{OH}$ into a much better leaving group, either a chlorosulfite ($-\text{OSOCl}$) or a dibromophosphite ($-\text{OPBr}_2$), which is readily expelled by backside nucleophilic substitution.

Conversion of Alcohols into Tosylates

Alcohols react with *p*-toluenesulfonyl chloride (tosyl chloride, *p*-TosCl) in pyridine solution to yield alkyl

tosylates, ROTos (Section 11.1). Only the O–H bond of the alcohol is broken in this reaction; the C–O bond remains intact, so no change of configuration occurs if the oxygen is attached to a chirality center. The resultant alkyl tosylates behave much like alkyl halides, undergoing both S_N1 and S_N2 substitution reactions.

One of the most important reasons for using tosylates in S_N2 reactions is stereochemical. The S_N2 reaction of an alcohol with an alkyl halide proceeds with two inversions of configuration—one to make the halide from the alcohol and one to substitute the halide—and yields a product with the same stereochemistry as the starting alcohol. The S_N2 reaction of an alcohol with a tosylate, however, proceeds with only one inversion and yields a product of opposite stereochemistry to the starting alcohol. FIGURE 17.6 shows a series of reactions on the *R* enantiomer of 2-octanol that illustrates these stereochemical relationships.

FIGURE 17.6 Stereochemical consequences of S_N2 reactions on derivatives of (*R*)-2-octanol. Substitution through the halide gives a product with the same stereochemistry as the starting alcohol; substitution through the tosylate gives a product with opposite stereochemistry to the starting alcohol.

PROBLEM How would you carry out the following transformation, a step used in the commercial synthesis of 17-12 (*S*)-ibuprofen?

Dehydration of Alcohols to Yield Alkenes

A third important reaction of alcohols, both in the laboratory and in biological pathways, is their dehydration to give alkenes. Because of the usefulness of the reaction, a number of methods have been devised for carrying out dehydrations. One method that works particularly well for tertiary alcohols is the acid-catalyzed reaction discussed in Section 8.1. For example, treatment of 1-methylcyclohexanol with warm, aqueous sulfuric acid in a solvent such as tetrahydrofuran results in loss of water and formation of 1-methylcyclohexene.

Acid-catalyzed dehydrations usually follow Zaitsev's rule (Section 11.7) and yield the more stable alkene as the major product. Thus, 2-methyl-2-butanol gives primarily 2-methyl-2-butene (trisubstituted double bond)

rather than 2-methyl-1-butene (disubstituted double bond).

This reaction is an E1 process (Section 11.10) and occurs by the three-step mechanism shown in FIGURE 17.7 on the next page. Protonation of the alcohol oxygen is followed by unimolecular loss of water to generate a carbocation intermediate and final loss of a proton from the neighboring carbon atom to complete the process. As with most E1 reactions, tertiary alcohols react fastest because they lead to stabilized, tertiary carbocation intermediates. Secondary alcohols can be made to react, but the conditions are severe (75% H₂SO₄, 100 °C) and sensitive molecules don't survive.

FIGURE 17.7 MECHANISM

Mechanism for the acid-catalyzed dehydration of a tertiary alcohol to yield an alkene. The process is an E1 reaction and involves a carbocation intermediate.

- Two electrons from the oxygen atom bond to H⁺, yielding a protonated alcohol intermediate.
- The carbon–oxygen bond breaks, and the two electrons from the bond stay with oxygen, leaving a carbocation intermediate.
- Two electrons from a neighboring carbon–hydrogen bond form the alkene π bond, and H⁺ (a proton) is eliminated.

To circumvent the need for strong acid and allow the dehydration of secondary alcohols in a gentler way, reagents have been developed that are effective under mild, basic conditions. One such reagent, phosphorus oxychloride (POCl₃) in the basic amine solvent pyridine, is often able to effect the dehydration of secondary and

tertiary alcohols at 0 °C.

Alcohol dehydrations carried out with POCl_3 in pyridine take place by an E2 mechanism, as shown in **FIGURE 17.8**. Because hydroxide ion is a poor leaving group (**Section 11.3**), direct E2 elimination of water from an alcohol does not occur. On reaction with POCl_3 , however, the $-\text{OH}$ group is converted into a dichlorophosphate ($-\text{OPOCl}_2$), which is a good leaving group and is readily eliminated. Pyridine is both the reaction solvent and the base that removes a neighboring proton in the E2 elimination step.

FIGURE 17.8 MECHANISM

Mechanism for the dehydration of secondary and tertiary alcohols by reaction with POCl_3 in pyridine. The reaction is an E2 process.

1 The alcohol hydroxyl group reacts with POCl_3 to form a dichlorophosphate intermediate.

2 E2 elimination then occurs by the usual one-step mechanism as the amine base pyridine abstracts a proton from the neighboring carbon at the same time that the dichlorophosphate group is leaving.

As noted in **Section 11.11**, biological dehydrations are also common and usually occur by an E1cB mechanism on a substrate in which the $-\text{OH}$ group is two carbons away from a carbonyl group. One example occurs in the biosynthesis of the aromatic amino acid tyrosine. A base ($:\text{B}$) first abstracts a proton from the carbon adjacent to the carbonyl group, and the anion intermediate then expels the $-\text{OH}$ group with simultaneous protonation by an acid (HA) to form water.

PROBLEM What product(s) would you expect from dehydration of the following alcohols with $POCl_3$ in pyridine? Indicate the major product in each case.

Conversion of Alcohols into Esters

Alcohols react with carboxylic acids to give esters, a reaction that is common in both the laboratory and living organisms. In the laboratory, the reaction can be carried out in a single step if a strong acid is used as catalyst. More frequently, though, the reactivity of the carboxylic acid is enhanced by first converting it into a carboxylic acid chloride, which then reacts with the alcohol.

In living organisms, a similar process occurs, though a thioester or acyl adenosyl phosphate acts as substrate rather than a carboxylic acid chloride. We'll look at the mechanisms of these reactions in Chapter 21.

17.7 Oxidation of Alcohols

Perhaps the most valuable reaction of alcohols is their oxidation to give carbonyl compounds—the opposite of the reduction of carbonyl compounds to give alcohols. Primary alcohols are oxidized either to aldehydes or carboxylic acids, and secondary alcohols are oxidized to ketones, but tertiary alcohols don't normally react with most oxidizing agents.

Primary and secondary alcohols can be oxidized by any of a number of reagents, including CrO_3 in aqueous acetic acid and KMnO_4 in aqueous NaOH , but chromium-based reagents are rarely used today because of their toxicity and fire danger. Today, primary and secondary alcohols are oxidized to aldehydes and ketones, respectively, using the iodine-containing *Dess–Martin periodinane* in dichloromethane solution.

Primary alcohols are oxidized to carboxylic acids by heating with KMnO_4 in a basic aqueous solution. An aldehyde is involved as an intermediate in the KMnO_4 reaction but can't usually be isolated because it is further oxidized too rapidly.

All these oxidations occur by a mechanism that is closely related to the $\text{E}2$ reaction ([Section 11.8](#)). In the Dess–Martin oxidation, for instance, the first step involves a substitution reaction between the alcohol and the I(V) reagent to form a new periodinane intermediate, followed by expulsion of reduced I(III) as the leaving group. Similarly, when a Cr(VI) reagent, such as CrO_3 , is the oxidant, reaction with the alcohol gives a chromate

intermediate followed by expulsion of a reduced Cr(VI) species.

Biological alcohol oxidations are the opposite of biological carbonyl reductions and are facilitated by the coenzymes NAD^+ and NADP^+ . A base removes the $-\text{OH}$ proton, and the alkoxide ion transfers a hydride ion to the coenzyme. An example is the oxidation of *sn*-glycerol 3-phosphate to dihydroxyacetone phosphate, a step in the biological metabolism of fats (**FIGURE 17.9**). Note that addition occurs exclusively on the Re face of the NAD^+ ring, adding a hydrogen with pro-*R* stereochemistry.

FIGURE 17.9 The biological oxidation of an alcohol (*sn*-glycerol 3-phosphate) to give a ketone (dihydroxyacetone phosphate). This mechanism is the exact opposite of the ketone reduction shown previously in **FIGURE 17.5**.

PROBLEM What alcohols would give the following products on oxidation?

17-14 (a)

(b)

(c)

PROBLEM What products would you expect from oxidation of the following compounds with the Dess–Martin periodinane?

17-15 periodinane?

(a) 1-Hexanol (b) 2-Hexanol (c) Hexanal

17.8 Protection of Alcohols

It often happens, particularly during the synthesis of complex molecules, that one functional group in a molecule interferes with an intended reaction on another functional group elsewhere in the same molecule. We saw earlier in this chapter, for instance, that a Grignard reagent can't be prepared from an alcohol-containing halide because the C–Mg bond is not compatible with the presence of an acidic –OH group in the same molecule.

When this kind of incompatibility arises, it's sometimes possible to circumvent the problem by *protecting* the interfering functional group. Protection involves three steps: (1) introducing a **protecting group** to block the interfering function, (2) carrying out the desired reaction, and (3) removing the protecting group.

One of the more common methods of alcohol protection involves reaction with a chlorotrialkylsilane, Cl–SiR₃, to yield a trialkylsilyl ether, R'–O–SiR₃. (Chloro-*tert*-butyldimethylsilane), usually abbreviated either TBS or TBDMS is often used, as is chlorotrimethylsilane (TMS), and the reaction is carried out in the presence of a base, such as triethylamine, to help form the alkoxide anion from the alcohol and to remove the HCl by-product from the reaction.

For example:

The ether-forming step is an S_N2-like reaction of the alkoxide ion on the silicon atom, with concurrent loss of the leaving chloride anion. Unlike most S_N2 reactions, though, this reaction takes place at a *tertiary* center—a trialkyl-substituted silicon atom. The reaction occurs because silicon, a third-row atom, is larger than carbon and forms longer bonds. In addition, three alkyl substituents attached to silicon offer little steric hindrance to ether formation.

Like most other ethers, which we'll study in the next chapter, trialkylsilyl ethers are relatively unreactive. They have no acidic hydrogens and don't react with oxidizing agents, reducing agents, or Grignard reagents. They do, however, react with aqueous acid or with fluoride ion to regenerate the alcohol. Tetrabutylammonium fluoride is often used.

To solve the problem posed at the beginning of this section, note that it's possible to use an alcohol-containing halide in a Grignard reaction by employing a protection sequence. For example, we can add 3-bromo-1-propanol to acetaldehyde by the route shown in **FIGURE 17.10**.

Step 1 Protect alcohol:

Step 2a Form Grignard reagent:

Step 2b Do Grignard reaction:

Step 3 Remove protecting group:

FIGURE 17.10 Use of a trialkylsilyl-protected alcohol during a Grignard reaction.

PROBLEM 17-16 Propose a mechanism for the reaction of cyclohexyl TMS ether with LiF to deprotect the silyl ether.

17.9 Phenols and Their Uses

The outbreak of World War I provided a stimulus for the industrial preparation of large amounts of synthetic phenol, which was needed as a raw material to manufacture the explosive, picric acid (2,4,6-trinitrophenol). Today, approximately 132 million tons of phenol is manufactured worldwide each year for use in such products as Bakelite resin and adhesives for binding plywood.

Phenol was manufactured for many years by the Dow process, in which chlorobenzene reacts with NaOH at high temperature and pressure (Section 16.7). Now, however, an alternative synthesis uses isopropylbenzene, commonly called *cumene*. Cumene reacts with air at high temperature by benzylic oxidation through a radical mechanism to form cumene hydroperoxide, which is converted into phenol and acetone by treatment with acid. This is a particularly efficient process because two valuable chemicals are prepared at the same time.

As shown in **FIGURE 17.11**, the reaction occurs by protonation of oxygen followed by shift of the phenyl group from carbon to oxygen with simultaneous loss of water. Replacement of the water then yields an intermediate called a *hemiacetal*—a compound that contains one -OR group and one -OH group bonded to the same carbon atom—which breaks down to phenol and acetone.

FIGURE 17.11 MECHANISM**Mechanism for the formation of phenol by acid-catalyzed rearrangement of cumene hydroperoxide.**

1 Protonation of the hydroperoxy group on the terminal oxygen atom gives an oxonium ion . . .

2 . . . which undergoes rearrangement by migration of the phenyl ring from carbon to oxygen, expelling water as the leaving group and giving a carbocation.

3 Nucleophilic addition of water to the carbocation yields another oxonium ion . . .

4 . . . which rearranges by a proton shift from one oxygen to another.

5 Elimination of phenol gives acetone as co-product and regenerates the acid catalyst.

In addition to its use in making resins and adhesives, phenol is also the starting material for the synthesis of chlorinated phenols and the food preservatives BHT (butylated hydroxytoluene) and BHA (butylated hydroxyanisole). Pentachlorophenol, a widely used wood preservative, is prepared by reaction of phenol with excess Cl_2 . The herbicide 2,4-D (2,4-dichlorophenoxyacetic acid) is prepared from 2,4-dichlorophenol, and the hospital antiseptic agent hexachlorophene is prepared from 2,4,5-trichlorophenol.

Pentachlorophenol
(wood preservative)

2,4-Dichlorophenoxyacetic acid,
2,4-D (herbicide)

Hexachlorophene
(antiseptic)

The food preservative BHT is prepared by Friedel–Crafts alkylation of *p*-methylphenol (*p*-cresol) with 2-methylpropene in the presence of acid; BHA is prepared similarly by alkylation of *p*-methoxyphenol.

PROBLEM 17-17 Show the mechanism for the reaction of *p*-methylphenol with 2-methylpropene and H_3PO_4 catalyst to yield the food additive BHT.

17.10 Reactions of Phenols

Electrophilic Aromatic Substitution Reactions

The hydroxyl group is a strongly activating, ortho- and para-directing substituent in electrophilic aromatic substitution reactions (Section 16.4). As a result, phenols are highly reactive substrates for electrophilic halogenation, nitration, sulfonation, and Friedel–Crafts reactions.

Oxidation of Phenols: Quinones

Phenols don't undergo oxidation in the same way as alcohols because they don't have a hydrogen atom on the hydroxyl-bearing carbon. Instead, oxidation of a phenol yields a 2,5-cyclohexadiene-1,4-dione, or **quinone**. Many different oxidizing agents will accomplish the transformation, but potassium nitrosodisulfonate $[(\text{KSO}_3)_2\text{NO}]$, called Fremy's salt, is often used.

Quinones are a valuable class of compounds because of their oxidation–reduction, or *redox*, properties. They can be easily reduced to **hydroquinones** (*p*-dihydroxybenzenes) by reagents such as NaBH_4 and SnCl_2 , and hydroquinones can be easily reoxidized back to quinones.

The redox properties of quinones are crucial to the functioning of living cells, where compounds called *ubiquinones* act as biochemical oxidizing agents to mediate the electron-transfer processes involved in energy production. Ubiquinones, also called *coenzymes Q*, are components of the cells in all aerobic organisms, from the simplest bacterium to humans. They are so named because of their ubiquitous occurrence throughout nature.

Ubiquinones ($n = 1-10$)

Ubiquinones function within the mitochondria of cells to mediate the respiration process in which electrons are transported from the biological reducing agent NADH to molecular oxygen. Through a complex series of steps, the ultimate result is a cycle whereby NADH is oxidized to NAD^+ , O_2 is reduced to water, and energy is produced. Ubiquinone acts only as an intermediary and is itself unchanged.

Step 1

Step 2

17.11 Spectroscopy of Alcohols and Phenols

Infrared Spectroscopy

Alcohols have a strong C–O stretching absorption near 1050 cm^{-1} and a characteristic O–H stretching absorption at 3300 to 3600 cm^{-1} . The exact position of the O–H stretch depends on the extent of hydrogen-bonding in the molecule. Unassociated alcohols show a fairly sharp absorption near 3600 cm^{-1} , whereas hydrogen-bonded alcohols show a broader absorption in the 3300 to 3400 cm^{-1} range. The hydrogen-bonded hydroxyl absorption appears at 3350 cm^{-1} in the IR spectrum of cyclohexanol (**FIGURE 17.12**).

FIGURE 17.12 IR spectrum of cyclohexanol. Characteristic O–H and C–O stretching absorptions are indicated.

Phenols also show a characteristic broad IR absorption at 3500 cm^{-1} due to the –OH group, as well as the usual 1500 and 1600 cm^{-1} aromatic bands (**FIGURE 17.13**). In phenol itself, monosubstituted aromatic-ring peaks are visible at 690 and 760 cm^{-1} .

FIGURE 17.13 IR spectrum of phenol.

PROBLEM 17-18 Assume that you need to prepare 5-cholesten-3-one from cholesterol. How could you use IR spectroscopy to tell whether the reaction was successful? What differences would you look for in the IR spectra of starting material and product?

Nuclear Magnetic Resonance Spectroscopy

Carbon atoms bonded to electron-withdrawing –OH groups are deshielded and absorb at a lower field in the ^{13}C NMR spectrum than do typical alkane carbons. Most alcohol carbon absorptions fall in the range 50 to $80\ \delta$, as shown in the following drawing for cyclohexanol:

Alcohols also show characteristic absorptions in the ^1H NMR spectrum. Hydrogens on the oxygen-bearing carbon atom are deshielded by the electron-withdrawing effect of the nearby oxygen, and their absorptions

occur in the range 3.4 to 4.5 δ . Spin–spin splitting, however, is not usually observed between the O–H proton of an alcohol and the neighboring protons on carbon. Most samples contain small amounts of acidic impurities, which catalyze an exchange of the O–H proton on a timescale so rapid that the effect of spin–spin splitting is removed. It's often possible to take advantage of this rapid proton exchange to identify the position of the O–H absorption. If a small amount of deuterated water, D_2O , is added to an NMR sample tube, the O–H proton is rapidly exchanged for deuterium and the hydroxyl absorption disappears from the spectrum.

Typical spin–spin splitting *is* observed between protons on the oxygen-bearing carbon and other neighbors. For example, the signal of the two $-CH_2O-$ protons in 1-propanol is split into a triplet by coupling with the neighboring $-CH_2-$ protons (FIGURE 17.14).

FIGURE 17.14 1H NMR spectrum of 1-propanol. The protons on the oxygen-bearing carbon are split into a triplet at 3.58 δ .

Phenols, like all aromatic compounds, show 1H NMR absorptions near 7 to 8 δ , the expected position for aromatic-ring protons (Section 15.7). In addition, phenol O–H protons absorb at 3 to 8 δ . In neither case are these absorptions uniquely diagnostic for phenols, since other kinds of protons absorb in the same range.

PROBLEM When the 1H NMR spectrum of an alcohol is run in dimethyl sulfoxide (DMSO) solvent rather than in chloroform, exchange of the O–H proton is slow and spin–spin splitting is seen between the O–H proton and C–H protons on the adjacent carbon. What spin multiplicities would you expect for the hydroxyl protons in the following alcohols?

- 17-19 (a) 2-Methyl-2-propanol (b) Cyclohexanol (c) Ethanol (d) 2-Propanol (e) Cholesterol
(f) 1-Methylcyclohexanol

Mass Spectrometry

As noted in Section 12.3, alcohols undergo fragmentation in the mass spectrometer by two characteristic pathways, alpha cleavage and dehydration. In the alpha-cleavage pathway, a C–C bond nearest the hydroxyl group is broken, yielding a neutral radical plus a resonance-stabilized, oxygen-containing cation.

In the dehydration pathway, water is eliminated, yielding an alkene radical cation.

Both fragmentation modes are apparent in the mass spectrum of 1-butanol (FIGURE 17.15). The peak at $m/z = 56$ is due to loss of water from the molecular ion, and the peak at $m/z = 31$ is due to an alpha cleavage.

FIGURE 17.15 Mass spectrum of 1-butanol ($M^+ = 74$). Dehydration gives a peak at $m/z = 56$, and fragmentation by alpha cleavage gives a peak at $m/z = 31$.

CHEMISTRY MATTERS

Ethanol: Chemical, Drug, and Poison

The production of ethanol by fermentation of grains and sugars is one of the oldest known organic reactions, going back at least 8000 years in the Middle East and perhaps as many as 9000 years in China. Fermentation is carried out by adding yeast to an aqueous sugar solution, where enzymes break down carbohydrates into ethanol and CO_2 . As noted in the chapter introduction, approximately 26 billion gallons of ethanol is produced each year by fermentation of corn and sugar, with essentially the entire amount used to make bus and automobile fuel.

A carbohydrate

Ethanol is classified medically as a central nervous system (CNS) depressant. Its effects—that is, being drunk—resemble the human response to anesthetics. There is an initial excitability and increase in sociable behavior, but this results from depression of inhibition rather than from stimulation. At a blood alcohol concentration of 0.1% to 0.3%, motor coordination is affected, accompanied by loss of balance, slurred speech, and amnesia. When blood alcohol concentration rises to between 0.3% and 0.4%, nausea and loss of consciousness occur. Above 0.6%, spontaneous respiration and cardiovascular regulation are affected, ultimately leading to death. The LD_{50} of ethanol is 10.6 g/kg (**Chapter 1 Chemistry Matters**).

The passage of ethanol through the body begins with its absorption in the stomach and small intestine, followed by rapid distribution to all body fluids and organs. In the pituitary gland, ethanol inhibits the production of a hormone that regulates urine flow, causing increased urine production and dehydration. In the stomach, ethanol stimulates production of acid. Throughout the body, ethanol causes blood vessels to dilate, resulting in flushing of the skin and a sensation of warmth as blood moves into capillaries beneath the surface. The result is not a warming of the body, but an increased loss of heat at the surface.

FIGURE 17.16 The Harger Drunkometer was the first breath analyzer, introduced in 1938 to help convict drunk drivers. (credit: “Unidentified police officer with a Harger “Drunkometer” breathalyzer” by Florida Memory, State Library and Archives of Florida/Wikimedia Commons, Public Domain)

Ethanol metabolism occurs mainly in the liver and proceeds by oxidation in two steps, first to acetaldehyde (CH_3CHO) and then to acetic acid ($\text{CH}_3\text{CO}_2\text{H}$). When continuously present in the body, ethanol and acetaldehyde are toxic, leading to the devastating physical and metabolic deterioration seen in people with chronic alcohol use disorder. The liver usually suffers the worst damage since it is the major site of alcohol metabolism.

Approximately 17,000 people are killed each year in the United States in alcohol-related automobile accidents. Thus, all 50 states have made it illegal to drive with a blood alcohol concentration (BAC) above 0.08%.

Fortunately, simple tests have been devised for measuring blood alcohol concentration. The original breath analyzer test measured alcohol concentration in expired air by the color change occurring when the bright-orange oxidizing agent potassium dichromate ($K_2Cr_2O_7$) reduced to blue-green chromium(III). Current consumer devices use a conductivity sensor, and tests used by law-enforcement agencies use IR spectroscopy to measure blood-alcohol levels in expired air. Just breathe into the machine, and let the spectrum tell the tale.

Key Terms

- alcohol
- alkoxide ion, RO^-
- hydroquinone
- phenol
- phenoxide ion ArO^-
- protecting group
- quinone

Summary

In previous chapters, we focused on developing general ideas of organic reactivity, looking at the chemistry of hydrocarbons and alkyl halides and seeing some of the tools used in structural studies. With that accomplished, we have now begun to study the oxygen-containing functional groups that lie at the heart of organic and biological chemistry.

Alcohols are among the most versatile of all organic compounds. They occur widely in nature, are important industrially, and have an unusually rich chemistry. The most widely used methods of alcohol synthesis start with carbonyl compounds. Aldehydes, esters, and carboxylic acids are reduced by reaction with $LiAlH_4$ to give primary alcohols (RCH_2OH); ketones are reduced to yield secondary alcohols (R_2CHOH).

Alcohols are also prepared by reaction of carbonyl compounds with Grignard reagents, $RMgX$. Addition of a Grignard reagent to formaldehyde yields a primary alcohol, addition to an aldehyde yields a secondary alcohol, and addition to a ketone or an ester yields a tertiary alcohol. The Grignard reaction is limited by the fact that Grignard reagents can't be prepared from alkyl halides that contain reactive functional groups in the same molecule. This problem can sometimes be avoided by **protecting** the interfering functional group. Alcohols are often protected by formation of trialkylsilyl ethers.

Alcohols undergo many reactions and can be converted into many other functional groups. They can be dehydrated to give alkenes by treatment with $POCl_3$ and can be transformed into alkyl halides by treatment with PBr_3 or $SOCl_2$. Furthermore, alcohols are weakly acidic ($pK_a \approx 16-18$) and react with strong bases and with alkali metals to form **alkoxide anions**, which are used frequently in organic synthesis. Perhaps the most important reaction of alcohols is their oxidation to carbonyl compounds. Primary alcohols yield either aldehydes or carboxylic acids, secondary alcohols yield ketones, but tertiary alcohols are not normally oxidized.

Phenols are aromatic counterparts of alcohols but are more acidic ($pK_a \approx 10$) because their corresponding **phenoxide anions** are resonance stabilized by delocalization of the negative charge into the aromatic ring. Substitution of the aromatic ring by an electron-withdrawing group increases phenol acidity, and substitution by an electron-donating group decreases acidity. Phenols can be oxidized to **quinones**, and quinones can be reduced back to **hydroquinones**.

Summary of Reactions

Additional Problems

Visualizing Chemistry

PROBLEM Give IUPAC names for the following compounds:

17-20 (a)

(b)

(c)

(d)

**PROBLEM** Draw the structure of the carbonyl compound(s) from which each of the following alcohols might17-21 have been prepared, and show the products you would obtain by treatment of each alcohol with (1) Na metal, (2) SOCl₂, and (3) Dess-Martin periodinane.

PROBLEM 17-22 Predict the product from reaction of the following substance (reddish brown = Br) with:

(a) PBr_3 (b) Aqueous H_2SO_4 (c) SOCl_2 (d) Dess–Martin periodinane (e) $\text{Br}_2, \text{FeBr}_3$

PROBLEM 17-23 Predict the product from reaction of the following substance with:

(a) NaBH_4 ; then H_3O^+ (b) LiAlH_4 ; then H_3O^+ (c) $2 \text{CH}_3\text{CH}_2\text{MgBr}$; then H_3O^+

PROBLEM 17-24 Name and assign *R* or *S* stereochemistry to the product(s) you would obtain by reaction of the following substance with ethylmagnesium bromide. Is the product chiral? Is it optically active? Explain.

Mechanism Problems

PROBLEM 17-25 Evidence for the intermediate carbocations in the acid-catalyzed dehydration of alcohols comes from the observation that rearrangements sometimes occur. Propose a mechanism to account for the formation of 2,3-dimethyl-2-butene from 3,3-dimethyl-2-butanol.

PROBLEM 17-26 Acid-catalyzed dehydration of 2,2-dimethylcyclohexanol yields a mixture of 1,2-dimethylcyclohexene and isopropylidenecyclopentane. Propose a mechanism to account for the formation of both products.

PROBLEM 17-27 Epoxides react with Grignard reagents to yield alcohols. Propose a mechanism.

PROBLEM 17-28 Treatment of the following epoxide with aqueous acid produces a carbocation intermediate that reacts with water to give a diol product. Show the structure of the carbocation, and propose a mechanism for the second step.

PROBLEM 17-29 Reduction of 2-butanone with NaBH_4 yields 2-butanol. Is the product chiral? Is it optically active? Explain.

PROBLEM 17-30 The conversion of 3° alcohols into 3° alkyl halides under acidic conditions involves two cationic intermediates. For each reaction, draw the complete mechanism using curved arrows.

PROBLEM 17-31 Identify the type of substitution mechanism ($\text{S}_{\text{N}}1$, $\text{S}_{\text{N}}2$) involved in the conversion of the following alcohols into the corresponding alkyl halide.

PROBLEM 17-32 The conversion of 3° alcohols into alkenes under acidic conditions involves two cationic intermediates. For each reaction, draw the complete mechanism using curved arrows.

PROBLEM 17-33 For each reaction, write the mechanism using curved arrows for the conversion of the alcohol into the corresponding alkene with POCl_3 . In each case, explain the regiochemistry of the elimination.

PROBLEM 17-34 The trimethylsilyl (TMS) protecting group is one of several silicon protecting groups for alcohols.

For each reaction, draw the mechanism for the protection of (*R*)-3-bromo-1-butanol with the following silyl chlorides, using triethylamine as the base:

- (a) *tert*-butyldimethylsilyl chloride (TBS-Cl) (b) triisopropylsilyl chloride (TIPS-Cl)
(c) triethylsilyl chloride (TES-Cl)

PROBLEM 17-35 When the following alcohol is treated with POCl_3 and pyridine, the expected elimination product is formed. However, when the same alcohol is treated with H_2SO_4 , the elimination product is 1,2-dimethylcyclopentene. Propose a mechanism for each pathway to account for these differences.

PROBLEM 17-36 Phenols generally have lower $\text{p}K_a$'s than alcohols because of resonance stabilization with the aromatic ring. Draw all of the resonance contributors for the following phenolate ions.

Naming Alcohols

PROBLEM 17-37 Give IUPAC names for the following compounds:

PROBLEM 17-38 Draw and name the eight isomeric alcohols with formula $\text{C}_5\text{H}_{12}\text{O}$.

PROBLEM Draw structures corresponding to the following IUPAC names:

- 17-39** (a) *Trans*-3-Chlorocycloheptanol (b) 2-Ethyl-2-buten-1-ol (c) *o*-(2-Hydroxyethyl)phenol
(d) 3-Methyl-1-phenyl-1-butanol

PROBLEM Bombykol, the sex pheromone secreted by the female silkworm moth has the formula $C_{16}H_{28}O$
17-40 and the systematic name (10*E*,12*Z*)-10,12-hexadecadien-1-ol. Draw bombykol, showing the correct geometry for the two double bonds.

PROBLEM Carvacrol is a naturally occurring substance isolated from oregano, thyme, and marjoram. What is
17-41 its IUPAC name?

Synthesizing Alcohols

PROBLEM What Grignard reagent and what carbonyl compound might you start with to prepare the following
17-42 alcohols:

PROBLEM What carbonyl compounds would you reduce to prepare the following alcohols: List all possibilities.

PROBLEM What carbonyl compounds might you start with to prepare the following compounds by Grignard
17-44 reaction? List all possibilities.

PROBLEM How would you synthesize the following alcohols, starting with benzene and other alcohols of six or
17-45 fewer carbons as your only organic reagents?

Reactions of Alcohols

PROBLEM What products would you obtain from reaction of 1-pentanol with the following reagents:

17-46 (a) PBr_3 (b) SOCl_2 (c) Dess–Martin periodinane

PROBLEM How would you prepare the following compounds from 2-phenylethanol: More than one step may be required.

17-47 (a) Styrene ($\text{PhCH}=\text{CH}_2$) (b) Phenylacetaldehyde (PhCH_2CHO)
 (c) Phenylacetic acid ($\text{PhCH}_2\text{CO}_2\text{H}$) (d) Benzoic acid (e) Ethylbenzene (f) Benzaldehyde
 (g) 1-Phenylethanol (h) 1-Bromo-2-phenylethane

PROBLEM How would you prepare the following compounds from 1-phenylethanol: More than one step may be required.

17-48 (a) Acetophenone (PhCOCH_3) (b) Benzyl alcohol (c) *m*-Bromobenzoic acid
 (d) 2-Phenyl-2-propanol

PROBLEM How would you prepare the following substances from cyclopentanol: More than one step may be required.

17-49 (a) Cyclopentanone (b) Cyclopentene (c) 1-Methylcyclopentanol
 (d) *trans*-2-Methylcyclopentanol

PROBLEM What products would you expect to obtain from reaction of 1-methylcyclohexanol with the following reagents?

17-50 (a) HBr (b) NaH (c) H_2SO_4

Spectroscopy

PROBLEM The following ^1H NMR spectrum is that of an alcohol, $\text{C}_8\text{H}_{10}\text{O}$. Propose a structure.

17-51

PROBLEM Propose structures for alcohols that have the following ^1H NMR spectra:

17-52

(a) $C_5H_{12}O$ (b) $C_8H_{10}O$ **PROBLEM** Propose a structure consistent with the following spectral data for a compound $C_8H_{18}O_2$:**17-53**IR: 3350 cm^{-1} $^1\text{H NMR}$: $1.24\ \delta$ (12 H, singlet); $1.56\ \delta$ (4 H, singlet); $1.95\ \delta$ (2 H, singlet)**PROBLEM** The $^1\text{H NMR}$ spectrum shown is that of 3-methyl-3-buten-1-ol. Assign all the observed resonance**17-54** peaks to specific protons, and account for the splitting patterns.**PROBLEM** A compound of unknown structure gave the following spectroscopic data:**17-55**Mass spectrum: $M^+ = 88.1$ IR: 3600 cm^{-1} $^1\text{H NMR}$: $1.4\ \delta$ (2 H, quartet, $J = 7\text{ Hz}$); $1.2\ \delta$ (6 H, singlet); $1.0\ \delta$ (1 H, singlet); $0.9\ \delta$ (3 H, triplet, $J = 7\text{ Hz}$) $^{13}\text{C NMR}$: $74, 35, 27, 25\ \delta$

- (a) Assuming that the compound contains C and H but may or may not contain O, give three possible molecular formulas.
- (b) How many hydrogens does the compound contain?
- (c) What functional group(s) does the compound contain?
- (d) How many carbons does the compound contain?
- (e) What is the molecular formula of the compound?
- (f) What is the structure of the compound?
- (g) Assign peaks in the molecule's ^1H NMR spectrum corresponding to specific protons.

PROBLEM 17-56 Propose a structure for a compound $\text{C}_{15}\text{H}_{24}\text{O}$ that has the following ^1H NMR spectrum. The peak marked by an asterisk disappears when D_2O is added to the sample.

General Problems

PROBLEM 17-57 How would you carry out the following transformations?

PROBLEM 17-58 Benzoquinone is an excellent dienophile in the Diels–Alder reaction. What product would you expect from reaction of benzoquinone with 1 equivalent of 1,3-butadiene? From reaction with 2 equivalents of 1,3-butadiene?

PROBLEM 17-59 Rank the following substituted phenols in order of increasing acidity, and explain your answer:

PROBLEM 17-60 Benzyl chloride can be converted into benzaldehyde by treatment with nitromethane and base. The reaction involves initial conversion of nitromethane into its anion, followed by $\text{S}_{\text{N}}2$ reaction of the anion with benzyl chloride and subsequent $\text{E}2$ reaction. Write the mechanism in detail, using curved arrows to indicate the electron flow in each step.

PROBLEM 17-61 Reaction of (*S*)-3-methyl-2-pentanone with methylmagnesium bromide followed by acidification yields 2,3-dimethyl-2-pentanol. What is the stereochemistry of the product? Is the product optically active?

PROBLEM 17-62 Testosterone is one of the most important male steroid hormones. When testosterone is dehydrated by treatment with acid, rearrangement occurs to yield the product shown. Propose a mechanism to account for this reaction.

PROBLEM 17-63 Starting from testosterone (Problem 17-62), how would you prepare the following substances?

PROBLEM 17-64 *p*-Nitrophenol and 2,6-dimethyl-4-nitrophenol both have $pK_a = 7.15$, but 3,5-dimethyl-4-nitrophenol has $pK_a = 8.25$. Why is 3,5-dimethyl-4-nitrophenol so much less acidic?

PROBLEM 17-65 Compound **A**, $C_{10}H_{18}O$, undergoes reaction with dilute H_2SO_4 at $25\text{ }^\circ\text{C}$ to yield a mixture of two alkenes, $C_{10}H_{16}$. The major alkene product, **B**, gives only cyclopentanone after ozone treatment followed by reduction with zinc in acetic acid. Write the reactions involved, and identify **A** and **B**.

PROBLEM 17-66 Compound **A**, $C_5H_{10}O$, is one of the basic building blocks of nature. All steroids and many other naturally occurring compounds are built from compound **A**. Spectroscopic analysis of **A** yields the following information:

IR: 3400 cm^{-1} ; 1640 cm^{-1}

$^1\text{H NMR}$: $1.63\ \delta$ (3 H, singlet); $1.70\ \delta$ (3 H, singlet); $3.83\ \delta$ (1 H, broad singlet); $4.15\ \delta$ (2 H, doublet, $J = 7\text{ Hz}$); $5.70\ \delta$ (1 H, triplet, $J = 7\text{ Hz}$)

- How many double bonds and/or rings does **A** have?
- From the IR spectrum, what is the identity of the oxygen-containing functional group?
- What kinds of hydrogens are responsible for the NMR absorptions listed?
- Propose a structure for **A**.

PROBLEM 17-67 Dehydration of *trans*-2-methylcyclopentanol with $POCl_3$ in pyridine yields predominantly 3-methylcyclopentene. Is the stereochemistry of this dehydration syn or anti?

PROBLEM 17-68 2,3-Dimethyl-2,3-butanediol has the common name *pinacol*. On heating with aqueous acid, pinacol rearranges to *pinacolone*, 3,3-dimethyl-2-butanone. Suggest a mechanism for this reaction.

PROBLEM 17-69 As a rule, axial alcohols oxidize somewhat faster than equatorial alcohols. Which would you expect to oxidize faster, *cis*-4-*tert*-butylcyclohexanol or *trans*-4-*tert*-butylcyclohexanol? Draw the more stable chair conformation of each molecule.

PROBLEM 17-70 Propose a synthesis of bicyclohexylidene, starting from cyclohexanone as the only source of carbon.

PROBLEM 17-71 A problem often encountered in the oxidation of primary alcohols to carboxylic acids is that esters are sometimes produced as by-products. For example, oxidation of ethanol yields acetic acid and ethyl acetate:

Propose a mechanism to account for the formation of ethyl acetate. Take into account the reversible reaction between aldehydes and alcohols:

PROBLEM 17-72 Identify the reagents **a–f** in the following scheme:

PROBLEM 17-73 Galactose, a constituent of the disaccharide lactose found in dairy products, is metabolized by a pathway that includes the isomerization of UDP-galactose to UDP-glucose, where UDP = uridylyl diphosphate. The enzyme responsible for the transformation uses NAD^+ as cofactor. Propose a mechanism.

PROBLEM 17-74 (a) Propose structures for alcohols that have the following ^1H NMR spectra:

(a) $\text{C}_9\text{H}_{12}\text{O}$

(b) $\text{C}_8\text{H}_{10}\text{O}_2$

PROBLEM 17-75 Compound A, $\text{C}_8\text{H}_{10}\text{O}$, has the IR and ^1H NMR spectra shown. Propose a structure consistent with the observed spectra, and label each peak in the NMR spectrum. Note that the absorption at 5.5δ disappears when D_2O is added.

18.8 Spectroscopy of Ethers

WHY THIS CHAPTER? This chapter finishes the coverage of functional groups with C–O and C–S single bonds that was begun in the chapter on **Alcohols and Phenols**. We'll focus primarily on ethers and take only a brief look at thiols and sulfides before going on to an extensive coverage of compounds with C=O double bonds in Chapters 19 through 23.

Ethers (R–O–R'), like the alcohols we saw in the preceding chapter, are organic derivatives of water, but they have two organic groups bonded to the same oxygen atom rather than one. The organic groups might be alkyl, aryl, or vinylic, and the oxygen atom might be in an open chain or a ring.

Perhaps the most well-known ether is diethyl ether, which has a long history of medicinal use as an anesthetic and industrial use as a solvent. Other useful ethers include anisole, a pleasant-smelling aromatic ether used in perfumery, and tetrahydrofuran (THF), a cyclic ether often used as a solvent.

Thiols (R–S–H) and **sulfides** (R–S–R') are sulfur analogs of alcohols and ethers, respectively. Both functional groups are found in various biomolecules, although not as commonly as their oxygen-containing relatives.

18.1 Names and Properties of Ethers

Simple ethers with no other functional groups are named by identifying the two organic substituents and adding the word *ether*.

If other functional groups are present, the ether part is considered an *alkoxy* substituent. For example:

Like alcohols, ethers have nearly the same geometry as water. The R–O–R bonds have an approximately tetrahedral bond angle (112° in dimethyl ether), and the oxygen atom is sp^3 -hybridized.

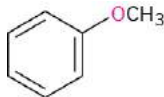

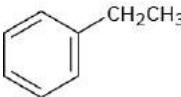

The electronegative oxygen atom gives ethers a slight dipole moment, and the boiling points of ethers are often slightly higher than the boiling points of comparable alkanes. **TABLE 18.1** compares the boiling points of some common ethers and their corresponding hydrocarbons.

TABLE 18.1 Comparison of Boiling Points of Ethers and Hydrocarbons

Ether	Boiling point $^\circ\text{C}$	Hydrocarbon	Boiling point $^\circ\text{C}$
CH_3OCH_3	–25	$\text{CH}_3\text{CH}_2\text{CH}_3$	–45
$\text{CH}_3\text{CH}_2\text{OCH}_2\text{CH}_3$	34.6	$\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$	36

TABLE 18.1 Comparison of Boiling Points of Ethers and Hydrocarbons

Ether	Boiling point °C	Hydrocarbon	Boiling point °C
	65		49
	158		136

Ethers are relatively stable and unreactive in many respects, but some ethers react slowly with the oxygen in air to give *peroxides*, compounds that contain an O–O bond. The peroxides from low-molecular-weight ethers such as diisopropyl ether and tetrahydrofuran are explosive and extremely dangerous, even in small amounts. Ethers are very useful as solvents in the laboratory, but they must always be used cautiously and should not be stored for long periods of time.

PROBLEM Name the following ethers:

18.2 Preparing Ethers

Diethyl ether and other simple symmetrical ethers are prepared industrially by the sulfuric-acid-catalyzed reaction of alcohols. The reaction occurs by $\text{S}_{\text{N}}2$ displacement of water from a protonated ethanol molecule by the oxygen atom of a second ethanol. Unfortunately, this method is limited to use with primary alcohols because secondary and tertiary alcohols dehydrate by an $\text{E}1$ mechanism to yield alkenes (Section 17.6).

The Williamson Ether Synthesis

The most generally useful method of preparing ethers is the **Williamson ether synthesis**, in which an alkoxide ion reacts with a primary alkyl halide or tosylate in an $\text{S}_{\text{N}}2$ reaction. As we saw in Section 17.2, the alkoxide ion is normally prepared by reaction of an alcohol with a strong base such as sodium hydride, NaH.

A useful variation of the Williamson synthesis involves silver oxide, Ag_2O , as a mild base rather than NaH. Under these conditions, the free alcohol reacts directly with the alkyl halide, so there is no need to preform the metal

alkoxide intermediate. Sugars react particularly well; glucose, for example, reacts with excess iodomethane in the presence of Ag_2O to generate a pentaether in 85% yield.

Because the Williamson synthesis is an $\text{S}_{\text{N}}2$ reaction, it is subject to all the usual constraints, as discussed in [Section 11.3](#). Primary halides and tosylates work best because competitive $\text{E}2$ elimination can occur with more hindered substrates. Unsymmetrical ethers should therefore be synthesized by reaction between the more hindered alkoxide partner and less hindered halide partner rather than vice versa. For example, *tert*-butyl methyl ether, a substance used in the 1990s as an octane booster in gasoline, is best prepared by reaction of *tert*-butoxide ion with iodomethane rather than by reaction of methoxide ion with 2-chloro-2-methylpropane.

PROBLEM 18-2 Why do you suppose only symmetrical ethers are prepared by the sulfuric-acid-catalyzed dehydration procedure? What product(s) would you expect if ethanol and 1-propanol were allowed to react together? In what ratio would the products be formed if the two alcohols were of equal reactivity?

PROBLEM 18-3 How would you prepare the following ethers using a Williamson synthesis?

- (a) Methyl propyl ether (b) Anisole (methyl phenyl ether) (c) Benzyl isopropyl ether
(d) Ethyl 2,2-dimethylpropyl ether

Alkoxymercuration of Alkenes

We saw in [Section 8.4](#) that alkenes react with water in the presence of mercuric acetate to yield a hydroxymercuration product. Subsequent treatment with NaBH_4 breaks the C-Hg bond and yields the alcohol. A similar **alkoxymercuration** reaction occurs when an alkene is treated with an alcohol in the presence of mercuric acetate or, even better, mercuric trifluoroacetate, $(\text{CF}_3\text{CO}_2)_2\text{Hg}$. Demercuration by reaction with NaBH_4 then yields an ether. The net result is Markovnikov addition of the alcohol to the alkene.

The mechanism of the alkoxymercuration reaction is similar to that described in Section 8.4 for hydroxymercuration. The reaction is initiated by electrophilic addition of Hg^{2+} to the alkene, followed by reaction of the intermediate cation with alcohol and reduction of the C–Hg bond by NaBH_4 . A variety of alcohols and alkenes can be used in alkoxymercuration. Primary, secondary, and even tertiary alcohols react well, but ditertiary ethers can't be prepared because of steric hindrance.

WORKED EXAMPLE 18.1

Synthesizing an Ether

How would you prepare ethyl phenyl ether? Use whichever method you think is more appropriate, Williamson synthesis or the alkoxymercuration reaction.

Strategy

Draw the target ether, identify the two groups attached to oxygen, and recall the limitations of the two methods for preparing ethers. Williamson synthesis uses an $\text{S}_{\text{N}}2$ reaction and requires that one of the two groups attached to oxygen be either secondary or (preferably) primary. The alkoxymercuration reaction requires that one of the two groups come from an alkene precursor. Ethyl phenyl ether could be made by either method.

Solution

PROBLEM 18-4 Review the mechanism of oxymercuration shown in Figure 8.4, and then write the mechanism of the alkoxymercuration reaction of 1-methylcyclopentene with ethanol. Use curved arrows to show the electron flow in each step.

PROBLEM 18-5 How would you prepare the following ethers? Use whichever method you think is more appropriate, Williamson synthesis or the alkoxymercuration reaction.

- (a) Butyl cyclohexyl ether (b) Benzyl ethyl ether ($\text{C}_6\text{H}_5\text{CH}_2\text{OCH}_2\text{CH}_3$)
 (c) *sec*-Butyl *tert*-butyl ether (d) Tetrahydrofuran

PROBLEM Rank the following halides in order of their reactivity in the Williamson synthesis:

18-6 (a) Bromoethane, 2-bromopropane, bromobenzene

(b) Chloroethane, bromoethane, 1-Iodopropene

18.3 Reactions of Ethers: Acidic Cleavage

Ethers are unreactive to many reagents used in organic chemistry, a property that accounts for their wide use as reaction solvents. Halogens, dilute acids, bases, and nucleophiles have no effect on most ethers. In fact, ethers undergo only one truly general reaction—they are cleaved by strong acids. Aqueous HBr and HI both work well, but HCl does not cleave ethers.

Acidic ether cleavages are typical nucleophilic substitution reactions and take place by either S_N1 or S_N2 mechanisms, depending on the structure of the substrate. Ethers with only primary and secondary alkyl groups react by an S_N2 mechanism, in which I^- or Br^- reacts with the protonated ether at the less hindered site. This usually results in a selective cleavage into a single alcohol and a single alkyl halide. For example, ethyl isopropyl ether exclusively yields isopropyl alcohol and iodoethane on cleavage by HI because nucleophilic attack by iodide ion occurs at the less hindered primary site rather than at the more hindered secondary site.

Ethers with a tertiary, benzylic, or allylic group cleave by either an S_N1 or E1 mechanism because these substrates can produce stable intermediate carbocations. These reactions are often fast and take place at moderate temperatures. *tert*-Butyl ethers, for example, react by an E1 mechanism on treatment with trifluoroacetic acid at 0 °C. We'll see in **Section 26.7** that this reaction is often used in the laboratory synthesis of peptides.

WORKED EXAMPLE 18.2

Predicting the Product of an Ether Cleavage Reaction

Predict the products of the following reaction:

Strategy

Identify the substitution pattern of the two groups attached to oxygen—in this case a tertiary alkyl group and a primary alkyl group. Then recall the guidelines for ether cleavages. An ether with only primary and secondary alkyl groups usually undergoes cleavage by S_N2 attack of a nucleophile on the less hindered alkyl group, but an ether with a tertiary alkyl group usually undergoes cleavage by an S_N1 mechanism. In this case, an S_N1 cleavage

of the tertiary C–O bond will occur, giving 1-propanol and a tertiary alkyl bromide. In addition, a competitive E1 reaction leading to alkene might occur.

Solution

PROBLEM Predict the products of the following reactions:

18-7 (a)

(b)

PROBLEM Write the mechanism of the acid-induced cleavage of *tert*-butyl cyclohexyl ether to yield 18-8 cyclohexanol and 2-methylpropene.

PROBLEM Why are HI and HBr more effective than HCl in cleaving ethers? (See Section 11.3.) 18-9

18.4 Cyclic Ethers: Epoxides

For the most part, cyclic ethers behave like acyclic ethers. The chemistry of the ether functional group is the same, whether it's in an open chain or in a ring. Common cyclic ethers such as tetrahydrofuran and dioxane are often used as solvents because of their inertness, yet they can be cleaved by strong acids.

1,4-Dioxane

Tetrahydrofuran

The one group of cyclic ethers that behaves differently from open-chain ethers are the three-membered-ring compounds called *epoxides*, or *oxiranes*, which we saw in Section 8.7. The strain of the three-membered ring gives epoxides unique chemical reactivity.

Ethylene oxide, the simplest epoxide, is an intermediate in the manufacture of both ethylene glycol, used for automobile antifreeze, and polyester polymers. Approximately 37 million tons of ethylene oxide is produced worldwide each year, most of it by air oxidation of ethylene over a silver oxide catalyst at 300 °C. This process is not useful for other epoxides, however, and is of little value in the laboratory.

Note that the name *ethylene oxide* is not a systematic one because the *-ene* ending implies the presence of a double bond in the molecule. The name is frequently used, however, because ethylene oxide is derived *from* ethylene by addition of an oxygen atom. Other simple epoxides are named similarly. The systematic name for ethylene oxide is 1,2-epoxyethane.

In the laboratory, as we saw in Section 8.7, epoxides are usually prepared by treatment of an alkene with a

peroxyacid (RCO₃H), typically *m*-chloroperoxybenzoic acid.

Epoxides can also be prepared from halohydrins, themselves produced by electrophilic addition of Cl₂ or Br₂ to an alkene in the presence of water (Section 8.3). When a halohydrin is treated with base, HX is eliminated and an epoxide is produced by an intramolecular Williamson ether synthesis. That is, the nucleophilic alkoxide ion and the electrophilic alkyl halide are in the same molecule.

PROBLEM What product would you expect from reaction of *trans*-2-butene with *m*-chloroperoxybenzoic acid?
18-10 Show the stereochemistry.

PROBLEM Reaction of *cis*-2-butene with *m*-chloroperoxybenzoic acid yields an epoxide different from that
18-11 obtained by reaction of the *trans* isomer. Explain.

18.5 Reactions of Epoxides: Ring-Opening

Acid-Catalyzed Epoxide Opening

Epoxides are cleaved by treatment with acid just as other ethers are, but under much milder conditions because of ring strain. As we saw in Section 8.7, dilute aqueous acid at room temperature is sufficient for facilitating the hydrolysis of epoxides to give 1,2-diols, also called *vicinal glycols*. (The word *vicinal* means “adjacent,” and a *glycol* is a diol.) The epoxide cleavage takes place by S_N2-like backside attack of a nucleophile on the protonated epoxide, giving a *trans*-1,2-diol as product.

Epoxides can also be opened by reaction with acids other than H₃O⁺. If anhydrous HX is used, for instance, an epoxide is converted into a *trans* halohydrin.

A trans 2-halocyclohexanol

where X = F, Br, Cl, or I

The regiochemistry of acid-catalyzed ring-opening depends on the epoxide's structure, and a mixture of products is often formed. When both epoxide carbon atoms are either primary or secondary, attack of the nucleophile occurs primarily at the less highly substituted site: an S_N2 -like result. When one of the epoxide carbon atoms is tertiary, however, nucleophilic attack occurs primarily at the *more* highly substituted site—an S_N1 -like result. Thus, 1,2-epoxypropane reacts with HCl to give primarily 1-chloro-2-propanol, but 2-methyl-1,2-epoxypropane gives 2-chloro-2-methyl-1-propanol as the major product.

The mechanisms of these acid-catalyzed epoxide openings are more complex than they initially appear. They seem to be neither purely S_N1 nor S_N2 but instead to be midway between the two extremes and to have characteristics of both. For instance, take the reaction of 1,2-epoxy-1-methylcyclohexane with HBr, shown in **FIGURE 18.2**. The reaction yields only a single stereoisomer of 2-bromo-2-methylcyclohexanol in which the $-Br$ and $-OH$ groups are trans, an S_N2 -like result caused by backside displacement of the epoxide oxygen. But the fact that Br^- attacks the more hindered tertiary side of the epoxide rather than the less hindered secondary side is an S_N1 -like result in which the more stable, tertiary carbocation is involved.

Evidently, the transition state for acid-catalyzed epoxide opening has an S_N2 -like geometry but also has a high degree of S_N1 -like carbocationic character. Because the positive charge in the protonated epoxide is shared by the more highly substituted carbon atom, backside attack of Br^- occurs at the more highly substituted site.

FIGURE 18.2 Ring-opening of 1,2-epoxy-1-methylcyclohexane with HBr. There is a high degree of S_N1 -like carbocation character in the transition state, which leads to backside attack of the nucleophile at the tertiary center and to formation of a product isomer that has -Br and -OH groups trans.

WORKED EXAMPLE 18.3

Predicting the Product of Epoxide Ring-Opening

Predict the major product of the following reaction:

Strategy

Identify the substitution pattern of the two epoxide carbon atoms. In this case, one carbon is secondary and one is primary. Then recall the guidelines for epoxide cleavages. An epoxide with only primary and secondary carbons usually undergoes cleavage by S_N2 -like attack of a nucleophile on the less hindered carbon, but an epoxide with a tertiary carbon atom usually undergoes cleavage by backside attack on the more hindered carbon. In this case, an S_N2 cleavage of the primary C–O epoxide bond will occur.

Solution

PROBLEM Predict the major product of each of the following reactions:

18-12 (a)

(b)

PROBLEM How would you prepare the following diols?

18-13

Base-Catalyzed Epoxide Opening

Unlike other ethers, epoxide rings can be cleaved by bases and nucleophiles as well as by acid. Although an ether oxygen is normally a poor leaving group in an S_N2 reaction (Section 11.3), the strain of the three-membered ring causes epoxides to react with hydroxide ion at elevated temperatures.

Base-catalyzed epoxide opening is a typical S_N2 reaction in which attack of the nucleophile takes place at the less hindered epoxide carbon. For example, 1,2-epoxypropane reacts with ethoxide ion exclusively at the less highly substituted, primary carbon to give 1-ethoxy-2-propanol.

Many different nucleophiles can be used for epoxide opening, including amines (RNH_2 or R_2NH) and Grignard reagents ($RMgX$). An example of an amine reacting with an epoxide occurs in the commercial synthesis of metoprolol, a so-called β -blocker that is used for treatment of cardiac arrhythmias, hypertension, and heart attacks. β -Blockers are among the most widely prescribed drugs in the world.

A similar nucleophilic ring-opening occurs when epoxides are treated with Grignard reagents. Ethylene oxide is frequently used, thereby allowing the conversion of a Grignard reagent into a primary alcohol having two more carbons than the starting alkyl halide. 1-Bromobutane, for example, is converted into 1-hexanol by reaction of its Grignard reagent with ethylene oxide.

Valinomycin

PROBLEM 18-15 15-Crown-5 and 12-crown-4 ethers complex Na^+ and Li^+ , respectively. Make models of these crown ethers, and compare the sizes of the cavities.

18.7 Thiols and Sulfides

Thiols

Thiols, also called **mercaptans**, are sulfur analogs of alcohols. They are named by the same system used for alcohols, with the suffix *-thiol* used in place of *-ol*. The $-\text{SH}$ group itself is referred to as a **mercapto group**. Like alcohols, thiols are weakly acidic; the $\text{p}K_a$ of CH_3SH , for instance, is 10.3. Unlike alcohols, however, thiols don't typically form hydrogen bonds because the sulfur atom is not sufficiently electronegative.

Ethanethiol

Cyclohexanethiol

m-Mercaptobenzoic acid

The most striking characteristic of thiols is their appalling odor. Skunk scent, for instance, is caused primarily by the simple thiols 3-methyl-1-butanethiol and 2-butene-1-thiol. Volatile thiols such as ethanethiol are also added to natural gas and liquefied propane to serve as an easily detectable warning in case of leaks.

Thiols are usually prepared from alkyl halides by $\text{S}_{\text{N}}2$ displacement with a sulfur nucleophile such as hydrosulfide anion, ^-SH .

1-Bromooctane

1-Octanethiol (83%)

The reaction often works poorly unless an excess of the nucleophile is used because the product thiol can undergo a second $\text{S}_{\text{N}}2$ reaction with alkyl halide to give a **sulfide ($\text{R-S-R}'$)** as by-product. To circumvent this problem, thiourea, $(\text{NH}_2)_2\text{C}=\text{S}$, is often used as the nucleophile in the preparation of a thiol from an alkyl halide. The reaction occurs by displacement of the halide ion to yield an intermediate alkyl isothioureia salt, which is hydrolyzed by subsequent reaction with aqueous base.

Thiols can be oxidized by Br_2 or I_2 to yield **disulfides (R-S-S-R')**. The reaction is easily reversed, and a disulfide can be reduced back to a thiol by treatment with zinc and acid.

This thiol–disulfide interconversion is a key part of numerous biological processes. We'll see in Chapter 26, for instance, that disulfide formation is involved in defining the structure and three-dimensional conformations of proteins, where disulfide “bridges” often form cross-links between cysteine amino-acid units in the protein chains. Disulfide formation is also involved in the process by which cells protect themselves from oxidative degradation. A cellular component called *glutathione* removes potentially harmful oxidants and is itself oxidized to glutathione disulfide in the process. Reduction back to the thiol requires the coenzyme reduced flavin adenine dinucleotide, abbreviated FADH_2 .

Sulfides

Sulfides are the sulfur analogs of ethers just as thiols are the sulfur analogs of alcohols. Sulfides are named by following the same rules used for ethers, with *sulfide* used in place of *ether* for simple compounds and *alkylthio* used in place of *alkoxy* for more complex substances.

Treatment of a thiol with a base, such as NaH , gives the corresponding **thiolate ion (RS^-)**, which undergoes reaction with a primary or secondary alkyl halide to give a sulfide. The reaction occurs by an $\text{S}_{\text{N}}2$ mechanism, analogous to the Williamson synthesis of ethers ([Section 18.2](#)).

Despite their close structural similarity, sulfides and ethers differ substantially in their chemistry. Because the valence electrons on sulfur are farther from the nucleus and are less tightly held than those on oxygen (3*p* electrons versus 2*p* electrons), sulfur compounds are more nucleophilic than their oxygen analogs. Unlike dialkyl ethers, dialkyl sulfides react rapidly with primary alkyl halides by an S_N2 mechanism to give **sulfonium ions** (R₃S⁺).

The most common example of this process in living organisms is the reaction of the amino acid methionine with adenosine triphosphate (ATP; Section 6.8) to give *S*-adenosylmethionine. The reaction is somewhat unusual in that the biological leaving group in this S_N2 process is the *triphosphate* ion rather than the more frequently seen diphosphate ion (Section 11.6).

Sulfonium ions are themselves useful alkylating agents because a nucleophile can attack one of the groups bonded to the positively charged sulfur, displacing a neutral sulfide as leaving group. We saw an example of this in Section 11.6 (FIGURE 11.17), in which *S*-adenosylmethionine transferred a methyl group to norepinephrine to give adrenaline.

Another difference between sulfides and ethers is that sulfides are easily oxidized. Treatment of a sulfide with hydrogen peroxide, H₂O₂, at room temperature yields the corresponding **sulfoxide** (R₂SO), and further oxidation of the sulfoxide with a peroxyacid yields a **sulfone** (R₂SO₂).

Dimethyl sulfoxide (DMSO) is a particularly well-known sulfoxide that is often used as a polar aprotic solvent. It must be handled with care, however, because it has a remarkable ability to penetrate the skin, carrying along whatever is dissolved in it.

PROBLEM Name the following compounds:

PROBLEM 2-Butene-1-thiol is one component of skunk spray. How would you synthesize this substance
18-17 (either cis or trans) from methyl 2-butenate? From 1,3-butadiene?

18.8 Spectroscopy of Ethers

Infrared Spectroscopy

Ethers are difficult to identify by IR spectroscopy. Although they show an absorption due to C–O single-bond stretching in the range 1050 to 1150 cm^{-1} , many other kinds of absorptions occur in the same range. **FIGURE 18.3** shows the IR spectrum of diethyl ether and identifies the C–O stretch. Phenyl alkyl ethers show two strong absorbances for C–O stretching at 1050 and 1250 cm^{-1} . **FIGURE 18.4** shows the IR spectrum of anisole.

FIGURE 18.3 The infrared spectrum of diethyl ether, $\text{CH}_3\text{CH}_2\text{OCH}_2\text{CH}_3$.

FIGURE 18.4 The infrared spectrum of anisole.

Nuclear Magnetic Resonance Spectroscopy

Hydrogens on carbon next to an ether oxygen are shifted downfield from the normal alkane resonance and show ^1H NMR absorptions in the region 3.4 to 4.5 δ . This downfield shift is clearly seen in the spectrum of dipropyl ether shown in **FIGURE 18.5**.

FIGURE 18.5 The ^1H NMR spectrum of dipropyl ether. Protons on carbon next to oxygen are shifted downfield to 3.4 δ .

Epoxides absorb at a slightly higher field than other ethers and show characteristic resonances at 2.5 to 3.5 δ in their ^1H NMR spectra, as indicated for 1,2-epoxypropane in **FIGURE 18.6**. The methylene protons of this epoxide are diastereotopic, and display complex splitting (see **Section 13.7** and **Section 13.8**).

FIGURE 18.6 The ^1H NMR spectrum of 1,2-epoxypropane.

Ether carbon atoms also exhibit a downfield shift in the ^{13}C NMR spectrum, where they usually absorb in the 50 to 80 δ range. For example, the carbon atoms next to oxygen in methyl propyl ether absorb at 58.5 and 74.8 δ . Similarly, the methyl carbon in anisole absorbs at 54.8 δ .

PROBLEM 18-18 The ^1H NMR spectrum shown is that of a cyclic ether with the formula $\text{C}_4\text{H}_8\text{O}$. Propose a structure.

CHEMISTRY MATTERS

Epoxy Resins and Adhesives

Few nonchemists know exactly what an epoxide is, but practically everyone has used an “epoxy glue” for household repairs or an epoxy resin for a protective coating. Worldwide, approximately 14 billion dollars’ worth of epoxy resins and adhesives are used annually for a vast number of applications, including many in the aerospace industry. Much of the Boeing 787 Dreamliner, for instance, is held together with epoxy-based adhesives.

Epoxy resins and adhesives generally consist of two components that are mixed just prior to use. One component is a liquid “prepolymer,” and the second is a “curing agent” that reacts with the prepolymer and causes it to solidify.

The most widely used epoxy resins and adhesives are based on a prepolymer made from bisphenol A and epichlorohydrin. On treatment with base, bisphenol A is converted into its anion, which acts as a nucleophile in an S_N2 reaction with epichlorohydrin. Each epichlorohydrin molecule can react with two molecules of bisphenol A, once by S_N2 displacement of chloride ion and once by nucleophilic opening of the epoxide ring. At the same time, each bisphenol A molecule can react with two epichlorohydrins, leading to a long polymer chain. Each end of a prepolymer chain has an unreacted epoxy group, and each chain has numerous secondary alcohol groups spaced regularly along its midsection.

FIGURE 18.7 Kayaks are often made of a high-strength polymer coated with epoxy resin. (credit: “Potomac River Festival Virginia 2017 Great Falls Kayak Race” by Watts/Flickr, CC BY 2.0)

When an epoxide is to be used, a basic curing agent such as a tertiary amine, R_3N , is added to cause the individual prepolymer chains to link together. This cross-linking of chains is simply a base-catalyzed, S_N2 epoxide ring-opening of an $-OH$ group in the middle of one chain with an epoxide group on the end of another chain. The result of such cross-linking is formation of a vast, three-dimensional tangle that has enormous strength and chemical resistance.

Key Terms

- alkoxymercuration
- crown ether
- disulfide ($R-S-S-R'$)
- ether ($R-O-R'$)
- mercapto group
- sulfide ($R-S-R'$)
- sulfone
- sulfonium ion
- sulfoxide
- thiol
- thiolate ion (RS^-)
- Williamson ether synthesis

Summary

This chapter has finished the coverage of functional groups with C–O and C–S single bonds, focusing primarily on ethers, epoxides, thiols, and sulfides. **Ethers** are compounds that have two organic groups bonded to the same oxygen atom, ROR' . The organic groups can be alkyl, vinylic, or aryl, and the oxygen atom can be in a ring or in an open chain. Ethers are prepared by either Williamson ether synthesis, which involves S_N2 reaction of an alkoxide ion with a primary alkyl halide, or the **alkoxymercuration** reaction, which involves Markovnikov addition of an alcohol to an alkene.

Ethers are inert to most reagents but react with strong acids to give cleavage products. Both HI and HBr are often used. The cleavage reaction takes place by an S_N2 mechanism at the less highly substituted site if only primary and secondary alkyl groups are bonded to the ether oxygen, but by an S_N1 or $E1$ mechanism if one of the alkyl groups bonded to oxygen is tertiary.

Epoxides are cyclic ethers with a three-membered, oxygen-containing ring. Because of the strain in the ring, epoxides undergo a cleavage reaction with both acids and bases. Acid-catalyzed ring-opening occurs with a regiochemistry that depends on the structure of the epoxide. Cleavage of the C–O bond at the less highly substituted site occurs if both epoxide carbons are primary or secondary, but cleavage of the C–O bond to the more highly substituted site occurs if one of the epoxide carbons is tertiary. Base-catalyzed epoxide ring-opening occurs by S_N2 reaction of a nucleophile at the less hindered epoxide carbon.

Thiols, the sulfur analogs of alcohols, are usually prepared by S_N2 reaction of an alkyl halide with thiourea. Mild oxidation of a thiol yields a **disulfide**, and mild reduction of a disulfide returns the thiol. **Sulfides**, the sulfur analogs of ethers, are prepared by an S_N2 reaction between a thiolate anion and a primary or secondary alkyl halide. Sulfides are more nucleophilic than ethers and can be alkylated by reaction with a primary alkyl halide to yield a **sulfonium ion**. Sulfides can also be oxidized to **sulfoxides** and to **sulfones**.

Summary of Reactions

1. Synthesis of ethers (Section 18.2)

a. Williamson ether synthesis

b. Alkoxymercuration/demercuration

2. Reactions of ethers

a. Cleavage by HBr or HI (Section 18.3)

b. Acid-catalyzed epoxide opening (Section 18.5)

c. Base-catalyzed epoxide opening (Section 18.5)

3. Synthesis of thiols (Section 18.7)

4. Oxidation of thiols to disulfides (Section 18.7)

5. Synthesis of sulfides (Section 18.7)

6. Oxidation of sulfides to sulfoxides and sulfones (Section 18.7)

Additional Problems

Visualizing Chemistry

PROBLEM Give IUPAC names for the following compounds (red = O; reddish brown = Br; yellow = S):

18-19 (a)

(b)

(c)

PROBLEM 18-20 Show the product, including stereochemistry, that would result from reaction of the following epoxide with HBr:

PROBLEM 18-21 Show the product, including stereochemistry, of the following reaction:

PROBLEM 18-22 Treatment of the following alkene with a peroxyacid yields an epoxide different from that obtained by reaction with aqueous Br_2 followed by base treatment. Propose structures for the two epoxides, and explain the result.

Mechanism Problems

PROBLEM 18-23 Predict the product(s) and provide the mechanism for each of the following reactions.

(a)

(b)

PROBLEM 18-24 Predict the product(s) and provide the mechanism for each of the following reactions.

PROBLEM Predict the product(s) and provide the mechanism for each of the following two-step processes.

PROBLEM The alkoxymercuration of alkenes involves the formation of an organomercury intermediate (I),

18-26 which is reduced with NaBH_4 to give an ether product. Predict the ether product and provide the mechanism for the following reaction.

PROBLEM Predict the product(s) and provide the mechanism for the following reactions:

PROBLEM Predict the product(s) and provide the mechanism for each of the following reactions.

PROBLEM In the formation of the prepolymer used to make epoxy resins, a bisphenol reacts with

18-29 epichlorohydrin in the presence of a base. Show the product and mechanism when two moles of phenol react with epichlorohydrin.

Epichlorohydrin

PROBLEM Ethers undergo an acid-catalyzed cleavage reaction when treated with the Lewis acid BBr_3 at room

18-30 temperature. Propose a mechanism for the reaction.

PROBLEM Treatment of 1,1-diphenyl-1,2-epoxyethane with aqueous acid yields diphenyl acetaldehyde as the

18-31 major product. Propose a mechanism for the reaction.

PROBLEM Fluoxetine, a heavily prescribed antidepressant marketed under the name Prozac, can be prepared

18-32 by a route that begins with reaction between a phenol and an alkyl chloride.

- (a) The rate of the reaction depends on both phenol and alkyl halide. Is this an S_N1 or an S_N2 reaction? Show the mechanism.
- (b) The physiologically active enantiomer of fluoxetine has (*S*) stereochemistry. Based on your answer in part (a), draw the structure of the alkyl chloride you would need, showing the correct stereochemistry.

PROBLEM 18-33 When 2-methyl-2,5-pentandiol is treated with sulfuric acid, dehydration occurs and 2,2-dimethyltetrahydrofuran is formed. Suggest a mechanism for this reaction. Which of the two oxygen atoms is most likely to be eliminated, and why?

PROBLEM 18-34 Methyl aryl ethers, such as anisole, are cleaved to iodomethane and a phenoxide ion by treatment with LiI in hot DMF. Propose a mechanism for this reaction.

PROBLEM 18-35 The herbicide acifluorfen can be prepared by a route that begins with reaction between a phenol and an aryl fluoride. Propose a mechanism.

PROBLEM 18-36 Aldehydes and ketones undergo acid-catalyzed reaction with alcohols to yield *hemiacetals*, from aldehydes or ketals with ketones compounds that have one alcohol-like oxygen and one ether-like oxygen bonded to the same carbon. Further reaction of a hemiacetal with alcohol then yields an *acetal*, a compound that has two ether-like oxygens bonded to the same carbon.

- (a) Show the structures of the hemiketal and ketal you would obtain by reaction of cyclohexanone with ethanol.
- (b) Propose a mechanism for the conversion of a hemiacetal into a ketal.

PROBLEM 18-37 Propose a mechanism to account for the following transformation. What two kinds of reactions are occurring?

Naming Ethers

PROBLEM 18-38 Draw structures corresponding to the following IUPAC names:

- (a) Ethyl 1-ethylpropyl ether (b) Di(*p*-chlorophenyl) ether (c) 3,4-Dimethoxybenzoic acid
(d) Cyclopentyloxycyclohexane (e) 4-Allyl-2-methoxyphenol (eugenol; from oil of cloves)

PROBLEM 18-39 Give IUPAC names for the following structures:

18-39

A ketone

A hemiketal

A ketal

Synthesizing Ethers

PROBLEM 18-40 How would you prepare the following ethers?

PROBLEM 18-41 How would you prepare the following compounds from 1-phenylethanol?

- (a) Methyl 1-phenylethyl ether (b) Phenylepoxyethane (c) *tert*-Butyl 1-phenylethyl ether
(d) 1-Phenylethanethiol

PROBLEM 18-42 *tert*-Butyl ethers can be prepared by the reaction of an alcohol with 2-methylpropene in the presence of an acid catalyst. Propose a mechanism for this reaction.

PROBLEM 18-43 Treatment of *trans*-2-chlorocyclohexanol with NaOH yields 1,2-epoxycyclohexane, but reaction of the *cis* isomer under the same conditions yields cyclohexanone. Propose mechanisms for both reactions, and explain why the different results are obtained.

Reactions of Ethers and Epoxides

PROBLEM 18-44 Predict the products of the following ether cleavage reactions:

PROBLEM 18-45 How would you carry out the following transformations? More than one step may be required.

PROBLEM 18-46 What product would you expect from cleavage of tetrahydrofuran with HI?

PROBLEM 18-47 Write the mechanism of the hydrolysis of *cis*-5,6-epoxydecane by reaction with aqueous acid. What is the stereochemistry of the product, assuming normal backside S_N2 attack?

PROBLEM 18-48 What is the stereochemistry of the product from acid-catalyzed hydrolysis of *trans*-5,6-epoxydecane? How does the product differ from that formed in Problem 18-47?

PROBLEM 18-49 Acid-catalyzed hydrolysis of a 1,2-epoxycyclohexane produces a *trans*-diaxial 1,2-diol. What product would you expect to obtain from acidic hydrolysis of *cis*-3-*tert*-butyl-1,2-epoxycyclohexane? (Recall that the bulky *tert*-butyl group locks the

cyclohexane ring into a specific conformation.)

PROBLEM 18-50 Imagine that you have treated (2*R*,3*R*)-2,3-epoxy-3-methylpentane with aqueous acid to carry out a ring-opening reaction.

- (a) Draw the epoxide, showing stereochemistry.
 (b) Draw and name the product, showing stereochemistry. (c) Is the product chiral? Explain.
 (d) Is the product optically active? Explain.

PROBLEM 18-51 Epoxides are reduced by treatment with lithium aluminum hydride to yield alcohols. Propose a mechanism for this reaction.

PROBLEM 18-52 Show the structure and stereochemistry of the alcohol that would result if 1,2-epoxycyclohexane were reduced with lithium aluminum deuteride, LiAlD₄ (Problem 18-51).

Spectroscopy

PROBLEM 18-53 The red fox (*Vulpes vulpes*) uses a chemical communication system based on scent marks in urine. One component of fox urine is a sulfide whose mass spectrum has $M^+ = 116$. IR spectroscopy shows an intense band at 890 cm^{-1} , and ^1H NMR spectroscopy reveals the following peaks:

1.74 δ (3 H, singlet); 2.11 δ (3 H, singlet); 2.27 δ (2 H, triplet, $J = 4.2\text{ Hz}$); 2.57 δ (2 H, triplet, $J = 4.2\text{ Hz}$); 4.73 δ (2 H, broad)

Propose a structure consistent with these data. [Note: $(\text{CH}_3)_2\text{S}$ absorbs at 2.1 δ].

PROBLEM 18-54 Anethole, $\text{C}_{10}\text{H}_{12}\text{O}$, a major constituent of the oil of anise, has the ^1H NMR spectrum shown. On careful oxidation with $\text{Na}_2\text{Cr}_2\text{O}_7$, anethole yields *p*-methoxybenzoic acid. What is the structure of anethole? Assign all peaks in the NMR spectrum, and account for the observed splitting patterns.

PROBLEM 18-55 Propose structures for compounds that have the following ^1H NMR spectra:

(a) $C_5H_{12}S$ (An $-SH$ proton absorbs near 1.6δ)(b) $C_9H_{11}BrO$ (c) $C_5H_{12}O_2$ **General Problems****PROBLEM** Predict the products of the following reactions:

18-56 (a)

(b)

PROBLEM How would you synthesize anethole (Problem 18-54) from phenol?

18-57

PROBLEM How could you prepare benzyl phenyl ether from benzene and phenol? More than one step is

18-58 required.

PROBLEM *Meerwein's reagent*, triethyloxonium tetrafluoroborate, is a powerful ethylating agent that converts

18-59 alcohols into ethyl ethers at neutral pH. Show the reaction of Meerwein's reagent with cyclohexanol, and account for the fact that trialkyloxonium salts are much more reactive alkylating agents than alkyl iodides.

PROBLEM Safrole, a substance isolated from oil of sassafras, is used as a perfumery agent. Propose a synthesis

18-60 of safrole from catechol (1,2-benzenediol).

PROBLEM Grignard reagents react with oxetane, a four-membered cyclic ether, to yield primary alcohols, but

18-61 the reaction is much slower than the corresponding reaction with ethylene oxide. Suggest a reason for the difference in reactivity between oxetane and ethylene oxide.

Oxetane

PROBLEM The *Zeisel method* is an old analytical procedure for determining the number of methoxyl groups

18-62 in a compound. A weighed amount of the compound is heated with concentrated HI, ether cleavage occurs, and the iodomethane product is distilled off and passed into an alcohol solution of AgNO_3 , where it reacts to form a precipitate of silver iodide. The AgI is then collected and weighed, and the percentage of methoxyl groups in the sample is thereby determined. For example, 1.06 g of vanillin, the material responsible for the characteristic odor of vanilla, yields 1.60 g of AgI . If vanillin has a molecular weight of 152, how many methoxyl groups does it contain?

PROBLEM Disparlure, $\text{C}_{19}\text{H}_{38}\text{O}$, is a sex attractant released by the female spongy moth, *Lymantria dispar*.

18-63 The ^1H NMR spectrum of disparlure shows a large absorption in the alkane region, 1 to 2 δ , and a triplet at 2.8 δ . Treatment of disparlure, first with aqueous acid and then with KMnO_4 , yields two carboxylic acids identified as undecanoic acid and 6-methylheptanoic acid. (KMnO_4 cleaves 1,2-diols to yield carboxylic acids.) Neglecting stereochemistry, propose a structure for disparlure. The actual compound is a chiral molecule with 7*R*,8*S* stereochemistry. Draw disparlure, showing the correct stereochemistry.

PROBLEM How would you synthesize racemic disparlure (Problem 18-63) from compounds having ten or

18-64 fewer carbons?

PROBLEM How would you prepare *o*-hydroxyphenylacetaldehyde from phenol? More than one step is

18-65 required.

PROBLEM Identify the reagents **a–e** in the following scheme:

18-66

PROBLEM Propose structures for compounds that have the following ^1H NMR spectra:

18-67 (a) $\text{C}_4\text{H}_{10}\text{O}_2$

(b) $\text{C}_9\text{H}_{10}\text{O}$

PROBLEM We saw in **Section 17.4** that ketones react with NaBH_4 to yield alcohols. We'll also see in **Section 18-68 22.3** that ketones react with Br_2 to yield α -bromo ketones. Perhaps surprisingly, treatment with NaBH_4 of the α -bromo ketone from acetophenone yields an epoxide rather than a bromo alcohol. Show the structure of the epoxide, and explain its formation.

Preview of Carbonyl Chemistry

Carbonyl compounds are everywhere. Most biological molecules contain carbonyl groups, as do most pharmaceutical agents and many of the synthetic chemicals that affect our everyday lives. Citric acid, found in lemons and oranges; acetaminophen, the active ingredient in many over-the-counter headache remedies; and Dacron, the polyester material used in clothing, all contain different kinds of carbonyl groups.

To a great extent, the chemistry of living organisms is the chemistry of carbonyl compounds. Thus, we'll spend the next five chapters discussing the chemistry of the **carbonyl group**, $\text{C}=\text{O}$ (pronounced car-bo-**neel**). There are many different kinds of carbonyl compounds and many different reactions, but there are only a few fundamental principles that tie the entire field together. The purpose of this brief preview is not to show details of specific reactions but rather to provide a framework for learning carbonyl-group chemistry. Read through this preview now, and return to it on occasion to remind yourself of the larger picture.

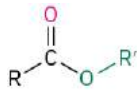

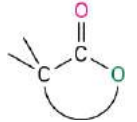

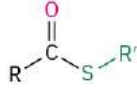

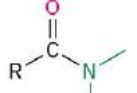

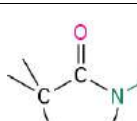

I Kinds of Carbonyl Compounds

TABLE 18.2 shows some of the many different kinds of carbonyl compounds. All contain an **acyl group** ($\text{R}-\text{C}=\text{O}$) bonded to another substituent. The R part of the acyl group can be practically any organic part/structure, and the other substituent to which the acyl group is bonded might be a carbon, hydrogen, oxygen, halogen, nitrogen, or sulfur.

TABLE 18.2 Some Types of Carbonyl Compounds

Name	General formula	Name ending
Aldehyde		-al
Ketone		-one
Carboxylic acid		-oic acid
Acid halide		-yl or -oyl halide
Acid anhydride		-oic anhydride
Acyl phosphate		-yl phosphate

TABLE 18.2 Some Types of Carbonyl Compounds

Name	General formula	Name ending
Ester		-oate
Lactone (cyclic ester)		None
Thioester		-thioate
Amide		-amide
Lactam (cyclic amide)		None

It's useful to classify carbonyl compounds into two categories based on the kinds of chemistry they undergo. In one category are aldehydes and ketones; in the other are carboxylic acids and their derivatives. The acyl group in an aldehyde or ketone is bonded to an atom (H or C, respectively) that can't stabilize a negative charge and therefore can't act as a leaving group in a nucleophilic substitution reaction. The acyl group in a carboxylic acid or its derivative, however, is bonded to an atom (oxygen, halogen, sulfur, nitrogen) that *can* stabilize a negative charge and therefore *can* act as a leaving group in a nucleophilic substitution reaction.

II Nature of the Carbonyl Group

The carbon–oxygen double bond of a carbonyl group is similar in many respects to the carbon–carbon double bond of an alkene. The carbonyl carbon atom is sp^2 -hybridized and forms three σ bonds. The fourth valence electron remains in a carbon p orbital and forms a π bond to oxygen by overlapping with an oxygen p orbital.

The oxygen atom also has two nonbonding pairs of electrons, which occupy its remaining two orbitals.

Like alkenes, carbonyl compounds are planar about the double bond and have bond angles of approximately 120° . **FIGURE 18.8** shows the structure of acetaldehyde and indicates its bond lengths and angles. As you might expect, the carbon–oxygen double bond is both shorter (122 pm versus 143 pm) and stronger [732 kJ/mol (175 kcal/mol) versus 385 kJ/mol (92 kcal/mol)] than a C–O single bond.

Bond angle	($^\circ$)	Bond length	(pm)
H–C–C	118	C=O	122
C–C=O	121	C–C	150
H–C=O	121	OC–H	109

FIGURE 18.8 Structure of acetaldehyde.

As indicated by the electrostatic potential map in **FIGURE 18.8**, the carbon–oxygen double bond is strongly polarized because of the high electronegativity of oxygen relative to carbon. Thus, the carbonyl carbon atom carries a partial positive charge, is an electrophilic (Lewis acidic) site, and reacts with nucleophiles. Conversely, the carbonyl oxygen atom carries a partial negative charge, is a nucleophilic (Lewis basic) site, and reacts with electrophiles. We'll see in the next five chapters that the majority of carbonyl-group reactions can be rationalized by simple polarity arguments.

III General Reactions of Carbonyl Compounds

Both in the laboratory and in living organisms, most reactions of carbonyl compounds take place by one of four general mechanisms: *nucleophilic addition*, *nucleophilic acyl substitution*, *alpha substitution*, and *carbonyl condensation*. These mechanisms have many variations, just as alkene electrophilic addition reactions and S_N2 reactions do, but the variations are much easier to learn when the fundamental features of the mechanisms are made clear. Let's see what the four mechanisms are and what kinds of chemistry carbonyl compounds undergo.

Nucleophilic Addition Reactions of Aldehydes and Ketones (Chapter 19)

The most common reaction of aldehydes and ketones is the **nucleophilic addition reaction**, in which a nucleophile, :Nu^- , adds to the electrophilic carbon of the carbonyl group. Because the nucleophile uses an electron pair to form a new bond to carbon, two electrons from the carbon–oxygen double bond must move toward the electronegative oxygen atom to give an alkoxide anion. The carbonyl carbon rehybridizes from sp^2 to sp^3 during the reaction, and the alkoxide ion product therefore has tetrahedral geometry.

Once formed, and depending on the nature of the nucleophile, the tetrahedral alkoxide intermediate can undergo one of two further reactions, as shown in **FIGURE 18.9**. Often, the tetrahedral alkoxide intermediate is simply protonated by water or acid to form an alcohol product. Alternatively, the tetrahedral intermediate

can be protonated and expel the oxygen to form a new double bond between the carbonyl carbon and the nucleophile. We'll study both processes in detail in Chapter 19.

FIGURE 18.9 The addition reaction of an aldehyde or a ketone with a nucleophile. Depending on the nucleophile, either an alcohol or a compound with a $\text{C}=\text{Nu}$ double bond is formed.

FORMATION OF AN ALCOHOL

The simplest reaction of a tetrahedral alkoxide intermediate is protonation to yield an alcohol. We've already seen two examples of this kind of process during reduction of aldehydes and ketones with hydride reagents such as NaBH_4 and LiAlH_4 (Section 17.4) and during Grignard reactions (Section 17.5). During a reduction, the nucleophile that adds to the carbonyl group is a hydride ion, H^- , while during a Grignard reaction, the nucleophile is a carbanion, R_3C^- .

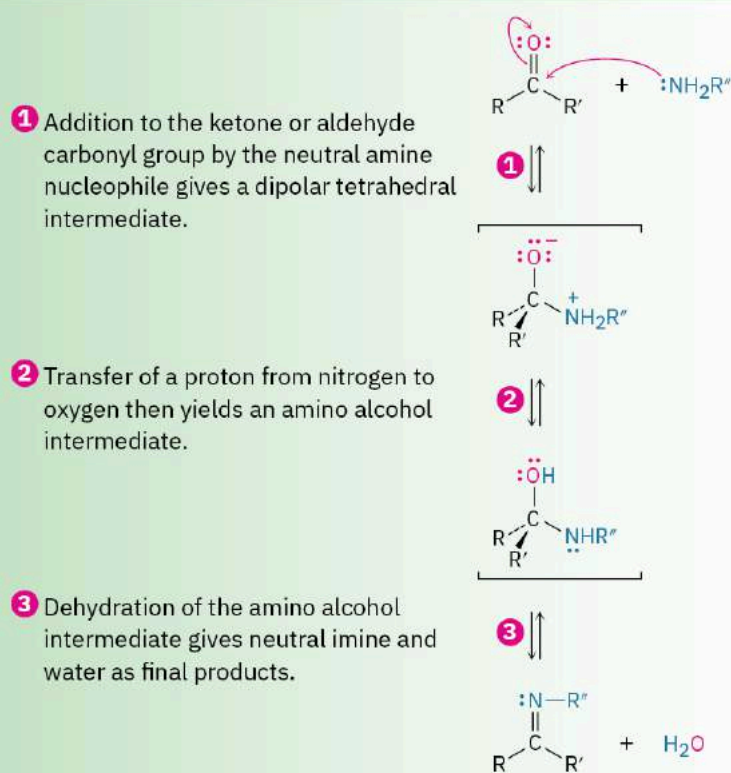

FORMATION OF $\text{C}=\text{Nu}$

The second mode of nucleophilic addition, which often occurs with amine nucleophiles, involves elimination of oxygen and formation of a $\text{C}=\text{Nu}$ double bond. For example, aldehydes and ketones react with primary amines, RNH_2 , to form *imines*, $\text{R}_2\text{C}=\text{NR}'$. These reactions use the same kind of tetrahedral intermediate as that formed during hydride reduction and Grignard reaction, but the initially formed alkoxide ion is not isolated. Instead, it is protonated and then loses water to form an imine, as shown in **FIGURE 18.10**.

FIGURE 18.10 MECHANISM

Formation of an imine, $R_2C=NR'$, by reaction of an amine with an aldehyde or a ketone.

Nucleophilic Acyl Substitution Reactions of Carboxylic Acid Derivatives (Chapter 21)

The second fundamental reaction of carbonyl compounds, **nucleophilic acyl substitution**, is related to the nucleophilic addition reaction just discussed but occurs only with carboxylic acid derivatives rather than with aldehydes and ketones. When the carbonyl group of a carboxylic acid derivative reacts with a nucleophile, addition occurs in the usual way, but the initially formed tetrahedral alkoxide intermediate is not isolated. Because carboxylic acid derivatives have a leaving group bonded to the carbonyl-group carbon, the tetrahedral intermediate can react further by expelling the leaving group and forming a new carbonyl compound:

The net effect of nucleophilic acyl substitution is the replacement of the leaving group by the entering nucleophile. We'll see in Chapter 21, for instance, that acid chlorides are rapidly converted into esters by treatment with alkoxide ions (FIGURE 18.11).

FIGURE 18.11 MECHANISM

Nucleophilic acyl substitution of an acid chloride with an alkoxide ion yields an ester.

1 Nucleophilic addition of alkoxide ion to an acid chloride yields a tetrahedral intermediate.

2 An electron pair from oxygen expels chloride ion and yields the substitution product, an ester.

Alpha-Substitution Reactions (Chapter 22)

The third major reaction of carbonyl compounds, **alpha substitution**, occurs at the position next to the carbonyl group—the alpha (α) position. This reaction results in the substitution of an α hydrogen by an electrophile through the formation of an intermediate *enol* or *enolate ion*:

For reasons that we'll explore in Chapter 22, the presence of a carbonyl group renders the hydrogens on the α carbon acidic. Carbonyl compounds therefore react with strong base to yield enolate ions.

Because they're negatively charged, enolate ions act as nucleophiles and undergo many of the reactions we've already studied. For example, enolates react with primary alkyl halides in the $\text{S}_{\text{N}}2$ reaction. The nucleophilic enolate ion displaces halide ion, and a new $\text{C}-\text{C}$ bond forms:

The S_N2 alkylation reaction between an enolate ion and an alkyl halide is a powerful method for making C–C bonds, thereby building up larger molecules from smaller precursors. We'll study the alkylation of many kinds of carbonyl compounds in Chapter 22.

Carbonyl Condensation Reactions (Chapter 23)

The fourth and last fundamental reaction of carbonyl groups, **carbonyl condensation**, takes place when two carbonyl compounds react with each other. When acetaldehyde is treated with base, for instance, two molecules combine to yield the hydroxy aldehyde product known as *aldol* (*aldehyde + alcohol*):

Although carbonyl condensation appears to be different from the three processes already discussed, it's actually quite similar. A carbonyl condensation reaction is simply a combination of a nucleophilic addition step and an α -substitution step. The initially formed enolate ion of one acetaldehyde molecule acts as a nucleophile and adds to the carbonyl group of another acetaldehyde molecule, as shown in **FIGURE 18.12**.

FIGURE 18.12 MECHANISM

A carbonyl condensation reaction between two molecules of acetaldehyde yields a hydroxy aldehyde product.

- 1 Base abstracts an acidic alpha hydrogen from one acetaldehyde molecule, yielding a resonance-stabilized enolate ion.
- 2 The enolate ion adds as a nucleophile to the carbonyl group of a second acetaldehyde, producing a tetrahedral alkoxide ion.
- 3 The tetrahedral intermediate is protonated by solvent to yield the neutral aldol product and regenerate the base catalyst.

IV Summary

To a great extent, the chemistry of living organisms is the chemistry of carbonyl compounds. We have not looked at the details of specific carbonyl reactions in this short preview but rather have laid the groundwork for the next five chapters. All the carbonyl-group reactions we'll be studying in Chapters 19 through 23 fall into one of the four fundamental categories discussed in this preview. Knowing where we'll be heading should help you keep matters straight in understanding this most important of all functional groups.

PROBLEM 18-69 Judging from the following electrostatic potential maps, which kind of carbonyl compound has the more electrophilic carbonyl carbon atom, a ketone or an acid chloride? Which has the more nucleophilic carbonyl oxygen atom? Explain.

Acetone
(ketone)

Acetyl chloride
(acid chloride)

PROBLEM 18-70 Predict the product formed by nucleophilic addition of cyanide ion (CN^-) to the carbonyl group of acetone, followed by protonation to give an alcohol:

Acetone

PROBLEM 18-71 Identify each of the following reactions as a nucleophilic addition, nucleophilic acyl substitution, an α substitution, or a carbonyl condensation:

CHAPTER 19

Aldehydes and Ketones: Nucleophilic Addition Reactions

FIGURE 19.1 Few flowers are more beautiful or more fragrant than roses. Their perfumed odor is due to several simple organic compounds, including the ketone β -damascenone. (credit: modification of work “Rosa ‘Precious Platinum’” by Bernard Spragg/Wikimedia Commons, CC BY 1.0)

19.14 Spectroscopy of Aldehydes and Ketones

WHY THIS CHAPTER? Much of organic chemistry is the chemistry of carbonyl compounds. Aldehydes and ketones, in particular, are intermediates in the synthesis of many pharmaceutical agents, in almost all biological

pathways, and in numerous industrial processes, so an understanding of their properties and reactions is essential. In this chapter, we'll look at some of their most important reactions.

Aldehydes (RCHO) and **ketones (R₂CO)** are among the most widely occurring of all compounds. In nature, many substances required by living organisms are aldehydes or ketones. The aldehyde pyridoxal phosphate, for instance, is a coenzyme involved in a large number of metabolic reactions; the ketone hydrocortisone is a steroid hormone secreted by the adrenal glands to regulate fat, protein, and carbohydrate metabolism.

**Pyridoxal
phosphate (PLP)**

Hydrocortisone

In the chemical industry, simple aldehydes and ketones are produced in large quantities for use as solvents and as starting materials to prepare a host of other compounds. For example, more than 50 million tons per year of formaldehyde, $\text{H}_2\text{C}=\text{O}$, is produced worldwide for use in building insulation materials and in the adhesive resins that bind particle board and plywood. Acetone, $(\text{CH}_3)_2\text{C}=\text{O}$, is widely used as an industrial solvent, with approximately 8 million tons per year produced worldwide. Formaldehyde is synthesized industrially by catalytic oxidation of methanol, and one method of acetone preparation involves oxidation of 2-propanol produced by hydration of propylene.

Acetone

19.1 Naming Aldehydes and Ketones

Aldehydes are named by replacing the terminal *-e* of the corresponding alkane name with *-al*. The parent chain must contain the $-\text{CHO}$ group, and the $-\text{CHO}$ carbon is numbered as carbon 1. Note in the following examples that the longest chain in 2-ethyl-4-methylpentanal is actually a hexane, but this chain does not include the $-\text{CHO}$ group and thus is not the parent.

Ethanal
(acetaldehyde)

Propanal
(propionaldehyde)

2-Ethyl-4-methylpentanal

For cyclic aldehydes in which the $-\text{CHO}$ group is directly attached to a ring, the ring name followed by *carbaldehyde* is used.

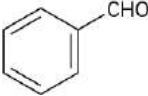

Cyclohexanecarbaldehyde

2-Naphthalenecarbaldehyde

A few simple and well-known aldehydes have common names that are recognized by IUPAC. Several that you might encounter are listed in [TABLE 19.1](#).

TABLE 19.1 Common Names of Some Simple Aldehydes

Formula	Common name	Systematic name
HCHO	Formaldehyde	Methanal
CH ₃ CHO	Acetaldehyde	Ethanal
H ₂ C=CHCHO	Acrolein	Propenal
CH ₃ CH=CHCHO	Crotonaldehyde	2-Butenal
	Benzaldehyde	Benzenecarbaldehyde

Ketones are named by replacing the terminal *-e* of the corresponding alkane name with *-one*. The parent chain is the longest one that includes the ketone group, and the numbering begins at the end nearer the carbonyl carbon. As with alkenes ([Section 7.3](#)) and alcohols ([Section 17.1](#)), the locant is placed before the parent name using older rules but before the suffix with the newer IUPAC guidelines. For example:

3-Hexanone
(New: **Hexan-3-one**)

4-Hexen-2-one
(New: **Hex-4-en-2-one**)

2,4-Hexanedione
(New: **Hexane-2,4-dione**)

A few ketones are allowed by IUPAC to retain their common names.

Acetone

Acetophenone

Benzophenone

When it's necessary to refer to the R-C=O group as a substituent, the name **acyl (a-sil) group** is used and the name ending *-yl* is attached. Thus, -COCH₃ is an *acetyl* group, -CHO is a *formyl* group, -COAr is an *aroyl* group, and -COC₆H₅ is a *benzoyl* group.

An acyl group

Acetyl

Formyl

Benzoyl

If other functional groups are present and the double-bonded oxygen is considered a substituent on a parent chain, the prefix *oxo-* is used. For example:

PROBLEM Name the following aldehydes and ketones:

(e)

(f)

PROBLEM Draw structures corresponding to the following names:

- 19-2 (a) 3-Methylbutanal (b) 4-Chloro-2-pentanone (c) Phenylacetaldehyde
 (d) *cis*-3-*tert*-Butylcyclohexanecarbaldehyde (e) 3-Methyl-3-butenal
 (f) 2-(1-Chloroethyl)-5-methylheptanal

19.2 Preparing Aldehydes and Ketones

Preparing Aldehydes

Perhaps the best method of aldehyde synthesis is by oxidation of a primary alcohol, as we saw in [Section 17.7](#). The reaction is usually carried out using the Dess–Martin periodinane reagent in dichloromethane solvent at room temperature:

Another method of aldehyde synthesis is one that we'll mention here just briefly and then return to in [Section 21.6](#). Certain carboxylic acid derivatives can be *partially* reduced to yield aldehydes. The partial reduction of an ester by diisobutylaluminum hydride (DIBAH, or DIBAL-H), for instance, is an important laboratory-scale method of aldehyde synthesis, and mechanistically related processes also occur in biological pathways. The reaction is normally carried out at -78°C (dry-ice temperature) in toluene solution.

PROBLEM How would you prepare pentanal from the following starting materials?

- 19-3 (a) $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{OH}$ (b) $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}=\text{CH}_2$ (c) $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{CH}_3$
 (d) $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}=\text{CH}_2$

Preparing Ketones

For the most part, methods of ketone synthesis are similar to those for aldehydes. Secondary alcohols are

oxidized by a variety of reagents to give ketones (Section 17.7). The choice of oxidant depends on such factors as reaction scale, cost, and acid or base sensitivity of the alcohol. The Dess–Martin periodinane is a common choice although chromic acid (H_2CrO_4) was frequently used in older work.

Other methods include the ozonolysis of alkenes in which one of the unsaturated carbon atoms is disubstituted (Section 8.8) and Friedel–Crafts acylation of an aromatic ring with an acid chloride in the presence of AlCl_3 catalyst (Section 16.3).

In addition to those methods already discussed, ketones can also be prepared from certain carboxylic acid derivatives, just as aldehydes can. Among the most useful reactions of this sort is that between an acid chloride and a lithium diorganocopper reagent, as we saw in Section 10.7. We'll discuss this reaction in more detail in Section 21.4.

PROBLEM How would you carry out the following reactions? More than one step may be needed.

- 19-4** (a) 3-Hexyne \rightarrow 3-Hexanone (b) Benzene \rightarrow m-Bromoacetophenone
(c) Bromobenzene \rightarrow Acetophenone (d) 1-Methylcyclohexene \rightarrow 2-Methylcyclohexanone

19.3 Oxidation of Aldehydes and Ketones

Aldehydes are easily oxidized to yield carboxylic acids, but ketones are generally inert toward oxidation. The difference is a consequence of structure: aldehydes have a $-\text{CHO}$ proton that can be abstracted during oxidation, but ketones do not.

Many oxidizing agents, including alkaline KMnO_4 and hot HNO_3 , convert aldehydes into carboxylic acids. The oxidation occurs rapidly at room temperature and generally works well.

Aldehyde oxidations occur through intermediate 1,1-diols, or *hydrates*, which are formed by a reversible nucleophilic addition of water to the carbonyl group. Even though it's formed to only a small extent at equilibrium, the hydrate reacts like any typical primary or secondary alcohol and is oxidized to a carbonyl compound (Section 17.7).

Ketones are inert to most oxidizing agents but undergo a slow cleavage reaction of the C–C bond next to the carbonyl group when treated with hot alkaline KMnO_4 . The reaction is not often used, however, and is mentioned here only for completeness.

19.4 Nucleophilic Addition Reactions of Aldehydes and Ketones

As we saw in the *Preview of Carbonyl Chemistry*, the most general reaction of aldehydes and ketones is the **nucleophilic addition reaction**. As shown in **FIGURE 19.2**, a nucleophile, $:\text{Nu}^-$, approaches the carbonyl group from an angle of about 105° opposite the carbonyl oxygen and forms a bond to the electrophilic C–O carbon atom. At the same time, rehybridization of the carbonyl carbon from sp^2 to sp^3 occurs, an electron pair from the C=O bond moves toward the electronegative oxygen atom, and a tetrahedral alkoxide ion intermediate is produced. Protonation of the alkoxide by addition of acid then gives an alcohol.

FIGURE 19.2 MECHANISM

A nucleophilic addition reaction to an aldehyde or ketone. The nucleophile approaches the carbonyl group from an angle of approximately 75° to the plane of the sp^2 orbitals, the carbonyl carbon rehybridizes from sp^2 to sp^3 , and an alkoxide ion is formed. Protonation by addition of acid then gives an alcohol.

1 An electron pair from the nucleophile adds to the electrophilic carbon of the carbonyl group, pushing an electron pair from the C=O bond onto oxygen and giving an alkoxide ion intermediate. The carbonyl carbon rehybridizes from sp^2 to sp^3 .

2 Protonation of the alkoxide anion intermediate gives the neutral alcohol addition product.

The nucleophile can be either negatively charged ($:\text{Nu}^-$) or neutral ($:\text{Nu}$). If it's neutral, however, it usually carries a hydrogen atom that can subsequently be eliminated, $:\text{Nu}-\text{H}$. For example:

Some negatively charged nucleophiles

Some neutral nucleophiles

Nucleophilic additions to aldehydes and ketones have two general variations, as shown in **FIGURE 19.3**. In one variation, the tetrahedral intermediate is protonated by water or acid to give an alcohol as the final product. In the second variation, the carbonyl oxygen atom is protonated and then eliminated as HO^- or H_2O to give a product with a $\text{C}=\text{Nu}$ double bond.

FIGURE 19.3 Two general reaction pathways following addition of a nucleophile to an aldehyde or ketone. The top pathway leads to an alcohol product; the bottom pathway leads to a product with a C=Nu double bond.

Aldehydes are generally more reactive than ketones in nucleophilic addition reactions for both steric and electronic reasons. Sterically, the presence of only one large substituent bonded to the C=O carbon in an aldehyde versus two large substituents in a ketone means that a nucleophile is able to approach an aldehyde more readily. Thus, the transition state leading to the tetrahedral intermediate is less crowded and lower in energy for an aldehyde than for a ketone (**FIGURE 19.4**).

FIGURE 19.4 Steric hindrance in nucleophilic addition reactions. **(a)** Nucleophilic addition to an aldehyde is sterically less hindered because only one relatively large substituent is attached to the carbonyl-group carbon. **(b)** A ketone, however, has two large substituents and is more hindered. The approach of the nucleophile is along the C=O bond at an angle of about 75° to the plane of the carbon sp^2 orbitals.

Electronically, aldehydes are more reactive than ketones because of the greater polarization of aldehyde carbonyl groups. To see this polarity difference, recall the stability order of carbocations (**Section 7.9**). A primary carbocation is higher in energy and thus more reactive than a secondary carbocation since it has only one alkyl group inductively stabilizing the positive charge rather than two. In the same way, an aldehyde has only one alkyl group inductively stabilizing the partial positive charge on the carbonyl carbon rather than two, and is a bit more electrophilic, and, therefore, more reactive than a ketone.

One further comparison: aromatic aldehydes, such as benzaldehyde, are less reactive in nucleophilic addition reactions than aliphatic aldehydes because the electron-donating resonance effect of the aromatic ring makes the carbonyl group less electrophilic. Comparing electrostatic potential maps of formaldehyde and benzaldehyde, for example, shows that the carbonyl carbon atom is less positive (less blue) in the aromatic

aldehyde.

Formaldehyde

Benzaldehyde

PROBLEM 19-5 Treatment of an aldehyde or ketone with cyanide ion ($\text{:C}\equiv\text{N}$), followed by protonation of the tetrahedral alkoxide ion intermediate, gives a *cyanohydrin*. Show the structure of the cyanohydrin obtained from cyclohexanone.

PROBLEM 19-6 *p*-Nitrobenzaldehyde is more reactive toward nucleophilic additions than *p*-methoxybenzaldehyde. Explain.

19.5 Nucleophilic Addition of H₂O: Hydration

Aldehydes and ketones react with water to yield 1,1-diols, or *geminal* (*gem*) diols. The hydration reaction is reversible, and a gem diol can eliminate water to regenerate an aldehyde or ketone.

Acetone (99.9%)

Acetone hydrate (0.1%)

The position of the equilibrium between a gem diol and an aldehyde or ketone depends on the structure of the carbonyl compound. Equilibrium generally favors the carbonyl compound for steric reasons, but the gem diol is favored for a few simple aldehydes. For example, an aqueous solution of formaldehyde consists of 99.9% gem diol and 0.1% aldehyde at equilibrium, whereas an aqueous solution of acetone consists of only about 0.1% gem diol and 99.9% ketone.

Formaldehyde (0.1%)

Formaldehyde hydrate (99.9%)

The hydrate is also favored for α -keto carboxylic acids, which have adjacent positively charged carbons that destabilize the keto form and favor the hydrate. Such compounds occur commonly in many biological pathways. Pyruvic acid, which is 60% hydrate at equilibrium, and α -ketoglutaric acid, which is 50% hydrate, are examples.

FIGURE 19.5 MECHANISM

The mechanism for a nucleophilic addition reaction of aldehydes and ketones under both basic and acidic conditions. (a) Under basic conditions, a negatively charged nucleophile adds to the carbonyl group to give an alkoxide ion intermediate, which is subsequently protonated. **(b)** Under acidic conditions, protonation of the carbonyl group occurs first, followed by addition of a neutral nucleophile and subsequent deprotonation.

The hydration reaction just described is typical of what happens when an aldehyde or ketone is treated with a nucleophile of the type $\text{H}-\text{Y}$, where the Y atom is electronegative and can stabilize a negative charge (oxygen, halogen, or sulfur, for instance). In such reactions, the nucleophilic addition is reversible, with the equilibrium generally favoring the carbonyl reactant rather than the tetrahedral addition product. In other words, treatment of an aldehyde or ketone with CH_3OH , H_2O , HCl , HBr , or H_2SO_4 does not normally lead to a stable alcohol addition product.

PROBLEM When dissolved in water, trichloroacetaldehyde exists primarily as its hydrate, called chloral 19-7 hydrate. Show the structure of chloral hydrate.

PROBLEM The oxygen in water is primarily (99.8%) ^{16}O , but water enriched with the heavy isotope ^{18}O is also available. When an aldehyde or ketone is dissolved in ^{18}O -enriched water, the isotopic label becomes incorporated into the carbonyl group. Explain.

19-8

19.6 Nucleophilic Addition of HCN: Cyanohydrin Formation

Aldehydes and unhindered ketones undergo a nucleophilic addition reaction with HCN to yield **cyanohydrins**, $\text{RCH}(\text{OH})\text{C}\equiv\text{N}$. Studies carried out in the early 1900s by Arthur Lapworth showed that cyanohydrin formation is reversible and base-catalyzed. Reaction occurs slowly when pure HCN is used but rapidly when a small amount of base is added to generate the nucleophilic cyanide ion, CN^- . Addition of CN^- takes place by a typical nucleophilic addition pathway, yielding a tetrahedral intermediate that is protonated by HCN to give cyanohydrin product plus regenerated CN^- .

Cyanohydrin formation is somewhat unusual because it is one of the few examples of the addition of a protic acid ($\text{H}-\text{Y}$) to a carbonyl group. As noted in the previous section, protic acids such as H_2O , HBr , HCl , and H_2SO_4 don't normally yield carbonyl addition products because the equilibrium constants are unfavorable. With HCN, however, equilibrium favors the cyanohydrin adduct.

Cyanohydrin formation is useful because of the further chemistry that can be carried out on the product. For example, a nitrile ($\text{R}-\text{C}\equiv\text{N}$) can be reduced with LiAlH_4 to yield a primary amine (RCH_2NH_2) and can be hydrolyzed by hot aqueous acid to yield a carboxylic acid. Thus, cyanohydrin formation provides a method for transforming an aldehyde or ketone into a different functional group.

PROBLEM Cyclohexanone forms a cyanohydrin in good yield but 2,2,6-trimethylcyclohexanone does not. Explain.

19-9

19.7 Nucleophilic Addition of Hydride and Grignard Reagents: Alcohol Formation

Addition of Hydride Reagents: Reduction

We saw in [Section 17.4](#) that the most common method for preparing alcohols, both in the laboratory and in living organisms, is by the reduction of carbonyl compounds. Aldehydes are reduced with sodium borohydride (NaBH_4) to give primary alcohols, and ketones are reduced similarly to give secondary alcohols.

Carbonyl reduction occurs by a typical nucleophilic addition mechanism under basic conditions, as shown earlier in **FIGURE 19.5a**. Although the details of carbonyl-group reductions are complex, LiAlH_4 and NaBH_4 act as if they were donors of hydride ion nucleophile, H^- , and the initially formed alkoxide ion intermediate is then protonated by addition of aqueous acid. The reaction is effectively irreversible because the reverse process would require expulsion of a very poor leaving group.

FIGURE 19.6 MECHANISM

Mechanism of the Grignard reaction. Complexation of the carbonyl oxygen with the Lewis acid Mg^{2+} and subsequent nucleophilic addition of a carbanion to an aldehyde or ketone is followed by protonation of the alkoxide intermediate to yield an alcohol.

1 The Lewis acid Mg^{2+} first forms an acid–base complex with the basic oxygen atom of the aldehyde or ketone, thereby making the carbonyl group a better acceptor.

2 Nucleophilic addition of an alkyl group R^- to the aldehyde or ketone produces a tetrahedral magnesium alkoxide intermediate . . .

3 . . . which undergoes hydrolysis when water is added in a separate step. The final product is a neutral alcohol.

Addition of Grignard Reagents, RMgX

Just as aldehydes and ketones undergo nucleophilic addition with hydride ion to give alcohols, they undergo a similar addition with Grignard reagent nucleophiles, $\text{R}^- + \text{MgX}$. Aldehydes give secondary alcohols on reaction with Grignard reagents in ether solution, and ketones give tertiary alcohols.

As shown in **FIGURE 19.6**, a Grignard reaction begins with an acid–base complexation of Mg^{2+} to the carbonyl oxygen atom of the aldehyde or ketone, thereby making the carbonyl group a better electrophile. Nucleophilic addition of R^- then produces a tetrahedral magnesium alkoxide intermediate, and protonation by addition of water or dilute aqueous acid in a separate step yields the neutral alcohol. Like reduction, Grignard additions are effectively irreversible because a carbanion is too poor a leaving group to be expelled in a reversal step.

19.8 Nucleophilic Addition of Amines: Imine and Enamine Formation

Primary amines, RNH_2 , add to aldehydes and ketones to yield **imines**, $\text{R}_2\text{C}=\text{NR}$. Secondary amines, R_2NH , add similarly to yield **enamines**, $\text{R}_2\text{N}-\text{CR}=\text{CR}_2$ (*ene* + *amine* = unsaturated amine).

Imines are particularly common as intermediates in biological pathways, where they are often called **Schiff bases**. The amino acid alanine, for instance, is metabolized in the body by reaction with the aldehyde pyridoxal phosphate (PLP), a derivative of vitamin B_6 , to yield a Schiff base that is further degraded.

Imine formation and enamine formation seem different because one leads to a product with a $\text{C}=\text{N}$ bond and the other leads to a product with a $\text{C}=\text{C}$ bond. Actually, though, the reactions are quite similar. Both are typical examples of nucleophilic addition reactions in which water is eliminated from the initially formed tetrahedral intermediate and a new $\text{C}=\text{Nu}$ double bond is formed.

Imines are formed in a reversible, acid-catalyzed process (**FIGURE 19.7**) that begins with nucleophilic addition of the primary amine to the carbonyl group, followed by transfer of a proton from nitrogen to oxygen to yield a neutral amino alcohol, or **carbinolamine**. Protonation of the carbinolamine oxygen by an acid catalyst then converts the $-\text{OH}$ into a better leaving group ($-\text{OH}_2^+$), and E1 -like loss of water produces an iminium ion. Loss of a proton from nitrogen gives the final product and regenerates the acid catalyst.

FIGURE 19.7 MECHANISM

Mechanism of imine formation by reaction of an aldehyde or ketone with a primary amine. The key step is the initial nucleophilic addition to yield a carbinolamine intermediate, which then loses water to give the imine.

Imine formation with such reagents as hydroxylamine and 2,4-dinitrophenylhydrazine is sometimes useful because the products of these reactions—*oximes* and *2,4-dinitrophenylhydrazones (2,4-DNPs)*, respectively—are often crystalline and easy to handle. Such crystalline derivatives are occasionally prepared as a means of purifying and characterizing liquid ketones or aldehydes.

Oxime**2,4-Dinitrophenyl-hydrazone**

Reaction of an aldehyde or ketone with a secondary amine, R₂NH, rather than a primary amine yields an enamine. As shown in **FIGURE 19.8**, the process is identical to imine formation up to the iminium ion stage, but at this point there is no proton on nitrogen that can be lost to form a neutral imine product. Instead, a proton is lost from the *neighboring* carbon (the α carbon), yielding an enamine.

FIGURE 19.8 MECHANISM

Mechanism for enamine formation by reaction of an aldehyde or ketone with a secondary amine, R_2NH . The iminium ion intermediate formed in step 3 has no hydrogen attached to N and so must lose H^+ from the carbon two atoms away.

1 Nucleophilic addition of a secondary amine to the ketone or aldehyde, followed by proton transfer from nitrogen to oxygen, yields an intermediate carbinolamine in the normal way.

2 Protonation of the hydroxyl by acid catalyst converts it into a better leaving group.

3 Elimination of water by the lone-pair electrons on nitrogen then yields an intermediate iminium ion.

4 Loss of a proton from the alpha carbon atom yields the enamine product and regenerates the acid catalyst.

Imine and enamine formation are slow at both high pH and low pH but reach a maximum rate at a weakly acidic pH around 4 to 5. For example, the profile of pH versus rate shown in **FIGURE 19.9** for the reaction between acetone and hydroxylamine, NH_2OH , indicates that the maximum reaction rate occurs at pH 4.5.

We can explain the observed pH dependence of imine formation by looking at the individual steps in the mechanism. As indicated in **FIGURE 19.8**, an acid catalyst is required in step 3 to protonate the intermediate carbinolamine, thereby converting the $-OH$ into a better leaving group. Thus, reaction will be slow if not enough acid is present (that is, at high pH). On the other hand, if too much acid is present (low pH), the basic amine nucleophile is completely protonated, so the initial nucleophilic addition step can't occur.

FIGURE 19.9 Dependence on pH of the rate of reaction between acetone and hydroxylamine: $(\text{CH}_3)_2\text{C}=\text{O} + \text{NH}_2\text{OH} \rightarrow (\text{CH}_3)_2\text{C}=\text{NOH} + \text{H}_2\text{O}$.

Evidently, a pH of 4.5 represents a compromise between the need for *some* acid to catalyze the rate-limiting dehydration step but *not too much* acid so as to avoid complete protonation of the amine. Each nucleophilic addition reaction has its own requirements, and conditions must be optimized to obtain maximum reaction rates.

WORKED EXAMPLE 19.1

Predicting the Product of Reaction between a Ketone and an Amine

Show the products you would obtain by acid-catalyzed reaction of 3-pentanone with methylamine, CH_3NH_2 , and with dimethylamine, $(\text{CH}_3)_2\text{NH}$.

Strategy

An aldehyde or ketone reacts with a primary amine, RNH_2 , to yield an imine, in which the carbonyl oxygen atom has been replaced by the $=\text{N}-\text{R}$ group of the amine. Reaction of the same aldehyde or ketone with a secondary amine, R_2NH , yields an enamine, in which the oxygen atom has been replaced by the $-\text{NR}_2$ group of the amine and the double bond has moved to a position between the former carbonyl carbon and the neighboring carbon.

Solution

PROBLEM 19-10 Show the products you would obtain by acid-catalyzed reaction of cyclohexanone with ethylamine, $\text{CH}_3\text{CH}_2\text{NH}_2$, and with diethylamine, $(\text{CH}_3\text{CH}_2)_2\text{NH}$.

PROBLEM 19-11 Imine formation is reversible. Show all the steps involved in the acid-catalyzed reaction of an imine with water (hydrolysis) to yield an aldehyde or ketone plus primary amine.

PROBLEM 19-12 Draw the following molecule as a skeletal structure, and show how it can be prepared from a ketone

FIGURE 19.10 MECHANISM**Mechanism for the Wolff–Kishner reduction of an aldehyde or ketone to yield an alkane.**

1 Reaction of the aldehyde or ketone with hydrazine yields a hydrazone in the normal way.

2 Base abstracts a weakly acidic N–H proton, yielding a hydrazone anion. This anion has a resonance form that places the negative charge on carbon and the double bond between nitrogens.

3 Protonation of the hydrazone anion takes place on carbon to yield a neutral intermediate.

4 Deprotonation of the remaining weakly acidic N–H occurs with simultaneous loss of nitrogen to give a carbanion . . .

5 . . . which is protonated to give the alkane product.

Note that the Wolff–Kishner reduction accomplishes the same overall transformation as the catalytic hydrogenation of an acylbenzene to yield an alkylbenzene (Section 16.10). The Wolff–Kishner reduction is more general and more useful than catalytic hydrogenation, however, because it works well with both alkyl and aryl ketones.

PROBLEM Show how you could prepare the following compounds from 4-methyl-3-penten-2-one, (CH₃)₂C=CHCOCH₃.

19-13

(b)

(c)

19.10 Nucleophilic Addition of Alcohols: Acetal Formation

Aldehydes and ketones react reversibly with 2 equivalents of an alcohol in the presence of an acid catalyst to yield **acetals**, $R_2C(OR')_2$, which are often called **ketals** if derived from a ketone. Cyclohexanone, for instance, reacts with methanol in the presence of HCl to give the corresponding dimethyl acetal.

Acetal formation is similar to the hydration reaction discussed in [Section 19.5](#). Like water, alcohols are weak nucleophiles that add to aldehydes and ketones slowly under neutral conditions. Under acidic conditions, however, the reactivity of the carbonyl group is increased by protonation, so addition of an alcohol occurs rapidly.

As shown in [FIGURE 19.11](#), nucleophilic addition of an alcohol to the carbonyl group initially yields a hydroxy ether called a **hemiacetal**, analogous to the gem diol formed by addition of water. Hemiacetals are formed reversibly, with equilibrium normally favoring the carbonyl compound. In the presence of acid, however, a further reaction occurs. Protonation of the $-OH$ group, followed by an $E1$ -like loss of water, leads to an oxonium ion, $R_2C=O^+R$, which undergoes a second nucleophilic addition of alcohol to yield the protonated acetal. Loss of a proton completes the reaction.

FIGURE 19.11 MECHANISM**Mechanism of acid-catalyzed acetal formation by reaction of an aldehyde or ketone with an alcohol.**

1 Protonation of the carbonyl oxygen strongly polarizes the carbonyl group and . . .

2 . . . activates the carbonyl group for nucleophilic attack by oxygen lone-pair electrons from the alcohol.

3 Loss of a proton yields a neutral hemiacetal tetrahedral intermediate.

4 Protonation of the hemiacetal hydroxyl converts it into a good leaving group.

5 Dehydration yields an intermediate oxonium ion.

6 Addition of a second equivalent of alcohol gives a protonated acetal.

7 Loss of a proton yields the neutral acetal product.

Because all the steps in acetal formation are reversible, the reaction can be driven either forward (from carbonyl

1,3-propanediol.

Strategy

Acid-catalyzed reaction of an aldehyde or ketone with 2 equivalents of a monoalcohol or 1 equivalent of a diol yields an acetal, in which the carbonyl oxygen atom is replaced by two –OR groups from the alcohol.

Solution

PROBLEM 19-14 Show all the steps in the acid-catalyzed formation of a cyclic acetal from ethylene glycol and an aldehyde or ketone.

PROBLEM 19-15 Identify the carbonyl compound and the alcohol that were used to prepare the following acetal:

19.11 Nucleophilic Addition of Phosphorus Ylides: The Wittig Reaction

Aldehydes and ketones are converted into alkenes by means of a nucleophilic addition called the **Wittig reaction**, after the German chemist Georg Wittig who won the 1979 Nobel Prize in Chemistry. The reaction has no direct biological counterpart but is important both because of its wide use in drug manufacture and because of its mechanistic similarity to reactions of the coenzyme thiamin diphosphate, which we'll see in **Section 29.6**.

In the Wittig reaction, a triphenylphosphorus *ylide*, $\text{R}_2\text{C}^--\text{P}^+\text{Ph}_3$ also called a **phosphorane** and sometimes written in the resonance form $\text{R}_2\text{C}=\text{P}(\text{Ph})_3$, adds to an aldehyde or ketone to yield a four-membered cyclic intermediate called an *oxaphosphetane*. The oxaphosphetane is not isolated, but instead spontaneously decomposes to give an alkene plus triphenylphosphine oxide, $\text{O}=\text{PPh}_3$. In effect, the oxygen atom of the aldehyde or ketone and the $\text{R}_2\text{C}=\text{C}$ bonded to phosphorus exchange places. (An **ylide**—pronounced **ill-id**—is a neutral, dipolar compound with adjacent positive and negative charges.)

The initial addition takes place by different pathways depending on the structure of the reactants and the exact experimental conditions. One pathway involves a one-step cycloaddition process analogous to the Diels–Alder cycloaddition reaction (**Section 14.4**). The other pathway involves a nucleophilic addition reaction to give a dipolar intermediate called a *betaine* (**bay-ta-ee-n**), which undergoes ring closure.

The phosphorus ylides necessary for Wittig reaction are easily prepared by S_N2 reaction of primary (and some secondary) alkyl halides with triphenylphosphine, (Ph)₃P, followed by treatment with base. Triphenylphosphine is a good nucleophile in S_N2 reactions, and yields of the resultant alkyltriphenylphosphonium salts are high. Because of the positive charge on phosphorus, the hydrogen on the neighboring carbon is weakly acidic and can be removed by a strong base such as butyllithium (BuLi) to generate the neutral ylide. For example:

The Wittig reaction is extremely general, and a great many monosubstituted, disubstituted, and trisubstituted alkenes can be prepared from the appropriate combination of phosphorane and aldehyde or ketone. Tetrasubstituted alkenes, however, can't be prepared this way because of steric hindrance.

The real value of the Wittig reaction is that it yields a pure alkene of predictable structure. The C=C bond in the product is always exactly where the C=O group was in the reactant, and no alkene isomers (except *E,Z* isomers) are formed. For example, Wittig reaction of cyclohexanone with methylenetriphenylphosphorane yields only the single alkene product methylenecyclohexane. By contrast, addition of methylmagnesium bromide to cyclohexanone, followed by dehydration with POCl₃, yields a roughly 9 : 1 mixture of two alkenes.

Wittig reactions are used commercially in the synthesis of numerous pharmaceutical products. For example, the German chemical company BASF prepares vitamin A by using a Wittig reaction between a 15-carbon ylide and a 5-carbon aldehyde.

WORKED EXAMPLE 19.3

Synthesizing an Alkene Using a Wittig Reaction

What carbonyl compound and what phosphorus ylide might you use to prepare 3-ethyl-2-pentene?

Strategy

An aldehyde or ketone reacts with a phosphorus ylide to yield an alkene in which the oxygen atom of the carbonyl reactant is replaced by the $=CR_2$ of the ylide. Preparation of the phosphorus ylide itself usually involves S_N2 reaction of a primary alkyl halide with triphenylphosphine, so the ylide is typically primary, $RCH=P(Ph)_3$. This means that the disubstituted alkene carbon in the product comes from the carbonyl reactant, while the monosubstituted alkene carbon comes from the ylide.

Solution

PROBLEM 19-16 What carbonyl compound and what phosphorus ylide might you use to prepare each of the following compounds?

PROBLEM 19-17 β -Carotene, a yellow food-coloring agent and dietary source of vitamin A can be prepared by a *double* Wittig reaction between 2 equivalents of β -ionylideneacetaldehyde and a *diylide*. Show the structure of the β -carotene product.

19.12 Biological Reductions

As a general rule, nucleophilic addition reactions are characteristic only of aldehydes and ketones, not of carboxylic acid derivatives. The reason for the difference is structural. As discussed previously in the **Preview of Carbonyl Chemistry**, and shown in **FIGURE 19.12**, the tetrahedral intermediate produced by addition of a nucleophile to a carboxylic acid derivative can eliminate a leaving group, leading to a net nucleophilic acyl substitution reaction. The tetrahedral intermediate produced by addition of a nucleophile to an aldehyde or ketone, however, has only alkyl or hydrogen substituents and thus can't usually expel a leaving group. One exception to this rule is the **Cannizzaro reaction**, discovered in 1853.

FIGURE 19.12 Carboxylic acid derivatives have an electronegative substituent $Y = -\text{Br}, -\text{Cl}, -\text{OR}, -\text{NR}_2$ that can be expelled as a leaving group from the tetrahedral intermediate formed by nucleophilic addition. Aldehydes and ketones have no such leaving group and thus do not usually undergo this reaction.

The Cannizzaro reaction takes place by nucleophilic addition of OH^- to an aldehyde to give a tetrahedral intermediate, which expels hydride ion as a leaving group and is thereby oxidized. A second aldehyde molecule accepts the hydride ion in another nucleophilic addition step and is thereby reduced. Benzaldehyde, for instance, yields benzyl alcohol plus benzoic acid when heated with aqueous NaOH .

The Cannizzaro reaction is rarely used today but is interesting mechanistically because it is a simple laboratory analogy for the primary biological pathway by which carbonyl reductions occur in living organisms. In nature, as we saw in **Section 17.4**, one of the most important reducing agents is NADH, reduced nicotinamide adenine dinucleotide. NADH donates H^- to aldehydes and ketones, thereby reducing them, in much the same way that the tetrahedral alkoxide intermediate in a Cannizzaro reaction does. The electron lone pair on a nitrogen atom of NADH expels H^- as leaving group, which adds to a carbonyl group in another molecule (**FIGURE 19.13**). As an example, pyruvate is converted during intense muscle activity to (*S*)-lactate, a reaction catalyzed by lactate dehydrogenase.

FIGURE 19.13 Mechanism of biological aldehyde and ketone reductions by the coenzyme NADH. The key step is an expulsion of hydride ion from NADH and donation to the carbonyl group.

PROBLEM 19-18 When *o*-phthalaldehyde is treated with base, *o*-(hydroxymethyl)benzoic acid is formed. Show the mechanism of this reaction.

PROBLEM 19-19 What is the stereochemistry of the pyruvate reduction shown in Figure 19.13? Does NADH lose its pro-*R* or pro-*S* hydrogen? Does addition occur to the Si face or Re face of pyruvate? (Review **Section 5.11**.)

19.13 Conjugate Nucleophilic Addition to α,β -Unsaturated Aldehydes and Ketones

All the reactions we've been discussing to this point have involved the addition of a nucleophile directly to the carbonyl group, a so-called **1,2-addition**. Closely related to this direct addition is the **conjugate addition**, or **1,4-addition**, of a nucleophile to the C=C bond of an α,β -unsaturated aldehyde or ketone. (The carbon atom next to a carbonyl group is often called the α carbon, the next carbon is the β carbon, and so on. Thus, an α,β -unsaturated aldehyde or ketone has a double bond conjugated with the carbonyl group.) The initial product of conjugate addition is a resonance-stabilized *enolate ion*, which typically undergoes protonation on the α carbon to give a saturated aldehyde or ketone product (**FIGURE 19.14**).

Direct (1,2) addition**Conjugate (1,4) addition**

FIGURE 19.14 A comparison of direct (1,2) and conjugate (1,4) nucleophilic addition reactions. In conjugate addition, a nucleophile adds to the β carbon of an α,β -unsaturated aldehyde or ketone and protonation occurs on the α carbon.

The conjugate addition of a nucleophile to an α,β -unsaturated aldehyde or ketone is caused by the same electronic factors that are responsible for direct addition. The electronegative oxygen atom of the α,β -unsaturated carbonyl compound withdraws electrons from the β carbon, thereby making it electron-poor and more electrophilic than a typical alkene carbon.

As noted, conjugate addition of a nucleophile to the β carbon of an α,β -unsaturated aldehyde or ketone leads to an enolate ion intermediate, which is protonated on the α carbon to give the saturated product (**FIGURE 19.14**). The net effect is addition of the nucleophile to the $C=C$ bond, with the carbonyl group itself unchanged. In fact, of course, the carbonyl group is crucial to the success of the reaction. Without the carbonyl group, the $C=C$ bond would not be activated for addition, and no reaction would occur.

Activated double bond**Unactivated double bond****Conjugate Addition of Amines**

Both primary and secondary amines add to α,β -unsaturated aldehydes and ketones to yield β -amino aldehydes and ketones rather than the alternative imines. Under typical reaction conditions, both modes of addition occur

rapidly. But because the reactions are reversible, they generally proceed with thermodynamic control rather than kinetic control (Section 14.3), so the more stable conjugate addition product is often obtained with the complete exclusion of the less stable direct addition product.

Conjugate Addition of Water

Water can add reversibly to α,β -unsaturated aldehydes and ketones to yield β -hydroxy aldehydes and ketones, although the position of the equilibrium generally favors unsaturated reactant rather than saturated adduct. Related additions to α,β -unsaturated carboxylic acids occur in numerous biological pathways, such as the citric acid cycle of food metabolism in which *cis*-aconitate is converted into isocitrate by conjugate addition of water to a double bond.

PROBLEM 19-20 Assign *R* or *S* stereochemistry to the two chirality centers in isocitrate, and tell whether OH and H add to the Si face or the Re face of the double bond.

Conjugate Addition of Alkyl Groups: Organocopper Reactions

The conjugate addition of an alkyl or other organic group to an α,β -unsaturated ketone (but not aldehyde) is one of the more useful 1,4-addition reactions, just as direct addition of a Grignard reagent is one of the more useful 1,2-additions.

Conjugate addition of an organic group is carried out by treating the α,β -unsaturated ketone with a lithium diorganocopper reagent, R_2CuLi . As we saw in Section 10.7, lithium diorganocopper (Gilman) reagents are prepared by reaction between 1 equivalent of copper(I) iodide and 2 equivalents of an organolithium reagent, RLi . The organolithium reagent, in turn, is formed by reaction of lithium metal with an organohalide in the same way that a Grignard reagent is prepared by reaction of magnesium metal with an organohalide.

Primary, secondary, and even tertiary alkyl groups undergo the conjugate addition reaction, as do aryl and alkenyl groups. Alkynyl groups, however, react poorly in the conjugate addition process. Diorganocopper reagents are unique in their ability to give conjugate addition products. Other organometallic reagents, such as Grignard reagents and organolithiums, normally result in direct carbonyl addition on reaction with α,β -unsaturated ketones.

The mechanism of this reaction is thought to involve conjugate nucleophilic addition of the diorganocopper anion, R_2Cu^- , to the unsaturated ketone to give a copper-containing intermediate. Transfer of an R group from copper to carbon, followed by elimination of a neutral organocopper species, RCu , gives the final product.

WORKED EXAMPLE 19.4

Using a Conjugate Addition Reaction

How might you use a conjugate addition reaction to prepare 2-methyl-3-propylcyclopentanone?

Strategy

A ketone with a substituent group in its β position might be prepared by a conjugate addition of that group to an α,β -unsaturated ketone. In the present instance, the target molecule has a propyl substituent on the β carbon and might therefore be prepared from 2-methyl-2-cyclopentenone by reaction with lithium dipropylcopper.

Solution

2-Methyl-2-cyclopentenone

2-Methyl-3-propylcyclopentanone

PROBLEM 19-21 Treatment of 2-cyclohexenone with HCN/KCN yields a saturated keto nitrile rather than an unsaturated cyanohydrin. Show the structure of the product, and propose a mechanism for the reaction.

PROBLEM 19-22 How might conjugate addition reactions of lithium diorganocopper reagents be used to synthesize the following compounds?

19.14 Spectroscopy of Aldehydes and Ketones

Infrared Spectroscopy

Aldehydes and ketones show a strong C=O bond absorption in the IR region from 1660 to 1770 cm^{-1} , as the spectra of benzaldehyde and cyclohexanone demonstrate (**FIGURE 19.15**). In addition, aldehydes show two characteristic C–H absorptions between 2700 – 2760 and 2800 – 2860 cm^{-1} . These absorbances are important for distinguishing between aldehydes and ketones. The higher-frequency absorbance is sometimes obscured in cases where the compound has numerous saturated C–H groups, but the lower-frequency peak is almost always visible.

FIGURE 19.15 Infrared spectra of (a) benzaldehyde and (b) cyclohexanone.

The exact position of the C=O absorption is diagnostic of the nature of the carbonyl group. As the data in [TABLE 19.2](#) indicate, saturated aldehydes usually show carbonyl absorptions near 1730 cm^{-1} in the IR spectrum, but conjugation of the aldehyde to an aromatic ring or a double bond lowers the absorption by 25 cm^{-1} to near 1705 cm^{-1} . Saturated aliphatic ketones and cyclohexanones both absorb near 1715 cm^{-1} , and conjugation with a double bond or an aromatic ring again lowers the absorption by 30 cm^{-1} to $1685\text{--}1690\text{ cm}^{-1}$. Angle strain in the carbonyl group, caused by reducing the ring size of cyclic ketones to four or five, raises the absorption position. Cyclohexanone has its C=O stretch absorbance at 1715 cm^{-1} while cyclopentanone's carbonyl stretch is at 1750 cm^{-1} and cyclobutanone's is at 1785 cm^{-1} .

TABLE 19.2 Infrared Absorptions of Some Aldehydes and Ketones

Carbonyl type	Example	Absorption (cm^{-1})
Saturated aldehyde	CH_3CHO	1730
Aromatic aldehyde	PhCHO	1705
α,β -Unsaturated aldehyde	$\text{H}_2\text{C}=\text{CHCHO}$	1705
Saturated ketone	CH_3COCH_3	1715
Cyclohexanone		1715
Cyclopentanone		1750
Cyclobutanone		1785
Aromatic ketone	PhCOCH_3	1690
α,β -Unsaturated ketone	$\text{H}_2\text{C}=\text{CHCOCH}_3$	1685

The values given in **TABLE 19.2** are remarkably constant from one aldehyde or ketone to another. As a result, IR spectroscopy is a powerful tool for identifying the kind of a carbonyl group in a molecule of unknown structure. An unknown that shows an IR absorption at 1730 cm^{-1} is almost certainly an aldehyde rather than a ketone; an unknown that shows an IR absorption at 1750 cm^{-1} is almost certainly a cyclopentanone, and so on.

PROBLEM How might you use IR spectroscopy to determine whether reaction between 2-cyclohexenone and **19-23** lithium dimethylcopper gives the direct addition product or the conjugate addition product?

PROBLEM Where would you expect each of the following compounds to absorb in the IR spectrum?

- 19-24** (a) 4-Penten-2-one (b) 3-Penten-2-one (c) 2,2-Dimethylcyclopentanone
(d) *m*-Chlorobenzaldehyde (e) 3-Cyclohexenone (f) 2-Hexenal

Nuclear Magnetic Resonance Spectroscopy

Aldehyde protons (RCHO) absorb near $10\ \delta$ in the ^1H NMR spectrum and are very distinctive because no other absorptions occur in this region. The aldehyde proton shows spin–spin coupling with protons on the neighboring carbon, with coupling constant $J \approx 3\text{ Hz}$. Acetaldehyde, for example, shows a quartet at $9.79\ \delta$ for the aldehyde proton, indicating that there are three protons neighboring the $-\text{CHO}$ group (**FIGURE 19.16**).

FIGURE 19.16 ^1H NMR spectrum of acetaldehyde. The absorption of the aldehyde proton appears at $9.79\ \delta$ and is split into a quartet.

Hydrogens on the carbon next to a carbonyl group are slightly deshielded and usually absorb near 2.0 to $2.3\ \delta$. The acetaldehyde methyl group in **FIGURE 19.16**, for instance, absorbs at $2.20\ \delta$. Methyl ketones are particularly distinctive because they always show a sharp three-proton singlet near $2.1\ \delta$.

The carbonyl-group carbon atoms of aldehydes and ketones have characteristic ^{13}C NMR resonances in the range 190 to $215\ \delta$. Since no other kinds of carbons absorb in this range, the presence of an NMR absorption near $200\ \delta$ is clear evidence for a carbonyl group. Saturated aldehyde or ketone carbons usually absorb in the region from 200 to $215\ \delta$, while aromatic and α,β -unsaturated carbonyl carbons absorb in the 190 to $200\ \delta$ region.

Mass Spectrometry

As discussed in **Section 12.3**, aliphatic aldehydes and ketones that have hydrogens on their gamma (γ) carbon atoms undergo a characteristic mass spectral cleavage called the **McLafferty rearrangement**. A hydrogen atom is transferred from the γ carbon to the carbonyl oxygen, the bond between the α and β carbons is broken, and a neutral alkene fragment is produced. The charge remains with the oxygen-containing fragment.

In addition to fragmentation by the McLafferty rearrangement, aldehydes and ketones also undergo cleavage of the bond between the carbonyl group and the α carbon, called an α cleavage. Alpha cleavage yields a neutral radical and a resonance-stabilized acyl cation.

Fragment ions from both McLafferty rearrangement and α cleavage are visible in the mass spectrum of 5-methyl-2-hexanone shown in **FIGURE 19.17**. McLafferty rearrangement with loss of 2-methylpropene yields a fragment with $m/z = 58$. Alpha cleavage occurs primarily at the more substituted side of the carbonyl group, leading to a $[\text{CH}_3\text{CO}]^+$ fragment with $m/z = 43$.

FIGURE 19.17 Mass spectrum and the related reactions of 5-methyl-2-hexanone. The peak at $m/z = 58$ is due to McLafferty rearrangement. The abundant peak at $m/z = 43$ is due to α cleavage at the more highly substituted side of the carbonyl group. Note that the peak due to the molecular ion is very small.

PROBLEM How might you use mass spectrometry to distinguish between the following pairs of isomers?

- 19-25** (a) 3-Methyl-2-hexanone and 4-methyl-2-hexanone (b) 3-Heptanone and 4-heptanone
 (c) 2-Methylpentanal and 3-methylpentanal

PROBLEM Describe the prominent IR absorptions and mass spectral peaks you would expect for the following compound:
19-26

CHEMISTRY MATTERS

Enantioselective Synthesis

Whenever a chiral product is formed by reaction between achiral reagents, the product is racemic; that is, both enantiomers of the product are formed in equal amounts. The epoxidation reaction of geraniol with *m*-chloroperoxybenzoic acid, for instance, gives a racemic mixture of (2*S*,3*S*) and (2*R*,3*R*) epoxides.

Unfortunately, it's usually the case that only one enantiomer of a given drug or other important substance has the desired biological properties. The other enantiomer might be inactive or even dangerous. Thus, much work is currently being done on developing *enantioselective* methods of synthesis, which yield only one of the two possible enantiomers. So important has enantioselective synthesis become that the 2001 Nobel Prize in Chemistry was awarded to three pioneers in the field: William S. Knowles of the Monsanto Co., K. Barry Sharpless of the Scripps Research Institute, and Ryoji Noyori of Nagoya University.

Several approaches to enantioselective synthesis have been developed, but the most efficient are those that use chiral catalysts to temporarily hold a substrate molecule in an unsymmetrical environment—the same strategy that nature uses when catalyzing reactions with chiral enzymes. While in that unsymmetrical environment, the substrate may be more open to reaction on one side than on another, leading to an excess of one enantiomeric product over another. As an analogy, think about picking up a coffee mug in your right hand to take a drink. The mug by itself is achiral, but as soon as you pick it up by the handle, it becomes chiral. One side of the mug now faces toward you so you can drink from it, but the other side faces away. The two sides are different, with one side much more accessible to you than the other.

FIGURE 19.18 A substance made from the tartaric acid found at the bottom of this wine vat catalyzes enantioselective reactions. (Credit: "Pinot Noir fermentation in open vat" by Pipers Brook Vineyard Media/Flickr, CC BY 2.0)

Among the thousands of enantioselective reactions now known, one of the most useful is the so-called Sharpless epoxidation, in which an allylic alcohol, such as geraniol, is treated with *tert*-butyl hydroperoxide,

$(\text{CH}_3)_3\text{C}-\text{OOH}$, in the presence of titanium tetraisopropoxide and diethyl tartrate (DET) as a chiral auxiliary reagent. When *(R,R)* tartrate is used, geraniol is converted into its *2S,3S* epoxide with 98% selectivity, whereas the use of *(S,S)* tartrate gives the *2R,3R* epoxide enantiomer. We say that the major product in each case is formed with an *enantiomeric excess* of 96%, meaning that 4% of the product is racemic (2% *2S,3S* plus 2% *2R,3R*) and an extra 96% of a single enantiomer is formed. The mechanistic details by which the chiral catalyst works are a bit complex, although it appears that a chiral complex of two tartrate molecules with one titanium is involved.

Summary

Aldehydes and ketones are among the most important of all functional groups, both in the chemical industry and in biological pathways. In this chapter, we've looked at some of their typical reactions. Aldehydes are normally prepared in the laboratory by oxidation of primary alcohols or by partial reduction of esters. Ketones are similarly prepared by oxidation of secondary alcohols.

The **nucleophilic addition reaction** is the most common general reaction type for aldehydes and ketones. Many different kinds of products can be prepared by nucleophilic additions. Aldehydes and ketones are reduced by NaBH_4 or LiAlH_4 to yield primary and secondary alcohols, respectively. Addition of Grignard reagents to aldehydes and ketones also gives alcohols (secondary and tertiary, respectively), and addition of HCN yields **cyanohydrins**. Primary amines add to carbonyl compounds yielding **imines**, or **Schiff bases**, and secondary

amines yield **enamines**. Reaction of an aldehyde or ketone with hydrazine and base gives an alkane (the **Wolff–Kishner reaction**). Alcohols add to carbonyl groups to yield **acetals**, which are valuable as protecting groups. Phosphorus **ylides** add to aldehydes and ketones in the **Wittig reaction** to give alkenes.

α,β -Unsaturated aldehydes and ketones often react with nucleophiles to give the product of **conjugate addition**, or **1,4-addition**. Particularly useful are the conjugate addition of an amine and the conjugate addition of an organic group by reaction with a diorganocopper reagent.

IR spectroscopy is helpful for identifying aldehydes and ketones. Carbonyl groups absorb in the IR range 1660 to 1770 cm^{-1} , with the exact position highly diagnostic of the kind of carbonyl group present in the molecule. ^{13}C NMR spectroscopy is also useful for aldehydes and ketones because their carbonyl carbons show resonances in the 190 to 215 δ range. ^1H NMR is useful for aldehyde $-\text{CHO}$ protons, which absorb near 10 δ . Aldehydes and ketones undergo two characteristic kinds of fragmentation in the mass spectrometer: α cleavage and McLafferty rearrangement.

Summary of Reactions

1. Preparation of aldehydes (Section 19.2)

a. Oxidation of primary alcohols (Section 17.7)

b. Partial reduction of esters (Section 19.2)

2. Preparation of ketones

a. Oxidation of secondary alcohols (Section 17.7)

b. Diorganocopper reaction with acid chlorides (Section 19.2)

3. Oxidation of aldehydes (Section 19.3)

4. Nucleophilic addition reactions of aldehydes and ketones

a. Addition of hydride to give alcohols: reduction (Section 19.7)

b. Addition of Grignard reagents to give alcohols (Section 19.7)

c. Addition of HCN to give cyanohydrins (Section 19.6)

d. Addition of primary amines to give imines (Section 19.8)

- e. Addition of secondary amines to give enamines (Section 19.8)

- f. Wolff–Kishner reaction to give alkanes (Section 19.9)

- g. Addition of alcohols to give acetals (Section 19.10)

- h. Addition of phosphorus ylides to give alkenes: Wittig reaction (Section 19.11)

5. Conjugate additions to α,β -unsaturated aldehydes and ketones (Section 19.13)

- a. Conjugate addition of amines

- b. Conjugate addition of water

- c. Conjugate addition of alkyl groups by diorganocopper reaction

Additional Problems

Visualizing Chemistry

PROBLEM 19-27 Each of the following substances can be prepared by a nucleophilic addition reaction between an aldehyde or ketone and a nucleophile. Identify the reactants from which each was prepared. If the substance is an acetal, identify the carbonyl compound and the alcohol; if it is an imine, identify the carbonyl compound and the amine; and so forth.

(a)

(b)

PROBLEM 19-28 The following molecular model represents a tetrahedral intermediate resulting from addition of a nucleophile to an aldehyde or ketone. Identify the reactants, and write the structure of the final product when the nucleophilic addition reaction is complete.

PROBLEM 19-29 The enamine prepared from acetone and dimethylamine is shown in its lowest-energy form.

- (a) What is the geometry and hybridization of the nitrogen atom?
 (b) What orbital on nitrogen holds the lone pair of electrons?
 (c) What is the geometric relationship between the *p* orbitals of the double bond and the nitrogen orbital that holds the lone pair? Why do you think this geometry represents the minimum energy?

Mechanism Problems

PROBLEM 19-30 Predict the product(s) and propose a mechanism for each of the following reactions:

PROBLEM 19-31 Predict the product(s) and propose a mechanism for each of the following reactions:

PROBLEM 19-32 Predict the product(s) and propose a mechanism for each of the following reactions:

PROBLEM Predict the product(s) and propose a mechanism for each of the following reactions:

PROBLEM Predict the product(s) and propose mechanisms for the following reactions:

PROBLEM The following reaction begins with an acetal and converts it into a different acetal. Predict the product(s) and propose a mechanism.

PROBLEM When α -glucose is treated with an acid catalyst in the presence of an alcohol, an acetal is formed.

19-36 Propose a mechanism for this process and give the structure of the stereoisomeric acetal that you would also expect as a product.

PROBLEM Predict the products of the following Wolff-Kishner reactions. Write the mechanism for each, beginning from the hydrazone intermediate.

PROBLEM Aldehydes can be prepared by the Wittig reaction using (methoxymethylene)triphenylphosphorane as the Wittig reagent and then hydrolyzing the product with acid. For example,

PROBLEM 19-45 Propose a mechanism to account for the formation of 3,5-dimethylpyrazole from hydrazine and 2,4-pentanedione. What has happened to each carbonyl carbon in going from starting material to product.

2,4-Pentanedione

3,5-Dimethylpyrazole

PROBLEM 19-46 In light of your answer to Problem 19-45, propose a mechanism for the formation of 3,5-dimethylisoxazole from hydroxylamine and 2,4-pentanedione.

PROBLEM 19-47 Trans alkenes are converted into their cis isomers and vice versa on epoxidation followed by treatment of the epoxide with triphenylphosphine. Propose a mechanism for the reaction.

PROBLEM 19-48 Treatment of an α,β -unsaturated ketone with basic aqueous hydrogen peroxide yields an epoxy ketone. The reaction is specific to unsaturated ketones; isolated alkene double bonds do not react. Propose a mechanism.

PROBLEM 19-49 One of the biological pathways by which an amine is converted to a ketone involves two steps: (1) oxidation of the amine by NAD^+ to give an imine and (2) hydrolysis of the imine to give a ketone plus ammonia. Glutamate, for instance, is converted by this process into α -ketoglutarate. Show the structure of the imine intermediate, and propose mechanisms for both steps.

PROBLEM 19-50 Primary amines react with esters to yield amides: $\text{RCO}_2\text{R}' + \text{R}''\text{NH}_2 \rightarrow \text{RCONHR}'' + \text{R}'\text{OH}$. Propose a mechanism for the following reaction of an α,β -unsaturated ester.

PROBLEM 19-51 When crystals of pure α -glucose are dissolved in water, isomerization occurs slowly to produce β -glucose. Propose a mechanism for the isomerization.

PROBLEM 19-52 The Wharton reaction converts an epoxy ketone to an allylic alcohol by reaction with hydrazine. Review the Wolff–Kishner reaction in Section 19.9 and then propose a mechanism.

Naming Aldehydes and Ketones

PROBLEM Draw structures corresponding to the following names:

- 19-53** (a) Bromoacetone (b) (*S*)-2-Hydroxypropanal (c) 2-Methyl-3-heptanone
 (d) (2*S*,3*R*)-2,3,4-Trihydroxybutanal (e) 2,2,4,4-Tetramethyl-3-pentanone
 (f) 4-Methyl-3-penten-2-one (g) Butanedial (h) 3-Phenyl-2-propenal
 (i) 6,6-Dimethyl-2,4-cyclohexadienone (j) *p*-Nitroacetophenone

PROBLEM 19-54 Draw and name the seven aldehydes and ketones with the formula $\text{C}_5\text{H}_{10}\text{O}$. Which are chiral?

PROBLEM 19-55 Give IUPAC names for the following compounds:

PROBLEM 19-56 Draw structures of compounds that fit the following descriptions:

- (a) An α,β -unsaturated ketone, $\text{C}_6\text{H}_8\text{O}$ (b) An α -diketone (c) An aromatic ketone, $\text{C}_9\text{H}_{10}\text{O}$
 (d) A diene aldehyde, $\text{C}_7\text{H}_8\text{O}$

Reactions of Aldehydes and Ketones

PROBLEM 19-57 Predict the products of the reaction of (1) phenylacetaldehyde and (2) acetophenone with the following reagents:

- (a) NaBH_4 , then H_3O^+ (b) Dess–Martin reagent (c) NH_2OH , HCl catalyst
 (d) CH_3MgBr , then H_3O^+ (e) $2 \text{CH}_3\text{OH}$, HCl catalyst (f) H_2NNH_2 , KOH (g) $(\text{C}_6\text{H}_5)_3\text{P}=\text{CH}_2$
 (h) HCN , KCN

PROBLEM 19-58 Show how you might use a Wittig reaction to prepare the following alkenes. Identify the alkyl halide and the carbonyl components.

PROBLEM 19-59 How would you use a Grignard reaction on an aldehyde or ketone to synthesize the following compounds?

(a) 2-Pentanol (b) 1-Butanol (c) 1-Phenylcyclohexanol (d) Diphenylmethanol

PROBLEM 19-60 How might you carry out the following selective transformations? One of the two schemes requires a protection step. (Recall from Section 19.4 that aldehydes are more reactive than ketones toward nucleophilic addition.)

PROBLEM 19-61 How would you prepare the following substances from 2-cyclohexenone? More than one step may be needed.

PROBLEM 19-62 How would you synthesize the following substances from benzaldehyde and any other reagents needed?

PROBLEM 19-63 Carvone is the major constituent of spearmint oil. What products would you expect from reaction of carvone with the following reagents?

(a) $(\text{CH}_3)_2\text{Cu}^-\text{Li}^+$, then H_3O^+ (b) LiAlH_4 , then H_3O^+ (c) CH_3NH_2 (d) $\text{C}_6\text{H}_5\text{MgBr}$, then H_3O^+
 (e) H_2/Pd (f) $\text{HOCH}_2\text{CH}_2\text{OH}$, HCl (g) $(\text{C}_6\text{H}_5)_3\text{P}^+\text{CH}_3^-$

PROBLEM 19-64 How would you synthesize the following compounds from cyclohexanone?

(a) 1-Methylcyclohexene (b) 2-Phenylcyclohexanone (c) *cis*-1,2-Cyclohexanediol
 (d) 1-Cyclohexylcyclohexanol

Spectroscopy

PROBLEM At what position would you expect to observe IR absorptions for the following molecules?

19-65 (a)

4-Androstene-3,17-dione

(b)

1-Indanone

(c)

(d)

PROBLEM Acid-catalyzed dehydration of 3-hydroxy-3-phenylcyclohexanone leads to an unsaturated ketone.

19-66 What possible structures are there for the product? At what position in the IR spectrum would you expect each to absorb? If the actual product has an absorption at 1670 cm^{-1} , what is its structure?

PROBLEM Choose the structure that best fits the IR spectrum shown.

19-67

(a)

(b)

(c)

(d)

PROBLEM Propose structures for molecules that meet the following descriptions. Assume that the kinds of carbons (1° , 2° , 3° , or 4°) have been assigned by DEPT-NMR.

19-68

(a) $\text{C}_6\text{H}_{12}\text{O}$; IR: 1715 cm^{-1} ; ^{13}C NMR: $8.0\ \delta$ (1°), $18.5\ \delta$ (1°), $33.5\ \delta$ (2°), $40.6\ \delta$ (3°), $214.0\ \delta$ (4°)

(b) $\text{C}_5\text{H}_{10}\text{O}$; IR: 1730 cm^{-1} ; ^{13}C NMR: $22.6\ \delta$ (1°), $23.6\ \delta$ (3°), $52.8\ \delta$ (2°), $202.4\ \delta$ (3°)

(c) $\text{C}_6\text{H}_8\text{O}$; IR: 1680 cm^{-1} ; ^{13}C NMR: $22.9\ \delta$ (2°), $25.8\ \delta$ (2°), $38.2\ \delta$ (2°), $129.8\ \delta$ (3°), $150.6\ \delta$ (3°), $198.7\ \delta$ (4°)

PROBLEM Compound A, $\text{C}_8\text{H}_{10}\text{O}_2$, has an intense IR absorption at 1750 cm^{-1} and gives the ^{13}C NMR spectrum

19-69 shown. Propose a structure for A.

PROBLEM Propose structures for ketones or aldehydes that have the following ^1H NMR spectra:

19-70 (a) $\text{C}_4\text{H}_7\text{ClO}$

IR: 1715 cm^{-1}

(b) $\text{C}_7\text{H}_{14}\text{O}$

IR: 1710 cm^{-1}

General Problems

PROBLEM When 4-hydroxybutanal is treated with methanol in the presence of an acid catalyst, **19-71** 2-methoxytetrahydrofuran is formed. Explain.

PROBLEM The $\text{S}_{\text{N}}2$ reaction of (dibromomethyl)benzene, $\text{C}_6\text{H}_5\text{CHBr}_2$, with NaOH yields benzaldehyde rather than (dihydroxymethyl)benzene, $\text{C}_6\text{H}_5\text{CH}(\text{OH})_2$. Explain. **19-72**

PROBLEM 19-73 Reaction of 2-butanone with HCN yields a chiral product. What stereochemistry does the product have? Is it optically active?

PROBLEM 19-74 The amino acid methionine is biosynthesized by a multistep route that includes reaction of an imine of pyridoxal phosphate (PLP) to give an unsaturated imine, which then reacts with cysteine. What kinds of reactions are occurring in the two steps?

PROBLEM 19-75 Each of the following reaction schemes has one or more flaws. What is wrong in each case? How would you correct each scheme?

PROBLEM 19-76 6-Methyl-5-hepten-2-one is a constituent of lemongrass oil. How could you synthesize this substance from methyl 4-oxopentanoate?

PROBLEM 19-77 Tamoxifen is a drug used in the treatment of breast cancer. How would you prepare tamoxifen from benzene, the following ketone, and any other reagents needed?

PROBLEM 19-78 Compound **A**, MW = 86, shows an IR absorption at 1730 cm^{-1} and a very simple ^1H NMR spectrum with peaks at $9.7\ \delta$ (1 H, singlet) and $1.2\ \delta$ (9 H, singlet). Propose a structure for **A**.

PROBLEM 19-79 Compound **B** is isomeric with **A** (Problem 19-78) and shows an IR peak at 1715 cm^{-1} . The ^1H NMR spectrum of **B** has peaks at $2.4\ \delta$ (1 H, septet, $J = 7\text{ Hz}$), $2.1\ \delta$ (3 H, singlet), and $1.2\ \delta$ (6 H, doublet, J

= 7 Hz). What is the structure of **B**?

PROBLEM The ^1H NMR spectrum shown is that of a compound with the formula $\text{C}_9\text{H}_{10}\text{O}$. How many double bonds and/or rings does this compound contain? If the unknown compound has an IR absorption at 1690 cm^{-1} , what is a likely structure?

19-80

PROBLEM The ^1H NMR spectrum shown is that of a compound isomeric with the one in Problem 19-80. This isomer has an IR absorption at 1730 cm^{-1} . Propose a structure. [Note: Aldehyde protons (CHO) often show low coupling constants to adjacent hydrogens, so the splitting of aldehyde signals is not always apparent.]

19-81

PROBLEM Propose structures for ketones or aldehydes that have the following ^1H NMR spectra:

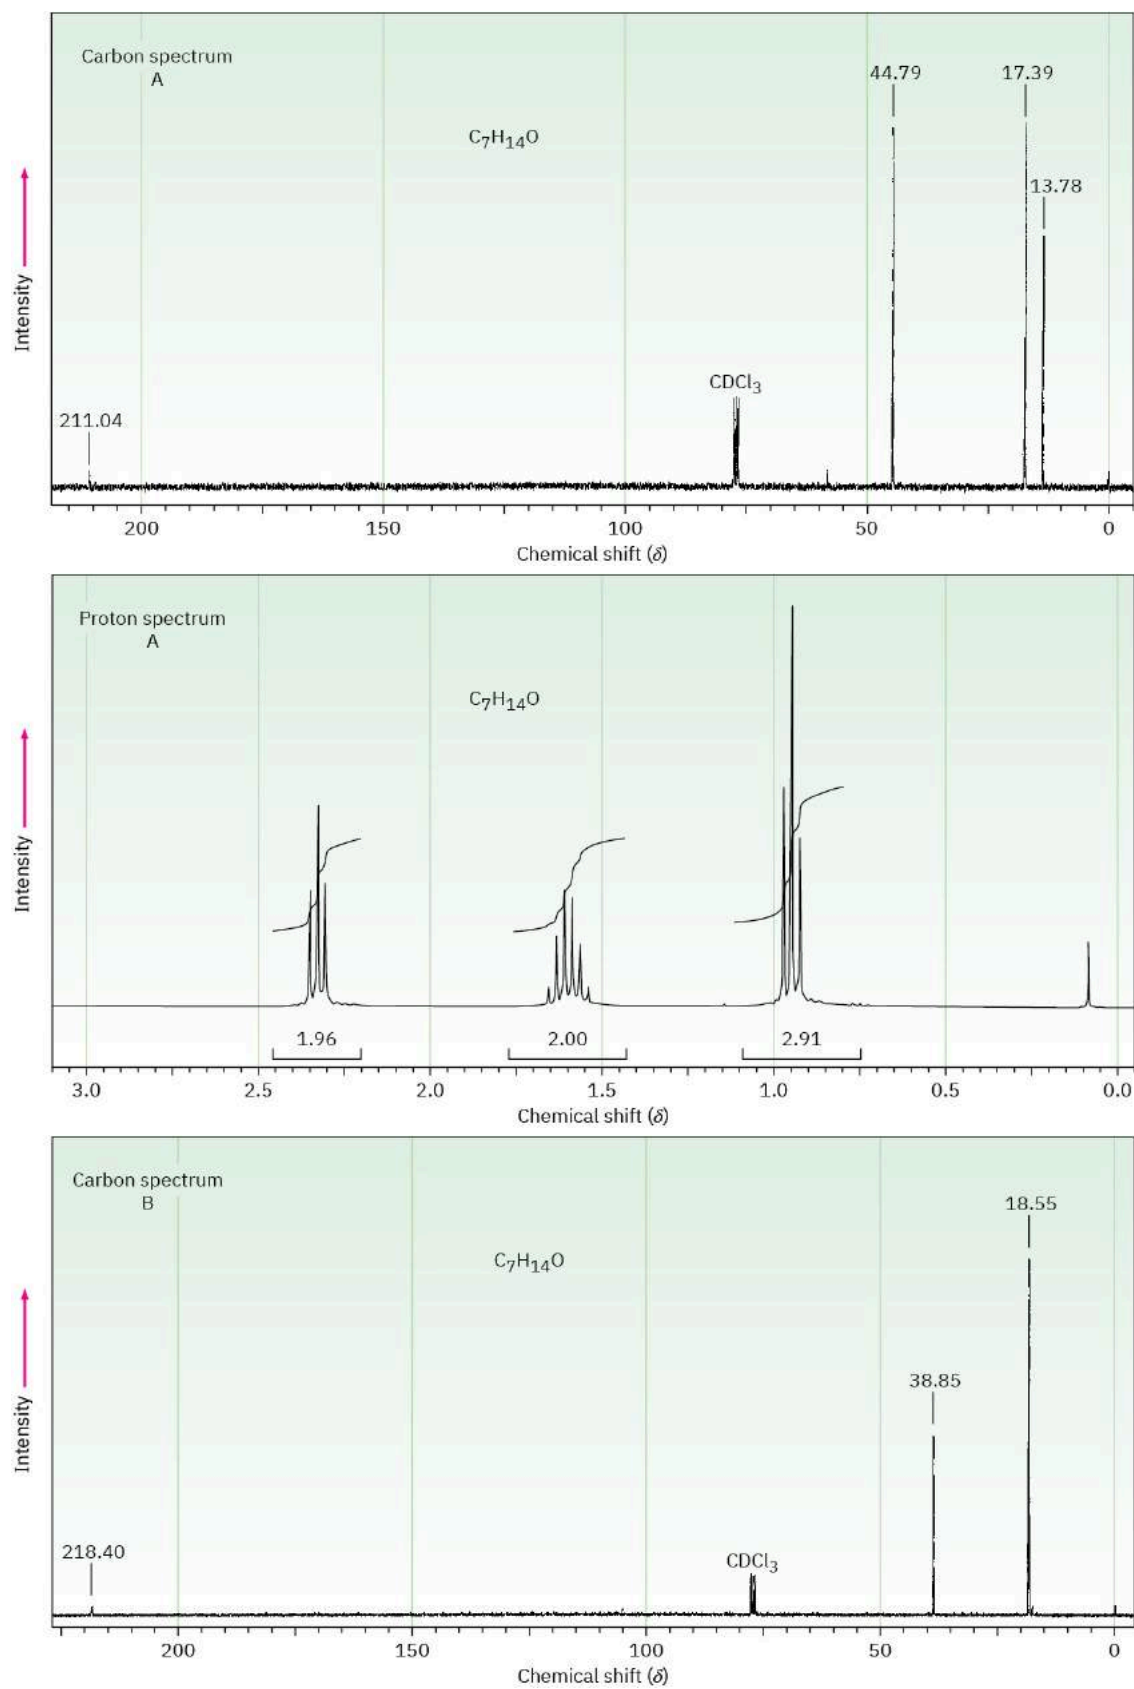

19-82 (a) $\text{C}_9\text{H}_{10}\text{O}_2$; IR: 1695 cm^{-1}

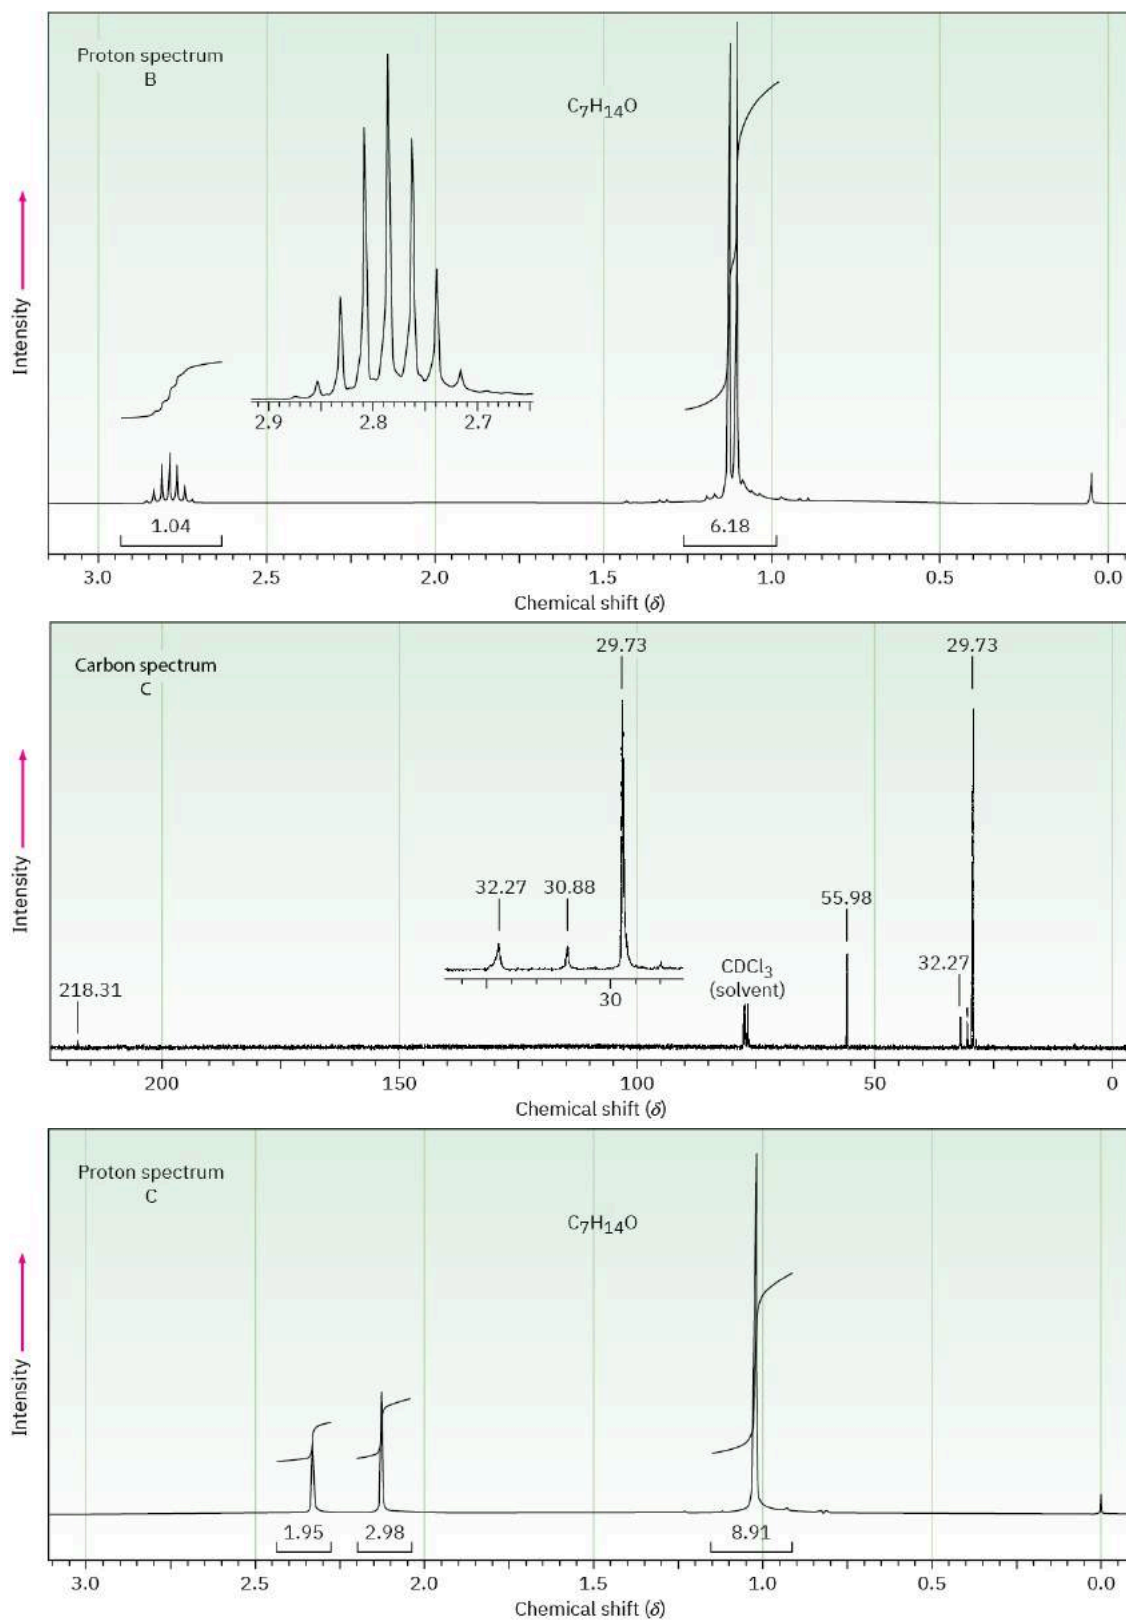

(b) C_4H_6O : IR: 1690 cm^{-1} **PROBLEM** Propose structures for ketones or aldehydes that have the following 1H NMR spectra.19-83 (a) $C_{10}H_{12}O$: IR: 1710 cm^{-1} (b) $C_6H_{12}O_3$: IR: 1715 cm^{-1} **PROBLEM** When glucose (Problem 19-51) is treated with $NaBH_4$, reaction occurs to yield *sorbitol*, a

19-84 polyalcohol commonly used as a food additive. Show how this reduction occurs.

**PROBLEM** The proton and carbon NMR spectra for each of three isomeric ketones with the formula $C_7H_{14}O$ are 19-85 shown. Assign a structure to each pair of spectra.

PROBLEM 19-86 The proton NMR spectrum for a compound with formula $C_{10}H_{12}O_2$ is shown below. The infrared spectrum has a strong band at 1711 cm^{-1} . The broadband-decoupled ^{13}C NMR spectral results are tabulated along with the DEPT-135 and DEPT-90 information. Draw the structure of this compound.

CHAPTER 20

Carboxylic Acids and Nitriles

- 20.7 Chemistry of Nitriles
- 20.8 Spectroscopy of Carboxylic Acids and Nitriles

WHY THIS CHAPTER? Carboxylic acids are present in many industrial processes and most biological pathways and are the starting materials from which other acyl derivatives are made. Thus, an understanding of their properties and reactions is fundamental to understanding organic chemistry. We'll look both at acids and at their close relatives, nitriles ($\text{RC}\equiv\text{N}$), in this chapter and at carboxylic acid derivatives in the next chapter.

Carboxylic acids, RCO_2H , occupy a central place among carbonyl compounds. Not only are they valuable in themselves, they also serve as starting materials for preparing numerous carboxylic acid derivatives such as acid chlorides, esters, amides, and thioesters. In addition, carboxylic acids are present in the majority of biological pathways.

A great many carboxylic acids are found in nature: acetic acid, $\text{CH}_3\text{CO}_2\text{H}$, is the chief organic component of vinegar; butanoic acid, $\text{CH}_3\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$, is responsible for the rancid odor of sour butter; and hexanoic acid (caproic acid), $\text{CH}_3(\text{CH}_2)_4\text{CO}_2\text{H}$, is responsible for the unmistakable aroma of goats and dirty gym socks (the name comes from the Latin *caper*, meaning “goat”). Other examples are cholic acid, a major component of human bile, and long-chain aliphatic acids such as palmitic acid, $\text{CH}_3(\text{CH}_2)_{14}\text{CO}_2\text{H}$, a biological precursor of fats and vegetable oils.

Approximately 20 million tons of acetic acid is produced worldwide each year for a variety of purposes, including preparation of the vinyl acetate polymer used in paints and adhesives. About 20% of the acetic acid synthesized industrially is obtained by oxidation of acetaldehyde. Much of the remaining 80% is prepared by the rhodium-catalyzed reaction of methanol with carbon monoxide.

20.1 Naming Carboxylic Acids and Nitriles

Carboxylic Acids, RCO_2H

Simple carboxylic acids derived from open-chain alkanes are systematically named by replacing the terminal *-e* of the corresponding alkane name with *-oic acid*. The $-\text{CO}_2\text{H}$ carbon atom is numbered C1.

Compounds that have a $-\text{CO}_2\text{H}$ group bonded to a ring are named using the suffix *-carboxylic acid*. The CO_2H carbon is attached to C1 in this system and is not itself numbered. As a substituent, the CO_2H group is called a **carboxyl group**.

**trans-4-Hydroxycyclohexanecarboxylic acid****1-Cyclopentenecarboxylic acid**

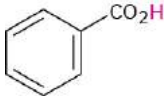

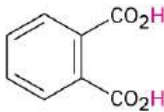

Because many carboxylic acids were among the first organic compounds to be isolated and purified, quite a few common names exist (TABLE 20.1). Biological chemists, in particular, make frequent use of these names, so you may find yourself referring back to this list on occasion. We'll use systematic names in this book, with a few exceptions such as formic (methanoic) acid and acetic (ethanoic) acid, whose names are accepted by IUPAC and are so well known that it makes little sense to refer to them any other way.

Also listed in TABLE 20.1 are the names of acyl groups $\left(\text{R}-\overset{\text{O}}{\parallel}{\text{C}}-\right)$ derived from the parent acids. Except for the eight entries at the top of TABLE 20.1, whose names have a *-yl* ending, all other acyl groups are named using an *-oyl* ending.

TABLE 20.1 Common Names of Some Carboxylic Acids and Acyl Groups

Structure	Name	Acyl group
HCO_2H	Formic	Formyl
$\text{CH}_3\text{CO}_2\text{H}$	Acetic	Acetyl
$\text{CH}_3\text{CH}_2\text{CO}_2\text{H}$	Propionic	Propionyl
$\text{CH}_3\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$	Butyric	Butyryl
$\text{HO}_2\text{CCO}_2\text{H}$	Oxalic	Oxalyl
$\text{HO}_2\text{CCH}_2\text{CO}_2\text{H}$	Malonic	Malonyl
$\text{HO}_2\text{CCH}_2\text{CH}_2\text{CO}_2\text{H}$	Succinic	Succinyl
$\text{HO}_2\text{CCH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$	Glutaric	Glutaryl
$\text{HO}_2\text{CCH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$	Adipic	Adipoyl
$\text{H}_2\text{C}=\text{CHCO}_2\text{H}$	Acrylic	Acryloyl
$\text{HO}_2\text{CCH}=\text{CHCO}_2\text{H}$	Maleic (cis) Fumaric (trans)	Maleoyl Fumaroyl
$\text{HOCH}_2\text{CO}_2\text{H}$	Glycolic	Glycoloyl
$\begin{array}{c} \text{OH} \\ \\ \text{CH}_3\text{CHCO}_2\text{H} \end{array}$	Lactic	Lactoyl
$\begin{array}{c} \text{O} \\ \\ \text{CH}_3\text{CCO}_2\text{H} \end{array}$	Pyruvic	Pyruvoyl
$\begin{array}{c} \text{OH} \\ \\ \text{HOCH}_2\text{CHCO}_2\text{H} \end{array}$	Glyceric	Glyceroyl

TABLE 20.1 Common Names of Some Carboxylic Acids and Acyl Groups

Structure	Name	Acyl group
$\begin{array}{c} \text{OH} \\ \\ \text{HO}_2\text{CCHCH}_2\text{CO}_2\text{H} \end{array}$	Malic	Maloyl
$\begin{array}{c} \text{O} \\ \\ \text{HO}_2\text{CCCH}_2\text{CO}_2\text{H} \end{array}$	Oxaloacetic	Oxaloacetyl
	Benzoic	Benzoyl
	Phthalic	Phthaloyl

Nitriles, $\text{RC}\equiv\text{N}$

Compounds containing the $\text{-C}\equiv\text{N}$ functional group are called **nitriles** and can undergo some chemistry similar to that of carboxylic acids. Simple open-chain nitriles are named by adding *-nitrile* as a suffix to the alkane name, with the nitrile carbon numbered C1.

Nitriles can also be named as derivatives of carboxylic acids by replacing the *-ic acid* or *-oic acid* ending with *-onitrile*, or by replacing the *-carboxylic acid* ending with *-carbonitrile*. The nitrile carbon atom is attached to C1 but is not itself numbered.

If another carboxylic acid derivative is present in the same molecule, the prefix *ciano-* is used for the $\text{C}\equiv\text{N}$ group.

PROBLEM Give IUPAC names for the following compounds:

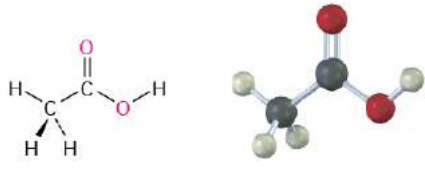

PROBLEM Draw structures corresponding to the following IUPAC names:

- 20-2** (a) 2,3-Dimethylhexanoic acid (b) 4-Methylpentanoic acid
 (c) *trans*-1,2-Cyclobutanedicarboxylic acid (d) *o*-Hydroxybenzoic acid
 (e) (9*Z*,12*Z*)-9,12-Octadecadienoic acid (f) 2-Pentenenitrile

20.2 Structure and Properties of Carboxylic Acids

Carboxylic acids are similar in some respects to both ketones and alcohols. Like ketones, the carboxyl carbon is sp^2 -hybridized, and carboxylic acid groups are therefore planar with C–C=O and O=C–O bond angles of approximately 120° (TABLE 20.2).

TABLE 20.2 Physical Parameters for Acetic Acid

Bond angle	(degrees)	Bond length	(pm)
C–C=O	119	C–C	152
C–C–OH	119	C=O	125
O=C–OH	122	C–OH	131

Like alcohols, carboxylic acids are strongly associated because of hydrogen-bonding. Most carboxylic acids exist as cyclic dimers held together by two hydrogen bonds. This strong hydrogen-bonding has a noticeable effect on boiling points, making carboxylic acids boil far less easily than their corresponding alcohols. Acetic acid, for instance, has a boiling point of 117.9°C , versus 78.3°C for ethanol, even though both compounds have two carbons.

The most obvious property of carboxylic acids is implied by their name: carboxylic acids are *acidic*. They therefore react with bases such as NaOH and NaHCO_3 to give metal carboxylate salts, $\text{RCO}_2^- \text{M}^+$. Carboxylic acids with more than six carbons are only slightly soluble in water, but the alkali metal salts of carboxylic acids are often highly water-soluble. In fact, it's often possible to purify an acid by extracting its salt into aqueous base, then reacidifying and extracting the pure acid back into an organic solvent.

Like other Brønsted–Lowry acids discussed in Section 2.7, carboxylic acids dissociate slightly in dilute aqueous solution to give H_3O^+ and the corresponding carboxylate anions, RCO_2^- . The extent of dissociation is given by an acidity constant, K_a .

$$K_a = \frac{[\text{RCO}_2^-][\text{H}_3\text{O}^+]}{[\text{RCO}_2\text{H}]} \quad \text{and} \quad \text{p}K_a = -\log K_a$$

A list of K_a values for various carboxylic acids is given in **TABLE 20.3**. For most, K_a is approximately 10^{-4} to 10^{-5} . Acetic acid, for instance, has $K_a = 1.75 \times 10^{-5}$ at 25 °C, which corresponds to a $\text{p}K_a$ of 4.76. In practical terms, a K_a value near 10^{-5} means that only about 0.1% of the molecules in a 0.1 M solution are dissociated, as opposed to the 100% dissociation found with strong mineral acids like HCl.

TABLE 20.3 Acidity of Some Carboxylic Acids

Structure	K_a	$\text{p}K_a$	
$\text{CF}_3\text{CO}_2\text{H}$	0.59	0.23	
HCO_2H	1.77×10^{-4}	3.75	
$\text{HOCH}_2\text{CO}_2\text{H}$	1.5×10^{-4}	3.84	
$\text{C}_6\text{H}_5\text{CO}_2\text{H}$	6.46×10^{-5}	4.19	
$\text{H}_2\text{C}=\text{CHCO}_2\text{H}$	5.6×10^{-5}	4.25	
$\text{CH}_3\text{CO}_2\text{H}$	1.75×10^{-5}	4.76	
$\text{CH}_3\text{CH}_2\text{CO}_2\text{H}$	1.34×10^{-5}	4.87	
$\text{CH}_3\text{CH}_2\text{OH}$ (ethanol)	(1×10^{-16})	(16)	

Although much weaker than mineral acids, carboxylic acids are nevertheless much stronger acids than alcohols and phenols. The K_a of ethanol, for example, is approximately 10^{-16} , making it a weaker acid than acetic acid by a factor of 10^{11} .

Why are carboxylic acids so much more acidic than alcohols, even though both contain $-\text{OH}$ groups? An alcohol dissociates to give an alkoxide ion, in which the negative charge is localized on a single electronegative atom. A carboxylic acid, however, gives a carboxylate ion, in which the negative charge is delocalized over two equivalent oxygen atoms (**FIGURE 20.2**). In resonance terms (**Section 2.4**), a carboxylate ion is a stabilized resonance hybrid of two equivalent structures. Since a carboxylate ion is more stable than an alkoxide ion, it is lower in energy and more favored in the dissociation equilibrium.

FIGURE 20.2 An alkoxide ion has its charge localized on one oxygen atom and is less stable, while a carboxylate ion has the charge spread equally over both oxygens and is therefore more stable.

Experimental evidence for the equivalence of the two carboxylate oxygens comes from X-ray crystallographic studies on sodium formate. Both carbon–oxygen bonds are 127 pm in length, midway between the C=O double bond (120 pm) and the C–O single bond (134 pm) of formic acid. An electrostatic potential map of the formate ion also shows how the negative charge (red) is spread equally over both oxygens.

PROBLEM 20-3 Assume you have a mixture of naphthalene and benzoic acid that you want to separate. How might you take advantage of the acidity of one component in the mixture to effect a separation?

PROBLEM 20-4 The K_a for dichloroacetic acid is 3.32×10^{-2} . Approximately what percentage of the acid is dissociated in a 0.10 M aqueous solution?

20.3 Biological Acids and the Henderson–Hasselbalch Equation

In acidic solution, at low pH, a carboxylic acid is completely undissociated and exists entirely as RCOH. In basic solution, at high pH, a carboxylic acid is completely dissociated and exists entirely as RCO₂[−]. Inside living cells, however, the pH is neither acidic nor basic but is instead buffered to a nearly neutral pH of 3.5–4.5 in humans, a value often referred to as *physiological pH*. In what form, then, do carboxylic acids exist inside cells? The question is an important one for understanding the acid catalysts so often found in biological reactions.

If the pK_a value of a given acid and the pH of the medium are known, the percentages of dissociated and

undissociated forms can be calculated using the **Henderson–Hasselbalch equation**.

For any acid HA, we have

$$\begin{aligned} \text{p}K_{\text{a}} &= -\log \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]} = -\log[\text{H}_3\text{O}^+] - \log \frac{[\text{A}^-]}{[\text{HA}]} \\ &= \text{pH} - \log \frac{[\text{A}^-]}{[\text{HA}]} \end{aligned}$$

which can be rearranged to give

$$\text{pH} = \text{p}K_{\text{a}} + \log \frac{[\text{A}^-]}{[\text{HA}]} \quad \text{Henderson-Hasselbalch equation}$$

so

$$\log \frac{[\text{A}^-]}{[\text{HA}]} = \text{pH} - \text{p}K_{\text{a}}$$

This equation says that the logarithm of the concentration of dissociated acid $[\text{A}^-]$ divided by the concentration of undissociated acid $[\text{HA}]$ is equal to the pH of the solution minus the $\text{p}K_{\text{a}}$ of the acid. Thus, if we know both the pH of the solution and the $\text{p}K_{\text{a}}$ of the acid, we can calculate the ratio of $[\text{A}^-]$ to $[\text{HA}]$. Furthermore, when $\text{pH} = \text{p}K_{\text{a}}$, then HA and A^- are present in equal amounts because $\log 1 = 0$.

As an example of how to use the Henderson–Hasselbalch equation, let's find out what species are present in a 0.0010 M solution of acetic acid at $\text{pH} = 7.3$. According to Table 20-3, the $\text{p}K_{\text{a}}$ of acetic acid is 4.76. From the Henderson–Hasselbalch equation, we have

$$\begin{aligned} \log \frac{[\text{A}^-]}{[\text{HA}]} &= \text{pH} - \text{p}K_{\text{a}} = 7.3 - 4.76 = 2.54 \\ \frac{[\text{A}^-]}{[\text{HA}]} &= \text{antilog}(2.54) = 3.5 \times 10^2 \quad \text{so } [\text{A}^-] = (3.5 \times 10^2) [\text{HA}] \end{aligned}$$

In addition, we know that

$$[\text{A}^-] + [\text{HA}] = 0.0010 \text{ M}$$

Solving the two simultaneous equations gives $[\text{A}^-] = 0.0010 \text{ M}$ and $[\text{HA}] = 3 \times 10^{-6} \text{ M}$. In other words, at a physiological pH of 7.3, essentially 100% of acetic acid molecules in a 0.0010 M solution are dissociated to the acetate ion.

What is true for acetic acid is also true for other carboxylic acids: At the physiological pH that occurs inside cells, carboxylic acids are almost entirely dissociated. To reflect this fact, we always refer to cellular carboxylic acids by the name of their anion—acetate, lactate, citrate, and so forth, rather than acetic acid, lactic acid, and citric acid.

PROBLEM 20-5 Calculate the percentages of dissociated and undissociated forms present in the following solutions:

- (a) 0.0010 M glycolic acid ($\text{HOCH}_2\text{CO}_2\text{H}$; $\text{p}K_{\text{a}} = 3.83$) at $\text{pH} = 4.50$
- (b) 0.0020 M propanoic acid ($\text{p}K_{\text{a}} = 4.87$) at $\text{pH} = 5.30$

20.4 Substituent Effects on Acidity

The listing of $\text{p}K_{\text{a}}$ values shown previously in **TABLE 20.3** indicates that there are substantial differences in acidity from one carboxylic acid to another. For example, trifluoroacetic acid ($K_{\text{a}} = 0.59$) is 33,000 times as strong as acetic acid ($K_{\text{a}} = 1.75 \times 10^{-5}$). How can we account for such differences?

Because the dissociation of a carboxylic acid is an equilibrium process, any factor that stabilizes the carboxylate anion relative to undissociated carboxylic acid will drive the equilibrium toward increased dissociation and result in increased acidity. For instance, three electron-withdrawing fluorine atoms delocalize the negative charge in the trifluoroacetate anion, thereby stabilizing the ion and increasing the acidity of $\text{CF}_3\text{CO}_2\text{H}$. In the same way, glycolic acid ($\text{HOCH}_2\text{CO}_2\text{H}$; $\text{p}K_{\text{a}} = 3.83$) is stronger than acetic acid because of the electron-withdrawing effect of the electronegative oxygen atom.

Because inductive effects operate through σ bonds and are dependent on distance, the effect of halogen substitution decreases as the substituent moves farther from the carboxyl. Thus, 2-chlorobutanoic acid has $\text{p}K_{\text{a}} = 2.86$, 3-chlorobutanoic acid has $\text{p}K_{\text{a}} = 4.05$, and 4-chlorobutanoic acid has $\text{p}K_{\text{a}} = 4.52$, similar to that of butanoic acid itself.

Substituent effects on acidity are also found in substituted benzoic acids. We said during the discussion of electrophilic aromatic substitution in [Section 16.4](#) that substituents on the aromatic ring strongly affect reactivity. Aromatic rings with electron-donating groups are activated toward further electrophilic substitution, and aromatic rings with electron-withdrawing groups are deactivated. Exactly the same effects can be observed on the acidity of substituted benzoic acids ([TABLE 20.4](#)).

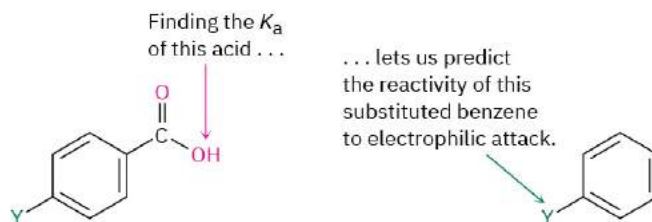

TABLE 20.4 Substituent Effects on the Acidity of *p*-Substituted Benzoic Acids

	Y	$K_{\text{a}} \times 10^{-5}$	$\text{p}K_{\text{a}}$	
Stronger acid Weaker acid	-NO ₂	39	3.41	Deactivating groups
	-CN	28	3.55	
	-CHO	18	3.75	
	-Br	11	3.96	
	-Cl	10	4.0	
	-H	6.46	4.19	
	-CH ₃	4.3	4.34	Activating groups
	-OCH ₃	3.5	4.46	
	-OH	3.3	4.48	

As [TABLE 20.4](#) shows, an electron-donating (activating) group such as methoxy decreases acidity by destabilizing the carboxylate anion, and an electron-withdrawing (deactivating) group such as nitro increases acidity by stabilizing the carboxylate anion.

Because it's much easier to measure the acidity of a substituted benzoic acid than it is to determine the relative reactivity of an aromatic ring toward electrophilic substitution, the correlation between the two effects is useful for predicting reactivity. If we want to know the effect of a certain substituent on electrophilic reactivity, we can simply find the acidity of the corresponding benzoic acid. Worked Example 20.1 gives an illustration.

WORKED EXAMPLE 20.1

Predicting the Effect of a Substituent on the Reactivity of an Aromatic Ring toward Electrophilic Substitution

The $\text{p}K_{\text{a}}$ of *p*-(trifluoromethyl)benzoic acid is 3.6. Is the trifluoromethyl substituent an activating or deactivating group in electrophilic aromatic substitution?

Strategy

Decide whether *p*-(trifluoromethyl)benzoic acid is stronger or weaker than benzoic acid. A substituent that strengthens the acid is a deactivating group because it withdraws electrons, and a substituent that weakens the acid is an activating group because it donates electrons.

Solution

A $\text{p}K_{\text{a}}$ of 3.6 means that *p*-(trifluoromethyl)benzoic acid is stronger than benzoic acid, whose $\text{p}K_{\text{a}}$ is 4.19. Thus, the trifluoromethyl substituent favors dissociation by helping stabilize the negative charge. Trifluoromethyl must therefore be an electron-withdrawing, deactivating group.

PROBLEM Which would you expect to be a stronger acid, the lactic acid found in tired muscles or acetic acid?

20-6 Explain.

PROBLEM Dicarboxylic acids have two dissociation constants, one for the initial dissociation into a monoanion and one for the second dissociation into a dianion. For oxalic acid, $\text{HO}_2\text{C}-\text{CO}_2\text{H}$, the first ionization constant is $\text{p}K_{\text{a}1} = 1.2$ and the second ionization constant is $\text{p}K_{\text{a}2} = 4.2$. Why is the second carboxyl group far less acidic than the first?

20-7

PROBLEM The $\text{p}K_{\text{a}}$ of *p*-cyclopropylbenzoic acid is 4.45. Is cyclopropylbenzene likely to be more reactive or less reactive than benzene toward electrophilic bromination?

20-8

PROBLEM Rank the following compounds in order of increasing acidity. Don't look at a table of $\text{p}K_{\text{a}}$ data to help with your answer.

20-9

(a) Benzoic acid, *p*-methylbenzoic acid, *p*-chlorobenzoic acid

(b) *p*-Nitrobenzoic acid, acetic acid, benzoic acid

20.5 Preparing Carboxylic Acids

Let's review briefly some of the methods for preparing carboxylic acids that we've seen in previous chapters.

- Oxidation of a substituted alkylbenzene with KMnO_4 gives a substituted benzoic acid (Section 16.8). Both primary and secondary alkyl groups can be oxidized, but tertiary groups are not affected.

- Oxidation of a primary alcohol or an aldehyde yields a carboxylic acid (Section 17.7 and Section 19.3). Primary alcohols are often oxidized with the Dess Martin periodinane, and aldehydes are similarly oxidized with alkaline KMnO_4 .

Hydrolysis of Nitriles

Carboxylic acids can be prepared from nitriles on heating with aqueous acid or base by a mechanism that we'll discuss in Section 20.7. Since nitriles themselves are usually made by $\text{S}_{\text{N}}2$ reaction of a primary or secondary alkyl halide with CN^- , the two-step sequence of cyanide displacement followed by nitrile hydrolysis is a good way to make a carboxylic acid from an alkyl halide ($\text{RBr} \rightarrow \text{RC}\equiv\text{N} \rightarrow \text{RCO}_2\text{H}$). Note that the product acid has one more carbon than the starting alkyl halide. One example occurs in a commercial route for the synthesis of the nonsteroidal anti-inflammatory drug ibuprofen. (See **Chapter 15 Chemistry Matters.**)

Carboxylation of Grignard Reagents

Another method for preparing carboxylic acids is by reaction of a Grignard reagent with CO_2 to yield a metal carboxylate, followed by protonation to give a carboxylic acid. This **carboxylation** reaction is usually carried out by bubbling a stream of dry CO_2 gas through a solution of the Grignard reagent. The organomagnesium halide adds to a $\text{C}=\text{O}$ bond of carbon dioxide in a typical nucleophilic carbonyl addition reaction, and protonation of

the carboxylate by addition of aqueous HCl in a separate step then gives the free carboxylic acid. For example:

As noted previously, there are no Grignard reagents inside living cells, but there are other types of stabilized carbanions that are often carboxylated. One of the initial steps in fatty-acid biosynthesis, for instance, involves the formation of a carbanion from acetyl CoA, followed by carboxylation to yield malonyl CoA.

WORKED EXAMPLE 20.2

Devising a Synthesis Route for a Carboxylic Acid

How would you prepare phenylacetic acid ($\text{PhCH}_2\text{CO}_2\text{H}$) from benzyl bromide (PhCH_2Br)?

Strategy

We've seen two methods for preparing carboxylic acids from alkyl halides: (1) cyanide ion displacement followed by hydrolysis and (2) formation of a Grignard reagent followed by carboxylation. The first method involves an $\text{S}_{\text{N}}2$ reaction and is therefore limited to use with primary and some secondary alkyl halides. The second method involves formation of a Grignard reagent and is therefore limited to use with organic halides that have no acidic hydrogens or reactive functional groups elsewhere in the molecule. In the present instance, either method would work well.

Solution

PROBLEM How would you prepare the following carboxylic acids?

20-10 (a) $(\text{CH}_3)_3\text{CCO}_2\text{H}$ from $(\text{CH}_3)_3\text{CCl}$ **(b)** $\text{CH}_3\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$ from $\text{CH}_3\text{CH}_2\text{CH}_2\text{Br}$

20.6 Reactions of Carboxylic Acids: An Overview

We commented earlier in this chapter that carboxylic acids are similar in some respects to both alcohols and

ketones. Like alcohols, carboxylic acids can be deprotonated to give anions, which are good nucleophiles in S_N2 reactions. Like ketones, carboxylic acids undergo addition of nucleophiles to the carbonyl group. However, carboxylic acids also undergo other reactions characteristic of neither alcohols nor ketones. **FIGURE 20.3** shows some of the general reactions of carboxylic acids.

FIGURE 20.3 Some general reactions of carboxylic acids.

Reactions of carboxylic acids can be grouped into the four categories indicated in **FIGURE 20.3**. Of the four, we've already discussed the acidic behavior of carboxylic acids in **Section 20.2** through **Section 20.4**, and we mentioned reduction by treatment with LiAlH_4 in **Section 17.4**. The remaining two categories are examples of fundamental carbonyl-group reaction mechanisms—nucleophilic acyl substitution and α substitution—that will be discussed in detail in Chapters 21 and 22.

PROBLEM How might you prepare 2-phenylethanol from benzyl bromide? More than one step is needed.

PROBLEM How might you carry out the following transformation? More than one step is needed.

20.7 Chemistry of Nitriles

Nitriles are analogous to carboxylic acids in that both have a carbon atom with three bonds to an electronegative atom and both contain a π bond. Thus, some reactions of nitriles and carboxylic acids are similar. Both kinds of compounds are electrophiles, for instance, and both undergo nucleophilic addition reactions.

Nitriles occur infrequently in living organisms, although several hundred examples are known. Cyanocycline A, for instance, has been isolated from the bacterium *Streptomyces lavendulae* and was found to have both antimicrobial and antitumor activity. In addition, more than 1000 compounds called *cyanogenic glycosides* are known. Derived primarily from plants, cyanogenic glycosides contain a sugar with an acetal carbon, one oxygen of which is bonded to a nitrile-bearing carbon (sugar-O-C-CN). On hydrolysis with aqueous acid, the acetal is cleaved (**Section 19.10**), generating a cyanohydrin ($\text{HO}-\text{C}-\text{CN}$), which releases hydrogen cyanide. It's thought that the primary function of cyanogenic glycosides is to protect the plant by poisoning any animal foolish enough to eat it. Lotaustralin from the cassava plant is an example.

Preparation of Nitriles

The simplest method of nitrile preparation is the S_N2 reaction of CN^- with a primary or secondary alkyl halide, as discussed in Section 20.5. Another method for preparing nitriles is by dehydration of a primary amide, $RCONH_2$. Thionyl chloride is often used for this reaction, although other dehydrating agents such as $POCl_3$ also work.

The dehydration occurs by initial reaction of SOCl_2 on the nucleophilic amide oxygen atom, followed by deprotonation and a subsequent $E2$ -like elimination reaction.

Both methods of nitrile synthesis— S_N2 displacement by CN^- on an alkyl halide and amide dehydration—are useful, but the synthesis from amides is more general because it is not limited by steric hindrance.

Reactions of Nitriles

Like a carbonyl group, a nitrile group is strongly polarized and has an electrophilic carbon atom. Nitriles therefore react with nucleophiles to yield sp^2 -hybridized imine anions in a reaction analogous to the formation of a sp^3 -hybridized alkoxide ion by nucleophilic addition to a carbonyl group.

Some general reactions of nitriles are shown in **FIGURE 20.4**.

FIGURE 20.4 Some reactions of nitriles.

Hydrolysis: Conversion of Nitriles into Carboxylic Acids

Among the most useful reactions of nitriles is their hydrolysis to yield first an amide and then a carboxylic acid plus ammonia or an amine. The reaction occurs in either basic or acidic aqueous solution:

As shown in **FIGURE 20.5**, base-catalyzed nitrile hydrolysis involves nucleophilic addition of hydroxide ion to the polar $\text{C}\equiv\text{N}$ bond to give an imine anion in a process similar to the nucleophilic addition to a polar $\text{C}=\text{O}$ bond to give an alkoxide anion. Protonation then gives a hydroxy imine, which tautomerizes (**Section 9.4**) to an amide in a step similar to the tautomerization of an enol to a ketone. Further hydrolysis gives a carboxylate ion.

FIGURE 20.5 MECHANISM

Mechanism for the basic hydrolysis of a nitrile to yield an amide, which is then hydrolyzed further to a carboxylic acid anion.

1 Nucleophilic addition of hydroxide ion to the CN triple bond gives an imine anion addition product.

2 Protonation of the imine anion by water yields a hydroxyimine and regenerates the base catalyst.

3 Tautomerization of the hydroxyimine yields an amide in a reaction analogous to the tautomerization of an enol to give a ketone.

4 Further hydrolysis of the amide gives the anion of a carboxylic acid by a mechanism we'll discuss in **Section 21.7**.

The further hydrolysis of the amide intermediate takes place by a nucleophilic addition of hydroxide ion to the amide carbonyl group, which yields a tetrahedral alkoxide ion. Expulsion of amide ion, NH_2^- , as leaving group gives the carboxylate ion, thereby driving the reaction toward the products. Subsequent acidification in a separate step yields the carboxylic acid. We'll look at this process in more detail in **Section 21.7**.

Reduction: Conversion of Nitriles into Amines

Reduction of a nitrile with LiAlH_4 gives a primary amine, RNH_2 . The reaction occurs by nucleophilic addition of hydride ion to the polar $\text{C}\equiv\text{N}$ bond, yielding an imine anion, which still contains a $\text{C}=\text{N}$ bond and therefore undergoes a second nucleophilic addition of hydride to give a *dianion*. Both monoanion and dianion intermediates are undoubtedly stabilized by Lewis acid–base complexation to an aluminum species, facilitating the second addition that would otherwise be difficult. Protonation of the dianion by addition of water in a subsequent step gives the amine.

Reaction of Nitriles with Grignard Reagents

Grignard reagents add to a nitrile to give an intermediate imine anion that is hydrolyzed by addition of water to yield a ketone. The mechanism of the hydrolysis is the exact reverse of imine formation (see **FIGURE 19.7**).

This reaction is similar to the reduction of a nitrile to an amine, except that only one nucleophilic addition occurs rather than two and the attacking nucleophile is a carbanion (R'^-) rather than a hydride ion. For example:

WORKED EXAMPLE 20.3

Synthesizing a Ketone from a Nitrile

How would you prepare 2-methyl-3-pentanone from a nitrile?

Strategy

A ketone results from the reaction between a Grignard reagent and a nitrile, with the $\text{C}\equiv\text{N}$ carbon of the nitrile becoming the carbonyl carbon. Identify the two groups attached to the carbonyl carbon atom in the product. One will come from the Grignard reagent and the other will come from the nitrile.

Solution

There are two possibilities.

PROBLEM How would you prepare the following carbonyl compounds from a nitrile?

20-13

PROBLEM How would you prepare 1-phenyl-2-butanone, $\text{C}_6\text{H}_5\text{CH}_2\text{COCH}_2\text{CH}_3$, from benzyl bromide, **20-14** $\text{C}_6\text{H}_5\text{CH}_2\text{Br}$? More than one step is needed.

20.8 Spectroscopy of Carboxylic Acids and Nitriles

Infrared Spectroscopy

Carboxylic acids have two characteristic IR absorptions that make the $-\text{CO}_2\text{H}$ group easily identifiable. The O–H bond of the carboxyl group gives rise to a very broad absorption over the range 2500 to 3300 cm^{-1} . The C=O bond shows an absorption between 1710 and 1760 cm^{-1} . The exact position of C=O absorption depends both on the structure of the molecule and on whether the acid is free (monomeric) or hydrogen-bonded (dimeric). Free carboxyl groups absorb at 1760 cm^{-1} , but the more commonly encountered dimeric carboxyl groups absorb in a broad band centered around 1710 cm^{-1} . As with other carbonyl-containing functional groups, conjugation with an alkene or benzene ring lowers the frequency of the C=O stretch by 20 to 30 cm^{-1} .

Both the broad O–H absorption and the C=O absorption at 1710 cm^{-1} (dimeric) are identified in the IR spectrum of butanoic acid shown in **FIGURE 20.6**.

FIGURE 20.6 IR spectrum of butanoic acid, $\text{CH}_3\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$.

Nitriles show an intense and easily recognizable $\text{C}\equiv\text{N}$ bond absorption near 2250 cm^{-1} for saturated compounds and 2230 cm^{-1} for aromatic and conjugated molecules. Few other functional groups absorb in this region, so IR spectroscopy is highly diagnostic for nitriles.

PROBLEM Cyclopentanecarboxylic acid and 4-hydroxycyclohexanone have the same formula ($\text{C}_6\text{H}_{10}\text{O}_2$), and **20-15** both contain an $-\text{OH}$ and a $\text{C}=\text{O}$ group. How could you distinguish between them using IR spectroscopy?

Nuclear Magnetic Resonance Spectroscopy

Carboxyl carbon atoms absorb in the range 165 to $185\text{ }\delta$ in the ^{13}C NMR spectrum, with aromatic and α,β -unsaturated acids near the upfield end of the range ($\sim 165\text{ }\delta$) and saturated aliphatic acids near the downfield end ($\sim 185\text{ }\delta$). Nitrile carbons absorb in the range 115 to $130\text{ }\delta$.

In the ^1H NMR spectrum, the acidic $-\text{CO}_2\text{H}$ proton normally absorbs as a singlet near $12\ \delta$. The chemical shift of the carboxyl proton is concentration and solvent dependent, as these variables can change the extent of hydrogen-bonding in the sample. In some cases, the carboxyl-proton resonance is broadened to the point of being nearly undetectable. Traces of water in the sample can exacerbate the situation. As with alcohols (Section 17.11), the $-\text{CO}_2\text{H}$ proton can be replaced by deuterium when D_2O is added to the sample tube, causing the absorption to disappear from the NMR spectrum. FIGURE 20.7 shows the ^1H NMR spectrum of phenylacetic acid. Note that the $-\text{CO}_2\text{H}$ absorption occurs at $12.0\ \delta$.

FIGURE 20.7 Proton NMR spectrum of phenylacetic acid, $\text{C}_6\text{H}_5\text{CH}_2\text{CO}_2\text{H}$.

PROBLEM How could you distinguish between the isomers cyclopentanecarboxylic acid and 20-16 4-hydroxycyclohexanone by ^1H and ^{13}C NMR spectroscopy? (See Problem 20-15.)

CHEMISTRY MATTERS

Vitamin C

The word *vitamin*, despite its common usage, is actually an imprecise term. Generally speaking, a vitamin is an organic substance that a given organism requires in small amounts to live and grow but is unable to synthesize and must obtain in its diet. Thus, to be considered a vitamin, only a *small* amount of the substance is needed—anywhere from a few micrograms to 100 mg or so per day. Dietary substances needed in larger amounts, such as some amino acids and unsaturated fats, are not considered vitamins.

FIGURE 20.8 In addition to the hazards of weather, participants in early polar expeditions often suffered from scurvy, caused by a dietary vitamin C deficiency. (credit: “Shackleton’s expedition to the Antarctic last moments of the Endurance” by Underwood & Underwood/Wikimedia Commons, Public Domain)

Furthermore, different organisms need different vitamins. More than 4000 species of mammals can synthesize ascorbic acid in their bodies, for instance, but humans are not among them. Ascorbic acid is therefore a human vitamin—what we all know as vitamin C—and must be provided by our diet. Small amounts of more than a dozen other substances are similarly required by humans: retinol (vitamin A), thiamine (vitamin B₁), and tocopherol (vitamin E), for instance.

Vitamin C is surely the best known of all human vitamins. It was the first to be discovered (1912), the first to be isolated (1928), the first to be structurally characterized (1933), and the first to be synthesized in the laboratory (1933). Over 121,000 tons of vitamin C is synthesized worldwide each year, more than the total amount of all other vitamins combined. In addition to its use as a supplement, vitamin C is used as a food preservative, a “flour improver” in bakeries, and an animal-food additive.

Vitamin C is perhaps most well-known for its antiscorbutic properties, meaning that it prevents the onset of scurvy, a bleeding disease affecting those with a deficiency of fresh vegetables and citrus fruits in their diet. Sailors in the Age of Exploration were particularly susceptible to scurvy, and the death toll was high. The

Portuguese explorer Vasco da Gama lost more than half his crew to scurvy during his two-year voyage around the Cape of Good Hope in 1497–1499.

More recently, large doses of vitamin C have been claimed to prevent the common cold, cure infertility, delay the onset of symptoms in acquired immunodeficiency syndrome (AIDS), and inhibit the development of gastric and cervical cancers. None of these claims have been backed by medical evidence, however. In the largest study yet of the effect of vitamin C on the common cold, a meta-analysis of more than 100 separate trials covering 40,000 people found no difference in the incidence of colds between those who took supplemental vitamin C regularly and those who did not. When taken *during* a cold, however, vitamin C does appear to decrease the cold's duration by perhaps a day.

The industrial preparation of vitamin C involves an unusual blend of biological and laboratory organic chemistry, beginning with glucose and following the five-step route shown in **FIGURE 20.9**. Glucose, a pentahydroxy aldehyde, is first reduced to sorbitol, which is then oxidized by the microorganism *Acetobacter suboxydans*. No chemical reagent is known that is selective enough to oxidize only one of the six alcohol groups in sorbitol, so an enzymatic reaction is used. Treatment with acetone and an acid catalyst then converts four of the other hydroxyl groups into acetal linkages, and the remaining hydroxyl group is chemically oxidized to a carboxylic acid by reaction with aqueous NaOCl (household bleach). Hydrolysis with acid then removes the two acetal groups and causes an internal ester-forming reaction to give ascorbic acid. Each of the five steps has a yield better than 90%.

FIGURE 20.9 The industrial synthesis of ascorbic acid from glucose.

Key Terms

- **carboxyl group**
- **carboxylation**
- **carboxylic acid, RCO₂H**
- **Henderson–Hasselbalch equation**
- **nitrile**

Summary

Carboxylic acids are among the most useful building blocks for synthesizing other molecules, both in nature and in the laboratory. Thus, an understanding of their properties and reactions is fundamental to understanding biological chemistry. In this chapter, we've looked both at acids and at their close relatives, **nitriles (RC≡N)**.

Carboxylic acids are named systematically by replacing the terminal *-e* of the corresponding alkane name with *-oic acid*. Like aldehydes and ketones, the carbonyl carbon atom is sp^2 -hybridized; like alcohols, carboxylic acids are associated through hydrogen-bonding and therefore have high boiling points.

The distinguishing characteristic of carboxylic acids is their acidity. Although weaker than mineral acids such as HCl, carboxylic acids dissociate much more readily than alcohols because the resultant carboxylate ions are stabilized by resonance between two equivalent forms.

Most carboxylic acids have pK_a values near 5, but the exact pK_a of a given acid depends on structure. Carboxylic acids substituted by electron-withdrawing groups are more acidic (have a lower pK_a) because their carboxylate ions are stabilized. Carboxylic acids substituted by electron-donating groups are less acidic (have a higher pK_a) because their carboxylate ions are destabilized. The extent of dissociation of a carboxylic acid in a buffered solution of a given pH can be calculated with the Henderson–Hasselbalch equation. Inside living cells, where the physiological pH = 7.3, carboxylic acids are entirely dissociated and exist as their carboxylate anions.

Methods of synthesis for carboxylic acids include (1) oxidation of alkylbenzenes, (2) oxidation of primary alcohols or aldehydes, (3) reaction of Grignard reagents with CO_2 (**carboxylation**), and (4) hydrolysis of nitriles. General reactions of carboxylic acids include (1) loss of the acidic proton, (2) nucleophilic acyl substitution at the carbonyl group, (3) substitution on the α carbon, and (4) reduction.

Nitriles are similar in some respects to carboxylic acids and are prepared either by S_N2 reaction of an alkyl halide with cyanide ion or by dehydration of an amide. Nitriles undergo nucleophilic addition to the polar $C\equiv N$ bond in the same way that carbonyl compounds do. The most important reactions of nitriles are their hydrolysis to carboxylic acids, reduction to primary amines, and reaction with Grignard reagents to yield ketones.

Carboxylic acids and nitriles are easily distinguished spectroscopically. Acids show a characteristic IR absorption at 2500 to 3300 cm^{-1} due to the O–H bond and another at 1710 to 1760 cm^{-1} due to the $C=O$ bond; nitriles have an absorption at 2250 cm^{-1} . Acids also show ^{13}C NMR absorptions at 165 to 185 δ and 1H NMR absorptions near 12 δ . Nitriles have a ^{13}C NMR absorption in the range 115 to 130 δ .

Summary of Reactions

1. Preparation of carboxylic acids (Section 20.5)

a. Carboxylation of Grignard reagents

b. Hydrolysis of nitriles

2. Preparation of nitriles (Section 20.7)

a. S_N2 reaction of alkyl halides

b. Dehydration of amides

3. Reactions of nitriles (Section 20.7)

a. Hydrolysis to yield carboxylic acids

b. Reduction to yield primary amines

c. Reaction with Grignard reagents to yield ketones

Additional Problems

Visualizing Chemistry

PROBLEM Give IUPAC names for the following carboxylic acids (reddish brown = Br):

20-17 (a)

(b)

(c)

(d)

PROBLEM Would you expect the following carboxylic acids to be more acidic or less acidic than benzoic acid?

20-18 Explain. (Reddish brown = Br.)

(a)

(b)

PROBLEM The following carboxylic acid can't be prepared from an alkyl halide by either the nitrile hydrolysis

20-19 route or the Grignard carboxylation route. Explain.

PROBLEM 20-20 Electrostatic potential maps of anisole and thioanisole are shown. Which do you think is the stronger acid, *p*-methoxybenzoic acid or *p*-(methylthio)benzoic acid? Explain.

Anisole (C₆H₅OCH₃)Thioanisole (C₆H₅SCH₃)

Mechanism Problems

PROBLEM 20-21 Predict the product(s) and write the mechanism of each of the following reactions:

PROBLEM 20-22 Predict the product(s) and write the mechanism of each of the following reactions:

PROBLEM 20-23 Predict the product(s) and write the mechanism of each of the following reactions:

PROBLEM 20-24 Predict the product(s) and write the complete mechanism of each of the following reactions:

PROBLEM 20-25 Acid-catalyzed hydrolysis of a nitrile to give a carboxylic acid occurs by initial protonation of the nitrogen atom, followed by nucleophilic addition of water. Review the mechanism of base-catalyzed nitrile hydrolysis in Section 20.7 and then predict the products for the following reactions. Write the steps involved in the acid-catalyzed reaction, using curved arrows.

PROBLEM 20-26 Nitriles can be converted directly to esters by the Pinner reaction, which first produces an iminoester salt that is isolated and then treated with water to give the final product. Propose a mechanism for the Pinner reaction using curved arrows to show the flow of electrons at each step.

- PROBLEM 20-27** Naturally occurring compounds called *cyanogenic glycosides*, such as lotaustralin, release hydrogen cyanide, HCN, when treated with aqueous acid. The reaction occurs by hydrolysis of the acetal linkage to form a cyanohydrin, which then expels HCN and gives a carbonyl compound.
- (a) Show the mechanism of the acetal hydrolysis and the structure of the cyanohydrin that results.
- (b) Propose a mechanism for the loss of HCN, and show the structure of the carbonyl compound that forms.

- PROBLEM 20-28** 2-Bromo-6,6-dimethylcyclohexanone gives 2,2-dimethylcyclopentanecarboxylic acid on treatment with aqueous NaOH followed by acidification, a process called the Favorskii reaction. Propose a mechanism.

- PROBLEM 20-29** Naturally occurring compounds called *terpenoids*, which we'll discuss in **Section 27.5**, are biosynthesized by a pathway that involves loss of CO₂ from 3-phosphomevalonate 5-diphosphate to yield isopentenyl diphosphate. Use curved arrows to show the mechanism of this reaction.

- PROBLEM 20-30** In the Ritter reaction, an alkene reacts with a nitrile in the presence of strong aqueous sulfuric acid to yield an amide. Propose a mechanism.

Naming Carboxylic Acids and Nitriles

- PROBLEM 20-31** Give IUPAC names for the following compounds:

PROBLEM Draw structures corresponding to the following IUPAC names:

- 20-32** (a) *cis*-1,2-Cyclohexanedicarboxylic acid (b) Heptanedioic acid (c) 2-Hexen-4-ynoic acid
 (d) 4-Ethyl-2-propyloctanoic acid (e) 3-Chlorophthalic acid (f) Triphenylacetic acid
 (g) 2-Cyclobutenecarbonitrile (h) *m*-Benzoylbenzotrile

PROBLEM Draw and name the following compounds:

- 20-33** (a) The eight carboxylic acids with the formula $C_6H_{12}O_2$
 (b) Three nitriles with the formula C_5H_7N

PROBLEM Pregabalin, marketed as Lyrica, is an anticonvulsant drug that is also effective in treating chronic pain. The IUPAC name of pregabalin is (*S*)-3-(aminomethyl)-5-methylhexanoic acid. (An aminomethyl group is $-CH_2NH_2$.) Draw the structure of pregabalin.

PROBLEM Isocitric acid, an intermediate in the citric acid cycle of food metabolism, has the systematic name

- 20-35** (2*R*,3*S*)-3-carboxy-2-hydroxypentanedioic acid. Draw the structure.

Acidity of Carboxylic Acids

PROBLEM Order the compounds in each of the following sets with respect to increasing acidity:

- 20-36** (a) Acetic acid, oxalic acid, formic acid
 (b) *p*-Bromobenzoic acid, *p*-nitrobenzoic acid, 2,4-dinitrobenzoic acid
 (c) Fluoroacetic acid, 3-fluoropropanoic acid, iodoacetic acid

PROBLEM Arrange the compounds in each of the following sets in order of increasing basicity:

- 20-37** (a) Magnesium acetate, magnesium hydroxide, methylmagnesium bromide
 (b) Sodium benzoate, sodium *p*-nitrobenzoate, sodium acetylide
 (c) Lithium hydroxide, lithium ethoxide, lithium formate

PROBLEM Calculate the pK_a 's of the following acids:

- 20-38** (a) Lactic acid, $K_a = 8.4 \times 10^{-4}$ (b) Acrylic acid, $K_a = 5.6 \times 10^{-6}$

PROBLEM Calculate the K_a 's of the following acids:

- 20-39** (a) Citric acid, $pK_a = 3.14$ (b) Tartaric acid, $pK_a = 2.98$

PROBLEM Thioglycolic acid, $HSCH_2CO_2H$, a substance used in depilatory agents (hair removers) has $pK_a = 3.42$. What is the percent dissociation of thioglycolic acid in a buffer solution at $pH = 3.0$?

PROBLEM In humans, the final product of purine degradation from DNA is uric acid, $pK_a = 5.61$, which is excreted in the urine. What is the percent dissociation of uric acid in urine at a typical $pH = 6.0$? Why do you think uric acid is acidic even though it does not have a CO_2H group?

PROBLEM Some pK_a data for simple dibasic acids is shown. How can you account for the fact that the difference between the first and second ionization constants decreases with increasing distance between the carboxyl groups?

Name	Structure	pK_1	pK_2
Oxalic	HO_2CCO_2H	1.2	4.2

Succinic	HO ₂ CCH ₂ CH ₂ CO ₂ H	4.2	5.6
Adipic	HO ₂ C(CH ₂) ₄ CO ₂ H	4.4	5.4

Reactions of Carboxylic Acids and Nitriles

PROBLEM How could you convert butanoic acid into the following compounds? Write each step showing the reagents needed.

20-43

(a) 1-Butanol (b) 1-Bromobutane (c) Pentanoic acid (d) 1-Butene (e) Octane

PROBLEM How could you convert each of the following compounds into butanoic acid? Write each step showing all reagents.

20-44

(a) 1-Butanol (b) 1-Bromobutane (c) 1-Butene (d) 1-Bromopropane (e) 4-Octene

PROBLEM How could you convert butanenitrile into the following compounds? Write each step showing the reagents needed.

20-45

(a) 1-Butanol (b) Butylamine (c) 2-Methyl-3-hexanone

PROBLEM How would you prepare the following compounds from benzene? More than one step is needed in each case.

20-46

(a) *m*-Chlorobenzoic acid (b) *p*-Bromobenzoic acid (c) Phenylacetic acid, C₆H₅CH₂CO₂H

PROBLEM Predict the product of the reaction of *p*-methylbenzoic acid with each of the following:

20-47 (a) LiAlH₄, then H₃O⁺ (b) *N*-Bromosuccinimide in CCl₄ (c) CH₃MgBr in ether, then H₃O⁺

(d) KMnO₄, H₃O⁺

PROBLEM Using ¹³C₂O₂ as your only source of labeled carbon, along with any other compounds needed, how would you synthesize the following compounds?

20-48

(a) CH₃CH₂¹³CO₂H (b) CH₃¹³CH₂CO₂H

PROBLEM How would you carry out the following transformations?

20-49

PROBLEM Which method—Grignard carboxylation or nitrile hydrolysis—would you use for each of the following reactions? Explain.

20-50

PROBLEM 1,6-Hexanediamine, a starting material needed for making nylon, can be made from 1,3-butadiene.

20-51 How would you accomplish the synthesis?

PROBLEM 3-Methyl-2-hexenoic acid (mixture of *E* and *Z* isomers) has been identified as the substance
20-52 responsible for the odor of human sweat. Synthesize the compound from starting materials having five or fewer carbons.

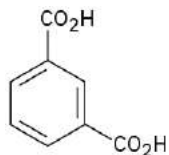

Spectroscopy

PROBLEM Propose a structure for a compound $C_6H_{12}O_2$ that dissolves in dilute NaOH and shows the following
20-53 1H NMR spectrum: 1.08 δ (9 H, singlet), 2.2 δ (2 H, singlet), and 11.2 δ (1 H, singlet).

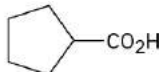

PROBLEM What spectroscopic method could you use to distinguish among the following three isomeric acids?
20-54 Tell what characteristic features you would expect for each acid.

PROBLEM How would you use NMR (either ^{13}C or 1H) to distinguish between the following pairs of isomers?

20-55 (a)  and  (b) $HO_2CCH_2CH_2CO_2H$ and $CH_3CH(CO_2H)_2$

(c) $CH_3CH_2CH_2CO_2H$ and $HOCH_2CH_2CH_2CHO$

(d) $(CH_3)_2C=CHCH_2CO_2H$ and 

PROBLEM Compound A, $C_4H_8O_3$, has infrared absorptions at 1710 and 2500 to 3100 cm^{-1} and has the 1H
20-56 NMR spectrum shown. Propose a structure for A.

General Problems

PROBLEM A chemist in need of 2,2-dimethylpentanoic acid decided to synthesize some by reaction of
20-57 2-chloro-2-methylpentane with NaCN, followed by hydrolysis of the product. After the reaction sequence was carried out, however, none of the desired product could be found. What do you suppose went wrong?

PROBLEM Show how you might prepare the anti-inflammatory agent ibuprofen starting from
20-58 isobutylbenzene. More than one step is needed.

PROBLEM The following synthetic schemes all have at least one flaw in them. What is wrong with each?

PROBLEM *p*-Aminobenzoic acid (PABA) was once widely used as a sunscreen agent. Propose a synthesis of PABA starting from toluene.

20-60 PABA starting from toluene.

PROBLEM Propose a synthesis of the anti-inflammatory drug fenclorac from phenylcyclohexane.

PROBLEM The pK_a 's of five *p*-substituted benzoic acids ($\text{Y-C}_6\text{H}_4\text{CO}_2\text{H}$) are listed below. Rank the corresponding substituted benzenes ($\text{Y-C}_6\text{H}_5$) in order of their increasing reactivity toward electrophilic aromatic substitution. If benzoic acid has $pK_a = 4.19$, which of the substituents are activators and which are deactivators?

Substituent Y	pK_a of $\text{Y-C}_6\text{H}_4\text{CO}_2\text{H}$
$-\text{Si}(\text{CH}_3)_3$	4.27
$-\text{CH}=\text{CHC}\equiv\text{N}$	4.03
$-\text{HgCH}_3$	4.10
$-\text{OSO}_2\text{CH}_3$	3.84
$-\text{PCl}_2$	3.59

PROBLEM How would you carry out the following transformations? More than one step is needed in each case.

PROBLEM The following pK_a values have been measured. Explain why a hydroxyl group in the para position decreases the acidity while a hydroxyl group in the meta position increases the acidity.

PROBLEM Identify the missing reagents **a–f** in the following scheme:

20-65

PROBLEM Propose a structure for a compound, C_4H_7N , that has the following IR and 1H NMR spectra:

20-66

PROBLEM The two 1H NMR spectra shown here belong to crotonic acid ($trans\text{-CH}_3\text{CH}=\text{CHCO}_2\text{H}$) and methacrylic acid [$\text{H}_2\text{C}=\text{C}(\text{CH}_3)\text{CO}_2\text{H}$]. Which spectrum corresponds to which acid? Explain.

PROBLEM 20-68 The ^1H and ^{13}C NMR spectra below belong to a compound with formula $\text{C}_6\text{H}_{10}\text{O}_2$. Propose a structure for this compound.

PROBLEM 20-69 Propose structures for carboxylic acids that show the following peaks in their ^{13}C NMR spectra. Assume that the kinds of carbons (1° , 2° , 3° , or 4°) have been assigned by DEPT-NMR.

(a) $C_7H_{12}O_2$: 25.5 δ (2°), 25.9 δ (2°), 29.0 δ (2°), 43.1 δ (3°), 183.0 δ (4°)

(b) $C_8H_8O_2$: 21.4 δ (1°), 128.3 δ (4°), 129.0 δ (3°), 129.7 δ (3°), 143.1 δ (4°), 168.2 δ (4°)

PROBLEM Carboxylic acids having a second carbonyl group two atoms away lose CO_2 (*decarboxylate*) through an intermediate enolate ion when treated with base. Write the mechanism of this decarboxylation reaction using curved arrows to show the electron flow in each step.

21.10 Spectroscopy of Carboxylic Acid Derivatives

WHY THIS CHAPTER? Carboxylic acid derivatives are among the most widely occurring of all molecules, both in laboratory chemistry and in biological pathways. Thus, a study of them and their primary reaction—nucleophilic acyl substitution—is fundamental to understanding organic chemistry. We'll begin this chapter by first learning about carboxylic acid derivatives, and we'll then explore the chemistry of acyl substitution reactions.

Closely related to the carboxylic acids and nitriles discussed in the previous chapter are the **carboxylic acid**

derivatives, compounds in which an acyl group is bonded to an electronegative atom or substituent that can act as a leaving group in the nucleophilic acyl substitution reaction that we saw briefly in the **Preview of Carbonyl Chemistry**:

Many kinds of acid derivatives are known, but we'll be concerned primarily with four of the most common ones: **acid halides**, **acid anhydrides**, **esters**, and **amides**. Acid halides and acid anhydrides are used only in the laboratory, while esters and amides are common in both laboratory and biological chemistry. In addition, carboxylic acid derivatives called **thioesters** and **acyl phosphates** are encountered primarily in biological chemistry. Note the structural similarity between acid anhydrides and acyl phosphates.

21.1 Naming Carboxylic Acid Derivatives

Acid Halides, RCOX

Acid halides are named by identifying first the acyl group and then the halide. As described in **Section 20.1** and shown in **TABLE 20.1**, the acyl group name is derived from the carboxylic acid name by replacing the *-ic acid* or *-oic acid* ending with *-oyl*, or the *-carboxylic acid* ending with *-carbonyl*. To keep things interesting, however, IUPAC recognizes eight exceptions for which a *-yl* rather than an *-oyl* ending is used: formic (formyl), acetic (acetyl), propionic (propionyl), butyric (butyryl), oxalic (oxaly), malonic (malonyl), succinic (succinyl), and glutaric (glutaryl).

Acid Anhydrides, RCO₂COR'

Symmetrical anhydrides of unsubstituted monocarboxylic acids and cyclic anhydrides of dicarboxylic acids are named by replacing the word *acid* with *anhydride*.

Unsymmetrical anhydrides—those prepared from two different carboxylic acids—are named by listing the two acids alphabetically and then adding *anhydride*.

Esters, $\text{RCO}_2\text{R}'$

Esters are named by first identifying the alkyl group attached to oxygen and then the carboxylic acid, with the *-ic acid* ending replaced by *-ate*.

Amides, RCONH_2

Amides with an unsubstituted $-\text{NH}_2$ group are named by replacing the *-oic acid* or *-ic acid* ending with *-amide*, or by replacing the *-carboxylic acid* ending with *-carboxamide*.

If the nitrogen atom is further substituted, the compound is named by first identifying the substituent groups and then the parent amide. The substituents are preceded by the letter *N* to identify them as being directly attached to nitrogen.

Thioesters, RCOSR'

Thioesters are named like the corresponding esters. If the related ester has a common name, the prefix *thio-* is added to the name of the carboxylate: acetate becomes thioacetate, for instance. If the related ester has a systematic name, the *-oate* or *-carboxylate* ending is replaced by *-thioate* or *-carbothioate*: butanoate becomes butanethioate and cyclohexanecarboxylate becomes cyclohexanecarbothioate, for instance.

Acyl Phosphates, $\text{RCO}_2\text{PO}_3^{2-}$ and $\text{RCO}_2\text{PO}_3\text{R}'^-$

Acyl phosphates are named by citing the acyl group and adding the word *phosphate*. If an alkyl group is attached to one of the phosphate oxygens, it is identified after the name of the acyl group. In biological chemistry, acyl

adenosyl phosphates are particularly common.

Benzoyl phosphate

Acetyl adenosyl phosphate

A summary of nomenclature rules for carboxylic acid derivatives is given in [TABLE 21.1](#).

TABLE 21.1 Nomenclature of Carboxylic Acid Derivatives

Functional group	Structure	Name ending
Carboxylic acid		-ic acid (-carboxylic acid)
Acid halide		-oyl halide (-carbonyl halide)
Acid anhydride		anhydride
Amide		-amide (-carboxamide)
Ester		-oate (-carboxylate)
Thioester		-thioate (-carbothioate)
Acyl phosphate		-oyl phosphate

PROBLEM Give IUPAC names for the following substances:

21-1 (a)

(b)

(c)

(d)

PROBLEM Draw structures corresponding to the following names:

- 21-2 (a) Phenyl benzoate (b) *N*-Ethyl-*N*-methylbutanamide (c) 2,4-Dimethylpentanoyl chloride
 (d) Methyl 1-methylcyclohexanecarboxylate (e) Ethyl 3-oxopentanoate
 (f) Methyl *p*-bromobenzenethioate (g) Formic propanoic anhydride
 (h) *cis*-2-Methylcyclopentanecarbonyl bromide

21.2 Nucleophilic Acyl Substitution Reactions

The addition of a nucleophile to a polar C=O bond is the key step in three of the four major carbonyl-group reactions. We saw in the chapter on **Aldehydes and Ketones: Nucleophilic Addition Reactions** that when a nucleophile adds to an aldehyde or ketone, the initially formed tetrahedral intermediate can be protonated to yield an alcohol. When a nucleophile adds to a carboxylic acid derivative, however, a different reaction path is taken. The initially formed tetrahedral intermediate eliminates one of the two substituents originally bonded to the carbonyl carbon, leading to a net **nucleophilic acyl substitution reaction** (FIGURE 21.2).

(a) Aldehyde or ketone: nucleophilic addition

(b) Carboxylic acid derivative: nucleophilic acyl substitution

FIGURE 21.2 The general mechanisms of nucleophilic addition and nucleophilic acyl substitution reactions. Both reactions begin with addition of a nucleophile to a polar C=O bond to give a tetrahedral, alkoxide ion intermediate. (a) The intermediate formed from an aldehyde or ketone is protonated to give an alcohol, but (b) the intermediate formed from a carboxylic acid derivative expels a leaving group to give a new carbonyl compound.

The difference in behavior between aldehydes/ketones and carboxylic acid derivatives is a consequence of structure. Carboxylic acid derivatives have an acyl carbon bonded to a group $-Y$ that can act as a leaving group, often as a stable anion. As soon as the tetrahedral intermediate is formed, the leaving group is expelled to generate a new carbonyl compound. Aldehydes and ketones, however, have no such leaving group, and therefore don't undergo substitution.

The net effect of the addition/elimination sequence is a substitution of the nucleophile for the $-Y$ group that was originally bonded to the acyl carbon. Thus, the overall reaction is superficially similar to the kind of nucleophilic substitution that occurs during an S_N2 reaction (Section 11.3), but the mechanisms of the two reactions are completely different. An S_N2 reaction occurs in a single step by backside displacement of the leaving group, while a nucleophilic acyl substitution takes place in two steps and involves a tetrahedral intermediate.

PROBLEM Show the mechanism of the following nucleophilic acyl substitution reaction, using curved arrows **21-3** to indicate the electron flow in each step:

Relative Reactivity of Carboxylic Acid Derivatives

Both the initial addition step and the subsequent elimination step can affect the overall rate of a nucleophilic acyl substitution reaction, but the addition is usually the rate-limiting step. Thus, any factor that makes the carbonyl group more reactive toward nucleophiles favors the substitution process.

Steric and electronic factors are both important in determining reactivity. Sterically, we find within a series of similar acid derivatives that unhindered, accessible carbonyl groups react with nucleophiles more readily than do sterically hindered carbonyl groups. The reactivity order is

The way in which various substituents affect the polarization of a carbonyl group is similar to the way they affect the reactivity of an aromatic ring toward electrophilic substitution (Section 16.4). A chlorine substituent, for example, inductively withdraws electrons from an acyl group in the same way that it withdraws electrons from and thus deactivates an aromatic ring. Similarly, amino, methoxyl, and methylthio substituents donate electrons to acyl groups by resonance in the same way that they donate electrons to, and thus activate, aromatic rings.

As a consequence of these reactivity differences, it's usually possible to convert a more reactive acid derivative into a less reactive one. Acid chlorides, for instance, can be directly converted into anhydrides, thioesters, esters, and amides, but amides can't be directly converted into esters, thioesters, anhydrides, or acid chlorides. Remembering the reactivity order is therefore a way to keep track of a large number of reactions (Figure 21.3). Another consequence, as noted previously, is that only acyl phosphates, thioesters, esters, and amides are commonly found in nature. Acid halides and acid anhydrides react so rapidly with water that they can't exist for long in living organisms.

FIGURE 21.3 Interconversions of carboxylic acid derivatives. A more reactive acid derivative can be converted into a less reactive one, but not vice versa.

In studying the chemistry of carboxylic acid derivatives in the next few sections, we'll be concerned largely with the reactions of just a few nucleophiles and will see that the same kinds of reactions tend to reoccur (Figure 21.4).

- **Hydrolysis** Reaction with water to yield a carboxylic acid
- **Alcoholysis** Reaction with an alcohol to yield an ester
- **Aminolysis** Reaction with ammonia or an amine to yield an amide
- **Reduction** Reaction with a hydride reducing agent to yield an aldehyde or an alcohol
- **Grignard reaction** Reaction with an organometallic reagent to yield a ketone or an alcohol

FIGURE 21.4 Some general reactions of carboxylic acid derivatives.

WORKED EXAMPLE 21.1

Predicting the Product of a Nucleophilic Acyl Substitution Reaction

Predict the product of the following nucleophilic acyl substitution reaction of benzoyl chloride with 2-propanol:

Strategy

A nucleophilic acyl substitution reaction involves the substitution of a nucleophile for a leaving group in a carboxylic acid derivative. Identify the leaving group (Cl^- in the case of an acid chloride) and the nucleophile (an alcohol in this case), and replace one by the other. The product is isopropyl benzoate.

Solution

PROBLEM 21-4 Rank the compounds in each of the following sets in order of their expected reactivity toward nucleophilic acyl substitution:

PROBLEM 21-5 Predict the products of the following nucleophilic acyl substitution reactions:

PROBLEM 21-6 The following structure represents a tetrahedral alkoxide ion intermediate formed by addition of a nucleophile to a carboxylic acid derivative. Identify the nucleophile, the leaving group, the starting acid derivative, and the ultimate product.

21.3 Reactions of Carboxylic Acids

The direct nucleophilic acyl substitution of a carboxylic acid is difficult because $-\text{OH}$ is a poor leaving group (Section 11.3). Thus, it's usually necessary to enhance the reactivity of the acid, either by using a strong acid catalyst to protonate the carboxyl and make it a better acceptor or by converting the $-\text{OH}$ into a better leaving group. Under the right circumstances, however, acid chlorides, anhydrides, esters, and amides can all be prepared from carboxylic acids by nucleophilic acyl substitution reactions.

Conversion of Carboxylic Acids into Acid Chlorides

In the laboratory, carboxylic acids are converted into acid chlorides by treatment with thionyl chloride, SOCl_2 .

This reaction occurs by a nucleophilic acyl substitution pathway in which the carboxylic acid is first converted into an acyl chlorosulfite intermediate, thereby replacing the $-\text{OH}$ of the acid with a much better leaving group. The chlorosulfite then reacts with a nucleophilic chloride ion. You might recall from Section 17.6 that an analogous chlorosulfite is involved in the reaction of an alcohol with SOCl_2 to yield an alkyl chloride.

Conversion of Carboxylic Acids into Acid Anhydrides

Acid anhydrides can be derived from two molecules of carboxylic acid by heating to remove 1 equivalent of water. Because of the high temperatures needed, however, only acetic anhydride is commonly prepared this

way.

Conversion of Carboxylic Acids into Esters

Perhaps the most useful reaction of carboxylic acids is their conversion into esters. There are many methods for accomplishing this, including the $\text{S}_{\text{N}}2$ reaction of a carboxylate anion with a primary alkyl halide that we saw in [Section 11.3](#).

Esters can also be synthesized by an acid-catalyzed nucleophilic acyl substitution reaction of a carboxylic acid with an alcohol, a process called the **Fischer esterification reaction**. Unfortunately, the need for an excess of a liquid alcohol as solvent effectively limits the method to the synthesis of methyl, ethyl, propyl, and butyl esters.

The mechanism of the Fischer esterification reaction is shown in [FIGURE 21.5](#). Carboxylic acids are not reactive enough to undergo nucleophilic addition directly, but their reactivity is greatly enhanced in the presence of a strong acid such as HCl or H_2SO_4 . The mineral acid protonates the carbonyl-group oxygen atom, thereby giving the carboxylic acid a positive charge and rendering it much more reactive toward nucleophiles. Subsequent loss of water from the tetrahedral intermediate yields the ester product.

FIGURE 21.5 MECHANISM

Mechanism of Fischer esterification. The reaction is an acid-catalyzed, nucleophilic acyl substitution of a carboxylic acid.

1 Protonation of the carbonyl oxygen activates the carboxylic acid . . .

2 . . . toward nucleophilic attack by alcohol, yielding a tetrahedral intermediate.

3 Transfer of a proton from one oxygen atom to another yields a second tetrahedral intermediate and converts the OH group into a good leaving group.

4 Loss of a proton and expulsion of H₂O regenerates the acid catalyst and gives the ester product.

The net effect of Fischer esterification is substitution of an -OH group by $\text{-OR}'$. All steps are reversible, and the reaction typically has an equilibrium constant close to 1. Thus, the reaction can be driven in either direction by the choice of reaction conditions. Ester formation is favored when a large excess of alcohol is used as solvent, but carboxylic acid formation is favored when a large excess of water is present.

Evidence in support of the mechanism shown in **FIGURE 21.5** comes from isotope-labeling experiments. When ^{18}O -labeled methanol reacts with benzoic acid, the methyl benzoate produced is found to be ^{18}O -labeled whereas the water produced is unlabeled. Thus, it is the C-OH bond of the carboxylic acid that is broken during the reaction rather than the CO-H bond and the RO-H bond of the alcohol that is broken rather than the R-OH bond.

WORKED EXAMPLE 21.2

Synthesizing an Ester from an Acid

How might you prepare the following ester using a Fischer esterification reaction?

Strategy

Begin by identifying the two parts of the ester. The acyl part comes from the carboxylic acid and the $-\text{OR}$ part comes from the alcohol. In this case, the target molecule is propyl *o*-bromobenzoate, so it can be prepared by treating *o*-bromobenzoic acid with 1-propanol.

Solution

PROBLEM How might you prepare the following esters from the corresponding acids?

21-7 (a)

(b)

(c)

PROBLEM If the following molecule is treated with acid catalyst, an intramolecular esterification reaction **21-8** occurs. What is the structure of the product? (*Intramolecular* means within the same molecule.)

Conversion of Carboxylic Acids into Amides

Amides are difficult to prepare by direct reaction of carboxylic acids with amines because amines are bases that convert acidic carboxyl groups into their unreactive carboxylate anions. Thus, the $-\text{OH}$ must be replaced by a better, nonacidic leaving group to carry out a nucleophilic acyl substitution. In practice, amides are often prepared by activating the carboxylic acid with a carbodiimide ($\text{R}-\text{N}=\text{C}=\text{N}-\text{R}$), followed by addition of the amine. Dicyclohexylcarbodiimide (DCC) and 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide (EDEC) are commonly used.

Dicyclohexylcarbodiimide **1-Ethyl-3-(3-dimethylaminopropyl)-carbodiimide**

As shown in **FIGURE 21.6**, the acid first adds to a C=N double bond of DCC, and nucleophilic acyl substitution by amine then ensues. Alternatively, and depending on the reaction solvent, the reactive acyl intermediate might also react with a second equivalent of carboxylate ion to generate an acid anhydride that then reacts with the amine. The product from either pathway is the same.

FIGURE 21.6 MECHANISM

Mechanism of amide formation by reaction of a carboxylic acid and an amine with dicyclohexylcarbodiimide (DCC).

1 Dicyclohexylcarbodiimide is first protonated by the carboxylic acid to make it a better acceptor.

2 The carboxylate then adds to the protonated carbodiimide to yield a reactive acylating agent.

3 Nucleophilic attack of the amine on the acylating agent gives a tetrahedral intermediate.

4 The intermediate loses dicyclohexylurea and gives the amide.

We'll see in **Section 26.7** that this carbodiimide method of amide formation is the key step in the laboratory synthesis of small proteins, or *peptides*. For instance, when one amino acid with its NH_2 rendered unreactive and a second amino acid with its $-\text{CO}_2\text{H}$ rendered unreactive are treated with carbodiimide, a dipeptide is formed.

Conversion of Carboxylic Acids into Alcohols

We said in [Section 17.4](#) that carboxylic acids are reduced by LiAlH_4 to give primary alcohols, but we deferred a discussion of the reaction mechanism at that time. In fact, the reduction is a nucleophilic acyl substitution reaction in which $-\text{H}$ replaces $-\text{OH}$ to give an aldehyde that is further reduced by nucleophilic addition to produce a primary alcohol. The aldehyde intermediate is much more reactive than the starting acid, so it reacts instantly and is not isolated.

Because hydride ion is a base as well as a nucleophile, the actual nucleophilic acyl substitution step takes place on the carboxylate ion rather than on the free carboxylic acid and gives a high-energy **dianion** intermediate. In this intermediate, the two oxygens are complexed to a Lewis acidic aluminum species. Thus, the reaction is relatively difficult, and acid reductions require higher temperatures and extended reaction times.

Alternatively, borane in tetrahydrofuran (BH_3/THF) is a useful reagent for reducing carboxylic acids to primary alcohols. Reaction of an acid with BH_3/THF occurs rapidly at room temperature, and the procedure is often preferred to reduction with LiAlH_4 because of its relative ease and safety. Borane reacts with carboxylic acids faster than with any other functional group, thereby allowing selective transformations such as that on *p*-nitrophenylacetic acid. If the reduction of *p*-nitrophenylacetic acid were done with LiAlH_4 , both the nitro and carboxyl groups would be reduced.

Biological Conversions of Carboxylic Acids

The direct conversion of a carboxylic acid to an acyl derivative by nucleophilic acyl substitution does not occur in biological chemistry. As in the laboratory, the acid must first be activated by converting the $-\text{OH}$ into a better leaving group. This activation is often accomplished in living organisms by reaction of the acid with adenosine triphosphate (ATP) to give an acyl adenosyl phosphate, or *acyl adenylate*, a mixed anhydride combining a carboxylic acid and adenosine monophosphate (AMP, also known as adenylic acid). In the biosynthesis of fats, for example, a long-chain carboxylic acid reacts with ATP to give an acyl adenylate, followed by subsequent nucleophilic acyl substitution of a thiol group in coenzyme A to give the corresponding acyl CoA ([FIGURE 21.7](#)).

FIGURE 21.7 MECHANISM

In fatty-acid biosynthesis, a carboxylic acid is activated by reaction with ATP to give an acyl adenylate, which undergoes nucleophilic acyl substitution with the -SH group on coenzyme A. (ATP = adenosine triphosphate; AMP = adenosine monophosphate.)

- 1 ATP is activated by coordination to magnesium ion, and nucleophilic addition of a fatty acid carboxylate to phosphorus then yields a pentacoordinate intermediate . . .

- 2 . . . which expels diphosphate ion (PP_i) as leaving group and gives an acyl adenosyl phosphate in a process analogous to a nucleophilic acyl substitution reaction.

- 3 The -SH group of coenzyme A adds to the acyl adenosyl phosphate, giving a tetrahedral alkoxide intermediate . . .

- 4 . . . which expels adenosine monophosphate (AMP) as leaving group and yields the fatty acyl CoA.

Note that the first step in **FIGURE 21.7**—reaction of the carboxylate with ATP to give an acyl adenylate—is itself a nucleophilic acyl substitution *on phosphorus*. The carboxylate first adds to a P=O double bond, giving a five-coordinate phosphorus intermediate that expels diphosphate ion as a leaving group.

21.4 Chemistry of Acid Halides

Preparation of Acid Halides

Acid chlorides are prepared from carboxylic acids by reaction with thionyl chloride (SOCl_2), as we saw in the previous section. Similar reaction of a carboxylic acid with phosphorus tribromide (PBr_3) yields the acid bromide.

Reactions of Acid Halides

Acid halides are among the most reactive of carboxylic acid derivatives and can be converted into many other kinds of compounds by nucleophilic acyl substitution mechanisms. The halogen can be replaced by $-\text{OH}$ to yield an acid, by $-\text{OCOR}'$ to yield an anhydride, by $-\text{OR}'$ to yield an ester, by $-\text{NH}_2$ to yield an amide, or by R' to yield a ketone. In addition, the reduction of an acid halide yields a primary alcohol, and reaction with a Grignard reagent yields a tertiary alcohol. Although the reactions we'll be discussing in this section are illustrated only for acid chlorides, similar processes take place with other acid halides.

Conversion of Acid Halides into Carboxylic Acids: Hydrolysis

Acid chlorides react with water to yield carboxylic acids. This hydrolysis reaction is a typical nucleophilic acyl substitution process and is initiated by attack of water on the acid chloride carbonyl group. The tetrahedral intermediate undergoes elimination of Cl^- and loss of H^+ to give the product carboxylic acid plus HCl .

Because HCl is formed during hydrolysis, the reaction is often carried out in the presence of a base such as pyridine or NaOH to remove the HCl and prevent it from causing side reactions.

Conversion of Acid Halides into Anhydrides

Nucleophilic acyl substitution reaction of an acid chloride with a carboxylate anion gives an acid anhydride. Both symmetrical and unsymmetrical acid anhydrides can be prepared.

Conversion of Acid Halides into Esters: Alcoholysis

Acid chlorides react with alcohols to yield esters in a process analogous to their reaction with water to yield acids. In fact, this reaction is probably the most common method for preparing esters in the laboratory. As with hydrolysis, alcoholysis reactions are usually carried out in the presence of pyridine or NaOH to react with the HCl formed.

The reaction of an alcohol with an acid chloride is strongly affected by steric hindrance. Bulky groups on either partner slow down the reaction considerably, resulting in a reactivity order among alcohols of primary > secondary > tertiary. As a result, it's often possible to selectively esterify an unhindered alcohol in the presence of a more hindered one. This can be important in complex syntheses in which it's sometimes necessary to distinguish between similar functional groups. For example,

PROBLEM 21-9 How might you prepare the following esters using a nucleophilic acyl substitution reaction of an acid chloride?

- (a) $\text{CH}_3\text{CH}_2\text{CO}_2\text{CH}_3$ (b) $\text{CH}_3\text{CO}_2\text{CH}_2\text{CH}_3$ (c) Ethyl benzoate

PROBLEM 21-10 Which method would you choose if you wanted to prepare cyclohexyl benzoate—Fischer esterification or reaction of an acid chloride with an alcohol? Explain.

Conversion of Acid Halides into Amides: Aminolysis

Acid chlorides react rapidly with ammonia and amines to give amides. As with the acid chloride-plus-alcohol method for preparing esters, this reaction of acid chlorides with amines is the most commonly used laboratory method for preparing amides. Both monosubstituted and disubstituted amines can be used, but not trisubstituted amines (R_3N).

Because HCl is formed during the reaction, two equivalents of the amine must be used. One equivalent reacts with the acid chloride, and one equivalent reacts with the HCl by-product to form an ammonium chloride salt. If, however, the amine component is valuable, amide synthesis is often carried out using one equivalent of the amine plus one equivalent of an inexpensive base such as NaOH. For example, the sedative trimetozine is prepared commercially by reaction of 3,4,5-trimethoxybenzoyl chloride with the amine morpholine in the presence of one equivalent of NaOH.

WORKED EXAMPLE 21.3

Synthesizing an Amide from an Acid Chloride

How might you prepare *N*-methylpropanamide by reaction of an acid chloride with an amine?

Strategy

As its name implies, *N*-methylpropanamide can be made by reaction of *methylamine* with the acid chloride of *propanoic acid*.

Solution

PROBLEM 21-11 Write the mechanism of the reaction just shown between 3,4,5-trimethoxybenzoyl chloride and morpholine to form trimetozine. Use curved arrows to show the electron flow in each step.

PROBLEM 21-12 How could you prepare the following amides using an acid chloride and an amine or ammonia?

(a) $\text{CH}_3\text{CH}_2\text{CONHCH}_3$ (b) *N,N*-Diethylbenzamide (c) Propanamide

Conversion of Acid Chlorides into Alcohols: Reduction and Grignard Reaction

Acid chlorides are reduced by LiAlH_4 to yield primary alcohols. The reaction is of little practical value, however, because the parent carboxylic acids are generally more readily available and can themselves be reduced by LiAlH_4 to yield alcohols.

Reduction occurs via a typical nucleophilic acyl substitution mechanism in which a hydride ion (H^-) adds to the carbonyl group, yielding a tetrahedral intermediate that expels Cl^- . The net effect is a substitution of $-\text{Cl}$ by $-\text{H}$ to yield an aldehyde, which is then further reduced by LiAlH_4 in a second step to yield the primary alcohol.

Grignard reagents react with acid chlorides to yield tertiary alcohols with two identical substituents. The mechanism of the reaction is similar to that of LiAlH_4 reduction. The first equivalent of Grignard reagent adds to the acid chloride, loss of Cl^- from the tetrahedral intermediate yields a ketone, and a second equivalent of Grignard reagent immediately adds to the ketone to produce an alcohol.

Conversion of Acid Chlorides into Ketones: Diorganocopper Reaction

The ketone intermediate formed in the reaction of an acid chloride with a Grignard reagent can't usually be isolated because addition of the second equivalent of organomagnesium reagent occurs too rapidly. A ketone *can*, however, be isolated from the reaction of an acid chloride with a lithium diorganocopper (Gilman) reagent, $\text{Li}^+ \text{R}'_2\text{Cu}^-$. The reaction occurs by initial nucleophilic acyl substitution on the acid chloride by the diorganocopper anion to yield an acyl diorganocopper intermediate, followed by loss of $\text{R}'\text{Cu}$ and formation of the ketone.

The reaction is generally carried out at -78°C in ether solution, and yields are often excellent. For example, manicone, a substance secreted by male ants to coordinate ant pairing and mating, has been synthesized by reaction of lithium diethylcopper with (*E*)-2,4-dimethyl-2-hexenoyl chloride.

Note that the diorganocopper reaction occurs only with acid chlorides. Carboxylic acids, esters, acid anhydrides, and amides do not react with lithium diorganocopper reagents.

PROBLEM 21-13 How could you prepare the following ketones by reaction of an acid chloride with a lithium diorganocopper reagent?

21.5 Chemistry of Acid Anhydrides

Preparation of Acid Anhydrides

Acid anhydrides are typically prepared by nucleophilic acyl substitution reaction of an acid chloride with a carboxylate anion, as we saw in the previous section. Both symmetrical and unsymmetrical acid anhydrides can be prepared in this way.

Reactions of Acid Anhydrides

The chemistry of acid anhydrides is similar to that of acid chlorides, although anhydrides react more slowly. Thus, acid anhydrides react with water to form acids, with alcohols to form esters, with amines to form amides, and with LiAlH_4 to form primary alcohols. Only the ester- and amide-forming reactions are commonly used, however.

Conversion of Acid Anhydrides into Esters

Acetic anhydride is often used to prepare acetate esters from alcohols. For example, aspirin (acetylsalicylic acid) is prepared commercially by the acetylation of *o*-hydroxybenzoic acid (salicylic acid) with acetic anhydride.

Conversion of Acid Anhydrides into Amides

Acetic anhydride is also commonly used to prepare *N*-substituted acetamides from amines. For example, acetaminophen, a drug used in over-the-counter analgesics such as Tylenol, is prepared by reaction of *p*-hydroxyaniline with acetic anhydride. Only the more nucleophilic -NH_2 group reacts rather than the less nucleophilic -OH group.

Notice in both of the previous reactions that only “half” of the anhydride molecule is used, while the other half acts as the leaving group during the nucleophilic acyl substitution step and produces acetate ion as a by-product. Thus, anhydrides are inefficient, and acid chlorides are normally preferred for introducing acyl substituents other than acetyl groups.

PROBLEM 21-14 Write the mechanism of the reaction between *p*-hydroxyaniline and acetic anhydride to prepare acetaminophen.

PROBLEM 21-15 What product would you expect from reaction of one equivalent of methanol with a cyclic anhydride, such as phthalic anhydride (1,2-benzenedicarboxylic anhydride)? What is the fate of the second “half” of the anhydride?

21.6 Chemistry of Esters

Esters are among the most widespread of all naturally occurring compounds. Many simple esters are pleasant-smelling liquids that are responsible for the fragrant odors of fruits and flowers. For example, methyl butanoate is found in pineapple oil, and isopentyl acetate is a constituent of banana oil. The ester linkage is also present in animal fats and in many biologically important molecules.

The chemical industry uses esters for a variety of purposes. Ethyl acetate, for instance, is a commonly used solvent, and dialkyl phthalates are used as plasticizers to keep polymers from becoming brittle. You may be aware that there is current concern about the possible toxicity of phthalates at high concentrations, although a recent assessment by the U.S. Food and Drug Administration found the risk to be minimal for most people, with the possible exception of male infants.

Preparation of Esters

Esters are usually prepared from carboxylic acids by the methods already discussed. Thus, carboxylic acids are converted directly into esters by S_N2 reaction of a carboxylate ion with a primary alkyl halide or by Fischer esterification of a carboxylic acid with an alcohol in the presence of a mineral acid catalyst. In addition, acid chlorides are converted into esters by treatment with an alcohol in the presence of base (**Section 21.4**).

Reactions of Esters

Esters undergo the same kinds of reactions that we've seen for other carboxylic acid derivatives, but they are less reactive toward nucleophiles than either acid chlorides or anhydrides. All their reactions are applicable to both acyclic and cyclic esters, called **lactones**.

Conversion of Esters into Carboxylic Acids: Hydrolysis

An ester is hydrolyzed, either by aqueous base or aqueous acid, to yield a carboxylic acid plus an alcohol.

Ester hydrolysis in basic solution is called **saponification**, after the Latin word *sapo*, meaning “soap.” We'll see in **Section 27.2** that soap is in fact made by boiling animal fat with aqueous base to hydrolyze the ester linkages.

As shown in **FIGURE 21.8**, ester hydrolysis occurs through a typical nucleophilic acyl substitution pathway in which hydroxide ion is the nucleophile that adds to the ester carbonyl group to give a tetrahedral intermediate. Loss of alkoxide ion then gives a carboxylic acid, which is deprotonated to give the carboxylate ion. Addition of aqueous HCl, in a separate step after the saponification is complete, protonates the carboxylate ion and gives the carboxylic acid.

FIGURE 21.8 MECHANISM**Mechanism of base-induced ester hydrolysis (saponification).**

1 Nucleophilic addition of hydroxide ion to the ester carbonyl group gives the usual tetrahedral alkoxide intermediate.

2 Elimination of alkoxide ion then generates the carboxylic acid.

3 Alkoxide ion abstracts the acidic proton from the carboxylic acid and yields a carboxylate ion.

4 Protonation of the carboxylate ion by addition of aqueous mineral acid in a separate step then gives the free carboxylic acid.

The mechanism shown in **FIGURE 21.8** is supported by isotope-labeling studies. When ethyl propanoate labeled with ^{18}O in the ether-like oxygen is hydrolyzed in aqueous NaOH , the ^{18}O label shows up exclusively in the ethanol product. None of the label remains with the propanoic acid, indicating that saponification occurs by cleavage of the $\text{C}-\text{OR}'$ bond rather than the $\text{CO}-\text{R}'$ bond.

Acid-catalyzed ester hydrolysis can occur by more than one mechanism, depending on the structure of the ester. The usual pathway, however, is just the reverse of a Fischer esterification reaction (**Section 21.3**). As shown in **FIGURE 21.9**, the ester is first activated toward nucleophilic attack by protonation of the carboxyl oxygen atom, and nucleophilic addition of water then occurs. Transfer of a proton and elimination of alcohol yields the carboxylic acid. Because this hydrolysis reaction is the reverse of a Fischer esterification reaction, **FIGURE 21.9** is the reverse of **FIGURE 21.5**.

FIGURE 21.9 MECHANISM

Mechanism of acid-catalyzed ester hydrolysis. The forward reaction is a hydrolysis; the back-reaction is a Fischer esterification and is thus the reverse of **FIGURE 21.5**.

Ester hydrolysis is common in biological chemistry, particularly in the digestion of dietary fats and oils. We'll save a complete discussion of the mechanistic details of fat hydrolysis until **Section 29.2** but will note for now that the reaction is catalyzed by various lipase enzymes and involves two sequential nucleophilic acyl substitution reactions. The first is a *transesterification* reaction in which an alcohol group on the lipase adds to an ester linkage in the fat molecule to give a tetrahedral intermediate that expels alcohol and forms an acyl enzyme intermediate. The second is an addition of water to the acyl enzyme, followed by expulsion of the enzyme to give a hydrolyzed acid and a regenerated enzyme.

PROBLEM Why is the saponification of an ester irreversible? In other words, why doesn't treatment of a **21-16** carboxylic acid with an alkoxide ion yield an ester?

Conversion of Esters into Amides: Aminolysis

Esters react with ammonia and amines to yield amides. The reaction is not often used, however, because it's usually easier to prepare an amide by starting with an acid chloride ([Section 21.4](#)).

Conversion of Esters into Alcohols: Reduction

Esters are easily reduced by treatment with LiAlH_4 to yield primary alcohols ([Section 17.4](#)).

The mechanism of ester reduction is similar to that of acid chloride reduction in that a hydride ion first adds to the carbonyl group, followed by elimination of alkoxide ion to yield an aldehyde. Further reduction of the aldehyde gives the primary alcohol.

The aldehyde intermediate can be isolated if 1 equivalent of diisobutylaluminum hydride (DIBAL-H, or DIBAL-H) is used as the reducing agent instead of LiAlH_4 . The reaction has to be carried out at -78°C to avoid further reduction to the alcohol. Such partial reductions of carboxylic acid derivatives to aldehydes also occur

in numerous biological pathways, although the substrate is either a thioester or acyl phosphate rather than an ester.

PROBLEM What product would you expect from the reaction of butyrolactone with LiAlH_4 ? With DIBAH?

21-17

Butyrolactone

PROBLEM Show the products you would obtain by reduction of the following esters with LiAlH_4 :

21-18 (a)

(b)

Conversion of Esters into Alcohols: Grignard Reaction

Esters react with 2 equivalents of a Grignard reagent to yield a tertiary alcohol in which two of the substituents are identical (Section 17.5). The reaction occurs by the usual nucleophilic substitution mechanism to give an intermediate ketone, which reacts further with the Grignard reagent to yield a tertiary alcohol.

PROBLEM What ester and what Grignard reagent might you start with to prepare the following alcohols?

21-19 (a)

(b)

(c)

21.7 Chemistry of Amides

Amides, like esters, are abundant in all living organisms. Proteins, nucleic acids, and many pharmaceutical agents have amide functional groups. The reason for this abundance of amides is that they are stable in the aqueous conditions found in living organisms. Amides are the least reactive of the common acid derivatives and undergo relatively few nucleophilic acyl substitution reactions.

A protein segment

Benzylpenicillin
(penicillin G)Uridine 5'-phosphate
(a ribonucleotide)

Preparation of Amides

Amides are usually prepared by reaction of an amine with an acid chloride (Section 21.4). Ammonia, monosubstituted amines, and disubstituted amines all undergo the reaction.

Reactions of Amides

Conversion of Amides into Carboxylic Acids: Hydrolysis

Amides undergo hydrolysis to yield carboxylic acids plus ammonia or an amine upon heating in either aqueous acid or aqueous base. The conditions required for amide hydrolysis are more extreme than those required for the hydrolysis of acid chlorides or esters, but the mechanisms are similar. Acidic hydrolysis reaction occurs by nucleophilic addition of water to the protonated amide, followed by transfer of a proton from oxygen to nitrogen to make the nitrogen a better leaving group, and subsequent elimination. The steps are reversible, with the equilibrium shifted toward product by protonation of NH_3 in the final step.

Basic hydrolysis occurs by nucleophilic addition of OH^- to the amide carbonyl group, followed by elimination of amide ion (NH_2^-) and subsequent deprotonation of the initially formed carboxylic acid by ammonia. The steps are reversible, with the equilibrium shifted toward product by the final deprotonation of the carboxylic acid. Basic hydrolysis is substantially more difficult than the analogous acid-catalyzed reaction because amide ion is a very poor leaving group, making the elimination step difficult.

Amide hydrolysis is common in biological chemistry. Just as the hydrolysis of esters is the initial step in the digestion of dietary fats, the hydrolysis of amides is the initial step in the digestion of dietary proteins. The reaction is catalyzed by protease enzymes and occurs by a mechanism almost identical to what we just saw for fat hydrolysis. That is, an initial nucleophilic acyl substitution of an alcohol group in the enzyme on an amide linkage in the protein gives an acyl enzyme intermediate, which then undergoes hydrolysis.

Conversion of Amides into Amines: Reduction

Like other carboxylic acid derivatives, amides can be reduced by LiAlH_4 . The product of the reduction, however, is an amine rather than an alcohol. The net effect of an amide reduction is thus the conversion of the amide carbonyl group into a methylene group ($\text{C}=\text{O} \rightarrow \text{CH}_2$). This kind of reaction is specific to amides and does not occur with other carboxylic acid derivatives.

Amide reduction occurs by nucleophilic addition of hydride ion to the amide carbonyl group, followed by expulsion of the oxygen atom as an aluminate anion leaving group to give an iminium ion intermediate. The intermediate iminium ion is further reduced by LiAlH_4 to yield the amine.

The reaction is effective with both acyclic and cyclic amides, or **lactams**, and is a good method for preparing cyclic amines.

WORKED EXAMPLE 21.4

Synthesizing an Amine from an Amide

How could you prepare *N*-ethylaniline by reduction of an amide with LiAlH_4 ?

Strategy

Reduction of an amide with LiAlH_4 yields an amine. To find the starting material for synthesis of *N*-ethylaniline, look for a CH_2 position next to the nitrogen atom and replace that CH_2 by $\text{C}=\text{O}$. In this case, the amide is *N*-phenylacetamide.

Solution

PROBLEM How would you convert *N*-ethylbenzamide to each of the following products?

21-20 (a) Benzoic acid (b) Benzyl alcohol (c) $\text{C}_6\text{H}_5\text{CH}_2\text{NHCH}_2\text{CH}_3$

PROBLEM How would you use the reaction of an amide with LiAlH_4 as the key step in going from **21-21** bromocyclohexane to (*N,N*-dimethylaminomethyl)cyclohexane? Write all the steps in the reaction sequence.

21.8 Chemistry of Thioesters and Acyl Phosphates: Biological Carboxylic Acid Derivatives

As mentioned in the chapter introduction, the substrate for a nucleophilic acyl substitution reaction in living organisms is generally either a thioester (RCOSR') or an acyl phosphate ($\text{RCO}_2\text{PO}_3^{2-}$ or $\text{RCO}_2\text{PO}_3\text{R}'^-$). Neither is as reactive as an acid chloride or acid anhydride, yet both are stable enough to exist in living organisms while still reactive enough to undergo acyl substitution.

Acyl CoA's, such as acetyl CoA, are the most common thioesters in nature. Coenzyme A, abbreviated CoA, is a thiol formed by a phosphoric anhydride linkage ($\text{O}=\text{P}-\text{O}-\text{P}=\text{O}$) between phosphopantetheine and adenosine 3',5'-bisphosphate. (The prefix *bis*- means "two" and indicates that adenosine 3',5'-bisphosphate has two phosphate groups, one on C3' and one on C5'.) Reaction of coenzyme A with an acyl phosphate or acyl adenylate gives acyl CoA (FIGURE 21.10). As we saw in Section 21.3 (FIGURE 21.7), formation of the acyl adenylate occurs by reaction of a carboxylic acid with ATP and is itself a nucleophilic acyl substitution reaction that takes place on phosphorus.

FIGURE 21.10 Formation of the thioester acetyl CoA by nucleophilic acyl substitution reaction of coenzyme A (CoA) with acetyl adenylate.

Once formed, an acyl CoA is a substrate for further nucleophilic acyl substitution reactions. For example, *N*-acetylglucosamine, a component of cartilage and other connective tissues, is synthesized by an aminolysis reaction between glucosamine and acetyl CoA.

Another example of a nucleophilic acyl substitution reaction on a thioester—this one a substitution by hydride ion to effect the partial reduction of a thioester to an aldehyde—occurs in the biosynthesis of mevaldehyde, an intermediate in terpenoid synthesis, which we'll discuss in some detail in **Section 27.5**. In this reaction, (3*S*)-3-hydroxy-3-methylglutaryl CoA is reduced by hydride donation from NADPH.

PROBLEM Write the mechanism of the reaction shown in Figure 21.10 between coenzyme A and acetyl 21-22 adenylate to give acetyl CoA.

21.9 Polyamides and Polyesters: Step-Growth Polymers

When an amine reacts with an acid chloride, an amide is formed. What would happen, though, if a *diamine* and a *diacid chloride* were allowed to react? Each partner would form two amide bonds, linking more and more molecules together until a giant polyamide resulted. In the same way, reaction of a diol with a diacid would lead to a polyester.

There are two main classes of synthetic polymers: *chain-growth polymers* and *step-growth polymers*. The polyethylene and other alkene and diene polymers that we saw in [Section 8.10](#) and [Section 14.6](#) are called **chain-growth polymers** because they are produced in chain-reaction processes. An initiator adds to a C=C bond to give a reactive intermediate, which adds to a second alkene molecule to produce a new intermediate, which adds to a third molecule, and so on. By contrast, polyamides and polyesters are **step-growth polymers** because each bond in the polymer is formed independently in a discrete step, often the nucleophilic acyl substitution reaction of a carboxylic acid derivative. Some commercially important step-growth polymers are shown in [TABLE 21.2](#).

TABLE 21.2 Some Common Step-Growth Polymers and Their Uses

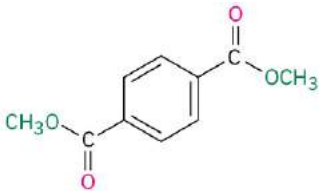

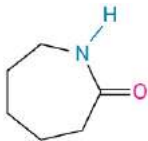

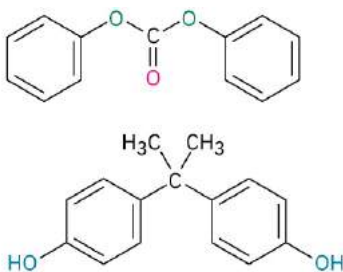

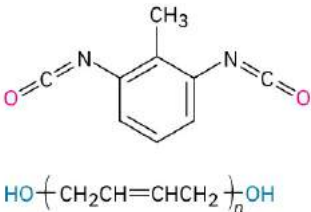

Monomers	Structure	Polymer	Uses
Adipic acid + Hexamethylenediamine	$\text{HOOCCH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{COH}$ $\text{H}_2\text{NCH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{NH}_2$	Nylon 66	Fibers, clothing, tire cord
Dimethyl terephthalate + Ethylene glycol	 $\text{HOCH}_2\text{CH}_2\text{OH}$	Dacron, Mylar, Terylene	Fibers, clothing, films, tire cord

TABLE 21.2 Some Common Step-Growth Polymers and Their Uses

Monomers	Structure	Polymer	Uses
Caprolactam		Nylon 6, Perlon	Fibers, castings
Diphenyl carbonate + Bisphenol A		Lexan, polycarbonate	Equipment housing, molded articles
Toluene-2,6-diisocyanate + Poly(2-butene-1,4-diol)		Polyurethane, Spandex	Fibers, coatings, foams

Polyamides (Nylons)

The best known step-growth polymers are the polyamides, or *nylons*, first prepared in 1930 by Wallace Carothers at the DuPont Company by heating a diamine with a diacid. For instance, nylon 66 is prepared by reaction of adipic acid (hexanedioic acid) with hexamethylenediamine (1,6-hexanediamine) at 280 °C. The designation “66” indicates the number of carbon atoms in the diamine (the first 6) and the diacid (the second 6).

Nylons are used both in engineering applications and in making fibers. A combination of high impact strength and abrasion resistance makes nylon an excellent metal substitute for bearings and gears. As fiber, nylon is used in a variety of applications, from clothing to tire cord to ropes.

Polyesters

The most generally useful polyester is made by reaction between dimethyl terephthalate (dimethyl 1,4-benzenedicarboxylate) and ethylene glycol (1,2-ethanediol). The product is used under the trade name Dacron to make clothing fiber or tire cord and under the name Mylar to make recording tape. The tensile strength of poly(ethylene terephthalate) film is nearly equal to that of steel.

Lexan, a polycarbonate prepared from diphenyl carbonate and bisphenol A, is another commercially valuable polyester. Lexan has an unusually high impact strength, making it valuable for use in bicycle helmets and laptop cases.

Sutures and Biodegradable Polymers

Because plastics are too often thrown away rather than recycled, much work has been carried out on developing biodegradable polymers, which can be broken down rapidly in landfills by soil microorganisms. Among the most common biodegradable polymers are poly(glycolic acid) (PGA), poly(lactic acid) (PLA), and poly(hydroxybutyrate) (PHB). All are polyesters and are therefore susceptible to hydrolysis of their ester links. Copolymers of PGA with PLA have found a particularly wide range of uses. A 90/10 copolymer of poly(glycolic acid) with poly(lactic acid) is used to make absorbable sutures, for instance. The sutures are entirely hydrolyzed and absorbed by the body within 90 days after surgery.

In Europe, interest has centered particularly on poly(hydroxybutyrate), which can be made into films for packaging as well as into molded items. The polymer degrades within four weeks in landfills, both by ester hydrolysis and by an E1cB elimination reaction of the oxygen atom β to the carbonyl group. The use of poly(hydroxybutyrate) is limited at present by its cost—about four times that of polypropylene.

PROBLEM 21-23 Draw structures of the step-growth polymers you would expect to obtain from the following reactions:

PROBLEM 21-24 Kevlar, a nylon polymer prepared by reaction of 1,4-benzenedicarboxylic acid (terephthalic acid) with 1,4-benzenediamine (*p*-phenylenediamine), is so strong that it's used to make bulletproof vests. Draw the structure of a segment of Kevlar.

21.10 Spectroscopy of Carboxylic Acid Derivatives

Infrared Spectroscopy

All carbonyl-containing compounds have intense IR absorptions in the range 1650 to 1850 cm^{-1} . As shown in **TABLE 21.3** the exact position of the absorption provides information about the specific kind of carbonyl group. For comparison, the IR absorptions of aldehydes, ketones, and carboxylic acids are included in the table, along with values for carboxylic acid derivatives.

TABLE 21.3 Infrared Absorptions of Some Carbonyl Compounds

Carbonyl type	Example	Absorption (cm^{-1})
Saturated acid chloride	Acetyl chloride	1810
Aromatic acid chloride	Benzoyl chloride	1770
Saturated acid anhydride	Acetic anhydride	1820, 1760
Saturated ester	Ethyl acetate	1735
Aromatic ester	Ethyl benzoate	1720
Saturated amide	Acetamide	1690
Aromatic amide	Benzamide	1675
<i>N</i> -Substituted amide	<i>N</i> -Methylacetamide	1680
<i>N,N</i> -Disubstituted amide	<i>N,N</i> -Dimethylacetamide	1650
Saturated aldehyde	Acetaldehyde	1730
Saturated ketone	Acetone	1715
Saturated carboxylic acid	Acetic acid	1710

Acid chlorides are easily detected by their characteristic absorption near 1810 cm^{-1} . Acid anhydrides can be identified by a pair of absorptions in the carbonyl region, one at 1820 cm^{-1} and another at 1760 cm^{-1} . Note that each of these functional groups has a strong electron-withdrawing group attached to the carbonyl. The inductive withdrawal of electron density shortens the C=O bond, thereby raising its stretching frequency. Esters are detected by their absorption at 1735 cm^{-1} , a position somewhat higher than that for either aldehydes or ketones. Amides, by contrast, absorb near the low-wavenumber end of the carbonyl region, with the degree of substitution on nitrogen affecting the exact position of the IR band. That is, for amides, the delocalization of

electron density (resonance) from nitrogen into the carbonyl lengthens the C=O bond and lowers its stretching frequency.

PROBLEM What kinds of functional groups might compounds have if they show the following IR absorptions?

- 21-25** (a) Absorption at 1735 cm^{-1} (b) Absorption at 1810 cm^{-1}
 (c) Absorptions at $2500\text{ to }3300\text{ cm}^{-1}$ and 1710 cm^{-1} (d) Absorption at 1715 cm^{-1}

PROBLEM Propose structures for compounds that have the following formulas and IR absorptions:

- 21-26** (a) $\text{C}_6\text{H}_{12}\text{O}_2$, 1735 cm^{-1} (b) $\text{C}_4\text{H}_9\text{NO}$, 1650 cm^{-1} (c) $\text{C}_4\text{H}_5\text{ClO}$, 1780 cm^{-1}

Nuclear Magnetic Resonance Spectroscopy

Hydrogens on the carbon next to a carbonyl group are slightly deshielded and absorb near 2δ in the ^1H NMR spectrum, although the exact identity of the carbonyl group can't be determined. **FIGURE 21.11** shows the ^1H NMR spectrum of ethyl acetate.

FIGURE 21.11 ^1H NMR spectrum of ethyl acetate.

Although ^{13}C NMR is useful for determining the presence or absence of a carbonyl group in a molecule, the identity of the carbonyl group is difficult to determine. Aldehydes and ketones absorb near 200δ , while the carbonyl carbon atoms of various acid derivatives absorb in the range $160\text{ to }180\delta$ (**TABLE 21.4**).

TABLE 21.4 ^{13}C NMR Absorptions of Some Carbonyl Compounds

Compound	Absorption (δ)
Acetic acid	177.3
Ethyl acetate	170.7
Acetyl chloride	170.3
Acetamide	172.6
Acetic anhydride	166.9
Acetone	205.6
Acetaldehyde	201.0

CHEMISTRY MATTERS

β -Lactam Antibiotics

You should never underestimate the value of hard work and logical thinking, but it's also true that blind luck often plays a role in most real scientific breakthroughs. What has been called "the supreme example of luck in all scientific history" occurred in the late summer of 1928, when the Scottish bacteriologist Alexander Fleming went on vacation, leaving in his lab a culture plate recently inoculated with the bacterium *Staphylococcus aureus*.

While Fleming was away, an extraordinary chain of events occurred. First, a nine-day cold spell lowered the laboratory temperature to a point where the *Staphylococcus* in the culture plate could not grow. During this time, spores from a colony of the mold *Penicillium notatum*, being grown in a lab on the floor below, wafted up into Fleming's lab and landed in the culture plate. The temperature then rose, and both *Staphylococcus* and *Penicillium* began to grow. On returning from vacation, Fleming discarded the plate into a tray of antiseptic, intending to sterilize it. Evidently, though, the plate did not sink deeply enough into the antiseptic, because when Fleming happened to glance at it a few days later, what he saw changed the course of history. He noticed that the growing *Penicillium* mold appeared to dissolve the colonies of staphylococci.

Fleming realized that the *Penicillium* mold must be producing a chemical that killed the *Staphylococcus* bacteria, and he spent several years trying to isolate the substance. Finally, in 1939, the Australian pathologist Howard Florey and the German refugee Ernst Chain managed to isolate the active substance, called *penicillin*. The dramatic ability of penicillin to cure infections in mice was soon demonstrated, and successful tests in humans followed shortly thereafter. By 1943, penicillin was being produced on a large scale for military use in World War II, and by 1944 it was being used on civilians. Fleming, Florey, and Chain shared the 1945 Nobel Prize in Physiology or Medicine.

Now called benzylpenicillin, or penicillin G, the substance first discovered by Fleming is but one member of a large class of so-called **β -lactam antibiotics**, compounds with a four-membered lactam (cyclic amide) ring. The four-membered lactam ring is fused to a five-membered, sulfur-containing ring, and the carbon atom next to the lactam carbonyl group is bonded to an acylamino substituent, RCONH-. This acylamino side chain can be varied in the laboratory to provide many hundreds of penicillin analogs with different biological activity profiles. Ampicillin, for instance, has an α -aminophenylacetamido substituent [PhCH(NH₂)CONH-].

Closely related to the penicillins are the *cephalosporins*, a group of β -lactam antibiotics that contain an unsaturated, six-membered, sulfur-containing ring. Cephalixin, marketed under the trade name Keflex, is an example. Cephalosporins generally have much greater antibacterial activity than penicillins, particularly against resistant strains of bacteria.

The biological activity of penicillins and cephalosporins is due to the presence of the strained β -lactam ring, which reacts with and deactivates the transpeptidase enzyme needed to synthesize and repair bacterial cell walls. With the wall either incomplete or weakened, the bacterial cell ruptures and dies.

Key Terms

- acid anhydride
- acid halide
- acyl phosphate
- amide
- carboxylic acid derivative
- chain-growth polymer
- ester
- Fischer esterification reaction
- lactam
- lactone
- nucleophilic acyl substitution reaction
- saponification
- step-growth polymer
- thioester

Summary

Carboxylic acid derivatives—compounds in which the -OH group of a carboxylic acid has been replaced by another substituent—are among the most widely occurring of all molecules and are involved in almost all biological pathways. In this chapter, we covered the chemistry necessary for understanding them and thus also necessary for understanding living organisms. **Acid halides**, **acid anhydrides**, **esters**, and **amides** are the most common such derivatives in the laboratory; **thioesters** and **acyl phosphates** are common in biological molecules.

The chemistry of carboxylic acid derivatives is dominated by the **nucleophilic acyl substitution reaction**. Mechanistically, these substitutions take place by addition of a nucleophile to the polar carbonyl group of the acid derivative to give a tetrahedral intermediate, followed by expulsion of a leaving group.

The reactivity of an acid derivative toward substitution depends both on the steric environment near the carbonyl group and on the electronic nature of the substituent, Y . The reactivity order is acid halide $>$ acid anhydride $>$ thioester $>$ ester $>$ amide.

The most common reactions of carboxylic acid derivatives are substitution by water to yield an acid (hydrolysis), by an alcohol to yield an ester (alcoholysis), by an amine to yield an amide (aminolysis), by hydride ion to yield

an alcohol (reduction), and by an organomagnesium halide to yield an alcohol (Grignard reaction).

Step-growth polymers, such as polyamides and polyesters, are prepared by reactions between difunctional molecules. Polyamides (nylons) are formed by reaction between a diacid and a diamine; polyesters are formed from a diacid and a diol.

IR spectroscopy is a valuable tool for the structural analysis of acid derivatives. Acid chlorides, anhydrides, esters, and amides all show characteristic IR absorptions that can be used to identify these functional groups.

Summary of Reactions

1. Reactions of carboxylic acids (Section 21.3)

a. Conversion into acid chlorides

b. Conversion into esters

c. Conversion into amides

d. Reduction to yield primary alcohols

2. Reactions of acid chlorides (Section 21.4)

a. Hydrolysis to yield acids

b. Reaction with carboxylates to yield anhydrides

c. Alcoholysis to yield esters

d. Aminolysis to yield amides

e. Reduction to yield primary alcohols

f. Grignard reaction to yield tertiary alcohols

- g. Diorganocopper reaction to yield ketones

3. Reactions of acid anhydrides (Section 21.5)

- a. Hydrolysis to yield acids

- b. Alcoholysis to yield esters

- c. Aminolysis to yield amides

4. Reactions of esters (Section 21.6)

- a. Hydrolysis to yield acids

- b. Reduction to yield primary alcohols

- c. Partial reduction to yield aldehydes

- d. Grignard reaction to yield tertiary alcohols

5. Reactions of amides (Section 21.7)

- a. Hydrolysis to yield acids

- b. Reduction to yield amines

Additional Problems

Visualizing Chemistry

PROBLEM Name the following compounds:

21-27

PROBLEM 21-28 How would you prepare the following compounds starting with an appropriate carboxylic acid and any other reagents needed? (reddish brown = Br.)

PROBLEM 21-29 The following structure represents a tetrahedral alkoxide-ion intermediate formed by addition of a nucleophile to a carboxylic acid derivative. Identify the nucleophile, the leaving group, the starting acid derivative, and the ultimate product (green = Cl).

PROBLEM 21-30 Electrostatic potential maps of a typical amide (acetamide) and an acyl azide (acetyl azide) are shown. Which of the two do you think is more reactive in nucleophilic acyl substitution reactions? Explain.

Mechanism Problems

PROBLEM 21-31 Predict the product(s) and write the mechanism for the following reactions:

PROBLEM Predict the product(s) and write the mechanism for the following reactions:

PROBLEM Predict the product(s) and write the mechanism for each of the following reactions:

PROBLEM Predict the product(s) and write the mechanism for the following reactions:

PROBLEM Pivalic mixed anhydrides are often used to form amide bonds between amino acids. Unlike with a symmetrical anhydride, this reaction is highly regioselective, with the nucleophile adding only to the amino-acid carbonyl. Provide the complete mechanism for the following reaction and explain the regioselectivity.

PROBLEM When 4-dimethylaminopyridine (DMAP) is added in catalytic amounts to acetic anhydride and an alcohol, it significantly increases the rate of ester formation. The process begins with a reaction between acetic anhydride and DMAP to form a highly reactive acetylpyridinium intermediate that is more reactive than acetic anhydride itself. Propose a mechanism for this process that includes the formation and reaction of the acetylpyridinium intermediate.

PROBLEM Fats are biosynthesized from glycerol 3-phosphate and fatty-acyl CoA's by a reaction sequence that begins with the following step. Show the mechanism of the reaction.

PROBLEM Treatment of an α -amino acid with DCC yields a 2,5-diketopiperazine. Propose a mechanism.

21-38

PROBLEM 21-39 Succinic anhydride yields the cyclic imide succinimide when heated with ammonium chloride at 200 °C. Propose a mechanism for this reaction. Why do you suppose such a high reaction temperature is required?

PROBLEM 21-40 The hydrolysis of a biological thioester to the corresponding carboxylate is often more complex than the overall result might suggest. The conversion of succinyl CoA to succinate in the citric acid cycle, for instance, occurs by initial formation of an acyl phosphate, followed by reaction with guanosine diphosphate (GDP, a relative of adenosine diphosphate [ADP]) to give succinate and guanosine triphosphate (GTP, a relative of ATP). Suggest mechanisms for both steps.

PROBLEM 21-41 One step in the *gluconeogenesis* pathway for the biosynthesis of glucose is the partial reduction of 3-phosphoglycerate to give glyceraldehyde 3-phosphate. The process occurs by phosphorylation with ATP to give 1,3-bisphosphoglycerate, reaction with a thiol group on the enzyme to give an enzyme-bound thioester, and reduction with NADH. Suggest mechanisms for all three reactions.

PROBLEM Draw structures corresponding to the following names:

- 21-46 (a) *p*-Bromophenylacetamide (b) *m*-Benzoylbenzamide (c) 2,2-Dimethylhexanamide
 (d) Cyclohexyl cyclohexanecarboxylate (e) Ethyl 2-cyclobutenecarboxylate
 (f) Succinic anhydride

PROBLEM Draw and name compounds that meet the following descriptions:

- 21-47 (a) Three acid chlorides having the formula C_6H_9ClO
 (b) Three amides having the formula $C_7H_{11}NO$

Nucleophilic Acyl Substitution Reactions

PROBLEM Predict the product, if any, of reaction between propanoyl chloride and the following reagents:

- 21-48 (a) $Li(Ph)_2Cu$ in ether (b) $LiAlH_4$, then H_3O^+ (c) CH_3MgBr , then H_3O^+ (d) H_3O^+
 (e) Cyclohexanol (f) Aniline (g) $CH_3CO_2^- Na^+$

PROBLEM Answer Problem 21-48 for reaction of the listed reagents with methyl propanoate.

21-49

PROBLEM Answer Problem 21-48 for reaction of the listed reagents with propanamide.

21-50

PROBLEM What product would you expect to obtain from Grignard reaction of an excess of phenylmagnesium

21-51 bromide with dimethyl carbonate, $CH_3OCO_2CH_3$?

PROBLEM How might you prepare the following compounds from butanoic acid?

- 21-52 (a) 1-Butanol (b) Butanal (c) 1-Bromobutane (d) Pentanenitrile (e) 1-Butene
 (f) *N*-Methylpentanamide (g) 2-Hexanone (h) Butylbenzene (i) Butanenitrile

PROBLEM Predict the product(s) of the following reactions:

PROBLEM The following reactivity order has been found for the saponification of alkyl acetates by aqueous NaOH. Explain.

21-54

PROBLEM Explain the observation that attempted Fischer esterification of 2,4,6-trimethylbenzoic acid with methanol and HCl is unsuccessful. No ester is obtained, and the acid is recovered unchanged. What alternative method of esterification might be successful?

21-55

PROBLEM Outline methods for the preparation of acetophenone (phenyl methyl ketone) starting from the following:

21-56

(a) Benzene (b) Bromobenzene (c) Methyl benzoate (d) Benzonitrile (e) Styrene

PROBLEM Treatment of 5-aminopentanoic acid with DCC (dicyclohexylcarbodiimide) yields a lactam. Show the structure of the product and the mechanism of the reaction.

21-57

PROBLEM When *ethyl* benzoate is heated in methanol containing a small amount of HCl, *methyl* benzoate is formed. Propose a mechanism for the reaction.

21-58

PROBLEM *tert*-Butoxycarbonyl azide, a reagent used in protein synthesis, is prepared by treating *tert*-butoxycarbonyl chloride with sodium azide. Propose a mechanism for this reaction.

21-59

Step-Growth Polymers

PROBLEM The step-growth polymer nylon 6 is prepared from caprolactam. The reaction involves initial reaction of caprolactam with water to give an intermediate open-chain amino acid, followed by heating to form the polymer. Propose mechanisms for both steps, and show the structure of nylon 6.

21-60

PROBLEM Qiana, a polyamide fiber with a silky texture, has the following structure. What are the monomer units used in the synthesis of Qiana?

21-61

PROBLEM What is the structure of the polymer produced by treatment of β -propiolactone with a small amount of hydroxide ion?

21-62

PROBLEM 21-63 Polyimides with the structure shown are used as coatings on glass and plastics to improve scratch resistance. How would you synthesize a polyimide? (See Problem 21-39.)

Spectroscopy

PROBLEM 21-64 How would you distinguish spectroscopically between the following isomer pairs? Tell what differences you would expect to see.

- N*-Methylpropanamide and *N,N*-dimethylacetamide
- 5-Hydroxypentanenitrile and cyclobutanecarboxamide
- 4-Chlorobutanoic acid and 3-methoxypropanoyl chloride
- Ethyl propanoate and propyl acetate

PROBLEM 21-65 Propose a structure for a compound, $C_4H_7ClO_2$, that has the following IR and 1H NMR spectra:

PROBLEM 21-66 Assign structures to compounds with the following 1H NMR spectra:

(a) C_4H_7ClO IR: 1810 cm^{-1} (b) $C_5H_7NO_2$ IR: $2250, 1735\text{ cm}^{-1}$ 

General Problems

PROBLEM 21-67 The following reactivity order has been found for the basic hydrolysis of *p*-substituted methyl benzoates:

How can you explain this reactivity order? Where would you expect $Y=\text{C}\equiv\text{N}$, $Y=\text{CHO}$, and $Y=\text{NH}_2$ to be in the reactivity list?

PROBLEM 21-68 When a carboxylic acid is dissolved in isotopically labeled water, the label rapidly becomes incorporated into both oxygen atoms of the carboxylic acid. Explain.

PROBLEM 21-69 We said in Section 21.6 that mechanistic studies on ester hydrolysis have been carried out using ethyl propanoate labeled with ^{18}O in the ether-like oxygen. Assume that ^{18}O -labeled acetic acid is your only source of isotopic oxygen, and then propose a synthesis of the labeled ethyl propanoate.

PROBLEM 21-70 Treatment of a carboxylic acid with trifluoroacetic anhydride leads to an unsymmetrical anhydride that rapidly reacts with alcohol to give an ester.

- (a) Propose a mechanism for formation of the unsymmetrical anhydride.
 (b) Why is the unsymmetrical anhydride unusually reactive?
 (c) Why does the unsymmetrical anhydride react as indicated rather than giving a trifluoroacetate ester plus carboxylic acid?

PROBLEM 21-71 Butacetin is an analgesic (pain-killing) agent that is synthesized commercially from *p*-fluoronitrobenzene. Propose a synthesis.

PROBLEM 21-72 Phenyl 4-aminosalicylate is a drug used in the treatment of tuberculosis. Propose a synthesis of this compound starting from 4-nitrosalicylic acid.

PROBLEM 21-73 *N,N*-Diethyl-*m*-toluamide (DEET) is the active ingredient in many insect-repellent preparations. How might you synthesize this substance from *m*-bromotoluene?

PROBLEM 21-74 Tranexamic acid, a drug useful against blood clotting, is prepared commercially from *p*-methylbenzonitrile. Formulate the steps likely to be used in the synthesis. (Don't worry about *cis*-*trans* isomers; heating to 300 °C interconverts the isomers.)

PROBLEM 21-75 One frequently used method for preparing methyl esters is by reaction of carboxylic acids with diazomethane, CH_2N_2 .

The reaction occurs in two steps: (1) protonation of diazomethane by the carboxylic acid to yield methyldiazonium ion, CH_3N_2^+ , plus a carboxylate ion; and (2) reaction of the carboxylate ion with CH_3N_2^+ .

- (a) Draw two resonance structures of diazomethane, and account for step 1.

(b) What kind of reaction occurs in step 2?

PROBLEM 21-76 Draw the structure of the polymer you would expect to obtain from reaction of dimethyl terephthalate with a triol such as glycerol. What structural feature would this new polymer have that was not present in Dacron (Table 21.2)? How do you think this new feature might affect the properties of the polymer?

PROBLEM 21-77 Assign structures to compounds with the following ^1H NMR spectra:

(a) $\text{C}_5\text{H}_{10}\text{O}_2$

IR: 1735 cm^{-1}

(b) $\text{C}_{11}\text{H}_{12}\text{O}_2$

IR: 1710 cm^{-1}

PROBLEM 21-78 Propose structures for compounds with the following ^1H NMR spectra:

(a) $\text{C}_5\text{H}_9\text{ClO}_2$

IR: 1735 cm^{-1}

(b) $C_7H_{12}O_4$ IR: 1735 cm^{-1} 

PROBLEM 21-79 Propose a structure for the compound with the formula $C_{19}H_{19}NO_2$ and the following IR and NMR spectra

PROBLEM Draw the structure of the compound that produced the following spectra. The infrared spectrum has strong bands at 1720 and 1738 cm^{-1} .

PROBLEM When an amide is formed from an acid chloride or an anhydride, two equivalents of base are required. However, when an ester is used as the starting material, only one equivalent of base is needed. Explain this reactivity in terms of basicity of the leaving groups.

21-81

PROBLEM Epoxy adhesives are prepared in two steps. $\text{S}_{\text{N}}2$ reaction of the disodium salt of bisphenol A with epichlorohydrin forms a “prepolymer,” which is then “cured” by treatment with a triamine such as $\text{H}_2\text{NCH}_2\text{CH}_2\text{NHCH}_2\text{CH}_2\text{NH}_2$.

21-82

Draw structures to show how addition of the triamine results in a strengthening of the polymer.

CHAPTER 22

Carbonyl Alpha-Substitution Reactions

FIGURE 22.1 Tear gas is a controversial riot-control device used by some military and police forces. It is a simple chloroacetone made by a carbonyl α -substitution reaction. (credit: modification of work “Tear Gas in CWB Hennessy Road View” by The Stand News/Wikimedia Commons, Public Domain)

22.6 Reactivity of Enolate Ions

22.7 Alkylation of Enolate Ions

WHY THIS CHAPTER? As with nucleophilic additions and nucleophilic acyl substitutions, many laboratory schemes, pharmaceutical syntheses, and biochemical pathways make frequent use of carbonyl α -substitution reactions. Their great value comes from the fact that they constitute one of the few general methods for forming carbon–carbon bonds, thereby making it possible to build larger molecules from smaller precursors. In this chapter, we’ll see how and why these reactions occur.

We said in the *Preview of Carbonyl Chemistry* that much of the chemistry of carbonyl compounds can be explained by just four fundamental reaction types: nucleophilic additions, nucleophilic acyl substitutions, α substitutions, and carbonyl condensations. Having studied the first two of these reactions in the past three chapters, let’s now look in more detail at the third major carbonyl-group process—the **α -substitution reaction**.

Alpha-substitution reactions occur at the position next to the carbonyl group—the α position—and involve the substitution of an α hydrogen atom by an electrophile, E, through either an enol or enolate ion intermediate. Let’s begin by learning more about these two species.

22.1 Keto–Enol Tautomerism

A carbonyl compound with a hydrogen atom on its α carbon is in equilibrium with its corresponding **enol** isomer (Section 9.4). This spontaneous interconversion between two isomers, usually with the change in position of a hydrogen, is called *tautomerism*, from the Greek *tauto*, meaning “the same,” and *meros*, meaning “part.” The individual keto and enol isomers are called **tautomers**.

Note the difference between tautomers and resonance forms. Tautomers are constitutional isomers—different compounds with different structures—while resonance forms are different representations of a single compound. Tautomers have their *atoms* arranged differently, while resonance forms differ only in the position of their π and nonbonding *electrons*.

Most monocarbonyl compounds exist almost entirely in their keto form at equilibrium, and it's usually difficult to isolate the pure enol. Cyclohexanone, for example, contains only about 0.0001% of its enol tautomer at room temperature. The percentage of enol tautomer is even lower for carboxylic acids, esters, and amides. The enol can only predominate when stabilized by conjugation or intramolecular hydrogen bonding. Thus, 2,4-pentanedione is about 76% enol tautomer. Although enols are scarce at equilibrium, they are nevertheless responsible for much of the chemistry of carbonyl compounds because they are so reactive.

Keto–enol tautomerism of carbonyl compounds is catalyzed by both acids and bases. Acid catalysis occurs by protonation of the carbonyl oxygen atom to give an intermediate cation that loses H^+ from its α carbon to yield a neutral enol (Figure 22.2a). This proton loss from the cation intermediate is similar to what occurs during an $E1$ reaction when a carbocation loses H^+ to form an alkene (Section 11.10).

Base-catalyzed enol formation occurs because the presence of a carbonyl group makes the hydrogens on the α carbon weakly acidic. Thus, a carbonyl compound can act as an acid and donate one of its α hydrogens

to a sufficiently strong base. The resultant resonance-stabilized anion, an **enolate ion**, is then protonated to yield a neutral compound. If protonation of the enolate ion takes place on the α carbon, the keto tautomer is regenerated and no net change occurs. If, however, protonation takes place on the oxygen atom, an enol tautomer is formed (**FIGURE 22.2b**).

FIGURE 22.2 MECHANISM

Mechanism of enol formation under both acid-catalyzed and base-catalyzed conditions. (a) Acid catalysis involves (1) initial protonation of the carbonyl oxygen followed by (2) removal of H^+ from the α position. **(b)** Base catalysis involves (1) initial deprotonation of the α position to give an enolate ion, followed by (2) reprotonation on oxygen.

Note that only the hydrogens on the α position of carbonyl compounds are acidic. Hydrogens at β , γ , δ , and so on, aren't acidic and can't be removed by base because the resulting anions can't be resonance-stabilized by the carbonyl group.

PROBLEM Draw structures for the enol tautomers of the following compounds:

- 22-1** (a) Cyclopentanone (b) Methyl thioacetate (c) Ethyl acetate (d) Propanal (e) Acetic acid (f) Phenylacetone

PROBLEM How many acidic hydrogens does each of the molecules listed in Problem 22-1 have? Identify them.

22-2

PROBLEM Draw structures for all monoenol forms of the following molecule. Which would you expect to be most stable? Explain.

22-3

22.2 Reactivity of Enols: α -Substitution Reactions

What kind of chemistry do enols have? Because their double bonds are electron-rich, enols behave as nucleophiles and react with electrophiles in much the same way that alkenes do. But because of resonance-electron donation of a lone pair of electrons on the neighboring oxygen, enols are more electron-rich and correspondingly more reactive than alkenes. Notice in the following electrostatic potential map of ethenol ($\text{H}_2\text{C}=\text{CHOH}$) how there is a substantial electron density (yellow-red) on the α carbon.

When an *alkene* reacts with an electrophile, E^+ , initial addition gives an intermediate cation and subsequent reaction with a nucleophile, such as a halide ion, yields an addition product (Section 7.7). When an *enol* reacts with an electrophile, however, only the initial addition step is the same (Figure 22.3). Instead of reacting with a nucleophile to give an addition product, the intermediate cation loses the $-\text{OH}$ proton to give an α -substituted carbonyl compound.

FIGURE 22.3 MECHANISM

General mechanism of a carbonyl α -substitution reaction. In step 3, the initially formed cation loses H^+ to regenerate a carbonyl compound.

1 Acid-catalyzed enol formation occurs by the usual mechanism.

2 An electron pair from the enol oxygen attacks an electrophile (E^+), forming a new bond and leaving a cation intermediate that is stabilized by resonance between two forms.

3 Loss of a proton from oxygen yields the neutral α -substitution product as a new $C=O$ bond is formed.

22.3 Alpha Halogenation of Aldehydes and Ketones

A particularly common α -substitution reaction in the laboratory is the halogenation of aldehydes and ketones at their α positions by reaction with Cl_2 , Br_2 , or I_2 in acidic solution. Bromine in acetic acid solvent is often used.

Remarkably, ketone halogenation also occurs in biological systems, particularly in marine alga, where dibromoacetaldehyde, bromoacetone, 1,1,1-tribromoacetone, and other related compounds have been found.

This form of halogenation is a typical α -substitution reaction that proceeds by acid-catalyzed formation of an enol intermediate, as shown in FIGURE 22.4.

FIGURE 22.4 MECHANISM

Mechanism of the acid-catalyzed bromination of acetone.

1 The carbonyl oxygen atom is protonated by acid catalyst.

2 Loss of an acidic proton from the alpha carbon takes place in the normal way to yield an enol intermediate.

3 An electron pair from the enol attacks bromine, giving an intermediate cation that is stabilized by resonance between two forms.

4 Loss of the -OH proton then gives the alpha-halogenated product and generates more acid catalyst.

Evidence for the mechanism shown in **FIGURE 22.4** includes the observation that acid-catalyzed halogenations show second-order kinetics and follow the rate law

$$\text{Reaction rate} = k[\text{Ketone}][\text{H}^+]$$

In other words, the rate of halogenation depends only on the concentrations of ketone and acid and is independent of halogen concentration. Since halogen is not involved in the rate-limiting step, chlorination, bromination, and iodination of a given substrate all occur at the same rate.

Furthermore, if an aldehyde or ketone is treated with D_3O^+ , the acidic α hydrogens are replaced by deuterium. For a given ketone, the rate of deuterium exchange is identical to the rate of halogenation, implying that a common intermediate—presumably the enol—is involved in both processes.

α -Bromo ketones are useful in the laboratory because they can be dehydrobrominated by base treatment to yield α,β -unsaturated ketones. For example, 2-methylcyclohexanone gives 2-bromo-2-methylcyclohexanone on halogenation, and the α -bromo ketone gives 2-methyl-2-cyclohexenone when heated in pyridine. The reaction takes place by an E2 elimination pathway (Section 11.8) and is a good method for introducing a C=C bond into a molecule. Note that bromination of 2-methylcyclohexanone occurs primarily on the more highly substituted α position because the more highly substituted enol is favored over the less highly substituted one (Section 7.6).

PROBLEM Write the complete mechanism for the deuteration of acetone on treatment with D_3O^+ .

22-4

PROBLEM Show how you might prepare 1-penten-3-one from 3-pentanone.

22-5

22.4 Alpha Bromination of Carboxylic Acids

The α bromination of carbonyl compounds by Br_2 in acetic acid is limited to aldehydes and ketones because acids, esters, and amides don't enolize to a sufficient extent. Carboxylic acids, however, can be α brominated by a mixture of Br_2 and PBr_3 in the *Hell-Volhard-Zelinskii (HVZ) reaction*.

The Hell-Volhard-Zelinskii reaction is a bit more complex than it looks and actually involves α substitution of an acid bromide enol rather than a carboxylic acid enol. The process begins by reaction of the carboxylic acid with PBr_3 to form an acid bromide plus HBr (Section 21.4). The HBr then catalyzes enolization of the acid bromide, and the resultant enol reacts with Br_2 in an α -substitution reaction to give an α -bromo acid bromide. Addition of water hydrolyzes the acid bromide in a nucleophilic acyl substitution reaction and yields the α -bromo carboxylic acid product.

PROBLEM 22-6 If methanol rather than water is added at the end of a Hell-Volhard-Zelinskii reaction, an ester rather than an acid is produced. Show how you would carry out the following transformation, and propose a mechanism for the ester-forming step.

22.5 Acidity of Alpha Hydrogen Atoms: Enolate Ion Formation

As noted in Section 22.1, a hydrogen on the α position of a carbonyl compound is weakly acidic and can be removed by a strong base to yield an enolate ion. In comparing acetone ($\text{p}K_{\text{a}} = 19.3$) with ethane ($\text{p}K_{\text{a}} \approx 60$), for instance, the presence of a neighboring carbonyl group increases the acidity of the ketone over the alkane by a factor of 10^{40} .

Proton abstraction from a carbonyl compound occurs when the α C–H bond is oriented roughly parallel to the p orbitals of the carbonyl group. The α carbon atom of the enolate ion is sp^2 -hybridized and has a p orbital that overlaps the neighboring carbonyl p orbitals. Thus, the negative charge is shared by the electronegative oxygen atom, and the enolate ion is stabilized by resonance (FIGURE 22.5).

FIGURE 22.5 Mechanism of enolate-ion formation by abstraction of an α proton from a carbonyl compound. The enolate ion is stabilized by resonance, and the negative charge (red) is shared by the oxygen and the α carbon atom, as indicated in the electrostatic potential map.

Because carbonyl compounds are only weakly acidic, a strong base is needed for the formation of an enolate ion. If an alkoxide ion, such as sodium ethoxide, is used as base, deprotonation of acetone only takes place to the extent of about 0.1% because acetone is a weaker acid than ethanol ($\text{p}K_{\text{a}} = 16$). If, however, a more powerful base is used, then a carbonyl compound is completely converted into its enolate ion.

In practice, the strong base lithium diisopropylamide [$\text{LiN}(i\text{-C}_3\text{H}_7)_2$; abbreviated LDA] is commonly used for making enolate ions. As the lithium salt of the weak acid diisopropylamine, $\text{p}K_{\text{a}} = 36$, LDA can readily deprotonate most carbonyl compounds. It is easily prepared by reaction of butyllithium with diisopropylamine and is soluble in organic solvents because of its two alkyl groups.

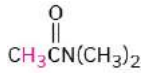

Many types of carbonyl compounds, including aldehydes, ketones, esters, thioesters, acids, and amides, can be converted into enolate ions by reaction with LDA. **TABLE 22.1** lists the approximate $\text{p}K_{\text{a}}$ values of different types of carbonyl compounds and shows how these values compare to other acidic substances we've seen. Note that nitriles, too, are acidic and can be converted into enolate-like anions.

TABLE 22.1 Acidity Constants for Some Organic Compounds

Functional group	Example	$\text{p}K_{\text{a}}$
Carboxylic acid	CH_3COH	5
1,3-Diketone	$\text{CH}_3\text{CCH}_2\text{CCH}_3$	9
3-Keto ester	$\text{CH}_3\text{CCH}_2\text{COCH}_3$	11
1,3-Diester	$\text{CH}_3\text{OCCH}_2\text{COCH}_3$	13
Alcohol	CH_3OH	16
Acid chloride	CH_3CCl	16
Aldehyde	CH_3CH	17
Ketone	CH_3CCH_3	19

TABLE 22.1 Acidity Constants for Some Organic Compounds

Functional group	Example	pK_a
Thioester		21
Ester		25
Nitrile	$\text{CH}_3\text{C}\equiv\text{N}$	25
<i>N,N</i> -Dialkylamide		30
Dialkylamine	$\text{HN}(i\text{-C}_3\text{H}_7)_2$	36

When a hydrogen atom is flanked by two carbonyl groups, its acidity is enhanced further. **TABLE 22.1** thus shows that 1,3-diketones (β -diketones), 3-oxo esters (β -keto esters), and 1,3-diester (malonic esters) are more acidic than water. The enolate ions derived from these β -dicarbonyl compounds are stabilized by sharing the negative charge of the two neighboring carbonyl oxygens. The enolate ion of 2,4-pentanedione, for instance, has three resonance forms. Similar resonance forms can be drawn for other doubly stabilized enolate ions.

WORKED EXAMPLE 22.1

Identifying the Acidic Hydrogens in a Compound

Identify the most acidic hydrogens in each of the following compounds, and rank the compounds in order of increasing acidity:

Strategy

Hydrogens on carbon next to a carbonyl group are acidic. In general, a β -dicarbonyl compound is most acidic, a ketone or aldehyde is next most acidic, and a carboxylic acid derivative is least acidic. Remember that alcohols, phenols, and carboxylic acids are also acidic because of their $-\text{OH}$ hydrogens.

Solution

The acidity order is (a) > (c) > (b). Acidic hydrogens are shown in red.

PROBLEM Identify the most acidic hydrogens in each of the following molecules:

- 22-7 (a) $\text{CH}_3\text{CH}_2\text{CHO}$ (b) $(\text{CH}_3)_3\text{C}-\text{COCH}_3$ (c) $\text{CH}_3\text{CO}_2\text{H}$ (d) Benzamide (e) $\text{CH}_3\text{CH}_2\text{CH}_2\text{CN}$
 (f) $\text{CH}_3\text{CON}(\text{CH}_3)_2$

PROBLEM Draw a resonance structure of the acetonitrile anion, $^-\text{CH}_2\text{C}\equiv\text{N}$, and account for the acidity of 22-8 nitriles.

22.6 Reactivity of Enolate Ions

Enolate ions are more useful than enols for two reasons. First, pure enols can't normally be isolated but are instead generated only as short-lived intermediates in low concentration. By contrast, stable solutions of pure enolate ions are easily prepared from most carbonyl compounds by reaction with a strong base. Second, enolate ions are more reactive than enols and undergo many reactions that enols don't. Whereas enols are neutral, enolate ions are negatively charged, making them much better nucleophiles.

Because they are resonance hybrids of two nonequivalent forms, enolate ions can be looked at either as vinylic alkoxides ($\text{C}=\text{C}-\text{O}^-$) or as α -keto carbanions ($^-\text{C}-\text{C}=\text{O}$). Thus, enolate ions can react with electrophiles either on oxygen or on carbon. Reaction on oxygen yields an enol derivative, while reaction on carbon yields an α -substituted carbonyl compound (FIGURE 22.6). Both kinds of reactivity are known, but reaction on carbon is more common.

FIGURE 22.6 The electrostatic potential map of acetone enolate ion shows how the negative charge is delocalized over both the oxygen and the α carbon. As a result, two modes of reaction of an enolate ion with an electrophile E^+ are possible. Reaction on carbon to yield an α -substituted carbonyl product is more common.

As an example of enolate ion reactivity, aldehydes and ketones undergo base-promoted α halogenation. Even relatively weak bases such as hydroxide ion are effective for halogenation because it's not necessary to convert the ketone completely into its enolate ion. As soon as a small amount of enolate is generated, halogen reacts with it immediately, removing it from the reaction and driving the equilibrium toward further enolate ion

formation.

Base-promoted halogenation of aldehydes and ketones is seldom used in practice because it's difficult to stop the reaction at the monosubstituted product. An α -halogenated ketone is generally more acidic than the starting, unsubstituted ketone because of the electron-withdrawing inductive effect of the halogen atom. Thus, the monohalogenated products are themselves rapidly turned into enolate ions and further halogenated.

If excess base and halogen are used, a methyl ketone is triply halogenated and then cleaved by base in the *haloform reaction*. The products are a carboxylic acid plus a so-called haloform (chloroform, CHCl_3 ; bromoform, CHBr_3 ; or iodoform, CHI_3). Note that the second step of the reaction is a nucleophilic acyl substitution of $^-\text{CX}_3$ by ^-OH . That is, a halogen-stabilized carbanion acts as a leaving group.

PROBLEM 22-9 Why do you suppose ketone halogenations in acidic media are referred to as being *acid-catalyzed*, whereas halogenations in basic media are *base-promoted*? In other words, why is a full equivalent of base required for halogenation?

22.7 Alkylation of Enolate Ions

Perhaps the most useful reaction of enolate ions is their alkylation by treatment with an alkyl halide, thereby forming a new C–C bond and joining two smaller pieces into one larger molecule. Alkylation occurs when the nucleophilic enolate ion reacts with the electrophilic alkyl halide in an $\text{S}_{\text{N}}2$ reaction and displaces the leaving group by backside attack.

Alkylation reactions are subject to the same constraints that affect all $\text{S}_{\text{N}}2$ reactions (**Section 11.3**). Thus, the leaving group X in the alkylating agent R–X can be chloride, bromide, or iodide. The alkyl group R should be primary or methyl, and preferably should be allylic or benzylic. Secondary halides react poorly, and tertiary halides don't react at all because a competing $\text{E}2$ elimination of HX occurs instead. Vinylic and aryl halides are also unreactive because a backside approach is sterically prevented.

The Malonic Ester Synthesis

One of the oldest and best known carbonyl alkylation reactions is the **malonic ester synthesis**, a method for preparing a carboxylic acid from an alkyl halide while lengthening the carbon chain by two atoms.

Diethyl propanedioate, commonly called diethyl malonate, or *malonic ester*, is relatively acidic ($\text{p}K_{\text{a}} = 13$) because its α hydrogens are flanked by two carbonyl groups. Thus, malonic ester is easily converted into its enolate ion by reaction with sodium ethoxide in ethanol. The enolate ion, in turn, is a good nucleophile that reacts rapidly with an alkyl halide to give an α -substituted malonic ester. Note in the following examples that the abbreviation “Et” is used for an ethyl group, $-\text{CH}_2\text{CH}_3$.

The product of a malonic ester alkylation has one acidic α hydrogen remaining, so the alkylation process can be repeated to yield a dialkylated malonic ester.

On heating with aqueous hydrochloric acid, the alkylated (or dialkylated) malonic ester undergoes hydrolysis of its two ester groups followed by **decarboxylation** (loss of CO_2) to yield a substituted monocarboxylic acid.

Decarboxylation is not a general reaction of carboxylic acids. Rather, it is unique to compounds that have a second carbonyl group two atoms away from the $-\text{CO}_2\text{H}$. That is, only substituted malonic acids and β -keto acids undergo loss of CO_2 on heating. The decarboxylation reaction occurs by a cyclic mechanism and involves initial formation of an enol, thereby accounting for the need to have a second carbonyl group appropriately positioned.

As noted previously, the overall effect of malonic ester synthesis is to convert an alkyl halide into a carboxylic acid while lengthening the carbon chain by two atoms ($\text{RX} \rightarrow \text{RCH}_2\text{CO}_2\text{H}$).

A malonic ester synthesis can also be used to prepare *cycloalkanecarboxylic acids*. For example, when 1,4-dibromobutane is treated with diethyl malonate in the presence of two equivalents of sodium ethoxide base, the second alkylation step occurs intramolecularly to yield a cyclic product. Hydrolysis and decarboxylation then give cyclopentanecarboxylic acid. Three-, four-, five-, and six-membered rings can be prepared in this way, but yields decrease for larger ring sizes.

WORKED EXAMPLE 22.2

Using Malonic Ester Synthesis to Prepare a Carboxylic Acid

How would you prepare heptanoic acid using a malonic ester synthesis?

Strategy

A malonic ester synthesis converts an alkyl halide into a carboxylic acid having two more carbons. Thus, a seven-carbon acid chain must be derived from the five-carbon alkyl halide 1-bromopentane.

Solution

PROBLEM How could you use a malonic ester synthesis to prepare the following compounds? Show all steps.

22-10 (a)

(b)

(c)

PROBLEM 22-11 Monoalkylated and dialkylated acetic acids can be prepared by malonic ester synthesis, but trialkylated acetic acids (R_3C-CO_2H) can't be prepared. Explain.

PROBLEM 22-12 How could you use a malonic ester synthesis to prepare the following compound?

The Acetoacetic Ester Synthesis

Just as the malonic ester synthesis converts an alkyl halide into a carboxylic acid, the **acetoacetic ester synthesis** converts an alkyl halide into a methyl ketone having three more carbons.

Ethyl 3-oxobutanoate, commonly called ethyl acetoacetate, or *acetoacetic ester*, is much like malonic ester in that its α hydrogens are flanked by two carbonyl groups. It is therefore readily converted into its enolate ion, which can be alkylated by reaction with an alkyl halide. A second alkylation can also be carried out if desired, since acetoacetic ester has two acidic α hydrogens.

On heating with aqueous HCl, the alkylated (or dialkylated) acetoacetic ester is hydrolyzed to a β -keto acid, which then undergoes decarboxylation to yield a ketone product. The decarboxylation occurs in the same way as in the malonic ester synthesis and involves a ketone enol as the initial product.

The three-step sequence of (1) enolate ion formation, (2) alkylation, and (3) hydrolysis/decarboxylation is applicable to all β -keto esters with acidic α hydrogens, not just to acetoacetic ester itself. For example, cyclic β -keto esters, such as ethyl 2-oxocyclohexanecarboxylate, can be alkylated and decarboxylated to give 2-substituted cyclohexanones.

WORKED EXAMPLE 22.3

Using Acetoacetic Ester Synthesis to Prepare a Ketone

How would you prepare 2-pentanone by an acetoacetic ester synthesis?

Strategy

An acetoacetic ester synthesis yields a methyl ketone by adding three carbons to an alkyl halide.

Thus, the acetoacetic ester synthesis of 2-pentanone must involve reaction of bromoethane.

Solution

PROBLEM 22-13 What alkyl halides would you use to prepare the following ketones by an acetoacetic ester synthesis?

PROBLEM 22-14 Which of the following compounds can't be prepared by an acetoacetic ester synthesis? Explain.

- (a) Phenylacetone (b) Acetophenone (c) 3,3-Dimethyl-2-butanone

PROBLEM 22-15 How would you prepare the following compound using an acetoacetic ester synthesis?

Direct Alkylation of Ketones, Esters, and Nitriles

Both the malonic ester synthesis and the acetoacetic ester synthesis are easy to carry out because they involve relatively acidic dicarbonyl compounds. As a result, sodium ethoxide in ethanol can be used to prepare the

necessary enolate ions. Alternatively, however, it's also possible in many cases to directly alkylate the α position of *monocarbonyl* compounds. A strong, sterically hindered base such as LDA is needed so that complete conversion to the enolate ion takes place rather than a nucleophilic addition, and a nonprotic solvent must be used.

Ketones, esters, and nitriles can all be alkylated using LDA or related dialkylamide bases in tetrahydrofuran (THF). Aldehydes, however, rarely give high yields of pure products because their enolate ions undergo carbonyl condensation reactions instead of alkylation. (We'll study this condensation reaction in the next chapter.) Some specific examples of alkylation reactions are shown.

Lactone**Ester****Ketone****Nitrile**

Nitrile

Note in the ketone example that alkylation of 2-methylcyclohexanone leads to a mixture of products because both possible enolate ions are formed. In general, the major product in such cases occurs by alkylation at the less hindered, more accessible position. Thus, alkylation of 2-methylcyclohexanone occurs primarily at C6 (secondary) rather than C2 (tertiary).

WORKED EXAMPLE 22.4

Using an Alkylation Reaction to Prepare a Substituted Ester

How might you use an alkylation reaction to prepare ethyl 1-methylcyclohexanecarboxylate?

**Strategy**

An alkylation reaction is used to introduce a methyl or primary alkyl group onto the α position of a ketone, ester, or nitrile by S_N2 reaction of an enolate ion with an alkyl halide. Thus, we need to look at the target molecule and identify any methyl or primary alkyl groups attached to an α carbon. In the present instance, the target has an α methyl group, which might be introduced by alkylation of an ester enolate ion with iodomethane.

Solution

PROBLEM Show how you might prepare the following compounds using an alkylation reaction as the key step:

Biological Alkylations

Alkylations are rare but not unknown in biological chemistry. One example occurs during biosynthesis of the antibiotic indolmycin from indolylpyruvate when a base abstracts an acidic hydrogen from an α position and the resultant enolate ion carries out an S_N2 alkylation reaction on the methyl group of *S*-adenosylmethionine (SAM; Section 11.6). Although it's convenient to speak of "enolate ion" intermediates in biological pathways, it's unlikely that they exist for long in an aqueous cellular environment. Rather, proton removal and alkylation

probably occur at essentially the same time (FIGURE 22.7).

FIGURE 22.7 The biosynthesis of indolmycin from indolylpyruvate occurs through a pathway that includes an alkylation reaction of a short-lived enolate ion intermediate.

CHEMISTRY MATTERS

Barbiturates

The use of herbal remedies to treat illness and disease goes back thousands of years, but the medical use of chemicals prepared in the laboratory has a much shorter history. Barbiturates, a large class of drugs with a wide variety of uses, constitute one of the earliest successes of medicinal chemistry. The synthesis and medical use of barbiturates goes back to 1904 when Bayer, a German chemical company, first marketed a compound called barbital, trade named Veronal, as a treatment for insomnia. Since that time, more than 2500 different barbiturate analogs have been synthesized by drug companies, more than 50 have been used medicinally, and about a dozen are still in use as anesthetics, anticonvulsants, sedatives, and anxiolytics.

FIGURE 22.8 Different barbiturates come in a multitude of colors, giving rise to similarly colorful street names when the drugs are abused. (credit: "Medications" by freestocks.org/Flickr, Public Domain)

The synthesis of barbiturates is relatively simple and relies on reactions that are now familiar: enolate alkylations and nucleophilic acyl substitutions. Starting with diethyl malonate, alkylation of the corresponding enolate ion with simple alkyl halides provides a wealth of different disubstituted malonic esters. Reaction with urea, $(\text{H}_2\text{N})_2\text{C}=\text{O}$, then gives the product barbiturates by a twofold nucleophilic acyl substitution reaction of the ester groups with the $-\text{NH}_2$ groups of urea (FIGURE 22.9). Amobarbital (Amytal), pentobarbital (Nembutal), and secobarbital (Seconal) are typical examples.

FIGURE 22.9 The synthesis of barbiturates relies on malonic ester alkylations and nucleophilic acyl substitution reactions. More than 2500 different barbiturates have been synthesized over the past 100 years.

In addition to their prescribed medical uses, many barbiturates have also found widespread illegal use as street drugs. Each barbiturate often comes as a tablet of regulated size, shape, and color. Although still used today, most barbiturates have been replaced by safer, more potent alternatives with markedly different structures.

Key Terms

- **acetoacetic ester synthesis**
- **α -substitution reaction**
- **decarboxylation**
- **enol**
- **enolate ion**
- **malonic ester synthesis**
- **tautomer**

Summary

The α -substitution reaction of a carbonyl compound through either an **enol** or **enolate ion** intermediate is one of the four fundamental reaction types in carbonyl-group chemistry.

Carbonyl compounds are in an equilibrium with their enols, a process called keto–enol tautomerism. Although enol **tautomers** are normally present to only a small extent at equilibrium and can't usually be isolated in pure form, they nevertheless contain a highly nucleophilic double bond and react with electrophiles in an **α -substitution reaction**. An example is the α halogenation of ketones on treatment with Cl_2 , Br_2 , or I_2 in acid solution. Alpha bromination of carboxylic acids can be similarly accomplished by the Hell–Volhard–Zelinskii (HVZ) reaction, in which an acid is treated with Br_2 and PBr_3 . The α -halogenated products can then undergo base-induced E_2 elimination to yield α,β -unsaturated carbonyl compounds.

Alpha hydrogen atoms of carbonyl compounds are weakly acidic and can be removed by strong bases, such as lithium diisopropylamide (LDA), to yield nucleophilic enolate ions. The most useful reaction of enolate ions is their $\text{S}_{\text{N}}2$ alkylation with alkyl halides. The **Malonic ester synthesis** converts an alkyl halide into a carboxylic acid with the addition of two carbon atoms ($\text{RX} \rightarrow \text{RCH}_2\text{CO}_2\text{H}$). Similarly, the **acetoacetic ester synthesis** converts an alkyl halide into a methyl ketone with the addition of three carbon atoms ($\text{RX} \rightarrow \text{RCH}_2\text{COCH}_3$). In addition, many carbonyl compounds, including ketones, esters, and nitriles, can be directly alkylated by treatment with LDA and an alkyl halide.

Summary of Reactions

1. Aldehyde/ketone halogenation (Section 22.3)

2. Hell–Volhard–Zelinskii bromination of acids (Section 22.4)

3. Dehydrobromination of α -bromo ketones (Section 22.3)

4. Haloform reaction (Section 22.6)

5. Alkylation of enolate ions (Section 22.7)
 - a. Malonic ester synthesis

b. Acetoacetic ester synthesis

c. Direct alkylation of ketones

d. Direct alkylation of esters

e. Direct alkylation of nitriles

Additional Problems

Visualizing Chemistry

PROBLEM 22-17 Show the steps in preparing each of the following substances using either a malonic ester synthesis or an acetoacetic ester synthesis:

(a)

(b)

PROBLEM 22-18 Unlike most β -diketones, the following β -diketone has no detectable enol content and is about as acidic as acetone. Explain.

PROBLEM 22-19 For a given α hydrogen atom to be acidic, the C–H bond must be parallel to the p orbitals of the C=O double bond (that is, perpendicular to the plane of the adjacent carbonyl group). Identify the most acidic hydrogen atom in the conformation shown for the following structure. Is it axial or equatorial?

Mechanism Problems

PROBLEM Draw the corresponding keto or enol tautomer for each of the following molecules.

PROBLEM Predict the product(s) and show the mechanism for each of the following reactions:

PROBLEM Predict the product(s) and show the mechanism for each of the following reactions:

PROBLEM The following two optically active β -keto acids were decarboxylated under the conditions typically used for the acetoacetic ester synthesis. Will the ketone products be optically active? Explain.

PROBLEM In the Hell-Volhard-Zelinskii reaction, only a catalytic amount of PBr_3 is necessary because of the following equilibrium. Propose a mechanism for formation of the equilibrium.

PROBLEM When a ketone is treated with a halogen under acidic conditions, the α -monohalogenated product can be obtained in high yield. Under basic conditions however it is difficult to isolate the monohalogenated product. Explain.

PROBLEM Nonconjugated β,γ -unsaturated ketones, such as 3-cyclohexenone, are in an acid-catalyzed equilibrium with their conjugated α,β -unsaturated isomers. Propose a mechanism for the isomerization.

PROBLEM 22-27 2-substituted 2-cyclopentenones can be interconverted with 5-substituted 2-cyclopentenones under basic conditions. Propose a mechanism for this isomerization.

PROBLEM 22-28 Using curved arrows, propose a mechanism for the following reaction, one of the steps in the metabolism of the amino acid alanine.

PROBLEM 22-29 Using curved arrows, propose a mechanism for the following reaction, one of the steps in the biosynthesis of the amino acid tyrosine.

PROBLEM 22-30 One of the later steps in glucose biosynthesis is the isomerization of fructose 6-phosphate to glucose 6-phosphate. Propose a mechanism, using acid or base catalysis as needed.

PROBLEM 22-31 The *Favorskii reaction* involves treatment of an α -bromo ketone with base to yield a ring-contracted product. For example, reaction of 2-bromocyclohexanone with aqueous NaOH yields cyclopentanecarboxylic acid. Propose a mechanism.

PROBLEM 22-32 Treatment of a cyclic ketone with diazomethane is a method for accomplishing a ring-expansion reaction. For example, treatment of cyclohexanone with diazomethane yields cycloheptanone. Propose a mechanism.

PROBLEM 22-33 The final step in an attempted synthesis of laurene, a hydrocarbon isolated from the marine alga *Laurencia glandulifera*, involved the Wittig reaction shown. The product obtained, however, was not laurene but an isomer. Propose a mechanism to account for the unexpected results.

PROBLEM 22-34 Amino acids can be prepared by reaction of alkyl halides with diethyl acetamidomalonate, followed by heating the initial alkylation product with aqueous HCl. Show how you would prepare alanine, $\text{CH}_3\text{CH}(\text{NH}_2)\text{CO}_2\text{H}$, one of the twenty amino acids found in proteins, and propose a mechanism for acid-catalyzed conversion of the initial alkylation product to the amino acid.

PROBLEM 22-35 Amino acids can also be prepared by a two-step sequence that involves Hell–Volhard–Zelinskii reaction of a carboxylic acid followed by treatment with ammonia. Show how you would prepare leucine, $(\text{CH}_3)_2\text{CHCH}_2\text{CH}(\text{NH}_2)\text{CO}_2\text{H}$, and identify the mechanism of the second step.

PROBLEM 22-36 Heating carvone with aqueous sulfuric acid converts it into carvacrol. Propose a mechanism for the isomerization.

Acidity of Carbonyl Compounds

PROBLEM 22-37 Identify all the acidic hydrogens ($\text{p}K_a < 25$) in the following molecules:

PROBLEM 22-38 Rank the following compounds in order of increasing acidity:

PROBLEM Write resonance structures for the following anions:

PROBLEM Base treatment of the following α,β -unsaturated carbonyl compound yields an anion by removal of H^+ from the γ carbon. Why are hydrogens on the γ carbon atom acidic?

PROBLEM Treatment of 1-phenyl-2-propenone with a strong base such as LDA does not yield an anion, even though it contains a hydrogen on the carbon atom next to the carbonyl group. Explain.

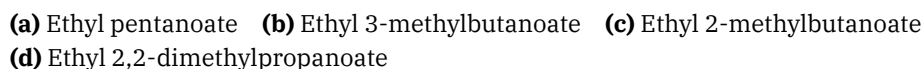

α -Substitution Reactions

PROBLEM Predict the product(s) of the following reactions:

PROBLEM Which, if any, of the following compounds can be prepared by a malonic ester synthesis? Show the alkyl halide you would use in each case.

PROBLEM Which, if any, of the following compounds can be prepared by an acetoacetic ester synthesis? Explain.

22-44

PROBLEM How would you prepare the following ketones using an acetoacetic ester synthesis?

PROBLEM How would you prepare the following compounds using either an acetoacetic ester synthesis or a malonic ester synthesis?

PROBLEM Which of the following substances would undergo the haloform reaction?

PROBLEM How might you convert geraniol into either ethyl geranylacetate or geranylacetone?

PROBLEM Aprobarbital, a barbiturate once used in treating insomnia, is synthesized in three steps from diethyl malonate. Show how you would synthesize the necessary dialkylated intermediate, and then propose a mechanism for the reaction of this intermediate with urea to give aprobarbital.

General Problems

PROBLEM One way to determine the number of acidic hydrogens in a molecule is to treat the compound with NaOD in D_2O , isolate the product, and determine its molecular weight by mass spectrometry. For example, if cyclohexanone is treated with NaOD in D_2O , the product has $\text{MW} = 102$. Explain how this method works.

PROBLEM 22-51 When optically active (*R*)-2-methylcyclohexanone is treated with either aqueous base or acid, racemization occurs. Explain.

PROBLEM 22-52 Would you expect optically active (*S*)-3-methylcyclohexanone to be racemized on acid or base treatment in the same way as 2-methylcyclohexanone (Problem 22-51)? Explain.

PROBLEM 22-53 When an optically active carboxylic acid such as (*R*)-2-phenylpropanoic acid is brominated under Hell-Volhard-Zelinskii conditions, is the product optically active or racemic? Explain.

PROBLEM 22-54 Fill in the reagents **a–c** that are missing from the following scheme:

PROBLEM 22-55 Although 2-substituted 2-cyclopentenones are in a base-catalyzed equilibrium with their 5-substituted 2-cyclopentenone isomers, the analogous isomerization is not observed for 2-substituted 2-cyclohexenones. Explain.

PROBLEM 22-56 How would you synthesize the following compounds from cyclohexanone? More than one step may be required.

PROBLEM 22-57 The two isomers *cis*- and *trans*-4-*tert*-butyl-2-methylcyclohexanone are interconverted by base treatment. Which isomer do you think is more stable, and why?

PROBLEM 22-58 The following synthetic routes are incorrect. What is wrong with each?

PROBLEM 22-59 Attempted Grignard reaction of cyclohexanone with *tert*-butylmagnesium bromide yields only about 1% of the expected addition product along with 99% unreacted cyclohexanone. If D_3O^+ is added to the reaction mixture after a suitable period, however, the “unreacted” cyclohexanone is found to have one deuterium atom incorporated into it. Explain.

PROBLEM 22-60 Ketones react slowly with benzeneselenenyl chloride in the presence of HCl to yield α -phenylseleno ketones. Propose a mechanism for this acid-catalyzed α -substitution reaction.

PROBLEM 22-61 South American Incas chewed the leaves of the coca bush, *Erythroxylon coca*, to combat fatigue. Chemical studies of *Erythroxylon coca* by Friedrich Wöhler in 1862 resulted in the discovery of cocaine, $\text{C}_{17}\text{H}_{21}\text{NO}_4$, as the active component. Basic hydrolysis of cocaine leads to methanol, benzoic acid, and another compound called ecgonine, $\text{C}_9\text{H}_{15}\text{NO}_3$. Oxidation of ecgonine with CrO_3 yields a keto acid that readily loses CO_2 on heating, giving tropinone.

- What is a likely structure for the keto acid?
- What is a likely structure for ecgonine, neglecting stereochemistry?
- What is a likely structure for cocaine, neglecting stereochemistry?

PROBLEM 22-62 The key step in a reported laboratory synthesis of sativene, a hydrocarbon isolated from the mold *Helminthosporium sativum*, involves the following base treatment of a keto tosylate. What kind of reaction is occurring? How would you complete the synthesis?

PROBLEM 22-63 Sodium pentothal is a short-acting barbiturate derivative used as a general anesthetic and known in popular culture as a truth serum. It is synthesized like other barbiturates (see the *Chemistry Matters* at the end of this chapter), using thiourea, $(\text{H}_2\text{N})_2\text{C}=\text{S}$, in place of urea. How would you synthesize sodium pentothal?

23.13 Some Biological Carbonyl Condensation Reactions

WHY THIS CHAPTER? We'll see later in this chapter and again in Chapter 29 that carbonyl condensation reactions occur in a large number of metabolic pathways. In fact, almost all classes of biomolecules—carbohydrates, lipids, proteins, nucleic acids, and many others—are biosynthesized through pathways that involve carbonyl condensation reactions. As with the α -substitution reaction discussed in the previous chapter, the great value of carbonyl condensations is that they are one of the few general methods for forming carbon–carbon bonds, thereby making it possible to build larger molecules from smaller precursors. In this chapter, we'll see how and why these reactions occur.

We've now studied three of the four general kinds of carbonyl-group reactions and have seen two general

kinds of behavior. In nucleophilic addition and nucleophilic acyl substitution reactions, a carbonyl compound behaves as an electrophile when an electron-rich reagent adds to it. In α -substitution reactions, however, a carbonyl compound behaves as a nucleophile when it is converted into its enol or enolate ion. In the carbonyl condensation reactions that we'll study in this chapter, the carbonyl compound behaves *both* as an electrophile and as a nucleophile.

**Electrophilic carbonyl group
reacts with nucleophiles.**

**Nucleophilic enolate ion
reacts with electrophiles.**

23.1 Carbonyl Condensations: The Aldol Reaction

Carbonyl condensation reactions take place between two carbonyl partners and involve a combination of nucleophilic addition and α -substitution steps. One partner is converted into an enolate-ion nucleophile and adds to the electrophilic carbonyl group of the second partner. In so doing, the nucleophilic partner undergoes an α -substitution reaction and the electrophilic partner undergoes a nucleophilic addition. The general mechanism of the process is shown in **FIGURE 23.2**.

FIGURE 23.2 MECHANISM

The general mechanism of a carbonyl condensation reaction. One partner becomes a nucleophilic donor and adds to the second partner as an electrophilic acceptor. After protonation, the final product is a β -hydroxy carbonyl compound.

- 1 A carbonyl compound with an α hydrogen atom is converted by base into its enolate ion.

- 2 The enolate ion acts as a nucleophilic donor and adds to the electrophilic carbonyl group of a second carbonyl compound.

- 3 Protonation of the tetrahedral alkoxide ion intermediate gives the neutral condensation product and regenerates the base catalyst.

Aldehydes and ketones with an α hydrogen atom undergo a base-catalyzed carbonyl condensation reaction called the **aldol reaction**. For example, treatment of acetaldehyde with a base such as sodium ethoxide or sodium hydroxide in a protic solvent leads to rapid and reversible formation of 3-hydroxybutanal, known commonly as *aldol* (*aldehyde* + *alcohol*), hence the general name of the reaction.

The exact position of the aldol equilibrium depends both on reaction conditions and on substrate structure. The equilibrium generally favors the condensation product in the case of aldehydes with no α substituent

(RCH_2CHO) but favors the reactant for disubstituted aldehydes (R_2CHCHO) and for most ketones. Steric factors are probably responsible for these trends, since increased substitution near the reaction site increases steric congestion in the aldol product.

Aldehydes

Ketones

WORKED EXAMPLE 23.1

Predicting the Product of an Aldol Reaction

What is the structure of the aldol product from propanal?

Strategy

An aldol reaction combines two molecules of reactant by forming a bond between the α carbon of one partner and the carbonyl carbon of the second partner. The product is a β -hydroxy aldehyde or ketone, meaning that the two oxygen atoms in the product have a 1,3 relationship.

Solution

PROBLEM Predict the aldol reaction product of the following compounds:

PROBLEM Using curved arrows to indicate the electron flow in each step, show how the base-catalyzed reverse-aldol reaction of 4-hydroxy-4-methyl-2-pentanone takes place to yield 2 equivalents of acetone.

23-2

23.2 Carbonyl Condensations versus Alpha Substitutions

Two of the four general carbonyl-group reactions—carbonyl condensations and α substitutions—take place under basic conditions and involve enolate-ion intermediates. Because the experimental conditions for the two reactions are similar, how can we predict which will occur in a given case? When we generate an enolate ion

with the intention of carrying out an α alkylation, how can we be sure that a carbonyl condensation reaction won't occur instead?

There is no simple answer to this question, but the exact experimental conditions usually have much to do with the result. Alpha-substitution reactions require a full equivalent of strong base and are normally carried out so that the carbonyl compound is rapidly and completely converted into its enolate ion at a low temperature. An electrophile is then added rapidly to ensure that the reactive enolate ion is quenched quickly. In a ketone alkylation reaction, for instance, we might use 1 equivalent of lithium diisopropylamide (LDA) in tetrahydrofuran solution at $-78\text{ }^\circ\text{C}$. Rapid and complete generation of the ketone enolate ion would occur, and no unreacted ketone would remain, meaning that no condensation reaction could take place. We would then immediately add an alkyl halide to complete the alkylation reaction.

On the other hand, carbonyl condensation reactions require only a catalytic amount of a relatively weak base, rather than a full equivalent, so that a small amount of enolate ion is generated in the presence of unreacted carbonyl compound. Once a condensation occurs, the basic catalyst is regenerated. To carry out an aldol reaction on propanal, for instance, we might dissolve the aldehyde in methanol, add 0.05 equivalent of sodium methoxide, and then warm the mixture to give the aldol product.

23.3 Dehydration of Aldol Products: Synthesis of Enones

When heated under either acidic or basic conditions, the β -hydroxy aldehydes or ketones formed in aldol reactions can be dehydrated to yield α,β -unsaturated products, or conjugated enones (ene + ketone). In fact, it's this loss of water that gives the carbonyl *condensation* reaction its name, because water condenses out when an enone product forms.

Most alcohols are resistant to dehydration by base (Section 17.6) because hydroxide ion is a poor leaving group, but aldol products dehydrate easily because of their carbonyl group. Under basic conditions, an acidic α hydrogen is removed, yielding an enolate ion that expels the nearby ^-OH leaving group in an E1cB reaction (Section 11.10). Under acidic conditions, an enol is formed, the $-OH$ group is protonated, and water is expelled in an E1 or E2 reaction.

The reaction conditions needed for aldol dehydration are often only a bit more vigorous (slightly higher temperature, for instance) than the conditions needed for the aldol formation itself. As a result, conjugated enones are usually obtained directly from aldol reactions without isolating the intermediate β -hydroxy carbonyl compounds.

Conjugated enones are more stable than nonconjugated enones for the same reason that conjugated dienes are more stable than nonconjugated dienes (Section 14.1). Interaction between the π electrons of the $C=C$ bond and the π electrons of the $C=O$ group leads to a molecular-orbital description for a conjugated enone with an interaction of the π electrons over all four atomic centers (FIGURE 23.3).

FIGURE 23.3 The π bonding molecular orbitals of a conjugated enone (propenal) and a conjugated diene (1,3-butadiene) are similar in shape and are spread over the entire π system.

The real value of aldol dehydration is that removal of water from the reaction mixture can be used to drive the aldol equilibrium toward the product. Even though the initial aldol step itself may be unfavorable, as it usually is for ketones, the subsequent dehydration step nevertheless allows many aldol condensations to be carried out in good yield. Cyclohexanone, for example, gives cyclohexylidenecyclohexanone in 92% yield, even though the initial equilibrium is unfavorable.

WORKED EXAMPLE 23.2

Predicting the Product of an Aldol Reaction

What is the structure of the enone obtained from aldol condensation of acetaldehyde?

Strategy

In the aldol reaction, H_2O is eliminated and a double bond is formed by removing two hydrogens from the acidic α position of one partner and the carbonyl oxygen from the second partner. The product is thus an α,β -unsaturated aldehyde or ketone.

Solution

PROBLEM 23-3 What enone product would you expect from aldol condensation of each of the following compounds?

PROBLEM 23-4 Aldol condensation of 3-methylcyclohexanone leads to a mixture of two enone products, not counting double-bond isomers. Draw them.

23.4 Using Aldol Reactions in Synthesis

The aldol reaction yields either a β -hydroxy aldehyde/ketone or an α,β -unsaturated aldehyde/ketone, depending on the experimental conditions. By learning how to work backward, it's possible to predict when the aldol reaction might be useful in synthesis. Whenever the target molecule contains either a β -hydroxy aldehyde/ketone or a conjugated enone functional group, it might come from an aldol reaction.

We can extend this kind of reasoning even further by imagining that subsequent transformations might be carried out on the aldol products. For example, a saturated ketone might be prepared by catalytic hydrogenation of the enone product. A good example can be found in the industrial preparation of 2-ethyl-1-hexanol, an alcohol used in the synthesis of plasticizers for polymers. Although 2-ethyl-1-hexanol bears little resemblance to an aldol product at first glance, it is in fact prepared commercially from butanal by an aldol reaction. Working backward, we can reason that 2-ethyl-1-hexanol might come from 2-ethylhexanal by a reduction. 2-Ethylhexanal, in turn, might be prepared by catalytic reduction of 2-ethyl-2-hexenal, which is the aldol condensation product of butanal. The reactions that follow show the sequence in reverse order.

PROBLEM 23-5 Which of the following compounds are aldol condensation products? What is the aldehyde or ketone precursor of each?

- (a) 2-Hydroxy-2-methylpentanal (b) 5-Ethyl-4-methyl-4-hepten-3-one

PROBLEM 23-6 1-Butanol is prepared commercially by a route that begins with an aldol reaction. Show the steps that are likely to be involved.

PROBLEM 23-7 Show how you would synthesize the following compound using an aldol reaction:

23.5 Mixed Aldol Reactions

Until now, we've considered only symmetrical aldol reactions, in which the two carbonyl components have been the same. What would happen, though, if an aldol reaction were carried out between two different carbonyl partners?

In general, a mixed aldol reaction between two similar aldehyde or ketone partners leads to a mixture of four possible products. For example, base treatment of a mixture of acetaldehyde and propanal gives a complex product mixture containing two "symmetrical" aldol products and two "mixed" aldol products. Clearly, such a reaction is of no practical value.

On the other hand, mixed aldol reactions can lead cleanly to a single product if either of two conditions is met:

- If one of the carbonyl partners contains no α hydrogens (and thus can't form an enolate ion to become a donor), but does contain an unhindered carbonyl group (and so is a good acceptor of nucleophiles), then a mixed aldol reaction is likely to be successful. This is the case, for instance, when either benzaldehyde or

formaldehyde is used as one of the carbonyl partners.

Neither benzaldehyde nor formaldehyde can form an enolate ion to add to another partner, yet both compounds have an unhindered carbonyl group. The ketone 2-methylcyclohexanone, for instance, gives the mixed aldol product on reaction with benzaldehyde.

- If one of the carbonyl partners is much more acidic than the other, and is thus transformed into its enolate ion in preference to the other, then a mixed aldol reaction is likely to be successful. Ethyl acetoacetate, for instance, is completely converted into its enolate ion in preference to enolate ion formation from monocarbonyl partners. Thus, aldol condensations of monoketones with ethyl acetoacetate occur preferentially to give the mixed product.

The situation can be summarized by saying that a mixed aldol reaction leads to a mixture of products unless one of the partners either has no α hydrogens but is a good electrophilic acceptor (such as benzaldehyde) or is an unusually acidic nucleophilic donor (such as ethyl acetoacetate).

PROBLEM Which of the following compounds can probably be prepared by a mixed aldol reaction? Show the reactants you would use in each case.

23.6 Intramolecular Aldol Reactions

The aldol reactions we've seen thus far have all been *intermolecular*, meaning that they have taken place between two different molecules. When certain *dicarbonyl* compounds are treated with base, however, an *intramolecular* aldol reaction can occur, leading to the formation of a cyclic product. For example, base treatment of a 1,4-diketone such as 2,5-hexanedione yields a cyclopentenone product, and base treatment of a 1,5-diketone such as 2,6-heptanedione yields a cyclohexenone.

The mechanism of intramolecular aldol reactions is similar to that of intermolecular reactions. The only difference is that both the nucleophilic carbonyl anion donor and the electrophilic carbonyl acceptor are now in the same molecule. One complication, however, is that intramolecular aldol reactions might lead to a mixture of products, depending on which enolate ion is formed. For example, 2,5-hexanedione might yield either the five-membered-ring product 3-methyl-2-cyclopentenone or the three-membered-ring product (2-methylcyclopropenyl) ethanone (FIGURE 23.4). In practice, though, only the cyclopentenone is formed.

FIGURE 23.4 Intramolecular aldol reaction of 2,5-hexanedione yields 3-methyl-2-cyclopentenone rather than the alternative cyclopropene.

The selectivity observed in the intramolecular aldol reaction of 2,5-hexanedione is due to the fact that all steps in the mechanism are reversible, so an equilibrium is reached. Thus, the relatively strain-free cyclopentenone product is considerably more stable than the highly strained cyclopropene alternative. For similar reasons, intramolecular aldol reactions of 1,5-diketones lead only to cyclohexenone products rather than to the more strained acylcyclobutenes.

PROBLEM 23-9 Treatment of a 1,3-diketone such as 2,4-pentanedione with base does not give an aldol condensation product. Explain.

PROBLEM 23-10 What product would you expect to obtain from base treatment of 1,6-cyclodecanedione?

1,6-Cyclodecanedione

23.7 The Claisen Condensation Reaction

Esters, like aldehydes and ketones, are weakly acidic. When an ester with an α hydrogen is treated with 1 equivalent of a base such as sodium ethoxide, a reversible carbonyl condensation reaction occurs to yield a β -keto ester. For instance, ethyl acetate yields ethyl acetoacetate on base treatment. This reaction between two ester molecules is known as the **Claisen condensation reaction**. (We'll use ethyl esters, abbreviated "Et," for consistency, but other esters will also work.)

The mechanism of the Claisen condensation is similar to that of the aldol condensation and involves the nucleophilic addition of an ester enolate ion to the carbonyl group of a second ester molecule (**FIGURE 23.5**). The only difference between the aldol condensation of an aldehyde or ketone and the Claisen condensation of an ester involves the fate of the initially formed tetrahedral intermediate. The tetrahedral intermediate in the aldol reaction is protonated to give an alcohol product—exactly the behavior previously seen for aldehydes and ketones (**Section 19.4**). The tetrahedral intermediate in the Claisen reaction, however, expels an alkoxide leaving group to yield an acyl substitution product—as previously seen for esters (**Section 21.6**).

FIGURE 23.5 MECHANISM

Mechanism of the Claisen condensation reaction.

- 1 Base abstracts an acidic alpha hydrogen atom from an ester molecule, yielding an ester enolate ion.

1

- 2 The enolate ion is added in a nucleophilic addition reaction to a second ester molecule, giving a tetrahedral alkoxide intermediate.

2

- 3 The tetrahedral intermediate expels ethoxide ion to yield a new carbonyl compound, ethyl acetoacetate.

3

- 4 But ethoxide ion is a strong enough base to deprotonate ethyl acetoacetate, shifting the equilibrium and driving the overall reaction to completion.

4

- 5 Protonation of the enolate ion by addition of aqueous acid in a separate step yields the final β -keto ester product.

5 H_3O^+ 

If the starting ester has more than one acidic α hydrogen, the product β -keto ester has a highly acidic, doubly activated hydrogen atom that can be abstracted by base. This deprotonation of the product requires the use of a full equivalent of base rather than a catalytic amount. Furthermore, the deprotonation serves to drive the equilibrium completely to the product side so that high yields are usually obtained in Claisen condensations.

WORKED EXAMPLE 23.3

Predicting the Product of a Claisen Condensation Reaction

What product would you obtain from Claisen condensation of ethyl propanoate?

Strategy

The Claisen condensation of an ester results in loss of one molecule of alcohol and formation of a product in which an acyl group of one reactant bonds to the α carbon of the second reactant. The product is a β -keto ester.

Solution

PROBLEM Show the products you would expect to obtain by Claisen condensation of the following esters:

23-11 (a) $(\text{CH}_3)_2\text{CHCH}_2\text{CO}_2\text{Et}$ (b) Ethyl phenylacetate (c) Ethyl cyclohexylacetate

PROBLEM As shown in Figure 23.5, the Claisen reaction is reversible. That is, a β -keto ester can be cleaved by base into two fragments. Using curved arrows to indicate electron flow, show the mechanism by which this cleavage occurs.

23.8 Mixed Claisen Condensations

The mixed Claisen condensation of two different esters is similar to the mixed aldol condensation of two different aldehydes or ketones (Section 23.5). Mixed Claisen reactions are successful only when one of the two ester components has no α hydrogens and thus can't form an enolate ion. For example, ethyl benzoate and ethyl formate can't form enolate ions and thus can't serve as donors. They can, however, act as the electrophilic acceptor components in reactions with other ester anions to give mixed β -keto ester products.

Mixed Claisen-like reactions can also be carried out between an ester and a ketone, resulting in the synthesis of a β -diketone. The reaction works best when the ester component has no α hydrogens and thus can't act as the nucleophilic donor. For example, ethyl formate gives high yields in mixed Claisen condensations with ketones.

WORKED EXAMPLE 23.4

Predicting the Product of a Mixed Claisen Condensation Reaction

Diethyl oxalate, $(\text{CO}_2\text{Et})_2$, often gives high yields in mixed Claisen reactions. What product would you expect to obtain from a mixed Claisen reaction of ethyl acetate with diethyl oxalate?

Strategy

A mixed Claisen reaction is effective when only one of the two partners has an acidic α hydrogen atom. In the present case, ethyl acetate can be converted into its enolate ion, but diethyl oxalate cannot. Thus, ethyl acetate acts as the donor and diethyl oxalate as the acceptor.

Solution

PROBLEM 23-13 What product would you expect from the following mixed Claisen-like reaction?

23.9 Intramolecular Claisen Condensations: The Dieckmann Cyclization

Intramolecular Claisen condensations can be carried out with diesters, just as intramolecular aldol condensations can be carried out with diketones (Section 23.6). Called the **Dieckmann cyclization**, this reaction works best on 1,6-diester and 1,7-diester. Intramolecular Claisen cyclization of a 1,6-diester gives a five-membered cyclic β -keto ester, and cyclization of a 1,7-diester gives a six-membered cyclic β -keto ester.

The mechanism of the Dieckmann cyclization, shown in **FIGURE 23.6**, is the same as that of the Claisen condensation. One of the two ester groups is converted into an enolate ion, which carries out a nucleophilic acyl substitution on the second ester group at the other end of the molecule. A cyclic β -keto ester product results.

FIGURE 23.6 MECHANISM

Mechanism of the Dieckmann cyclization of a 1,7-diester to yield a cyclic β -keto ester product.

- 1** Base abstracts an acidic α proton from the carbon atom next to one of the ester groups, yielding an enolate ion.

- 2** Intramolecular nucleophilic addition of the ester enolate ion to the carbonyl group of the second ester at the other end of the chain then gives a cyclic tetrahedral intermediate.

- 3** Loss of alkoxide ion from the tetrahedral intermediate forms a cyclic β -keto ester.

- 4** Deprotonation of the acidic β -keto ester gives an enolate ion . . .

- 5** . . . which is protonated by addition of aqueous acid at the end of the reaction to generate the neutral β -keto ester product.

The cyclic β -keto ester produced in a Dieckmann cyclization can be further alkylated and decarboxylated by a series of reactions analogous to those used in the acetoacetic ester synthesis (**Section 22.7**). Alkylation and

subsequent decarboxylation of ethyl 2-oxocyclohexanecarboxylate, for instance, yields a 2-alkylcyclohexanone. The overall sequence of (1) Dieckmann cyclization, (2) β -keto ester alkylation, and (3) decarboxylation is a powerful method for preparing 2-substituted cyclopentanones and cyclohexanones.

PROBLEM What product would you expect from the following reaction?

PROBLEM Dieckmann cyclization of diethyl 3-methylheptanedioate gives a mixture of two β -keto ester products. What are their structures, and why is a mixture formed?

23.10 Conjugate Carbonyl Additions: The Michael Reaction

We saw in [Section 19.13](#) that certain nucleophiles, such as amines, react with α,β -unsaturated aldehydes and ketones to give a conjugate addition product, rather than a direct addition product.

Exactly the same kind of conjugate addition can occur when a nucleophilic enolate ion reacts with an α,β -unsaturated carbonyl compound—a process known as the **Michael reaction** after Arthur Michael at Tufts College and Harvard University.

The best Michael reactions are those that take place when a particularly stable enolate ion, such as that derived from a β -keto ester or other 1,3-dicarbonyl compound, adds to an unhindered α,β -unsaturated ketone. For example, ethyl acetoacetate reacts with 3-buten-2-one in the presence of sodium ethoxide to yield the conjugate addition product.

Michael reactions take place by addition of a nucleophilic enolate ion donor to the β carbon of an α,β -unsaturated carbonyl acceptor, according to the mechanism shown in [FIGURE 23.7](#).

FIGURE 23.7 MECHANISM

Mechanism of the Michael reaction between a β -keto ester and an α,β -unsaturated ketone. The reaction is a conjugate addition of an enolate ion to the unsaturated carbonyl compound.

1 The base catalyst removes an acidic alpha proton from the starting β -keto ester to generate a stabilized enolate ion nucleophile.

2 The nucleophile adds to the α,β -unsaturated ketone electrophile in a Michael reaction to generate a new enolate as product.

3 The enolate product abstracts an acidic proton, either from solvent or from starting keto ester, to yield the final addition product.

The Michael reaction occurs with a variety of α,β -unsaturated carbonyl compounds, not just conjugated ketones. Unsaturated aldehydes, esters, thioesters, nitriles, amides, and nitro compounds can all act as the electrophilic acceptor component in Michael reactions (TABLE 23.1). Similarly, a variety of different donors can be used, including β -diketones, β -keto esters, malonic esters, β -keto nitriles, and nitro compounds.

TABLE 23.1 Some Michael Acceptors and Michael Donors

Michael acceptors		Michael donors	
$\text{H}_2\text{C}=\overset{\text{O}}{\parallel}\text{CH}$	Propenal	$\text{RCCH}_2\overset{\text{O}}{\parallel}\text{CR}'$	β -Diketone

WORKED EXAMPLE 23.5

Using the Michael Reaction

How might you obtain the following compound using a Michael reaction?

Strategy

A Michael reaction involves the conjugate addition of a stable enolate ion donor to an α,β -unsaturated carbonyl acceptor, yielding a 1,5-dicarbonyl product. Usually, the stable enolate ion is derived from a β -diketone, β -keto ester, malonic ester, or similar compound. The C–C bond formed in the conjugate addition step is the one between the α carbon of the acidic donor and the β carbon of the unsaturated acceptor.

Solution

PROBLEM 23-16 What product would you obtain from a base-catalyzed Michael reaction of 2,4-pentanedione with each of the following α,β -unsaturated acceptors?

- (a) 2-Cyclohexenone (b) Propenenitrile (c) Ethyl 2-butenate

PROBLEM 23-17 What product would you obtain from a base-catalyzed Michael reaction of 3-buten-2-one with each of the following nucleophilic donors?

PROBLEM 23-18 How would you prepare the following compound using a Michael reaction (gray = H, black = C, red = O, blue = N)?

23.11 Carbonyl Condensations with Enamines: The Stork Enamine Reaction

In addition to enolate ions, other kinds of carbon nucleophiles also add to α,β -unsaturated acceptors in Michael-like reactions. Among the most important and useful of such nucleophiles, particularly in biological chemistry, are *enamines*, which are readily prepared by reaction between a ketone and a secondary amine (Section 19.8). For example:

As the following resonance structures indicate, enamines are electronically similar to enolate ions. Overlap of the nitrogen lone-pair orbital with the double-bond p orbitals leads to an increase in electron density on the α carbon atom, making that carbon nucleophilic. An electrostatic potential map of N,N -dimethylaminoethylene shows this shift of electron density (red) toward the α position.

Enamines behave in much the same way as enolate ions and enter into many of the same kinds of reactions. In the **Stork enamine reaction**, named for its discoverer, Gilbert Stork of Columbia University, for example, an enamine adds to an α,β -unsaturated carbonyl acceptor in a Michael-like process. The initial product is then hydrolyzed by aqueous acid to yield a 1,5-dicarbonyl compound. The overall reaction is thus a three-step sequence of (1) enamine formation from a ketone, (2) Michael addition to an α,β -unsaturated carbonyl compound, and (3) enamine hydrolysis back to a ketone.

The net effect of the Stork enamine reaction is the Michael addition of a ketone to an α,β -unsaturated carbonyl compound. For example, cyclohexanone reacts with the cyclic amine pyrrolidine to yield an enamine; further reaction with an enone such as 3-buten-2-one yields a Michael adduct; and aqueous hydrolysis completes the sequence to give a 1,5-diketone (FIGURE 23.8).

FIGURE 23.8 The Stork enamine reaction between cyclohexanone and 3-buten-2-one. (1) Cyclohexanone is first converted into an enamine, (2) the enamine adds to the α,β -unsaturated ketone in a Michael reaction, and (3) the conjugate addition product is hydrolyzed to yield a 1,5-diketone.

The enamine–Michael reaction has two advantages over the enolate-ion–Michael reaction that makes it particularly useful in biological pathways. First, an enamine is neutral, easily prepared, and easily handled, while an enolate ion is charged, sometimes difficult to prepare, and must be handled carefully. Second, an enamine from a *monoketone* can be used in the Michael addition, whereas only enolate ions from β -dicarbonyl compounds can be used.

WORKED EXAMPLE 23.6

Using the Stork Enamine Reaction

How might you use an enamine reaction to prepare the following compound?

Strategy

The overall result of an enamine reaction is the Michael addition of a ketone as donor to an α,β -unsaturated carbonyl compound as acceptor, yielding a 1,5-dicarbonyl product. The C–C bond formed in the Michael addition step is the one between the α carbon of the ketone donor and the β carbon of the unsaturated acceptor.

Solution

PROBLEM 23-19 What products would result after hydrolysis from reaction of the enamine prepared from cyclopentanone and pyrrolidine with the following α,β -unsaturated acceptors?

- (a) $\text{H}_2\text{C}=\text{CHCO}_2\text{Et}$ (b) $\text{H}_2\text{C}=\text{CHCHO}$ (c) $\text{CH}_3\text{CH}=\text{CHCOCH}_3$

PROBLEM 23-20 Show how you might use an enamine reaction to prepare each of the following compounds:

23.12 The Robinson Annulation Reaction

Carbonyl condensation reactions are perhaps the most versatile methods available for synthesizing complex molecules. By putting a few fundamental reactions together in the proper sequence, some remarkably useful transformations can be carried out. One such example is the **Robinson annulation reaction** for the synthesis of polycyclic molecules. The word *annulation* derives from the Latin *annulus*, meaning “ring,” so an annulation reaction is one that builds a new ring onto a molecule.

Named after Robert Robinson, a British chemist and 1947 Nobel Prize winner, the Robinson annulation is a two-step process that combines a Michael reaction with an intramolecular aldol reaction. It takes place between a nucleophilic donor, such as a β -keto ester; an enamine, or a β -diketone; and an α,β -unsaturated ketone acceptor, such as 3-buten-2-one. The product is a substituted 2-cyclohexenone.

The first step of the Robinson annulation is simply a Michael reaction. An enamine or an enolate ion from a β -keto ester or β -diketone effects a conjugate addition to an α,β -unsaturated ketone, yielding a 1,5-diketone. But as we saw in [Section 23.6](#), 1,5-diketones undergo intramolecular aldol condensation to yield cyclohexenones when treated with base. Thus, the final product contains a six-membered ring, and an annulation has been accomplished. One example of this occurs during a synthesis of the steroid hormone estrone ([FIGURE 23.9](#)).

FIGURE 23.9 Synthesis of the steroid hormone estrone using a Robinson annulation reaction. The nucleophilic donor is a β -diketone.

In this example, the β -diketone 2-methyl-1,3-cyclopentanedione is used to generate the enolate ion required for Michael reaction and an aryl-substituted α,β -unsaturated ketone is used as the acceptor. Base-catalyzed Michael reaction between the two partners yields an intermediate triketone, which then cyclizes in an intramolecular aldol condensation to give a Robinson annulation product. Several further transformations are required to complete the synthesis of estrone.

PROBLEM What product would you expect from a Robinson annulation reaction of
23-21 2-methyl-1,3-cyclopentanedione with 3-buten-2-one?

2-Methyl-1,3-cyclo-
pentanedione

3-Buten-2-one

PROBLEM How would you prepare the following compound using a Robinson annulation reaction between
23-22 a β -diketone and an α,β -unsaturated ketone? Draw the structures of both reactants and the intermediate Michael addition product.

23.13 Some Biological Carbonyl Condensation Reactions

Biological Aldol Reactions

Aldol reactions occur in many biological pathways but are particularly common in carbohydrate metabolism, where enzymes called *aldolases* catalyze the addition of a ketone enolate ion to an aldehyde. Aldolases occur in all organisms and are of two types. Type I aldolases occur primarily in animals and higher plants; type II aldolases occur primarily in fungi and bacteria. Both types catalyze the same kind of reaction, but type I aldolases operate through an enamine while type II aldolases require a metal ion (usually Zn²⁺) as a Lewis acid and operate through an enolate ion.

An example of an aldolase-catalyzed reaction occurs in glucose biosynthesis when dihydroxyacetone phosphate reacts with glyceraldehyde 3-phosphate to give fructose 1,6-bisphosphate. In animals and higher plants, dihydroxyacetone phosphate is first converted into an enamine by reaction with the -NH₂ group on a lysine amino acid in the enzyme. The enamine then adds to glyceraldehyde 3-phosphate, and the iminium ion that results is hydrolyzed. In bacteria and fungi, the aldol reaction occurs directly, with the ketone carbonyl group of glyceraldehyde 3-phosphate complexed to a Zn²⁺ ion to make it a better acceptor.

Type I aldolase**Type II aldolase**

Note that the aldolase-catalyzed reactions are mixed aldol reactions, which take place between two different partners, as opposed to the symmetrical aldol reactions between identical partners usually carried out in the laboratory. Mixed aldol reactions often give mixtures of products in the laboratory but are successful in living systems because of the selectivity of the enzyme catalysts.

Biological Claisen Condensations

Claisen condensations, like aldol reactions, also occur in a large number of biological pathways. In fatty-acid biosynthesis, for instance, an enolate ion generated by decarboxylation ([Section 22.7](#)) of malonyl ACP adds to the carbonyl group of another acyl group bonded through a thioester linkage to a synthase enzyme. The tetrahedral intermediate that results then expels the synthase, giving acetoacetyl ACP. (The abbreviation ACP stands for acyl carrier protein, which forms thioester bonds to acyl groups.)

Mixed Claisen condensations also occur frequently in living organisms, particularly in the pathway for fatty-acid biosynthesis that we'll discuss in **Section 29.4**. Butyryl synthase, for instance, reacts with malonyl ACP in a mixed Claisen condensation to give 3-ketohexanoyl ACP.

CHEMISTRY MATTERS

A Prologue to Metabolism

Biochemistry is carbonyl chemistry. Almost all metabolic pathways used by living organisms involve one or more of the four fundamental carbonyl-group reactions we've seen in the chapters on **Aldehydes and Ketones: Nucleophilic Addition Reactions** through **Carbonyl Condensation Reactions**. The digestion and metabolic breakdown of all the major classes of food molecules—fats, carbohydrates, and proteins—take place by nucleophilic addition reactions, nucleophilic acyl substitutions, α substitutions, and carbonyl condensations. Similarly, hormones and other crucial biological molecules are built up from smaller precursors by these same carbonyl-group reactions.

FIGURE 23.10 You are what you eat. Food molecules are metabolized by pathways that involve the four major carbonyl-group reactions. (credit: “Spring” by Giuseppe Arcimboldo, Louvre Museum/Wikimedia Commons, Public Domain)

Take *glycolysis*, for example, the metabolic pathway by which organisms convert glucose to pyruvate as the first step in extracting energy from carbohydrates.

Glycolysis is a ten-step process that begins with isomerization of glucose from its cyclic hemiacetal form to its open-chain aldehyde form—the reverse of a nucleophilic addition reaction. The aldehyde then undergoes tautomerization to yield an enol, which undergoes yet another tautomerization to give the ketone fructose.

Fructose, a β -hydroxy ketone, is then cleaved by a retro-aldol reaction into two three-carbon molecules—one ketone and one aldehyde. Further carbonyl-group reactions then occur until pyruvate is formed.

These few examples are only an introduction; we'll look at several of the major metabolic pathways in more detail in Chapter 29. The bottom line, however, is that you haven't seen the end of carbonyl-group chemistry if you have any interest in biological or medical fields. A solid grasp of carbonyl-group reactions is crucial to an understanding of biochemistry.

Key Terms

- **aldol reaction**
- **carbonyl condensation reaction**
- **Claisen condensation reaction**
- **Dieckmann cyclization**
- **Michael reaction**
- **Robinson annulation reaction**
- **Stork enamine reaction**

Summary

In this chapter, we've discussed the fourth and last of the common carbonyl-group reactions—the carbonyl condensation. A **carbonyl condensation reaction** takes place between two carbonyl partners and involves both nucleophilic addition and α -substitution processes. One carbonyl partner is converted by base into a nucleophilic enolate ion, which then adds to the electrophilic carbonyl group of the second partner. The first partner thus undergoes an α substitution, while the second undergoes a nucleophilic addition.

The **aldol reaction** is a carbonyl condensation that occurs between two aldehyde or ketone molecules. Aldol reactions are reversible, leading first to β -hydroxy aldehydes/ketones and then to α,β -unsaturated products after dehydration. Mixed aldol condensations between two different aldehydes or ketones generally give a mixture of all four possible products. A mixed reaction can be successful, however, if one of the two partners is an unusually good donor (ethyl acetoacetate, for instance) or if it can act only as an acceptor (formaldehyde and benzaldehyde, for instance). Intramolecular aldol condensations of 1,4- and 1,5-diketones are also successful and provide a good way to make five- and six-membered rings.

The **Claisen condensation reaction** is a carbonyl condensation that occurs between two ester components and gives a β -keto ester product. Mixed Claisen condensations between two different esters are successful only when one of the two partners has no acidic α hydrogens (ethyl benzoate and ethyl formate, for instance) and thus can function only as the acceptor partner. Intramolecular Claisen condensations, called **Dieckmann cyclization reactions**, yield five- and six-membered cyclic β -keto esters starting from 1,6- and 1,7-diester.

The conjugate addition of a carbon nucleophile to an α,β -unsaturated acceptor is known as the **Michael reaction**. The best Michael reactions take place between relatively acidic donors (β -keto esters or β -diketones) and unhindered α,β -unsaturated acceptors. Enamines, prepared by reaction of a ketone with a disubstituted amine, are also good Michael donors in the Stork enamine reaction.

Carbonyl condensation reactions are widely used in synthesis. One example of their versatility is the **Robinson annulation reaction**, which leads to the formation of a substituted cyclohexenone. Treatment of a β -diketone or β -keto ester with an α,β -unsaturated ketone leads first to a Michael addition, which is followed by intramolecular aldol cyclization. Condensation reactions are also used widely in nature for the biosynthesis of such molecules as fats and steroids.

Summary of Reactions

1. Aldol reaction (Section 23.1)

2. Mixed aldol reaction (Section 23.5)

3. Intramolecular aldol reaction (Section 23.6)

4. Dehydration of aldol products (Section 23.3)

5. Claisen condensation reaction (Section 23.7)

6. Mixed Claisen condensation reaction (Section 23.8)

7. Intramolecular Claisen condensation (Dieckmann cyclization; Section 23.9)

8. Michael reaction (Section 23.10)

9. Carbonyl condensations with enamines (Stork enamine reaction; Section 23.11)

Additional Problems

Visualizing Chemistry

PROBLEM What ketones or aldehydes might the following enones have been prepared from by aldol reaction?

23-23 (a)

(b)

PROBLEM The following structure represents an intermediate formed by addition of an ester enolate ion to a second ester molecule. Identify the reactant, the leaving group, and the product.

PROBLEM The following molecule was formed by an intramolecular aldol reaction. What dicarbonyl precursor was used for its preparation?

23-25

PROBLEM 23-26 The following molecule was formed by a Robinson annulation reaction. What reactants were used?

Mechanism Problems

PROBLEM 23-27 Predict the addition product for each of the following reactions and write the mechanism.

PROBLEM 23-28 Based on your answers to Problem 23-27, predict the dehydration product for both reactions and write the mechanism.

PROBLEM 23-29 Predict the product(s) and provide the mechanisms for the following reactions.

PROBLEM 23-30 Predict the product(s) and provide the mechanisms for the following reactions.

PROBLEM 23-31 Predict the product(s) and provide the mechanisms for the following reactions.

PROBLEM 23-32 Knoevenagel condensation is a reaction involving an active methylene compound (a CH₂ flanked by two electron-withdrawing groups) and an aldehyde and ketone. Propose a mechanism for the reaction below.

PROBLEM 23-33 Azlactones are important starting materials used in the synthesis of dehydro- α -amino acids. They react with aldehydes to form an intermediate that is hydrolyzed under acidic conditions to give the final amino acid product. Provide the structure of the intermediate and propose a mechanism for its formation.

PROBLEM 23-34 Leucine, one of the twenty amino acids found in proteins, is metabolized by a pathway that includes the following step. Propose a mechanism.

PROBLEM 23-35 Isoleucine, another of the twenty amino acids found in proteins, is metabolized by a pathway that includes the following step. Propose a mechanism.

PROBLEM 23-36 The first step in the citric acid cycle of food metabolism is reaction of oxaloacetate with acetyl CoA to give citrate. Propose a mechanism, using acid or base catalysis as needed.

PROBLEM 23-37 The amino acid leucine is biosynthesized from α -ketoisovalerate by the following sequence of steps. Show the mechanism of each.

PROBLEM 23-38 The Knoevenagel reaction was introduced in Problem 23-2. Show the mechanism for the Knoevenagel reaction of diethyl malonate with benzaldehyde.

PROBLEM 23-39 The Darzens reaction involves a two-step, base-catalyzed condensation of ethyl chloroacetate with a ketone to yield an epoxy ester. The first step is a carbonyl condensation reaction, and the second step is an $\text{S}_{\text{N}}2$ reaction. Write both steps, and show their mechanisms.

PROBLEM 23-40 The following reaction involves a hydrolysis followed by an intramolecular nucleophilic acyl substitution reaction. Write both steps, and show their mechanisms.

PROBLEM 23-41 The following reaction involves an intramolecular Michael reaction followed by an intramolecular aldol reaction. Write both steps, and show their mechanisms.

PROBLEM 23-42 The following reaction involves a conjugate addition reaction followed by an intramolecular Claisen condensation. Write both steps, and show their mechanisms.

PROBLEM 23-43 The following reaction involves an intramolecular aldol reaction followed by a *retro* aldol-like reaction. Write both steps, and show their mechanisms.

PROBLEM 23-44 Propose a mechanism for the following base-catalyzed isomerization:

PROBLEM 23-45 The Mannich reaction of a ketone, an amine, and an aldehyde is one of the few three-component reactions in organic chemistry. Cyclohexanone, for example, reacts with dimethylamine and acetaldehyde to yield an amino ketone. The reaction takes place in two steps, both of which are typical carbonyl-group reactions.

- (a) The first step is reaction between the aldehyde and the amine to yield an intermediate iminium ion ($\text{R}_2\text{C}=\text{NR}_2^+$) plus water. Propose a mechanism, and show the structure of the intermediate iminium ion.
- (b) The second step is reaction between the iminium ion intermediate and the ketone to yield the final product. Propose a mechanism.

PROBLEM 23-46 Cocaine has been prepared by a sequence beginning with a Mannich reaction (Problem 23-45) between dimethyl acetonedicarboxylate, an amine, and a dialdehyde. Show the structures of the amine and dialdehyde.

PROBLEM 23-47 Propose a mechanism to account for the following reaction of an enamine with an alkyl halide:

Aldol Reactions

PROBLEM 23-48 Which of the following compounds would you expect to undergo aldol self-condensation? Show the product of each successful reaction.

- (a) Trimethylacetaldehyde (b) Cyclobutanone (c) Benzophenone (diphenyl ketone)
 (d) 3-Pentanone (e) Decanal (f) 3-Phenyl-2-propenal

PROBLEM 23-49 How might you synthesize each of the following compounds using an aldol reaction? Show the structure of the starting aldehyde(s) or ketone(s) you would use in each case.

PROBLEM 23-50 What product would you expect to obtain from aldol cyclization of hexanedial, $\text{OHCCH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CHO}$?

PROBLEM 23-51 Intramolecular aldol cyclization of 2,5-heptanedione with aqueous NaOH yields a mixture of two enone products in the approximate ratio 9 : 1. Write their structures, and show how each is formed.

PROBLEM 23-52 The major product formed by intramolecular aldol cyclization of 2,5-heptanedione (Problem 23-51) has two singlet absorptions in the ^1H NMR spectrum, at 1.65 δ and 1.90 δ , and has no absorptions in the range 3 to 10 δ . What is its structure?

PROBLEM 23-53 Treatment of the minor product formed in the intramolecular aldol cyclization of 2,5-heptanedione (Problems 23-51 and 23-52) with aqueous NaOH converts it into the major product. Propose a mechanism to account for this base-catalyzed isomerization.

PROBLEM 23-54 How can you account for the fact that 2,2,6-trimethylcyclohexanone yields no detectable aldol product even though it has an acidic α hydrogen?

PROBLEM 23-55 The aldol reaction is catalyzed by acid as well as base. What is the reactive nucleophile in the acid-catalyzed aldol reaction? Propose a mechanism.

PROBLEM 23-56 Cinnamaldehyde, the aromatic constituent of cinnamon oil, can be synthesized by a mixed aldol condensation. Show the starting materials you would use, and write the reaction.

PROBLEM 23-57 The following bicyclic ketone does not undergo aldol self-condensation even though it has two α hydrogen atoms. Explain.

Claisen Condensations

PROBLEM Give the structures of the possible Claisen condensation products from the following reactions. Tell which, if any, you would expect to predominate in each case.

- 23-58** (a) $\text{CH}_3\text{CO}_2\text{Et} + \text{CH}_3\text{CH}_2\text{CO}_2\text{Et}$ (b) $\text{C}_6\text{H}_5\text{CO}_2\text{Et} + \text{C}_6\text{H}_5\text{CH}_2\text{CO}_2\text{Et}$
 (c) $\text{EtOCO}_2\text{Et} + \text{cyclohexanone}$ (d) $\text{C}_6\text{H}_5\text{CHO} + \text{CH}_3\text{CO}_2\text{Et}$

PROBLEM In the mixed Claisen reaction of cyclopentanone with ethyl formate, a much higher yield of the desired product is obtained by first mixing the two carbonyl components and then adding base, rather than by first mixing base with cyclopentanone and then adding ethyl formate. Explain.

23-59

PROBLEM Ethyl dimethylacetoacetate reacts instantly at room temperature when treated with ethoxide ion to yield two products, ethyl acetate and ethyl 2-methylpropanoate. Propose a mechanism for this cleavage reaction.

23-60

PROBLEM In contrast to the rapid reaction shown in Problem 23-60, ethyl acetoacetate requires a temperature over 150 °C to undergo the same kind of cleavage reaction. How can you explain the difference in reactivity?

23-61

Michael and Enamine Reactions

PROBLEM How might the following compounds be prepared using Michael reactions? Show the nucleophilic donor and the electrophilic acceptor in each case.

23-62

PROBLEM The so-called Wieland–Miescher ketone is a valuable starting material used in the synthesis of steroid hormones. How might you prepare it from 1,3-cyclohexanedione?

23-63

PROBLEM 23-64 The Stork enamine reaction and the intramolecular aldol reaction can be carried out in sequence to allow the synthesis of cyclohexenones. For example, reaction of the pyrrolidine enamine of cyclohexanone with 3-buten-2-one, followed by enamine hydrolysis and base treatment, yields the product indicated. Write each step, and show the mechanism of each.

PROBLEM 23-65 How could you prepare the following cyclohexenones by combining a Stork enamine reaction with an intramolecular aldol condensation? (See Problem 23-64.)

PROBLEM 23-66 The following reaction involves two successive intramolecular Michael reactions. Write both steps, and show their mechanisms.

General Problems

PROBLEM 23-67 What condensation products would you expect to obtain by treatment of the following substances with sodium ethoxide in ethanol?

(a) Ethyl butanoate (b) Cycloheptanone (c) 3,7-Nonanedione (d) 3-Phenylpropanal

PROBLEM 23-68 The following reactions are unlikely to provide the indicated product in high yield. What is wrong with each?

PROBLEM 23-69 Fill in the missing reagents **a–h** in the following scheme:

PROBLEM How would you prepare the following compounds from cyclohexanone?

23-70 (a)

(b)

(c)

(d)

PROBLEM The compound known as Hagemann's ester is prepared by treatment of a mixture of formaldehyde and ethyl acetoacetate with base, followed by acid-catalyzed decarboxylation.

23-71

Hagemann's ester

- (a) The first step is an aldol-like condensation between ethyl acetoacetate and formaldehyde to yield an α,β -unsaturated product. Write the reaction, and show the structure of the product.
- (b) The second step is a Michael reaction between ethyl acetoacetate and the unsaturated product of the first step. Show the structure of the product.

PROBLEM The third and fourth steps in the synthesis of Hagemann's ester from ethyl acetoacetate and formaldehyde (Problem 23-71) are an intramolecular aldol cyclization to yield a substituted cyclohexenone, and a decarboxylation reaction. Write both reactions, and show the products of each step.

23-72

PROBLEM When 2-methylcyclohexanone is converted into an enamine, only one product is formed despite the fact that the starting ketone is unsymmetrical. Build molecular models of the two possible products and explain the fact that the sole product is the one with the double bond opposite the methyl-substituted carbon.

23-73

CHAPTER 24

Amines and Heterocycles

- 24.10 Spectroscopy of Amines

WHY THIS CHAPTER? By the end of this chapter, we will have seen all the common functional groups. Of those groups, carbonyl compounds and amines are the most abundant and have the richest chemistry. In addition to proteins and nucleic acids, the majority of pharmaceutical agents contain amine functional groups, and many of the common coenzymes necessary for biological catalysis are amines.

Amines are organic derivatives of ammonia in the same way that alcohols and ethers are organic derivatives of water. Like ammonia, amines contain a nitrogen atom with a lone pair of electrons, making amines both basic and nucleophilic. We'll soon see, in fact, that most of the chemistry of amines depends on the presence of this lone pair of electrons.

Amines occur widely in all living organisms. Trimethylamine, for instance, occurs in animal tissues and is partially responsible for the distinctive odor of fish; nicotine is found in tobacco; and cocaine is a stimulant found in the leaves of the South American coca bush. In addition, amino acids are the building blocks from

which all proteins are made, and cyclic amine bases are constituents of nucleic acids.

24.1 Naming Amines

Amines can be either alkyl-substituted (**alkylamines**) or aryl-substituted (**arylamines**). Although much of the chemistry of the two classes is similar, there are also substantial differences. Amines are classified as **primary (RNH₂)**, **secondary (R₂NH)**, or **tertiary (R₃N)**, depending on the number of organic substituents attached to nitrogen. Thus, methylamine (CH₃NH₂) is a primary amine, dimethylamine [(CH₃)₂NH] is a secondary amine, and trimethylamine [(CH₃)₃N] is a tertiary amine. Note that this usage of the terms *primary*, *secondary*, and *tertiary* differs from our previous usage. When we speak of a tertiary alcohol or alkyl halide, we refer to the degree of substitution at the alkyl carbon atom, but when we speak of a tertiary amine, we refer to the degree of substitution at the nitrogen atom.

Compounds containing a nitrogen atom with four attached groups also exist, but the nitrogen atom must carry a formal positive charge. Such compounds are called **quaternary ammonium salts**.

Primary amines are named in the IUPAC system in several ways. For simple amines, the suffix *-amine* is added to the name of the alkyl substituent. You might also recall from the chapter on **Benzene and Aromaticity** that the aromatic phenylamine, H₂N-C₆H₅, has the common name *aniline*.

Alternatively, the suffix *-amine* can be used in place of the final *-e* in the name of the parent compound.

Amines with more than one functional group are named by considering the -NH₂ as an *amino* substituent on the parent molecule.

**2-Aminobutanoic acid****2,4-Diaminobenzoic acid****4-Amino-2-butanone**

Symmetrical secondary and tertiary amines are named by adding the prefix *di-* or *tri-* to the alkyl group.

**Diphenylamine****Triethylamine**

Unsymmetrically substituted secondary and tertiary amines are referred to as *N*-substituted primary amines. The largest alkyl group takes the parent name, and the other alkyl groups are considered *N*-substituents on the parent (*N* because they're attached to nitrogen).

***N,N*-Dimethylpropylamine*****N*-Ethyl-*N*-methylcyclohexylamine**

Heterocyclic amines—compounds in which the nitrogen atom occurs as part of a ring—are also common, and each different heterocyclic ring system has its own parent name. The heterocyclic nitrogen atom is always numbered as position 1.

**Pyridine****Pyrrole****Quinoline****Imidazole****Indole****Pyrimidine****Pyrrolidine****Piperidine**

PROBLEM Name the following compounds:

PROBLEM Draw structures corresponding to the following IUPAC names:

- 24-2 (a) Triisopropylamine (b) Triallylamine (c) *N*-Methylaniline
 (d) *N*-Ethyl-*N*-methylcyclopentylamine (e) *N*-Isopropylcyclohexylamine (f) *N*-Ethylpyrrole

PROBLEM Draw structures for the following heterocyclic amines:

- 24-3 (a) 5-Methoxyindole (b) 1,3-Dimethylpyrrole (c) 4-(*N,N*-Dimethylamino)pyridine
 (d) 5-aminopyrimidine

24.2 Structure and Properties of Amines

The bonding in alkylamines is similar to the bonding in ammonia. The nitrogen atom is sp^3 -hybridized, with its three substituents occupying three corners of a regular tetrahedron and the lone pair of electrons occupying the fourth corner. As you might expect, the C–N–C bond angles are close to the 109° tetrahedral value. For trimethylamine, the C–N–C bond angle is 108° and the C–N bond length is 147 pm.

One consequence of tetrahedral geometry is that an amine with three different substituents on nitrogen is chiral, as we saw in [Section 5.10](#). Unlike chiral carbon compounds, however, chiral amines can't usually be resolved because the two enantiomeric forms rapidly interconvert by a *pyramidal inversion*, much as an alkyl halide inverts in an S_N2 reaction. Pyramidal inversion occurs by a momentary rehybridization of the nitrogen atom to planar, sp^2 geometry, followed by rehybridization of the planar intermediate to tetrahedral, sp^3 geometry ([FIGURE 24.2](#)). The barrier to inversion is about 25 kJ/mol (6 kcal/mol), an amount only twice as large as the barrier to rotation about a C–C single bond.

FIGURE 24.2 Pyramidal inversion rapidly interconverts the two mirror-image (enantiomeric) forms of an amine.

Alkylamines have a variety of applications in the chemical industry as starting materials for the preparation of insecticides and pharmaceuticals. Labetalol, for instance, a so-called β -blocker used for the treatment of high blood pressure, is prepared by S_N2 reaction of an epoxide with a primary amine. The substance marketed for drug use is a mixture of all four possible stereoisomers, but the biological activity results primarily from the (*R,R*) isomer.

Like alcohols, amines with fewer than five carbon atoms are generally water-soluble. Also like alcohols, primary and secondary amines form hydrogen bonds and are highly associated. As a result, amines have higher boiling points than alkanes of similar molecular weight. Diethylamine (MW = 73 amu) boils at 56.3 °C, for instance, while pentane (MW = 72 amu) boils at 36.1 °C.

FIGURE 24.3 Hydrogen bonding in amines.

One other characteristic of amines is their odor. Low-molecular-weight amines such as trimethylamine have a distinctive fishlike aroma, while diamines such as cadaverine (1,5-pentanediamine) and putrescine (1,4-butanediamine) have the appalling odors you might expect from their common names. Both of these diamines arise from the decomposition of decaying tissue.

24.3 Basicity of Amines

The chemistry of amines is dominated by the lone pair of electrons on nitrogen, which makes amines both basic and nucleophilic. They react with acids to form acid–base salts, and they react with electrophiles in many of the polar reactions seen in past chapters. Note in the following electrostatic potential map of trimethylamine how the negative (red) region corresponds to the lone pair of electrons on nitrogen.

Amines are much stronger bases than alcohols and ethers, their oxygen-containing analogs. When an amine is dissolved in water, an equilibrium is established in which water acts as an acid and transfers a proton to the amine. Just as the acid strength of a carboxylic acid can be measured by defining an acidity constant K_a (Section 2.8), the base strength of an amine can be measured by defining an analogous *basicity constant* K_b . The larger the value of K_b and the smaller the value of pK_b , the more favorable the proton-transfer equilibrium and the stronger the base.

For the reaction

In practice, K_b values are not often used. Instead, the most convenient way to measure the *basicity* of an amine (RNH_2) is to look at the *acidity* of the corresponding ammonium ion (RNH_3^+).

For the reaction

so

$$K_a \cdot K_b = \left[\frac{[\text{RNH}_2][\text{H}_3\text{O}^+]}{[\text{RNH}_3^+]} \right] \left[\frac{[\text{RNH}_3^+][\text{OH}^-]}{[\text{RNH}_2]} \right]$$

$$= [\text{H}_3\text{O}^+][\text{OH}^-] = K_w = 1.00 \times 10^{-14}$$

Thus

$$K_a = \frac{K_w}{K_b} \quad \text{and} \quad K_b = \frac{K_w}{K_a}$$

and

$$\text{p}K_a + \text{p}K_b = 14$$

These equations say that the K_b of an amine multiplied by the K_a of the corresponding ammonium ion is equal to K_w , the ion-product constant for water (1.00×10^{-14}). Thus, if we know K_a for an ammonium ion, we also know K_b for the corresponding amine base because $K_b = K_w/K_a$. The more acidic the ammonium ion, the less tightly the proton is held and the weaker the corresponding base. That is, a weaker base has an ammonium ion with a smaller $\text{p}K_a$ and a stronger base has an ammonium ion with a larger $\text{p}K_a$.

Weaker base Smaller $\text{p}K_a$ for ammonium ion

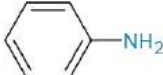

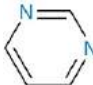

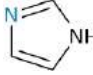

Stronger base Larger $\text{p}K_a$ for ammonium ion

TABLE 24.1 lists $\text{p}K_a$ values of the ammonium ions from a variety of amines and indicates that there is a substantial range of amine basicities. Most simple alkylamines are similar in their base strength, with $\text{p}K_a$'s for their ammonium ions in the narrow range 10 to 11. Arylamines, however, are considerably less basic than alkylamines, as are the heterocyclic amines pyridine and pyrrole.

TABLE 24.1 Basicity of Some Common Amines

Name	Structure	$\text{p}K_a$ of ammonium ion
Ammonia	NH_3	9.26
Primary alkylamine		
Methylamine	CH_3NH_2	10.64
Ethylamine	$\text{CH}_3\text{CH}_2\text{NH}_2$	10.75
Secondary alkylamine		

TABLE 24.1 Basicity of Some Common Amines

Name	Structure	pK_a of ammonium ion
Diethylamine	$(\text{CH}_3\text{CH}_2)_2\text{NH}$	10.98

Pyridine		5.25
Pyrimidine		1.3
Pyrrole		0.4
Imidazole		6.95

In contrast with amines, amides (RCONH_2) are nonbasic. Amides aren't protonated by aqueous acids, and they are poor nucleophiles. The main reason for this difference in basicity between amines and amides is that an amide is stabilized by delocalization of the nitrogen lone-pair electrons through orbital overlap with the carbonyl group. In resonance terms, amides are more stable and less reactive than amines because they are hybrids of two resonance forms. This amide resonance stabilization is lost when the nitrogen atom is protonated, so protonation is disfavored. The following electrostatic potential maps clearly show a reduced electron density on the amide nitrogen.

To purify amines, it's often possible to take advantage of their basicity. For example, if a mixture of a basic amine and a neutral compound such as a ketone or alcohol is dissolved in an organic solvent and aqueous acid is added, the basic amine dissolves in the water layer as its protonated salt, while the neutral compound remains in the organic solvent layer. Separation of the water layer and neutralization of the ammonium ion by addition of NaOH then provides the pure amine (FIGURE 24.4).

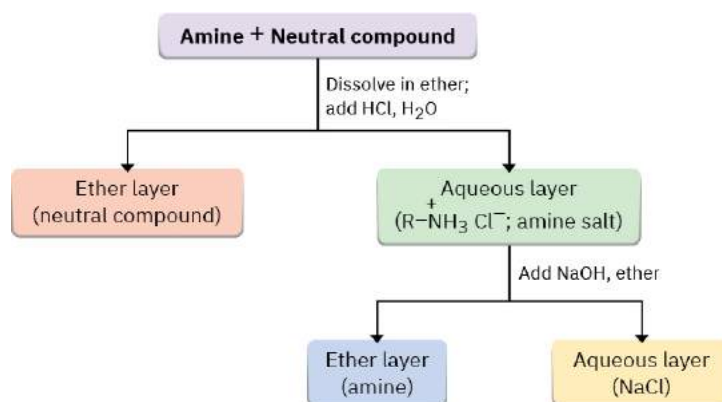

FIGURE 24.4 Separation and purification of an amine component from a mixture by extraction of its ammonium salt into water.

In addition to their behavior as bases, primary and secondary amines can also act as very weak acids because an N–H proton can be removed by a sufficiently strong base. We've seen, for example, how diisopropylamine ($pK_a \approx 36$) reacts with butyllithium to yield lithium diisopropylamide (LDA; Section 22.5). Dialkylamine anions like LDA are very strong bases that are often used in laboratory organic chemistry for the generation of enolate ions from carbonyl compounds (Section 22.7). They are not, however, encountered in biological chemistry.

PROBLEM Which compound in each of the following pairs is more basic?

24-4 (a) $\text{CH}_3\text{CH}_2\text{NH}_2$ or $\text{CH}_3\text{CH}_2\text{CONH}_2$ (b) NaOH or CH_3NH_2 (c) CH_3NHCH_3 or pyridine

PROBLEM The benzylammonium ion ($\text{C}_6\text{H}_5\text{CH}_2\text{NH}_3^+$) has $pK_a = 9.33$, and the propylammonium ion has $pK_a = 10.71$. Which is the stronger base, benzylamine or propylamine? What are the pK_b 's of benzylamine and propylamine?

24.4 Basicity of Arylamines

As noted previously, arylamines are generally less basic than alkylamines. Anilinium ion has $pK_a = 4.63$, for instance, whereas methylammonium ion has $pK_a = 10.64$. Arylamines are less basic than alkylamines because the nitrogen lone-pair electrons are delocalized by interaction with the aromatic ring's π electron system and are less available for bonding to H^+ . In resonance terms, arylamines are stabilized relative to alkylamines

because of their five resonance forms.

Much of the resonance stabilization is lost on protonation, however, so the energy difference between protonated and nonprotonated forms is higher for arylamines than it is for alkylamines. As a result, arylamines are less basic. **FIGURE 24.5** illustrates this difference.

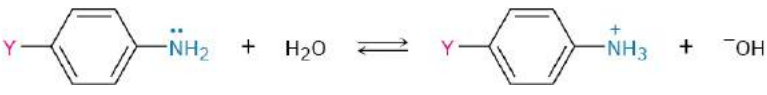

FIGURE 24.5 Arylamines have a larger positive ΔG° for protonation and are therefore less basic than alkylamines, primarily because of resonance stabilization of the ground state. Electrostatic potential maps show that lone-pair electron density is delocalized in the amine but the charge is localized in the corresponding ammonium ion.

Substituted arylamines can be either more basic or less basic than aniline, depending on the substituent. Electron-donating substituents, such as $-\text{CH}_3$, $-\text{NH}_2$, and $-\text{OCH}_3$, which increase the reactivity of an aromatic ring toward electrophilic substitution (**Section 16.4**), also increase the basicity of the corresponding arylamine. Electron-withdrawing substituents, such as $-\text{Cl}$, $-\text{NO}_2$, and $-\text{CN}$, which decrease ring reactivity toward electrophilic substitution, also decrease arylamine basicity. **TABLE 24.2** considers only *p*-substituted anilines, but similar trends are observed for ortho and meta derivatives.

TABLE 24.2 Base Strength of Some *p*-Substituted Anilines

	Substituent, Y	p <i>K</i> _a	
	-NH ₂	6.15	Activating groups
	-OCH ₃	5.34	
	-CH ₃	5.08	
	-H	4.63	Deactivating groups
	-Cl	3.98	
	-Br	3.86	
	-CN	1.74	
	-NO ₂	1.00	

PROBLEM Without looking at Table 24.2, rank the following compounds in order of ascending basicity.

- 24-6 (a) *p*-Nitroaniline, *p*-aminobenzaldehyde, *p*-bromoaniline
 (b) *p*-Chloroaniline, *p*-aminoacetophenone, *p*-methylaniline
 (c) *p*-(Trifluoromethyl)aniline, *p*-methylaniline, *p*-(fluoromethyl)aniline

24.5 Biological Amines and the Henderson–Hasselbalch Equation

We saw in Section 20.3 that the extent of dissociation of a carboxylic acid HA in an aqueous solution buffered to a given pH can be calculated with the Henderson–Hasselbalch equation. Furthermore, we concluded that at the physiological pH of 7.3 inside living cells, carboxylic acids are almost entirely dissociated into their carboxylate anions, RCO₂[−].

Henderson–Hasselbalch equation:

$$\text{pH} = \text{p}K_a + \log \frac{[\text{A}^-]}{[\text{HA}]} \quad \text{so} \quad \log \frac{[\text{A}^-]}{[\text{HA}]} = \text{pH} - \text{p}K_a$$

What about amine bases? In what form do they exist at physiological pH? As the amine (A[−] = RNH₂), or as the ammonium ion (HA = RNH₃⁺)? Let's take a 0.0010 M solution of methylamine at pH = 7.3, for example. According to TABLE 24.1, the p*K*_a of methylammonium ion is 10.64, so from the Henderson–Hasselbalch equation, we have

$$\log \frac{[\text{RNH}_2]}{[\text{RNH}_3^+]} = \text{pH} - \text{p}K_a = 7.3 - 10.64 = -3.34$$

$$\frac{[\text{RNH}_2]}{[\text{RNH}_3^+]} = \text{antilog}(-3.34) = 4.6 \times 10^{-4} \quad \text{so} \quad [\text{RNH}_2] = (4.6 \times 10^{-4})[\text{RNH}_3^+]$$

In addition, we know that

$$[\text{RNH}_2] + [\text{RNH}_3^+] = 0.0010 \text{ M}$$

Solving the two simultaneous equations gives [RNH₃⁺] = 0.0010 M and [RNH₂] = 5 × 10^{−7} M. In other words, at a physiological pH of 7.3, essentially 100% of the methylamine in a 0.0010 M solution exists in its protonated form as methylammonium ion. The same is true of other amine bases, so we always write cellular amines in their protonated form and amino acids in their ammonium carboxylate form to reflect their structures at

physiological pH.

PROBLEM 24-7 Calculate the percentages of neutral and protonated forms present in a solution of 0.0010 Molar pyrimidine at pH = 7.3. The pK_a of pyrimidinium ion is 1.3.

24.6 Synthesis of Amines

Reduction of Nitriles, Amides, and Nitro Compounds

We've already seen in [Section 20.7](#) and [Section 21.7](#) how amines can be prepared by reduction of nitriles and amides with LiAlH_4 . The two-step sequence of $\text{S}_{\text{N}}2$ displacement with CN^- followed by reduction thus converts an alkyl halide into a primary alkylamine having an additional carbon atom. Amide reduction converts carboxylic acids and their derivatives into amines with the same number of carbon atoms.

Arylamines are usually prepared by nitration of an aromatic starting material, followed by reduction of the nitro group ([Section 16.2](#)). The reduction step can be carried out in many different ways, depending on the circumstances. Catalytic hydrogenation over platinum works well but is often incompatible with the presence elsewhere in the molecule of other reducible groups, such as $\text{C}=\text{C}$ bonds or carbonyl groups. Iron, zinc, tin, and tin(II) chloride (SnCl_2) are also effective when used in acidic aqueous solution. Tin(II) chloride is particularly mild and is often used when other reducible functional groups are present.

PROBLEM 24-8 Propose structures for either a nitrile or an amide that might be a precursor of each of the following amines:

- (a) $\text{CH}_3\text{CH}_2\text{CH}_2\text{NH}_2$ (b) $(\text{CH}_3\text{CH}_2\text{CH}_2)_2\text{NH}$ (c) Benzylamine, $\text{C}_6\text{H}_5\text{CH}_2\text{NH}_2$
(d) *N*-Ethylaniline

PROBLEM 24-9 Write the mechanism of the last step in Gabriel amine synthesis, the base-promoted hydrolysis of a phthalimide to yield an amine plus phthalate ion.

PROBLEM 24-10 Show two methods for the synthesis of dopamine, a neurotransmitter involved in regulation of the central nervous system. Use any alkyl halide needed.

Reductive Amination of Aldehydes and Ketones

Amines can be synthesized in a single step by treatment of an aldehyde or ketone with ammonia or an amine in the presence of a reducing agent, a process called **reductive amination**. For example, amphetamine, a central nervous system stimulant, is prepared commercially by reductive amination of phenyl-2-propanone with ammonia using hydrogen gas over a nickel catalyst as the reducing agent. In the laboratory, either NaBH_4 or the related $\text{NaBH}(\text{OAc})_3$ is commonly used (OAc = acetate).

Reductive amination takes place by the pathway shown in **FIGURE 24.6**. An imine intermediate is first formed by a nucleophilic addition reaction (**Section 19.8**), and the $\text{C}=\text{N}$ bond of the imine is then reduced to the amine, much as the $\text{C}=\text{O}$ bond of a ketone can be reduced to an alcohol.

FIGURE 24.6 MECHANISM

Mechanism for reductive amination of a ketone to yield an amine. Details of the imine-forming step are shown in **FIGURE 19.7**.

Ammonia, primary amines, and secondary amines can all be used in the reductive amination reaction, yielding primary, secondary, and tertiary amines, respectively.

Reductive aminations also occur in various biological pathways. In the biosynthesis of the amino acid proline, for instance, glutamate 5-semialdehyde undergoes internal imine formation to give 1-pyrroline 5-carboxylate, which is then reduced by nucleophilic addition of hydride ion to the $\text{C}=\text{N}$ bond. Reduced nicotinamide adenine dinucleotide, NADH, acts as the biological reducing agent.

WORKED EXAMPLE 24.1

Using a Reductive Amination Reaction

How might you prepare *N*-methyl-2-phenylethylamine using a reductive amination reaction?

Strategy

Look at the target molecule, and identify the groups attached to nitrogen. One of the groups must be derived from the aldehyde or ketone component, and the other must be derived from the amine component. In the case of *N*-methyl-2-phenylethylamine, two combinations can lead to the product: phenylacetaldehyde plus methylamine or formaldehyde plus 2-phenylethylamine. It's usually better to choose the combination with the simpler amine component—methylamine in this case—and to use an excess of that amine as reactant.

Solution

PROBLEM 24-11 How might the following amines be prepared using reductive amination reactions? Show all precursors if more than one is possible.

PROBLEM 24-12 How could you prepare the following amine using a reductive amination reaction?

Hofmann and Curtius Rearrangements

Carboxylic acid derivatives can be converted into primary amines with loss of one carbon atom by both the **Hofmann rearrangement** and the **Curtius rearrangement**. Although the Hofmann rearrangement involves a primary amide and the Curtius rearrangement involves an acyl azide, both proceed through similar mechanisms.

Hofmann rearrangement**An amide****Curtius rearrangement****An acyl azide**

Hofmann rearrangement occurs when a primary amide, RCONH_2 , is treated with Br_2 and base (**FIGURE 24.7**). The overall mechanism is lengthy, but most of the individual steps have been encountered before. Thus, the bromination of an amide in steps **1** and **2** is analogous to the base-promoted bromination of a ketone enolate ion (**Section 22.6**), and the rearrangement of the bromoamide anion in step **4** is analogous to a carbocation rearrangement (**Section 7.11**). Nucleophilic addition of water to the isocyanate carbonyl group in step **5** is a typical carbonyl-group process (**Section 19.4**), as is the final decarboxylation step **6** (**Section 22.7**).

FIGURE 24.7 MECHANISM

Mechanism of the Hofmann rearrangement of an amide to an amine. Each step is analogous to a reaction studied previously.

Despite its mechanistic complexity, the Hofmann rearrangement often gives high yields of both arylamines and

alkylamines. For example, the appetite-suppressant drug phentermine is prepared commercially by Hofmann rearrangement of a primary amide. Commonly known by the name Fen-Phen, the combination of phentermine with another appetite-suppressant, fenfluramine, is suspected of causing heart damage.

The Curtius rearrangement, like the Hofmann rearrangement, involves migration of an -R group from the C=O carbon atom to the neighboring nitrogen with simultaneous loss of a leaving group. The reaction takes place on heating an acyl azide that is itself prepared by nucleophilic acyl substitution of an acid chloride.

Also like the Hofmann rearrangement, the Curtius rearrangement is often used commercially. The antidepressant drug tranlycypromine, for instance, is made by Curtius rearrangement of 2-phenylcyclopropanecarbonyl chloride.

WORKED EXAMPLE 24.2

Using the Hofmann and Curtius Rearrangements

How would you prepare *o*-methylbenzylamine from a carboxylic acid, using both Hofmann and Curtius rearrangements?

Strategy

Both Hofmann and Curtius rearrangements convert a carboxylic acid derivative—either an amide (Hofmann) or an acid chloride (Curtius)—into a primary amine with loss of one carbon, RCOY → RNH₂. Both reactions begin with the same carboxylic acid, which can be identified by replacing the -NH₂ group of the amine product by a -CO₂H group. In the present instance, *o*-methylphenylacetic acid is needed.

Solution

PROBLEM 24-13 How would you prepare the following amines, using both Hofmann and Curtius rearrangements on a carboxylic acid derivative?

24.7 Reactions of Amines

Alkylation and Acylation

We've already studied the two most general reactions of amines—alkylation and acylation. As we saw earlier in this chapter, primary, secondary, and tertiary amines can be alkylated by reaction with a primary alkyl halide. Alkylations of primary and secondary amines are difficult to control and often give mixtures of products, but tertiary amines are cleanly alkylated to give quaternary ammonium salts. Primary and secondary (but not tertiary) amines can also be acylated by nucleophilic acyl substitution reaction with an acid chloride or an acid anhydride to yield an amide (Section 21.4 and Section 21.5). Note that overacylation of the nitrogen does not occur because the amide product is much less nucleophilic and less reactive than the starting amine.

Hofmann Elimination Reaction

Like alcohols, amines can be converted into alkenes by an elimination reaction. But because an amide ion, NH_2^- , is such a poor leaving group, it must first be converted into a better leaving group. In the **Hofmann elimination reaction**, an amine is completely methylated by reaction with an excess amount of iodomethane to produce the corresponding quaternary ammonium salt. This salt then undergoes elimination to give an alkene on heating with a base, typically silver oxide, Ag_2O . For example, 1-methylpentylamine is converted into 1-hexene.

Silver oxide acts by exchanging iodide ion for hydroxide ion in the quaternary salt, thus providing the base necessary for elimination. The actual elimination step is an E2 reaction (Section 11.8) in which hydroxide ion removes a proton while the positively charged nitrogen atom leaves.

Unlike what happens in other E2 reactions, the major product of Hofmann elimination is the less highly substituted alkene rather than the more highly substituted one, as shown by the reaction of (1-methylbutyl)trimethylammonium hydroxide to give 1-pentene rather than the alternative 2-pentene. The reason for this non-Zaitsev result is probably steric. Because of the large size of the trialkylamine leaving group, the base must abstract a hydrogen from the more accessible, least hindered position.

The Hofmann elimination reaction is not often currently used in the laboratory, but analogous biological eliminations occur frequently, although usually with protonated ammonium ions rather than quaternary ammonium salts. In the biosynthesis of nucleic acids, for instance, a substance called adenylosuccinate undergoes an elimination of a positively charged nitrogen to give fumarate plus adenosine monophosphate.

WORKED EXAMPLE 24.3

Predicting the Product of a Hofmann Elimination

What product would you expect from Hofmann elimination of the following amine?

**Strategy**

The Hofmann elimination is an E2 reaction that converts an amine into an alkene and occurs with non-Zaitsev regiochemistry to form the less highly substituted double bond. To predict the product, look at the reactant and identify the positions from which elimination might occur (the positions two carbons away from nitrogen). Then, carry out an elimination using the most accessible hydrogen. In the present instance, there are three possible positions from which elimination might occur—one primary, one secondary, and one tertiary. The primary position is the most accessible and leads to the least highly substituted alkene, ethylene.

Solution

PROBLEM 24-14 What products would you expect from Hofmann elimination of the following amines? If more than one product is formed, indicate which is major.

PROBLEM 24-15 What product would you expect from Hofmann elimination of a heterocyclic amine such as piperidine? Write all the steps.

24.8 Reactions of Arylamines

Electrophilic Aromatic Substitutions

An amino group is strongly activating and ortho- and para-directing in electrophilic aromatic substitution reactions (Section 16.4). This high reactivity of amino-substituted benzenes can be a drawback at times because it's often difficult to prevent polysubstitution. Reaction of aniline with Br₂, for instance, takes place rapidly and yields the 2,4,6-tribrominated product. The amino group is so strongly activating that it's not possible to stop at the monobromo stage.

Another drawback to the use of amino-substituted benzenes in electrophilic aromatic substitution reactions is that Friedel–Crafts reactions are not successful (Section 16.3). The amino group forms an acid–base complex with the AlCl_3 catalyst, which prevents further reaction. Both drawbacks can be overcome, however, by carrying out electrophilic aromatic substitution reactions on the corresponding amide rather than on the free amine.

As we saw in Section 21.5, treatment of an amine with acetic anhydride yields the corresponding acetyl amide, or acetamide. Although still activating and ortho-, para-directing, amido substituents ($\text{R}-\text{N}-\text{C}=\text{O}$) are less strongly activating and less basic than amino groups because their nitrogen lone-pair electrons are delocalized by the neighboring carbonyl group. As a result, bromination of an *N*-arylamide occurs cleanly to give a monobromo product, and hydrolysis of the amide with aqueous base then gives the free amine. For example, *p*-toluidine (4-methylaniline) can be acetylated, brominated, and hydrolyzed to yield 2-bromo-4-methylaniline. None of the 2,6-dibrominated product is obtained.

Friedel–Crafts alkylations and acylations of *N*-arylamides also proceed normally. For example, benzoylation of acetanilide (*N*-acetylaniline) under Friedel–Crafts conditions gives 4-aminobenzophenone in 80% yield after hydrolysis.

Moderating the reactivity of an amino-substituted benzene by forming an amide is a useful trick that allows many kinds of electrophilic aromatic substitutions to be carried out that would otherwise be impossible. One example is the preparation of the sulfa drugs, such as sulfanilamide.

Sulfa drugs were among the first pharmaceutical agents to be used clinically against bacterial infection. Although they have largely been replaced today by safer and more powerful antibiotics, sulfa drugs are credited with saving the lives of thousands of wounded during World War II and are still prescribed for urinary tract infections. They are prepared by chlorosulfonation of acetanilide, followed by reaction of

p-(*N*-acetylamino)benzenesulfonyl chloride with ammonia or some other amine to give a sulfonamide. Hydrolysis of the amide then yields the sulfa drug. Note that hydrolysis of the amide can be carried out in the presence of the sulfonamide group because sulfonamides hydrolyze very slowly.

PROBLEM Propose a synthesis of the drug sulfathiazole from benzene and any necessary amine.

24-16

PROBLEM Propose syntheses of the following compounds from benzene:

24-17 (a) *N,N*-Dimethylaniline (b) *p*-Chloroaniline (c) *m*-Chloroaniline (d) 2,4-Dimethylaniline

Diazonium Salts: The Sandmeyer Reaction

Primary arylamines react with nitrous acid, HNO_2 , to yield stable *arene*diazonium salts, $\text{Ar}-\text{N}^+\equiv\text{N} \text{X}^-$, a process called a *diazotization* reaction. Alkylamines also react with nitrous acid, but the corresponding alkanediazonium products are so reactive they can't be isolated. Instead, they lose nitrogen instantly to yield carbocations. The analogous loss of N_2 from an arene diazonium ion to yield an aryl cation is disfavored by the instability of the cation.

Arene diazonium salts are useful because the diazonio group ($-\text{N}^+\equiv\text{N}$) can be replaced by a nucleophile in a substitution reaction.

Many different nucleophiles—halide, hydride, cyanide, and hydroxide among others—react with arene diazonium salts, yielding many different kinds of substituted benzenes. The overall sequence of (1) nitration, (2) reduction, (3) diazotization, and (4) nucleophilic substitution is perhaps the single most versatile method of aromatic substitution.

Aryl chlorides and bromides are prepared by reaction of an arene diazonium salt with the corresponding copper(I) halide, CuX , a process called the **Sandmeyer reaction**. Aryl iodides can be prepared by direct reaction

with NaI without using a copper(I) salt. Yields generally fall between 60% and 80%.

Similar treatment of an arenediazonium salt with CuCN yields the nitrile ArCN, which can then be further converted into other functional groups such as carboxyl. For example, Sandmeyer reaction of *o*-methylbenzenediazonium bisulfate with CuCN yields *o*-methylbenzonitrile, which can be hydrolyzed to give *o*-methylbenzoic acid. This product can't be prepared from *o*-xylene by the usual side-chain oxidation route because both methyl groups would be oxidized.

The diazonio group can also be replaced by $-\text{OH}$ to yield a phenol and by $-\text{H}$ to yield an arene. A phenol is prepared by reaction of the arenediazonium salt with copper(I) oxide in an aqueous solution of copper(II) nitrate, a reaction that is especially useful because few other general methods exist for introducing an $-\text{OH}$ group onto an aromatic ring.

Reduction of a diazonium salt to give an arene occurs on treatment with hypophosphorous acid, H_3PO_2 . This reaction is used primarily when there is a need for temporarily introducing an amino substituent onto a ring to take advantage of its directing effect. Suppose, for instance, that you needed to make 3,5-dibromotoluene. This product can't be made by direct bromination of toluene because reaction would occur at positions 2 and 4. Starting with *p*-methylaniline (*p*-toluidine), however, dibromination occurs ortho to the strongly directing amino substituent, and diazotization followed by treatment with H_3PO_2 to remove the amino group yields the desired product.

Mechanistically, these diazonio replacement reactions occur through radical rather than polar pathways. In the presence of a copper(I) compound, for instance, it's thought that the arenediazonium ion is first converted to an aryl radical plus copper(II), followed by subsequent reaction to give product plus regenerated copper(I) catalyst.

WORKED EXAMPLE 24.4

Using Diazonium Replacement Reactions

How would you prepare *m*-hydroxyacetophenone from benzene, using a diazonium replacement reaction in your scheme?

Strategy

As always, organic syntheses are planned by working retrosynthetically from the final product, one step at a time. First, identify the functional groups in the product and recall how those groups can be synthesized. *m*-Hydroxyacetophenone has an -OH group and a -COCH_3 group in a meta relationship on a benzene ring. A hydroxyl group is generally introduced onto an aromatic ring by a four-step sequence of nitration, reduction, diazotization, and diazonio replacement. An acetyl group is introduced by a Friedel–Crafts acylation reaction.

Next, ask yourself what an immediate precursor of the target might be. Since an acetyl group is a meta director while a hydroxyl group is an ortho and para director, acetophenone might be a precursor of *m*-hydroxyacetophenone. Benzene, in turn, is a precursor of acetophenone.

Solution

PROBLEM 24-18 How would you prepare the following compounds from benzene, using a diazonium replacement reaction in your scheme?

- (a) *p*-Bromobenzoic acid (b) *m*-Bromobenzoic acid (c) *m*-Bromochlorobenzene
 (d) *p*-Methylbenzoic acid (e) 1,2,4-Tribromobenzene

Diazonium Coupling Reactions

Arenediazonium salts undergo a coupling reaction with activated aromatic rings such as phenols and arylamines to yield brightly colored **azo compounds**, $\text{Ar-N=N-Ar}'$.

where $\text{Y} = -\text{OH}$ or $-\text{NR}_2$

Diazonium coupling reactions are typical electrophilic aromatic substitutions in which the positively charged diazonium ion is the electrophile that reacts with the electron-rich ring of a phenol or arylamine. Reaction usually occurs at the para position.

Azo-coupled products are widely used as dyes for textiles because their extended conjugated π electron system causes them to absorb in the visible region of the electromagnetic spectrum (Section 14.9). *p*-(Dimethylamino)-azobenzene, for instance, is a bright yellow compound that was at one time used as a coloring agent in margarine.

PROBLEM 24-19 Propose a synthesis of *p*-(dimethylamino)azobenzene with benzene as your only organic starting material.

24.9 Heterocyclic Amines

As noted in [Section 15.5](#) in connection with a discussion of aromaticity, a cyclic organic compound that contains atoms of two or more elements in its ring is called a *heterocycle*. Heterocyclic amines are particularly common, and many have important biological properties. Pyridoxal phosphate, a coenzyme; sildenafil (Viagra), a well-known pharmaceutical; and heme, the oxygen carrier in blood, are a few examples.

Most heterocycles have the same chemistry as their open-chain counterparts. Lactones and acyclic esters behave similarly, lactams and acyclic amides behave similarly, and cyclic and acyclic ethers behave similarly. In certain cases, however, particularly when the ring is unsaturated, heterocycles have unique and interesting properties.

Pyrrrole and Imidazole

Pyrrrole, the simplest five-membered unsaturated heterocyclic amine, is obtained commercially by treatment of furan with ammonia over an alumina catalyst at 400 °C. Furan, the oxygen-containing analog of pyrrrole, is obtained by acid-catalyzed dehydration of the five-carbon sugars found in oat hulls and corncobs.

Although pyrrrole appears to be both an amine and a conjugated diene, its chemical properties are not consistent with either of these structural features. Unlike most other amines, pyrrrole is not basic—the pK_a of the pyrrrolinium ion is 0.4; unlike most other conjugated dienes, pyrrrole undergoes electrophilic substitution reactions rather than additions. The reason for both of these properties, as noted in [Section 15.5](#), is that pyrrrole has six π electrons and is aromatic. Each of the four carbons contributes one π electron, and the sp^2 -hybridized nitrogen contributes two more from its lone pair.

Because the nitrogen lone pair is a part of the aromatic sextet, protonation on nitrogen would destroy the aromaticity of the ring. The nitrogen atom in pyrrole is therefore less electron-rich, less basic, and less nucleophilic than the nitrogen in an aliphatic amine. By the same token, the carbon atoms of pyrrole are more electron-rich and more nucleophilic than typical double-bond carbons. The pyrrole ring is therefore reactive toward electrophiles in the same way as enamines (Section 23.11). Electrostatic potential maps show how the pyrrole nitrogen is electron-poor (less red) compared with the nitrogen in its saturated counterpart pyrrolidine, while the pyrrole carbon atoms are electron-rich (more red) compared with the carbons in 1,3-cyclopentadiene.

The chemistry of pyrrole is similar to that of activated benzene rings. In general, however, the heterocycles are more reactive toward electrophiles than benzene rings, and low temperatures are often necessary to control the reactions. Halogenation, nitration, sulfonation, and Friedel-Crafts acylation can all be accomplished. For example:

Electrophilic substitutions normally occur at C2, the position next to the nitrogen, because reaction at this position leads to a more stable intermediate cation having three resonance forms, whereas reaction at C3 gives a less stable cation with only two resonance forms (FIGURE 24.8).

FIGURE 24.8 Electrophilic nitration of pyrrole. The intermediate produced by reaction at C2 is more stable than that produced by reaction at C3.

Other common five-membered heterocyclic amines include imidazole and thiazole. Imidazole, a constituent of the amino acid histidine, has two nitrogens, only one of which is basic. Thiazole, the five-membered ring system on which the structure of thiamin (vitamin B_1) is based, also contains a basic nitrogen that is alkylated in thiamin to form a quaternary ammonium ion.

PROBLEM 24-20 Draw an orbital picture of thiazole. Assume that both the nitrogen and sulfur atoms are sp^2 -hybridized, and show the orbitals that the lone pairs occupy.

PROBLEM 24-21 What is the percent protonation of the imidazole nitrogen atom in histidine at a physiological pH of 7.3 (Section 24.5)?

Pyridine and Pyrimidine

Pyridine is the nitrogen-containing heterocyclic analog of benzene. Like benzene, pyridine is a flat, aromatic molecule, with bond angles of 120° and C–C bond lengths of 139 pm, intermediate between typical single and double bonds. The five carbon atoms and the sp^2 -hybridized nitrogen atom each contribute one π electron to the aromatic sextet, and the lone-pair electrons occupy an sp^2 orbital in the plane of the ring (Section 15.5).

As shown previously in Table 24.1, pyridine ($\text{pK}_a = 5.25$) is a stronger base than pyrrole but a weaker base than the alkylamines. The diminished basicity of pyridine compared with that of alkylamines is due to the fact that the lone-pair electrons on the pyridine nitrogen are in an sp^2 orbital, while those on an alkylamine nitrogen are in an sp^3 orbital. Because s orbitals have their maximum electron density at the nucleus but p orbitals have a node at the nucleus, electrons in an orbital with more s character are held more closely to the positively charged nucleus and are less available for bonding. As a result, the sp^2 -hybridized nitrogen atom (33% s character) in

pyridine is less basic than the sp^3 -hybridized nitrogen in an alkylamine (25% s character).

Unlike benzene, pyridine undergoes electrophilic aromatic substitution reactions with difficulty. Halogenation can be carried out under drastic conditions, but nitration occurs in very low yield, and Friedel–Crafts reactions are not successful. Reactions usually give the 3-substituted product.

The low reactivity of pyridine toward electrophilic aromatic substitution is caused by a combination of factors. One is that acid–base complexation between the basic ring's nitrogen atom and the incoming electrophile places a positive charge on the ring, thereby deactivating it. Equally important is that the electron density of the ring is decreased by the electron-withdrawing inductive effect of the electronegative nitrogen atom. Thus, pyridine has a substantial dipole moment ($\mu = 2.26$ D), with the ring carbons acting as the positive end of the dipole. Reaction of an electrophile with the positively polarized carbon atoms is therefore difficult.

In addition to pyridine, the six-membered diamine pyrimidine is also found commonly in biological molecules, particularly as a constituent of nucleic acids. With a pK_a of 1.3, pyrimidine is substantially less basic than pyridine because of the inductive effect of the second nitrogen.

PROBLEM 24-22 Electrophilic aromatic substitution reactions of pyridine normally occur at C3. Draw the carbocation intermediates resulting from reaction of an electrophile at C2, C3, and C4, and explain the observed result.

Polycyclic Heterocycles

As we saw in [Section 15.6](#), quinoline, isoquinoline, indole, and purine are common polycyclic heterocycles. The first three contain both a benzene ring and a heterocyclic aromatic ring, while purine contains two heterocyclic rings joined together. All four ring systems occur commonly in nature, and many compounds with these rings have pronounced physiological activity. The quinoline alkaloid quinine, for instance, is widely used as an antimalarial drug; tryptophan is a common amino acid; and the purine adenine is a constituent of nucleic acids.

The chemistry of these polycyclic heterocycles is just what you might expect from a knowledge of the simpler heterocycles pyridine and pyrrole. Quinoline and isoquinoline both have basic, pyridine-like nitrogen atoms, and both undergo electrophilic substitutions. As with pyridine, both quinoline and isoquinoline are less reactive toward electrophilic substitution than benzene because of the electronegative nitrogen atom that withdraws electrons from the ring. Reaction occurs on the benzene ring rather than on the nitrogen-containing pyridine ring, and a mixture of substitution products is obtained.

Indole has a nonbasic, pyrrole-like nitrogen and undergoes electrophilic substitution more easily than benzene. Substitution occurs at C3 of the electron-rich pyrrole ring rather than on the benzene ring.

Purine has three basic, pyridine-like nitrogens with lone-pair electrons in sp^2 orbitals in the plane of the ring. The remaining purine nitrogen is nonbasic and pyrrole-like, with its lone-pair electrons as part of the aromatic

π electron system.

Purine

PROBLEM Which nitrogen atom in the hallucinogenic indole alkaloid *N,N*-dimethyltryptamine is more basic?
24-23 Explain.

N,N-Dimethyltryptamine

PROBLEM Indole reacts with electrophiles at C3 rather than at C2. Draw resonance forms of the intermediate cations resulting from reaction at C2 and C3, and explain the observed results.
24-24

24.10 Spectroscopy of Amines

Infrared Spectroscopy

Primary and secondary amines can be identified by a characteristic N–H stretching absorption in the 3300 to 3500 cm^{-1} range of the IR spectrum. Alcohols also absorb in this range (Section 17.11), but amine absorption bands are generally sharper and less intense than hydroxyl bands. Primary amines show a pair of bands at about 3350 and 3450 cm^{-1} from the symmetric and asymmetric stretching modes, and secondary amines show a single band at 3350 cm^{-1} . Tertiary amines have no absorption in this region because they have no N–H bonds.

FIGURE 24.9 recalls the IR spectrum of cyclohexylamine from Section 12.8.

FIGURE 24.9 IR spectrum of cyclohexylamine.

Nuclear Magnetic Resonance Spectroscopy

Amines are difficult to identify solely by ^1H NMR spectroscopy because N–H hydrogens tend to appear as broad signals without clear-cut coupling to neighboring C–H hydrogens. As with O–H absorptions (Section 17.11), amine N–H absorptions can appear over a wide range and are best identified by adding a small amount of D_2O to the sample. Exchange of N–D for N–H occurs, and the N–H signal disappears from the NMR spectrum.

Hydrogens on the carbon next to nitrogen are deshielded because of the electron-withdrawing effect of the nitrogen, and they therefore absorb further downfield than alkane hydrogens. *N*-Methyl groups are particularly distinctive because they absorb as a sharp three-proton singlet at 2.2 to 2.6 δ . This *N*-methyl resonance at 2.42 δ is easily seen in the ^1H NMR spectrum of *N*-methylcyclohexylamine (FIGURE 24.10).

FIGURE 24.10 Proton NMR spectrum of *N*-methylcyclohexylamine.

Carbons next to amine nitrogens are slightly deshielded in the ^{13}C NMR spectrum and absorb about 20 ppm downfield from where they would absorb in an alkane of similar structure. In *N*-methylcyclohexylamine, for example, the ring carbon to which nitrogen is attached absorbs at a position 24 ppm downfield from any other ring carbon.

PROBLEM Compound **A**, $\text{C}_6\text{H}_{12}\text{O}$, has an IR absorption at 1715 cm^{-1} and gives compound **B**, $\text{C}_6\text{H}_{15}\text{N}$, when treated with ammonia and NaBH_4 . The IR and ^1H NMR spectra of **B** are shown. What are the structures of **A** and **B**?

Mass Spectrometry

The *nitrogen rule* of mass spectrometry says that a compound with an odd number of nitrogen atoms has an odd-numbered molecular weight. Thus, the presence of nitrogen in a molecule is detected simply by observing its mass spectrum. An odd-numbered molecular ion usually means that the unknown compound has one or three nitrogen atoms, and an even-numbered molecular ion usually means that a compound has either zero or two nitrogen atoms. The logic behind the rule derives from the fact that nitrogen is trivalent, thus requiring an odd number of hydrogen atoms. For example, morphine has the formula $C_{17}H_{19}NO_3$ and a molecular weight of 285 amu.

Alkylamines undergo a characteristic α cleavage in the mass spectrometer, similar to the cleavage observed for alcohols (Section 17.11). C–C bond nearest the nitrogen atom is broken, yielding an alkyl radical and a resonance-stabilized, nitrogen-containing cation.

As an example, the mass spectrum of *N*-ethylpropylamine shown in **FIGURE 24.11** has peaks at $m/z = 58$ and $m/z = 72$, corresponding to the two possible modes of α cleavage.

FIGURE 24.11 Mass spectrum of *N*-ethylpropylamine. The two possible modes of α cleavage lead to the observed fragment ions at $m/z = 58$ and $m/z = 72$.

CHEMISTRY MATTERS

Green Chemistry II: Ionic Liquids

Liquids made of ions? Usually when we think of ionic compounds, we think of high-melting solids: sodium chloride, magnesium sulfate, lithium carbonate, and so forth. But yes, there are also ionic compounds that are liquid at room temperature, and they are gaining importance as reaction solvents, particularly for use in green chemistry processes (see the **Chapter 11 Chemistry Matters**). More than 1500 ionic liquids are known, and about 500 are available commercially.

Ionic liquids have been studied for nearly a century; the first to be discovered was ethylammonium nitrate, $\text{CH}_3\text{CH}_2\text{NH}_3^+ \text{NO}_3^-$, with a melting point of 12 °C. More generally, however, the ionic liquids in use today are salts in which the cation is unsymmetrical and in which one or both of the ions are bulky so that the charges are dispersed over a large volume. Both factors minimize the crystal lattice energy and disfavor formation of the solid. Typical cations are quaternary ammonium ions from heterocyclic amines, either 1,3-dialkylimidazolium ions, *N*-alkylpyridinium ions, or ring-substituted *N*-alkylpyridinium ions.

Anions are just as varied as the cations. Hexafluorophosphate, tetrafluoroborate, alkyl sulfates, trifluoromethanesulfonates (triflates), and halides are some anion possibilities.

Ionic liquids have several important features that make them attractive for use, both as solvents in green chemistry and as specialty chemicals in such applications as paint additives and refrigerants:

- They dissolve both polar and nonpolar organic compounds, giving high solute concentrations and thereby minimizing the amount of solvent needed.
- They can be optimized for specific reactions by varying cation and anion structures.
- They are nonflammable.
- They are thermally stable.
- They have negligible vapor pressures and do not evaporate.
- They are generally recoverable and can be reused many times.

As an example of their use in organic chemistry, the analgesic drug pravadoline has been synthesized in two steps using 1-butyl-3-methylimidazolium hexafluorophosphate, abbreviated [bmim][PF₆], as the solvent for both steps. The first step is a base-induced S_N2 reaction of 2-methylindole with a primary alkyl halide, and the second is a Friedel–Crafts acylation. Both steps take place with 95% yield, and the ionic solvent is recovered simply by washing the reaction mixture, first with toluene and then with water.

The first commercial process using an ionic liquid catalyst was introduced by PetroChina in 2008, when they opened a plant producing 65,000 tons per year of alkylate gasoline from isobutane. The aluminum-based ionic liquid catalyst replaced the sulfuric acid and hydrofluoric acid catalysts that had previously been used.

Key Terms

- **secondary amine (R₂NH)**
- **tertiary amine (R₃N)**

Summary

We've now seen all the common functional groups that occur in organic and biological chemistry. Of those groups, amines are among the most abundant and have among the richest chemistry. In addition to proteins and nucleic acids, the majority of pharmaceutical agents contain amine functional groups and many of the common coenzymes necessary for biological reactions are amines.

Amines are organic derivatives of ammonia. They are named in the IUPAC system either by adding the suffix *-amine* to the name of the alkyl substituent or by considering the amino group as a substituent on a more complex parent molecule.

The chemistry of amines is dominated by the lone-pair electrons on nitrogen, which makes amines both basic and nucleophilic. The basicity of **arylamines** is generally lower than that of **alkylamines** because the nitrogen lone-pair electrons are delocalized by interaction with the aromatic π system. Electron-withdrawing substituents on the aromatic ring further weaken the basicity of a substituted aniline, while electron-donating substituents increase basicity. Alkylamines are sufficiently basic that they exist almost entirely in their protonated form at the physiological pH of 7.3.

Heterocyclic amines are compounds that contain one or more nitrogen atoms as part of a ring. Saturated

heterocyclic amines usually have the same chemistry as their open-chain analogs, but unsaturated heterocycles such as pyrrole, imidazole, pyridine, and pyrimidine are aromatic. All four are unusually stable, and all undergo aromatic substitution on reaction with electrophiles. Pyrrole is nonbasic because its nitrogen lone-pair electrons are part of the aromatic π system. Fused-ring heterocycles such as quinoline, isoquinoline, indole, and purine are also commonly found in biological molecules.

Arylamines are prepared by nitration of an aromatic ring followed by reduction. Alkylamines are prepared by S_N2 reaction of ammonia or an amine with an alkyl halide or by the **Gabriel amine synthesis**. Amines can also be prepared by a number of reductive methods, including $LiAlH_4$ reduction of amides, nitriles, and azides. Also important is the **reductive amination** reaction in which a ketone or an aldehyde is treated with an amine in the presence of a reducing agent such as $NaBH_4$. In addition, amines result from **Hofmann** and **Curtius rearrangements** of carboxylic acid derivatives. Both methods involve migration of the $-R$ group bonded to the carbonyl carbon and yield a product that has one less carbon atom than the starting material.

Many of the reactions of amines are familiar from past chapters. Thus, amines react with alkyl halides in S_N2 reactions and with acid chlorides in nucleophilic acyl substitution reactions. Amines also undergo $E2$ elimination to yield alkenes if they are first quaternized by treatment with iodomethane and then heated with silver oxide, a process called the **Hofmann elimination**.

Arylamines are converted by diazotization with nitrous acid into **arene diazonium salts**, $ArN_2^+ X^-$. The diazonio group can then be replaced by many other substituents by the **Sandmeyer reaction** to give a wide variety of substituted aromatic compounds. Aryl chlorides, bromides, iodides, and nitriles can be prepared from arene diazonium salts, as can arenes and phenols. In addition to their reactivity toward substitution reactions, diazonium salts undergo coupling with phenols and arylamines to give brightly colored **azo compounds**.

Summary of Reactions

1. Synthesis of amines (Section 24.6)

a. Reduction of nitriles

b. Reduction of amides

c. Reduction of nitrobenzenes

d. S_N2 Alkylation of alkyl halides

e. Gabriel amine synthesis

f. Reduction of azides

g. Reductive amination of aldehydes/ketones

h. Hofmann rearrangement of amides

i. Curtius rearrangement of acyl azides

2. Reactions of amines

a. Alkylation with alkyl halides; see reaction 1(d)

b. Hofmann elimination (Section 24.7)

c. Diazotization (Section 24.8)

3. Reactions of arenediazonium salts (Section 24.8)

a. Nucleophilic substitutions

b. Diazonium coupling

PROBLEM Classify each of the amine nitrogen atoms in the following substances as primary, secondary, or tertiary:

24-49

Amine Basicity

PROBLEM Although pyrrole is a much weaker base than most other amines, it is a much stronger acid ($pK_a \approx$
24-50 15 for the pyrrole versus 35 for diethylamine). The N–H hydrogen is readily abstracted by base to yield the pyrrole anion, $C_4H_4N^-$. Explain.

PROBLEM Histamine, whose release in the body triggers nasal secretions and constricted airways, has three
24-51 nitrogen atoms. List them in order of increasing basicity and explain your ordering.

PROBLEM Account for the fact that *p*-nitroaniline ($pK_a = 1.0$) is less basic than *m*-nitroaniline ($pK_a = 2.5$) by
24-52 a factor of 30. Draw resonance structures to support your argument. (The pK_a values refer to the corresponding ammonium ions.)

Synthesis of Amines

PROBLEM How would you prepare the following substances from 1-butanol?

- 24-53** (a) Butylamine (b) Dibutylamine (c) Propylamine (d) Pentylamine
 (e) *N,N*-Dimethylbutylamine (f) Propene

PROBLEM How would you prepare the following substances from pentanoic acid?

- 24-54** (a) Pentanamide (b) Butylamine (c) Pentylamine (d) 2-Bromopentanoic acid
 (e) Hexanenitrile (f) Hexylamine

PROBLEM How would you prepare aniline from the following starting materials?

- 24-55** (a) Benzene (b) Benzamide (c) Toluene

PROBLEM How would you prepare benzylamine, $C_6H_5CH_2NH_2$, from benzene? More than one step is needed.
24-56

PROBLEM How might you prepare pentylamine from the following starting materials?

- 24-57** (a) Pentanamide (b) Pentanenitrile (c) 1-Butene (d) Hexanamide (e) 1-Butanol
 (f) 5-Decene (g) Pentanoic acid

PROBLEM How might a reductive amination be used to synthesize ephedrine, an amino alcohol that was
24-58 widely used for the treatment of bronchial asthma?

Reactions of Amines

PROBLEM How would you convert aniline into each of the following products?

24-59 (a) Benzene (b) Benzamide (c) Toluene

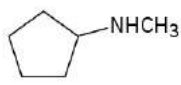

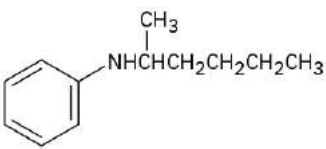

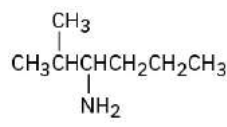

PROBLEM Write the structures of the major organic products you would expect from reaction of *m*-toluidine (24-60) (*m*-methylaniline) with the following reagents:

(a) Br₂ (1 equivalent) (b) CH₃I (excess) (c) CH₃COCl in pyridine
(d) The product of (c), then HSO₃Cl

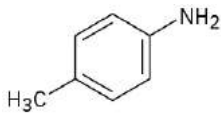

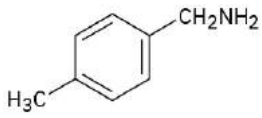

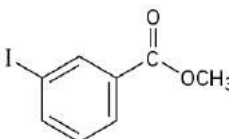

PROBLEM Show the products from reaction of *p*-bromoaniline with the following reagents:

24-61 (a) CH₃I (excess) (b) HCl (c) HNO₂, H₂SO₄ (d) CH₃COCl (e) CH₃MgBr
(f) CH₃CH₂Cl, AlCl₃ (g) Product of (c) with CuCl, HCl (h) Product of (d) with CH₃CH₂Cl, AlCl₃

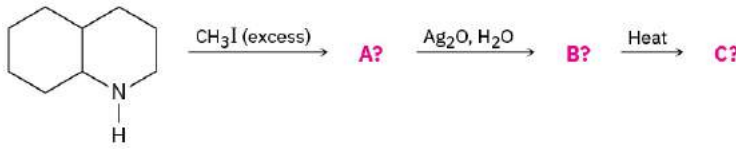

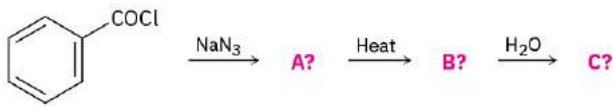

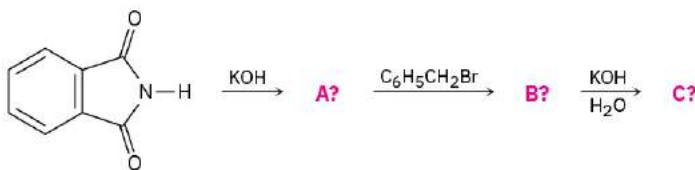

PROBLEM What are the major products you would expect from Hofmann elimination of the following amines?

24-62 (a)  (b)  (c) 

PROBLEM How would you prepare the following compounds from toluene? A diazonio replacement reaction (24-63) is needed in some instances.

(a)  (b)  (c) 

PROBLEM Predict the product(s) of the following reactions. If more than one product is formed, tell which is (24-64) major.

(a) 
(b) 
(c) 
(d) $\text{BrCH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{Br} + 1 \text{ equiv CH}_3\text{NH}_2 \xrightarrow[\text{H}_2\text{O}]{\text{NaOH}} ?$

Spectroscopy

PROBLEM Phenacetin, a substance formerly used in over-the-counter headache remedies, has the formula (24-65)

24-65 C₁₀H₁₃NO₂. Phenacetin is neutral and does not dissolve in either acid or base. When warmed with aqueous NaOH, phenacetin yields an amine, C₈H₁₁NO, whose ¹H NMR spectrum is shown. When heated with HI, the amine is cleaved to an aminophenol, C₆H₇NO. What is the structure of

phenacetin, and what are the structures of the amine and the aminophenol?

PROBLEM Propose structures for amines with the following ^1H NMR spectra:

24-66 (a) $\text{C}_3\text{H}_9\text{NO}$

(b) $\text{C}_4\text{H}_{11}\text{NO}_2$

(c) $\text{C}_8\text{H}_{11}\text{N}$

PROBLEM Draw the structure of the amine that produced the ^1H NMR spectrum shown in Problem 24-66(c).
24-67 This compound has a single strong peak in its IR spectrum at 3280 cm^{-1} .

General Problems

PROBLEM Fill in the missing reagents **a–e** in the following scheme:

24-68

PROBLEM Oxazole is a five-membered aromatic heterocycle. Would you expect oxazole to be more basic or less basic than pyrrole? Explain.
24-69

PROBLEM Protonation of an amide using strong acid occurs on oxygen rather than on nitrogen. Suggest a reason for this behavior, taking resonance into account.
24-70

PROBLEM What is the structure of the compound with formula $\text{C}_8\text{H}_{11}\text{N}$ that produced the following IR spectrum?
24-71

PROBLEM Fill in the missing reagents **a–d** in the following synthesis of racemic methamphetamine from benzene.
24-72

PROBLEM Cyclopentamine is an amphetamine-like central nervous system stimulant. Propose a synthesis of cyclopentamine from materials of five carbons or less.
24-73

PROBLEM 24-74 Tetracaine is a substance used as a spinal anesthetic.

- How would you prepare tetracaine from the corresponding aniline derivative, ArNH_2 ?
- How would you prepare tetracaine from *p*-nitrobenzoic acid?
- How would you prepare tetracaine from benzene?

PROBLEM 24-75 Atropine, $\text{C}_{17}\text{H}_{23}\text{NO}_3$, is a poisonous alkaloid isolated from the leaves and roots of *Atropa belladonna*, the deadly nightshade. In small doses, atropine acts as a muscle relaxant; 0.5 ng (nanogram, 10^{-9} g) is sufficient to cause pupil dilation. On basic hydrolysis, atropine yields tropic acid, $\text{C}_6\text{H}_5\text{CH}(\text{CH}_2\text{OH})\text{CO}_2\text{H}$, and tropine, $\text{C}_8\text{H}_{15}\text{NO}$. Tropine is an optically inactive alcohol that yields tropidene on dehydration with H_2SO_4 . Propose a structure for atropine.

PROBLEM 24-76 Tropidene (Problem 24-75) can be converted by a series of steps into tropilidene (1,3,5-cycloheptatriene). How would you accomplish this conversion?

PROBLEM 24-77 Propose a structure for the product with formula $\text{C}_9\text{H}_{17}\text{N}$ that results when 2-(2-cyanoethyl)cyclohexanone is reduced catalytically.

PROBLEM 24-78 Coniine, $\text{C}_8\text{H}_{17}\text{N}$, is the toxic principle of the poison hemlock drunk by Socrates. When subjected to Hofmann elimination, coniine yields 5-(*N,N*-dimethylamino)-1-octene. If coniine is a secondary amine, what is its structure?

PROBLEM 24-79 How would you synthesize coniine (Problem 24-78) from acrylonitrile ($\text{H}_2\text{C}=\text{CHCN}$) and ethyl 3-oxohexanoate ($\text{CH}_3\text{CH}_2\text{CH}_2\text{COCH}_2\text{CO}_2\text{Et}$)? (See Problem 24-77.)

PROBLEM 24-80 Tyramine is an alkaloid found, among other places, in mistletoe and ripe cheese. How would you synthesize tyramine from benzene? From toluene?

PROBLEM 24-81 Reaction of anthranilic acid (*o*-aminobenzoic acid) with HNO_2 and H_2SO_4 yields a diazonium salt that can be treated with base to yield a neutral diazonium carboxylate.

- What is the structure of the neutral diazonium carboxylate?

- (b) Heating the diazonium carboxylate results in the formation of CO_2 , N_2 , and an intermediate that reacts with 1,3-cyclopentadiene to yield the following product:

What is the structure of the intermediate, and what kind of reaction does it undergo with cyclopentadiene?

- PROBLEM 24-82** Cyclooctatetraene was first synthesized in 1911 by a route that involved the following transformation:

How might you use the Hofmann elimination to accomplish this reaction? How would you finish the synthesis by converting cyclooctatriene into cyclooctatetraene?

- PROBLEM 24-83** Propose structures for compounds that show the following ^1H NMR spectra.

(a) $\text{C}_9\text{H}_{13}\text{N}$

(b) $\text{C}_{15}\text{H}_{17}\text{N}$

- PROBLEM 24-84** 4-Dimethylaminopyridine (DMAP) acts as a catalyst in acyl transfer reactions. DMAP's catalytic activity stems from its nucleophilic character at the pyridine nitrogen, not the dimethylamino group. Explain this behavior, taking resonance into account.

25.10 Some Other Important Carbohydrates

WHY THIS CHAPTER? We’ve now seen all the common functional groups and reaction types that occur in organic and biological chemistry. In this and the next four chapters, we’ll focus on the major classes of biological molecules, beginning with a look at the structures and primary biological functions of carbohydrates. Then, in Chapter 29, we’ll return to the subject to see how carbohydrates are both synthesized and degraded in organisms.

Carbohydrates occur in every living organism. The sugar and starch in food, and the cellulose in wood, paper, and cotton are nearly pure carbohydrates. Modified carbohydrates form part of the coating around living cells, other carbohydrates are part of the nucleic acids that carry our genetic information, and still others are used as medicines.

The word carbohydrate derives historically from the fact that glucose, the first simple carbohydrate to be obtained in pure form, has the molecular formula $C_6H_{12}O_6$ and was originally thought to be a “hydrate of

carbon, $C_6(H_2O)_6$." This view was soon abandoned, but the name persisted. Today, the term *carbohydrate* is used to refer loosely to the broad class of polyhydroxylated aldehydes and ketones commonly called sugars. Glucose, also known as dextrose in medical work, is the most familiar example.

**Glucose (dextrose),
a pentahydroxyhexanal**

Carbohydrates are synthesized by green plants during photosynthesis, a complex process in which sunlight provides the energy to convert CO_2 and H_2O into glucose plus oxygen. Many molecules of glucose are then chemically linked for storage by the plant in the form of either cellulose or starch. It has been estimated that more than 50% of the dry weight of the earth's biomass—all plants and animals—consists of glucose polymers. When eaten and metabolized, carbohydrates then provide animals with a source of readily available energy. Thus, carbohydrates act as the chemical intermediaries by which solar energy is stored and used to support life.

Glucose

Because humans and most other mammals lack the enzymes needed for digestion of cellulose, they require starch as their dietary source of carbohydrates. Grazing animals such as cows, however, have microorganisms in their first stomach that are able to digest cellulose. The energy stored in cellulose is thus moved up the biological food chain when these ruminant animals eat grass and are themselves used for food.

25.1 Classification of Carbohydrates

Carbohydrates are generally classified as either simple or complex. **Simple sugars**, or **monosaccharides**, are carbohydrates like glucose and fructose that can't be converted into smaller sugars by hydrolysis. **Complex carbohydrates** are made of two or more simple sugars linked together by acetal bonds (Section 19.10). Sucrose (table sugar), for instance, consists of one glucose linked to one fructose. Similarly, cellulose is made up of several thousand glucose units linked together. Enzyme-catalyzed hydrolysis of a complex carbohydrate breaks it down into its constituent monosaccharides.

Monosaccharides are further classified as either **aldoses** or **ketoses**. The *-ose* suffix designates a carbohydrate, and the prefixes *aldo-* and *keto-* identify the kind of carbonyl group in the molecule, whether aldehyde or ketone.

The number of carbon atoms in the monosaccharide is indicated by the appropriate numerical prefix *tri-*, *tetr-*, *pent-*, *hex-*, and so forth, in the name. Putting it all together, glucose is an aldohexose, a six-carbon aldehyde sugar; fructose is a ketohexose, a six-carbon keto sugar; ribose is an aldopentose, a five-carbon aldehyde sugar; and sedoheptulose is a ketoheptose, a seven-carbon keto sugar. Most of the common simple sugars are either pentoses or hexoses.

PROBLEM Classify each of the following monosaccharides:

25.2 Representing Carbohydrate Stereochemistry: Fischer Projections

Because most carbohydrates have numerous chirality centers, it was recognized long ago that a quick method for representing their stereochemistry was needed. In 1891, the German chemist Emil Fischer suggested a method based on the projection of a tetrahedral carbon atom onto a flat surface. These **Fischer projections** were soon adopted and are still a common means of representing stereochemistry at chirality centers in carbohydrate chemistry.

A tetrahedral carbon atom is represented in a Fischer projection by two crossed lines. The horizontal lines represent bonds coming out of the page, and the vertical lines represent bonds going into the page.

For example, (*R*)-glyceraldehyde, the simplest monosaccharide, can be drawn as in **FIGURE 25.2**.

FIGURE 25.2 A Fischer projection of (*R*)-glyceraldehyde.

Because a given chiral molecule can be drawn in many ways, it's sometimes necessary to compare two projections to see if they represent the same or different enantiomers. To test for identity, Fischer projections can be moved around on the paper, but only two kinds of motions are allowed; moving a Fischer projection in any other way inverts its meaning.

- A Fischer projection can be rotated on the page by 180°, but not by 90° or 270°. Only a 180° rotation

maintains the Fischer convention by keeping the same substituent groups going into and coming out of the plane. In the following Fischer projection of (*R*)-glyceraldehyde, for instance, the –H and –OH groups come out of the plane both before and after a 180° rotation.

A 90° rotation breaks the Fischer convention by exchanging the groups that go into the plane with those that come out. In the following Fischer projections of (*R*)-glyceraldehyde, the –H and –OH groups originally come out of the plane but go into the plane after a 90° rotation. As a result, the rotated projection represents (*S*)-glyceraldehyde.

- A Fischer projection can also have one group held steady while the other three rotate in either a clockwise or a counterclockwise direction. The effect is simply to rotate around a single bond, which does not change the stereochemistry.

R,S stereochemical designations (Section 5.5) can be assigned to the chirality center in a Fischer projection by following three steps, as shown in Worked Example 25.1.

STEP 1

Rank the four substituents in the usual way (Section 5.5).

STEP 2

Place the group of lowest ranking, usually H, at the top of the Fischer projection by using one of the allowed motions. This means that the lowest-ranked group is oriented back, away from the viewer, as required for assigning configuration.

STEP 3

Determine the direction of rotation 1 → 2 → 3 of the remaining three groups, and assign *R* or *S* configuration.

Carbohydrates with more than one chirality center are shown in Fischer projections by stacking the centers on top of one another, with the carbonyl carbon at or near the top. Glucose, for example, has four chirality centers stacked on top of one another in a Fischer projection. Such representations don't, however, give an accurate

picture of the molecule's true three-dimensional conformation, which is curled around on itself like a bracelet.

WORKED EXAMPLE 25.1

Assigning *R* or *S* Configuration to a Fischer Projection

Assign *R* or *S* configuration to the following Fischer projection of alanine:

Strategy

Follow the steps in the text. (1) Rank the four substituents on the chiral carbon. (2) Manipulate the Fischer projection to place the group of lowest ranking at the top by carrying out one of the allowed motions. (3) Determine the direction 1 → 2 → 3 of the remaining three groups.

Solution

The rankings of the groups are (1) $-\text{NH}_2$, (2) $-\text{CO}_2\text{H}$, (3) $-\text{CH}_3$, and (4) $-\text{H}$. To bring the group of lowest ranking ($-\text{H}$) to the top, we might want to hold the $-\text{CH}_3$ group steady while rotating the other three groups counterclockwise.

Going from first- to second- to third-highest ranking requires a counterclockwise turn, corresponding to *S* stereochemistry.

PROBLEM Convert each of the following Fischer projections into a tetrahedral representation, and assign *R* or *S* stereochemistry:

25-2 *S* stereochemistry:

PROBLEM Which of the following Fischer projections of glyceraldehyde represent the same enantiomer?

25-3

PROBLEM Redraw the following molecule as a Fischer projection, and assign *R* or *S* configuration to the
25-4 chiral center (green = Cl):

PROBLEM Redraw the following aldotetrose as a Fischer projection, and assign *R* or *S* configuration to each
25-5 chiral center:

25.3 *D,L* Sugars

Glyceraldehyde, the simplest aldose, has only one chirality center and thus has two enantiomeric (nonidentical mirror-image) forms. Only the dextrorotatory enantiomer occurs naturally, however. That is, a sample of naturally occurring glyceraldehyde placed in a polarimeter rotates plane-polarized light in a clockwise direction, denoted (+). Since (+)-glyceraldehyde has been found to have an *R* configuration at C2, it can be represented by a Fischer projection as shown previously in **FIGURE 25.2**. For historical reasons dating back long before the adoption of the *R,S* system, (*R*)-(+)-glyceraldehyde is also referred to as *D*-glyceraldehyde (*D* for dextrorotatory). The other enantiomer, (*S*)-(–)-glyceraldehyde, is known as *L*-glyceraldehyde (*L* for levorotatory).

Because of the way that monosaccharides are biosynthesized in nature, glucose, fructose, and most other naturally occurring monosaccharides all have the same *R* stereochemical configuration as *D*-glyceraldehyde at the chirality center farthest from the carbonyl group. In Fischer projections, therefore, most naturally occurring sugars have the hydroxyl group at the bottom chirality center pointing to the right (**FIGURE 25.3**). Such compounds are referred to as ***D* sugars**.

FIGURE 25.3 Some naturally occurring D sugars. The -OH group at the chirality center farthest from the carbonyl group has the same configuration as (*R*)-(+)-glyceraldehyde and points toward the right in Fischer projections.

In contrast with D sugars, **L sugars** have an *S* configuration at the lowest chirality center, with the bottom -OH group pointing to the left in Fischer projections. Thus, an L sugar is the mirror image (enantiomer) of the corresponding D sugar and has the opposite configuration from the D sugar at all chirality centers.

Note that the D and L notations have no relation to the direction in which a given sugar rotates plane-polarized light. A D sugar can be either dextrorotatory or levorotatory. The prefix D indicates only that the -OH group at the lowest chirality center has *R* stereochemistry and points to the right when the molecule is drawn in a standard Fischer projection. Note also that the D,L system of carbohydrate nomenclature describes the configuration at only one chirality center and says nothing about the configuration of other chirality centers that may be present.

PROBLEM 25-6 Assign *R* or *S* configuration to each chirality center in the following monosaccharides, and tell whether each is a D sugar or an L sugar:

PROBLEM 25-7 (+)-Arabinose, an aldopentose that is widely distributed in plants, is systematically named (2*R*,3*S*,4*S*)-2,3,4,5-tetrahydroxypentanal. Draw a Fischer projection of (+)-arabinose, and identify it as a D sugar or an L sugar.

25.4 Configurations of the Aldoses

An aldotetrose is a four-carbon sugar with two chirality centers. Thus, there are $2^2 = 4$ possible stereoisomeric aldotetroses, or two D,L pairs of enantiomers named erythrose and threose.

Aldopentoses have three chirality centers and a total of $2^3 = 8$ possible stereoisomers, or four D,L pairs of enantiomers. These four pairs are called ribose, arabinose, xylose, and lyxose. All except lyxose occur widely in nature. D-Ribose is an important constituent of RNA (ribonucleic acid), L-arabinose is found in many plants, and

D-xylose is found in wood.

Aldohexoses have four chirality centers and a total of $2^4 = 16$ possible stereoisomers, or eight D,L pairs of enantiomers. The names of the eight are allose, altrose, glucose, mannose, gulose, idose, galactose, and talose. Only D-glucose, from starch and cellulose, and D-galactose, from gums and fruit pectins, are widely distributed in nature. D-mannose and D-talose also occur naturally but in lesser abundance.

Fischer projections of the four-, five-, and six-carbon D aldoses are shown in **FIGURE 25.4**. Starting with D-glyceraldehyde, we can imagine constructing the two D aldotetroses by inserting a new chirality center just below the aldehyde carbon. Each of the two D aldotetroses then leads to two D aldopentoses (four total), and each of the four D aldopentoses leads to two D aldohexoses (eight total). In addition, each of the D aldoses in **FIGURE 25.4** has an L enantiomer, which is not shown.

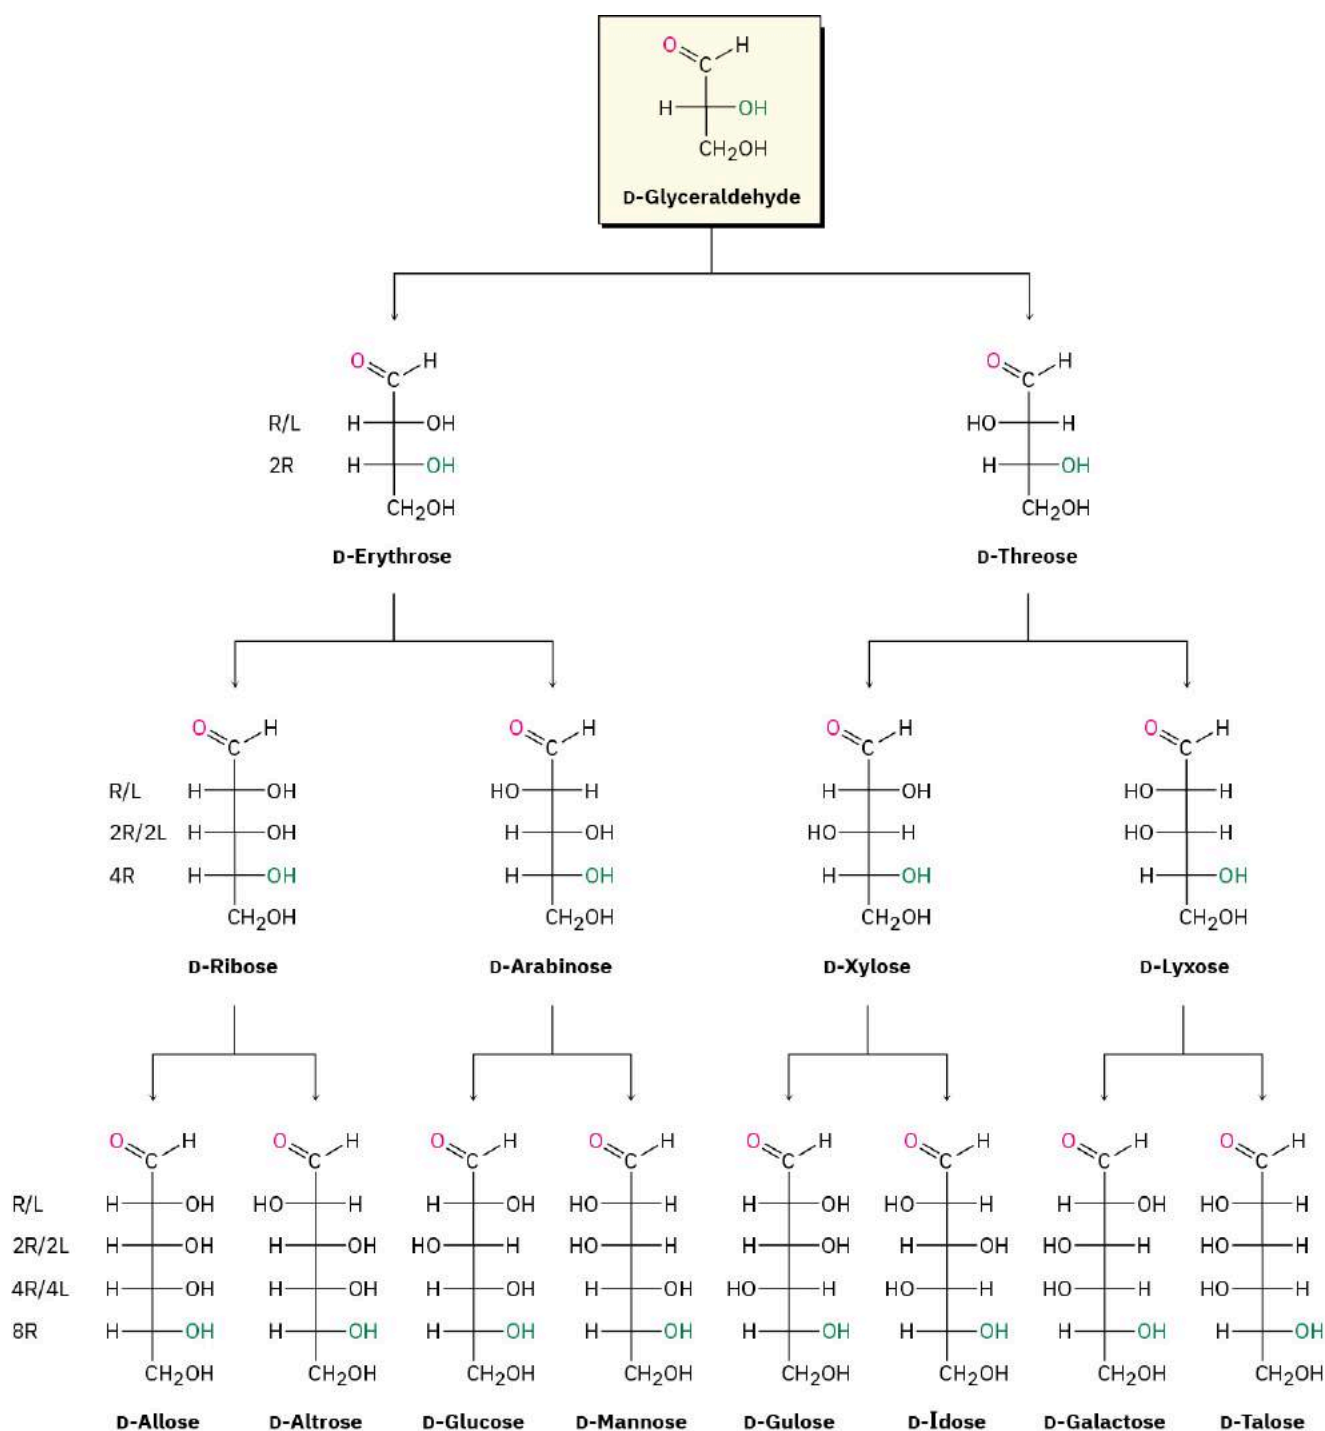

FIGURE 25.4 Configurations of D aldoses. The structures are arranged from left to right so that the -OH groups on C2 alternate right/left (R/L) across each series. Similarly, the -OH groups at C3 alternate two right/two left (2R/2L), the -OH groups at C4 alternate 4R/4L, and the -OH groups at C5 are to the right in all eight (8R). Each D aldose has a corresponding L enantiomer that is not shown.

Louis Fieser of Harvard University long ago suggested a simple procedure for remembering the names and structures of the eight D aldohexoses:

STEP 1

Set up eight Fischer projections with the -CHO group on top and the $\text{-CH}_2\text{OH}$ group at the bottom.

STEP 2

At C5, place all eight -OH groups to the right (D series).

STEP 3

At C4, alternate four –OH groups to the right and four to the left.

STEP 4

At C3, alternate two –OH groups to the right, two to the left.

STEP 5

At C2, alternate –OH groups right, left, right, left.

STEP 6

Name the eight isomers using the mnemonic “**All altruists gladly make gum in gallon tanks.**”

The structures of the four D aldopentoses can be generated in a similar way and named by the mnemonic suggested by a Cornell University undergraduate: “**RIBs ARE eXtra Lean.**”

WORKED EXAMPLE 25.2

Drawing a Fischer Projection

Draw a Fischer projection of L-fructose.

Strategy

Because L-fructose is the enantiomer of D-fructose, simply look at the structure of D-fructose and reverse the configuration at each chirality center.

Solution

WORKED EXAMPLE 25.3

Drawing a Fischer Projection of a Molecular Model

Draw the following aldotetrose as a Fischer projection, and identify it as a D sugar or an L sugar:

**Strategy**

The Fischer projection of a monosaccharide is drawn vertically, with the carbonyl group at or near the top and the –CH₂OH group at the bottom. The interior –H and –OH are drawn to the sides, pointing out of the page toward the viewer.

Solution

PROBLEM Only the D sugars are shown in Figure 25.4. Draw Fischer projections for the following L sugars:

25-8 (a) L-Xylose **(b)** L-Galactose **(c)** L-Allose

PROBLEM How many aldoheptoses are there? How many are D sugars, and how many are L sugars?

25-9

PROBLEM The following model is that of an aldopentose. Draw a Fischer projection of the sugar, name it, and

25-10 identify it as a D sugar or an L sugar.

25.5 Cyclic Structures of Monosaccharides: Anomers

We said in [Section 19.10](#) that aldehydes and ketones undergo a rapid and reversible nucleophilic addition reaction with alcohols to form hemiacetals.

If the carbonyl and the hydroxyl group are in the same molecule, an intramolecular nucleophilic addition can take place, leading to the formation of a cyclic hemiacetal. Five- and six-membered cyclic hemiacetals are relatively strain-free and particularly stable, and many carbohydrates therefore exist in an equilibrium between open-chain and cyclic forms. Glucose, for instance, exists in aqueous solution primarily in the six-membered **pyranose** form resulting from intramolecular nucleophilic addition of the -OH group at C5 to the C1 carbonyl group ([FIGURE 25.5](#)). The name *pyranose* is derived from *pyran*, the name of the unsaturated six-membered cyclic ether.

Like cyclohexane rings ([Section 4.6](#)), pyranose rings have a chairlike geometry with axial and equatorial substituents. By convention, the rings are usually drawn by placing the hemiacetal oxygen atom at the right rear,

as shown in **FIGURE 25.5**. Note that an -OH group on the right in a Fischer projection is on the bottom face of the pyranose ring, and an -OH group on the left in a Fischer projection is on the top face of the ring. For D sugars, the terminal $\text{-CH}_2\text{OH}$ group is on the top of the ring, whereas for L sugars, the $\text{-CH}_2\text{OH}$ group is on the bottom.

When an open-chain monosaccharide cyclizes to a pyranose form, a new chirality center is generated at the former carbonyl carbon and two diastereomers, called **anomers**, are produced. The hemiacetal carbon atom is referred to as the **anomeric center**. For example, glucose cyclizes reversibly in aqueous solution to a 37 : 63 mixture of two anomers (**FIGURE 25.5**). The compound with its newly generated -OH group at C1 cis to the -OH at the lowest chirality center in a Fischer projection is called the **α anomer**; its full name is α -D-glucopyranose. The compound with its newly generated -OH group trans to the -OH at the lowest chirality center is called the **β anomer**; its full name is β -D-glucopyranose. Note that in β -D-glucopyranose, all the substituents on the ring are equatorial. Thus, β -D-glucopyranose is the least sterically crowded and most stable of the eight D aldohexoses.

FIGURE 25.5 Glucose in its cyclic pyranose forms. As explained in the text, two anomers are formed by cyclization of glucose. The molecule whose newly formed -OH group at C1 is cis to the oxygen atom on the lowest chirality center (C5) in a Fischer projection is the α anomer. The molecule whose newly formed -OH group is trans to the oxygen atom on the lowest chirality center in a Fischer projection is the β anomer.

Some monosaccharides also exist in a five-membered cyclic hemiacetal form called a **furanose**. D-Fructose, for instance, exists in water solution as 68% β -pyranose, 2.7% α -pyranose, 0.5% open-chain, 22.4% β -furanose, and 6.2% α -furanose. The pyranose form results from addition of the -OH at C6 to the carbonyl group, while the furanose form results from addition of the -OH at C5 to the carbonyl group (**FIGURE 25.6**).

FIGURE 25.6 Pyranose and furanose forms of fructose in aqueous solution. The two pyranose anomers result from addition of the C6 –OH group to the C2 carbonyl; the two furanose anomers result from addition of the C5 –OH group to the C2 carbonyl.

Both anomers of D-glucopyranose can be crystallized and purified. Pure α-D-glucopyranose has a melting point of 146 °C and a specific rotation $[\alpha]_D = +112.2$; pure β-D-glucopyranose has a melting point of 148 to 155 °C and a specific rotation $[\alpha]_D = +18.7$. When a sample of either pure anomer is dissolved in water, however, its optical rotation slowly changes until it reaches a constant value of +52.6. That is, the specific rotation of the α-anomer solution decreases from +112.2 to +52.6, and the specific rotation of the β-anomer solution increases from +18.7 to +52.6. Called **mutarotation**, this change in optical rotation is due to the slow interconversion of the pure anomers to give the same 37 : 63 equilibrium mixture.

Mutarotation occurs by a reversible ring-opening of each anomer to the open-chain aldehyde, followed by reclosure. Although the equilibration is slow at neutral pH, it is catalyzed by both acid and base.

WORKED EXAMPLE 25.4

Drawing the Chair Conformation of an Aldohexose

D-Mannose differs from D-glucose in its stereochemistry at C2. Draw D-mannose in its chairlike pyranose form.

Strategy

First draw a Fischer projection of D-mannose. Then lay it on its side, and curl it around so that the –CHO group (C1) is on the right front and the –CH₂OH group (C6) is toward the left rear. Now, connect the –OH at C5 to the C1 carbonyl group to form the pyranose ring. In drawing the chair form, raise the leftmost carbon (C4) up and drop the rightmost carbon (C1) down.

Solution

WORKED EXAMPLE 25.5

Drawing the Chair Conformation of a Pyranose

Draw β -L-glucopyranose in its more stable chair conformation.

Strategy

It's probably easiest to begin by drawing the chair conformation of β -D-glucopyranose. Then draw its mirror-image L enantiomer by changing the stereochemistry at every position on the ring, and carry out a ring-flip to give the more stable chair conformation. Note that the $-\text{CH}_2\text{OH}$ group is on the bottom face of the ring in the L enantiomer, as is the anomeric $-\text{OH}$.

Solution

PROBLEM 25-11 Ribose exists largely in a furanose form, produced by addition of the C4 $-\text{OH}$ group to the C1 aldehyde. Draw D-ribose in its furanose form.

PROBLEM 25-12 Figure 25.6 shows only the β -pyranose and β -furanose anomers of D-fructose. Draw the α -pyranose and α -furanose anomers.

PROBLEM 25-13 Draw β -D-galactopyranose and β -D-mannopyranose in their more stable chair conformations. Label each ring substituent as either axial or equatorial. Which would you expect to be more stable, galactose or mannose?

PROBLEM 25-14 Draw β -L-galactopyranose in its more stable chair conformation, and label the substituents as either axial or equatorial.

PROBLEM 25-15 Identify the following monosaccharide, write its full name, and draw its open-chain form as a Fischer projection.

25.6 Reactions of Monosaccharides

Because monosaccharides have only two kinds of functional groups, hydroxyls and carbonyls, most of the chemistry of monosaccharides is the familiar chemistry of these two groups. As we've seen, alcohols can be converted into esters and ethers and can be oxidized; carbonyl compounds can react with nucleophiles and can be reduced.

Ester and Ether Formation

Monosaccharides behave as simple alcohols in much of their chemistry. For example, carbohydrate $-OH$ groups can be converted into esters and ethers, which are often easier to work with than the free sugars. Because of their many hydroxyl groups, monosaccharides are usually soluble in water but insoluble in organic solvents such as ether. They are also difficult to purify and have a tendency to form syrups rather than crystals when water is removed. Ester and ether derivatives, however, are soluble in organic solvents and are easily purified and crystallized.

Esterification is normally carried out by treating a carbohydrate with an acid chloride or acid anhydride in the presence of a base (Section 21.4 and Section 21.5). All the $-OH$ groups react, including the anomeric one. For example, β -D-glucopyranose is converted into its pentaacetate by treatment with acetic anhydride in pyridine solution.

Carbohydrates are converted into ethers by treatment with an alkyl halide in the presence of base—the Williamson ether synthesis (Section 18.2). Standard Williamson conditions using a strong base tend to degrade sensitive sugar molecules, but silver oxide works well as a mild base and gives high yields of ethers. For example, α -D-glucopyranose is converted into its pentamethyl ether in 85% yield on reaction with iodomethane and Ag_2O .

PROBLEM Draw the products you would obtain by reaction of β -D-ribofuranose with: **(a)** CH_3I , Ag_2O **(b)** **25-16** $(CH_3CO)_2O$, pyridine

Glycoside Formation

We saw in [Section 19.10](#) that treatment of a hemiacetal with an alcohol and an acid catalyst yields an acetal.

In the same way, treatment of a monosaccharide hemiacetal with an alcohol and an acid catalyst yields an acetal called a **glycoside**, in which the anomeric $-OH$ has been replaced by an $-OR$ group. For example, reaction of β -D-glucopyranose with methanol gives a mixture of α and β methyl D-glucopyranosides. (Note that a *glycoside* is the functional group name for any sugar, whereas a *glucoside* is formed specifically from glucose.)

Glycosides are named by first citing the alkyl group and then replacing the *-ose* ending of the sugar with *-oside*. Like all acetals, glycosides are stable in neutral water. They aren't in equilibrium with an open-chain form, and they don't show mutarotation. They can, however, be hydrolyzed to give back the free monosaccharide plus alcohol on treatment with aqueous acid ([Section 19.10](#)).

Glycosides are abundant in nature, and many biologically important molecules contain glycosidic linkages. For example, digitoxin, the active component of the digitalis preparations used for treatment of heart disease, is a glycoside consisting of a steroid alcohol linked to a trisaccharide. Note also that the three sugars are linked to one another by glycoside bonds.

The laboratory synthesis of glycosides can be difficult because of the numerous $-OH$ groups on the sugar molecule. One method that is particularly suitable for preparing glucose β -glycosides involves treatment of glucose pentaacetate with HBr , followed by addition of the appropriate alcohol in the presence of silver oxide. Called the **Koenigs–Knorr reaction**, the sequence involves formation of a pyranosyl bromide, followed by nucleophilic substitution. For example, methylarbutin, a glycoside found in pears, has been prepared by reaction of tetraacetyl- α -D-glucopyranosyl bromide with *p*-methoxyphenol.

Although the Koenigs–Knorr reaction appears to involve a simple backside S_N2 displacement of bromide ion by alkoxide ion, the situation is actually more complex. Both α and β anomers of tetraacetyl-D-glucopyranosyl bromide give the same β -glycoside product, implying that they react by a common pathway.

This result can be understood by assuming that tetraacetyl-D-glucopyranosyl bromide (either α or β anomer) undergoes a spontaneous S_N1 -like loss of Br^- , followed by internal reaction with the ester group at C2 to form an oxonium ion. Since the acetate at C2 is on the bottom of the glucose ring, the C–O bond also forms from the bottom. Backside S_N2 displacement of the oxonium ion then occurs with the usual inversion of configuration, yielding a β -glycoside and regenerating the acetate at C2 (FIGURE 25.7).

FIGURE 25.7 Mechanism of the Koenigs–Knorr reaction, showing the neighboring-group effect of a nearby acetate.

The participation shown by the nearby acetate group in the Koenigs–Knorr reaction is referred to as a *neighboring-group effect* and is a common occurrence in organic chemistry. Neighboring-group effects are usually noticeable only because they affect the rate or stereochemistry of a reaction; the nearby group itself does not undergo any evident change during the reaction.

Biological Ester Formation: Phosphorylation

In living organisms, carbohydrates occur not only in the free form but also linked through their anomeric center to other molecules such as lipids (glycolipids) or proteins (glycoproteins). Collectively called *glycoconjugates*, these sugar-linked molecules are components of cell walls that are crucial to the mechanism by which different cell types recognize one another.

Glycoconjugate formation occurs by reaction of the lipid or protein with a glycosyl nucleoside diphosphate. This diphosphate is itself formed by initial reaction of a monosaccharide with adenosine triphosphate (ATP) to give a glycosyl monophosphate, followed by reaction with uridine triphosphate (UTP), to give a glycosyl uridine diphosphate. (We'll see the structures of nucleoside phosphates in **Section 28.1**.) The purpose of the phosphorylation is to activate the anomeric –OH group of the sugar and make it a better leaving group in a nucleophilic substitution reaction by a protein or lipid (FIGURE 25.8).

FIGURE 25.8 Glycoprotein formation occurs by initial phosphorylation of the starting carbohydrate with ATP to a glycosyl monophosphate, followed by reaction with UTP to form a glycosyl uridine 5'-diphosphate. Nucleophilic substitution by an -OH (or -NH₂) group on a protein then gives the glycoprotein.

Reduction of Monosaccharides

Treatment of an aldose or ketose with NaBH₄ reduces it to a polyalcohol called an **alditol**. The reduction occurs by reaction of the open-chain form present in the aldehyde/ketone \rightleftharpoons hemiacetal equilibrium. Although only a small amount of the open-chain form is present at any given time, that small amount is reduced, more is produced by opening of the pyranose form, that additional amount is reduced, and so on, until the entire sample has undergone reaction.

D-Glucitol, the alditol produced by reduction of D-glucose, is itself a naturally occurring substance found in many fruits and berries. It is used under the name D-sorbitol as a sweetener and sugar substitute in many foods.

PROBLEM 25-17 Reduction of D-glucose leads to an optically active alditol (D-glucitol), whereas reduction of D-galactose leads to an optically inactive alditol. Explain.

PROBLEM 25-18 Reduction of L-gulose with NaBH₄ leads to the same alditol (D-glucitol) as reduction of D-glucose. Explain.

Oxidation of Monosaccharides

Like other aldehydes, aldoses are easily oxidized to yield the corresponding carboxylic acids, called **aldonic acids**. A buffered solution of aqueous Br_2 is often used for this purpose.

Historically, the oxidation of an aldose with either Ag^+ in aqueous ammonia (called *Tollens' reagent*) or Cu^{2+} with aqueous sodium citrate (*Benedict's reagent*) formed the basis of simple tests for what are called **reducing sugars**. (*Reducing* because the aldose reduces the metal oxidizing agent.) Some simple diabetes self-test kits sold in drugstores still use Benedict's reagent to detect glucose in urine, though more modern methods have largely replaced it.

All aldoses are reducing sugars because they contain an aldehyde group, but some ketoses are reducing sugars as well. Fructose reduces Tollens' reagent, for example, even though it contains no aldehyde group. Reduction occurs because fructose is readily isomerized to a mixture of aldoses (glucose and mannose) in basic solution by a series of keto–enol tautomeric shifts (**FIGURE 25.9**). Glycosides, however, are nonreducing because the acetal group is not hydrolyzed to an aldehyde under basic conditions.

FIGURE 25.9 Fructose, a ketose, is a reducing sugar because it undergoes two base-catalyzed keto–enol tautomerizations that result in conversion to a mixture of aldoses.

If warm, dilute HNO_3 (nitric acid) is used as the oxidizing agent, an aldose is oxidized to a dicarboxylic acid called an **aldaric acid**. Both the aldehyde carbonyl and the terminal $-\text{CH}_2\text{OH}$ group are oxidized in this reaction.

Finally, if only the $-\text{CH}_2\text{OH}$ end of the aldose is oxidized without affecting the $-\text{CHO}$ group, the product is a monocarboxylic acid called a **uronic acid**. The reaction can only be done enzymatically; no chemical reagent is known that can accomplish this selective oxidation in the laboratory.

PROBLEM 25-19 D-Glucose yields an optically active aldaric acid on treatment with HNO₃, but D-allose yields an optically inactive aldaric acid. Explain.

PROBLEM 25-20 Which of the other six D aldohexoses yield optically active aldaric acids on oxidation, and which yield optically inactive (meso) aldaric acids? (See Problem 25-19.)

Chain Lengthening: The Kiliani–Fischer Synthesis

Much early activity in carbohydrate chemistry was devoted to unraveling the stereochemical relationships among monosaccharides. One of the most important methods used was the **Kiliani–Fischer synthesis**, which results in the lengthening of an aldose chain by one carbon atom. The C1 aldehyde group of the starting sugar becomes C2 of the chain-lengthened sugar, and a new C1 carbon is added. For example, an aldopentose is converted by Kiliani–Fischer synthesis into two aldohexoses.

Discovery of the chain-lengthening sequence was initiated by the observation of Heinrich Kiliani in 1886 that aldoses react with HCN to form cyanohydrins (**Section 19.6**). Emil Fischer immediately realized the importance of Kiliani's discovery and devised a method for converting the cyanohydrin nitrile group into an aldehyde.

Fischer's original method for conversion of the nitrile into an aldehyde involved hydrolysis to a carboxylic acid, ring closure to a cyclic ester (lactone), and subsequent reduction. A modern improvement involves reducing the nitrile over a palladium catalyst, yielding an imine intermediate that is hydrolyzed to an aldehyde. Note that the cyanohydrin is formed as a mixture of stereoisomers at the new chirality center, so two new aldoses, differing only in their stereochemistry at C2, result from Kiliani–Fischer synthesis. Chain extension of D-arabinose, for example, yields a mixture of D-glucose and D-mannose.

PROBLEM 25-21 What product(s) would you expect from Kiliani–Fischer reaction of D-ribose?

PROBLEM 25-22 What aldopentose would give a mixture of L-gulose and L-idose on Kiliani–Fischer chain extension?

Chain Shortening: The Wohl Degradation

Just as the Kiliani–Fischer synthesis lengthens an aldose chain by one carbon, the **Wohl degradation** shortens an aldose chain by one carbon. Wohl degradation is almost the exact opposite of the Kiliani–Fischer sequence. That is, the aldose aldehyde carbonyl group is first converted into a nitrile, and the resulting cyanohydrin loses HCN under basic conditions—the reverse of a nucleophilic addition reaction.

Conversion of the aldehyde into a nitrile is accomplished by treatment of an aldose with hydroxylamine to give an imine called an **oxime** (Section 19.8), followed by dehydration of the oxime with acetic anhydride. The Wohl degradation does not give particularly high yields of chain-shortened aldoses, but the reaction is general for all aldopentoses and aldohexoses. For example, D-galactose is converted by Wohl degradation into D-lyxose.

PROBLEM 25-23 Two of the four D aldopentoses yield D-threose on Wohl degradation. What are their structures?

25.7 The Eight Essential Monosaccharides

Humans need to obtain eight monosaccharides for proper functioning. Although all eight can be biosynthesized from simpler precursors if necessary, it's more energetically efficient to obtain them from the diet. The eight are L-fucose (6-deoxy-L-galactose), D-galactose, D-glucose, D-mannose, N-acetyl-D-glucosamine, N-acetyl-D-galactosamine, D-xylose, and N-acetyl-D-neuraminic acid (FIGURE 25.10). All are used for the synthesis of the **glycoconjugate** components of cell membranes, and glucose is also the body's primary source of energy.

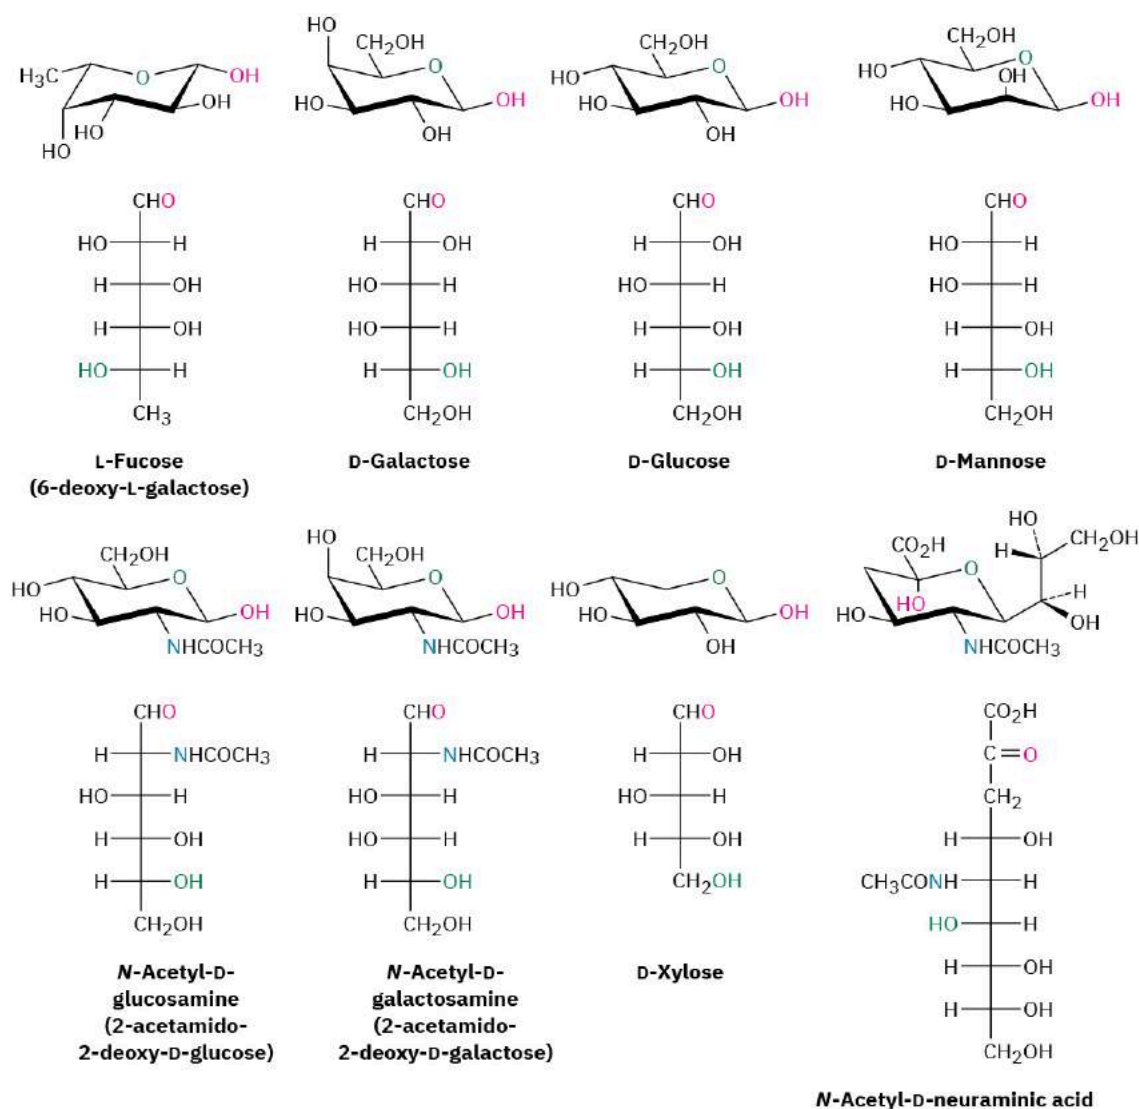

FIGURE 25.10 Structures of the eight monosaccharides essential to humans.

Of the eight essential monosaccharides, galactose, glucose, and mannose are simple aldohexoses, while xylose is an aldopentose. Fucose is a **deoxy sugar**, meaning that it has an oxygen atom “missing.” That is, an $-OH$ group (the one at C6) is replaced by an $-H$. *N*-Acetylglucosamine and *N*-acetylgalactosamine are amide derivatives of **amino sugars** in which an $-OH$ (the one at C2) is replaced by an $-NH_2$ group. *N*-Acetylneuraminic acid is the parent compound of the sialic acids, a group of more than 30 compounds with different modifications, including various oxidations, acetylations, sulfations, and methylations. Note that neuraminic acid has nine carbons and is an aldol reaction product of *N*-acetylmannosamine with pyruvate ($CH_3COCO_2^-$). Neuraminic acid is crucial to the mechanism by which an influenza virus spreads.

All the essential monosaccharides arise from glucose, by the conversions summarized in **FIGURE 25.11**. We'll not look specifically at these conversions, but might note that Problems 25-30 through 25-32 and 25-35 at the end of the chapter lead you through several of the biosynthetic pathways.

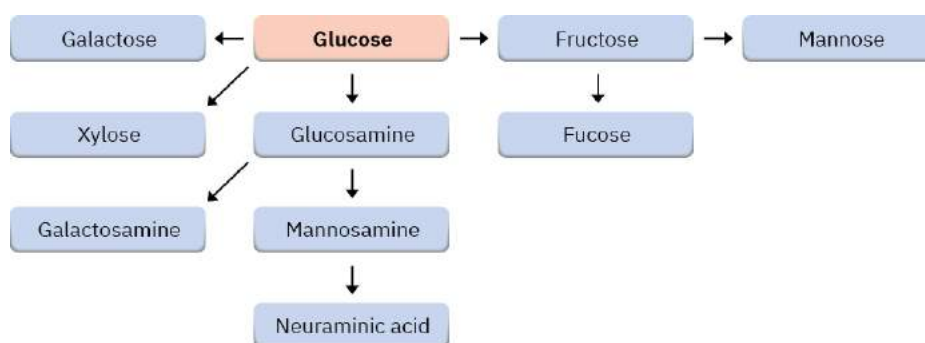

FIGURE 25.11 An overview of biosynthetic pathways for the eight essential monosaccharides.

PROBLEM 25-24 Show how neuraminic acid can arise by an aldol reaction of *N*-acetylmannosamine with pyruvate ($\text{CH}_3\text{COCO}_2^-$).

25.8 Disaccharides

We saw in Section 25.6 that reaction of a monosaccharide with an alcohol yields a glycoside in which the anomeric $-\text{OH}$ group is replaced by an $-\text{OR}$ substituent. If the alcohol is itself a sugar, the glycosidic product is a **disaccharide**.

Maltose and Cellobiose

Disaccharides contain a glycosidic acetal bond between the anomeric carbon of one sugar and an $-\text{OH}$ group at any position on the other sugar. A glycosidic bond between C1 of the first sugar and the $-\text{OH}$ at C4 of the second sugar is particularly common. Such a bond is called a 1 \rightarrow 4 link.

The glycosidic bond to an anomeric carbon can be either α or β . Maltose, the disaccharide obtained by enzyme-catalyzed hydrolysis of starch, consists of two α -D-glucopyranose units joined by a 1 \rightarrow 4- α -glycoside bond. Cellobiose, the disaccharide obtained by partial hydrolysis of cellulose, consists of two β -D-glucopyranose units joined by a 1 \rightarrow 4- β -glycoside bond.

Maltose and cellobiose are both reducing sugars because the anomeric carbons on their right-hand glucopyranose units have hemiacetal groups and are in equilibrium with aldehyde forms. For a similar reason, both maltose and cellobiose exhibit mutarotation of α and β anomers of the glucopyranose unit on the right.

Despite the similarities of their structures, cellobiose and maltose have dramatically different biological properties. Cellobiose can't be digested by humans and can't be fermented by yeast. Maltose, however, is digested without difficulty and is fermented readily.

PROBLEM Show the product you would obtain from the reaction of cellobiose with the following reagents:

25-25 (a) NaBH_4 **(b)** $\text{Br}_2, \text{H}_2\text{O}$ **(c)** CH_3COCl , pyridine

Lactose

Lactose is a disaccharide that occurs naturally in both human and cow's milk. It is widely used in baking and in commercial milk formulas for infants. Like maltose and cellobiose, lactose is a reducing sugar. It exhibits mutarotation and is a 1→4- β -linked glycoside. Unlike maltose and cellobiose, however, lactose contains two different monosaccharides—D-glucose and D-galactose—joined by a β -glycosidic bond between C1 of galactose and C4 of glucose.

Sucrose

Sucrose, or ordinary table sugar, is probably the most abundant pure organic chemical in the world. Whether from sugar cane (20% sucrose by weight) or sugar beets (15% by weight), and whether raw or refined, all table sugar is sucrose.

Sucrose is a disaccharide that yields 1 equivalent of glucose and 1 equivalent of fructose on hydrolysis. This 1 : 1 mixture of glucose and fructose is often referred to as *invert sugar* because the sign of optical rotation changes, or inverts, during the hydrolysis of sucrose ($[\alpha]_D = +66.5$) to a glucose/ fructose mixture ($[\alpha]_D = -22.0$). Some insects, such as honeybees, have enzymes called invertases that catalyze the sucrose hydrolysis. Honey, in fact, is primarily a mixture of glucose, fructose, and sucrose.

Unlike most other disaccharides, sucrose is not a reducing sugar and does not undergo mutarotation. These observations imply that sucrose is not a hemiacetal and that glucose and fructose must both be glycosides. This can happen only if the two sugars are joined by a glycoside link between the anomeric carbons of both sugars—C1 of glucose and C2 of fructose.

25.9 Polysaccharides and Their Synthesis

Polysaccharides are complex carbohydrates in which tens, hundreds, or even thousands of simple sugars are linked together through glycoside bonds. Because they have only the one free anomeric –OH group at the end of a very long chain, polysaccharides aren't reducing sugars and don't show noticeable mutarotation. Cellulose and starch are the two most widely occurring polysaccharides.

Cellulose

Cellulose consists of several thousand D-glucose units linked by 1→4-β-glycoside bonds like those in cellobiose. Different cellulose molecules then interact to form a large aggregate structure held together by hydrogen bonds.

Cellulose, a β -(1 \rightarrow 4)-D-Glucopyranoside polymer

Nature uses cellulose primarily as a structural material to impart strength and rigidity to plants. Leaves, grasses, and cotton, for instance, are primarily cellulose. Cellulose also serves as raw material for the manufacture of cellulose acetate, known commercially as acetate rayon, and cellulose nitrate, known as guncotton, which is the major ingredient in smokeless powder, the explosive propellant used in artillery shells and in ammunition for firearms.

Starch and Glycogen

Potatoes, corn, and cereal grains contain large amounts of *starch*, a polymer of glucose in which the monosaccharide units are linked by 1 \rightarrow 4- α -glycoside bonds like those in maltose. Starch can be separated into two fractions: amylose and amylopectin. Amylose accounts for about 20% by weight of starch and consists of several hundred glucose molecules linked together by 1 \rightarrow 4- α -glycoside bonds.

Amylose, an α -(1 \rightarrow 4)-D-Glucopyranoside polymer

Amylopectin accounts for the remaining 80% of starch and is more complex in structure than amylose. Unlike cellulose and amylose, which are linear polymers, amylopectin contains 1 \rightarrow 6- α -glycoside branches approximately every 25 glucose units.

**Amylopectin: α -(1 \rightarrow 4) links
with α -(1 \rightarrow 6) branches**

Starch is digested in the mouth and stomach by α -glycosidases, which catalyze the hydrolysis of glycoside bonds and release individual molecules of glucose. Like most enzymes, α -glycosidases are highly selective in their action. They hydrolyze only the α -glycoside links in starch and leave the β -glycoside links in cellulose

untouched. Thus, humans can digest potatoes and grains but not grass and leaves.

Glycogen is a polysaccharide that serves the same energy storage function in animals that starch serves in plants. Dietary carbohydrates not needed for immediate energy are converted by the body into glycogen for long-term storage. Like the amylopectin found in starch, glycogen contains a complex branching structure with both 1→4 and 1→6 links (FIGURE 25.12). Glycogen molecules are larger than those of amylopectin—up to 100,000 glucose units—and contain even more branches.

FIGURE 25.12 A representation of the structure of glycogen. The hexagons represent glucose units linked by 1→4 and 1→6 glycosidic bonds.

Polysaccharide Synthesis

With numerous $-OH$ groups of similar reactivity, polysaccharides are so structurally complex that their laboratory synthesis has long been a particularly difficult problem. Several methods have recently been devised, however, that have greatly simplified the problem. Among these approaches is the *glycal assembly method*.

Easily prepared from the appropriate monosaccharide, a glycal is an unsaturated sugar with a C1–C2 double bond. To ready it for use in polysaccharide synthesis, the glycal is first protected at its primary $-OH$ group by formation of a silyl ether (Section 17.8) and at its two adjacent secondary $-OH$ groups by formation of a cyclic carbonate ester. Then, the protected glycal is epoxidized.

Treatment of the protected glycal epoxide in the presence of $ZnCl_2$ as a Lewis acid with a second glycal having a free $-OH$ group causes acid-catalyzed opening of the epoxide ring by S_N2 backside attack (Section 18.6) and yields a disaccharide. The disaccharide is itself a glycal, so it can be epoxidized and coupled again to yield a trisaccharide, and so on. Using the appropriate sugars at each step, a great variety of polysaccharides can be prepared. After these sugars are linked, the silyl ethers and cyclic carbonate protecting groups are removed by hydrolysis.

Among the numerous complex polysaccharides that have been synthesized in the laboratory are several tumor-associated carbohydrate antigens (TACAs) that are currently being tested as potential vaccines for breast,

prostate, lung, colon, and ovarian cancers.

25.10 Some Other Important Carbohydrates

In addition to the common carbohydrates mentioned in previous sections, there are a variety of important carbohydrate-derived materials. Their structural resemblance to sugars is clear, but they aren't simple aldoses or ketoses.

Deoxy sugars, as we saw in [Section 25.7](#), have an oxygen atom “missing.” That is, an $-OH$ group is replaced by an $-H$. The most common deoxy sugar is 2-deoxyribose, a monosaccharide found in DNA (deoxyribonucleic acid). Note that 2-deoxyribose exists in water solution as a complex equilibrium mixture of both furanose and pyranose forms.

Amino sugars, such as D-glucosamine, have an $-OH$ group replaced by an $-NH_2$. The N-acetyl amide derived from D-glucosamine is the monosaccharide unit from which chitin, the hard crust that protects insects and shellfish, is made. Still other amino sugars are found in antibiotics such as streptomycin and gentamicin.

CHEMISTRY MATTERS

Sweetness

Say the word *sugar* and most people immediately think of sweet-tasting candies, desserts, and such. In fact, most simple carbohydrates do taste sweet but the degree of sweetness varies greatly from one sugar to another. With sucrose (table sugar) as a reference point, fructose is nearly twice as sweet, but lactose is only about one-sixth as sweet. Comparisons are difficult, though, because perceived sweetness varies depending on the concentration of the solution being tasted and on personal opinion. Nevertheless, the ordering in **TABLE 25.1** is generally accepted.

The desire of many people to cut their caloric intake has led to the development of synthetic sweeteners such as saccharin, aspartame, acesulfame, and sucralose. All are far sweeter than natural sugars, so the choice of one or another depends on personal taste, government regulations, and (for baked goods) heat stability. Saccharin, the oldest synthetic sweetener, has been used for more than a century, although it has a somewhat metallic aftertaste. Doubts about its safety and potential carcinogenicity were raised in the early 1970s, but it has now been cleared of suspicion for human consumption.

FIGURE 25.13 The real thing comes from sugarcane fields like this one. (credit: modification of work “Flowering sugarcane field” by “carrotmadman6”/Flickr, CC BY 2.0)

TABLE 25.1 Sweetness of Some Sugars and Sugar Substitutes

Name	Type	Sweetness
Lactose	Disaccharide	0.16
Glucose	Monosaccharide	0.75
Sucrose	Disaccharide	1.00
Fructose	Monosaccharide	1.75
Cyclamate	Synthetic	40
Aspartame	Semisynthetic	180
Acesulfame-K	Synthetic	200
Saccharin	Synthetic	350

TABLE 25.1 Sweetness of Some Sugars and Sugar Substitutes

Name	Type	Sweetness
Sucralose	Semisynthetic	600
Alitame	Semisynthetic	2,000
Neotame	Semisynthetic	6,000
Advantame	Semisynthetic	20,000

Acesulfame potassium, one of the more recently approved sweeteners, is proving to be extremely popular in soft drinks because it has little aftertaste. Sucralose, another recent sweetener, is particularly useful in baked goods because of its stability at high temperatures. Alitame, marketed in some countries under the name Aclame, is not approved for sale in the United States. It is some 2000 times as sweet as sucrose and, like acesulfame-K, has no aftertaste. Of the eight synthetic sweeteners listed in **TABLE 25.1**, only sucralose has clear structural resemblance to a carbohydrate, although it differs dramatically in containing three chlorine atoms. Aspartame, Alitame, and Advantame are dipeptides.

- **uronic acid**
- **Wohl degradation**

Summary

Now that we've now seen all the common functional groups and reaction types, our focus has changed to looking at the major classes of biological molecules. **Carbohydrates** are polyhydroxy aldehydes and ketones. They are classified according to the number of carbon atoms and the kind of carbonyl group they contain. Glucose, for example, is an aldohexose, a six-carbon aldehydo sugar. **Monosaccharides** are further classified as either **D sugars** or **L sugars**, depending on the stereochemistry of the chirality center farthest from the carbonyl group. Carbohydrate stereochemistry is frequently depicted using **Fischer projections**, which represent a chirality center as the intersection of two crossed lines.

Monosaccharides normally exist as cyclic hemiacetals rather than as open-chain aldehydes or ketones. The hemiacetal linkage results from reaction of the carbonyl group with an $-OH$ group three or four carbon atoms away. A five-membered cyclic hemiacetal is called a **furanose**, and a six-membered cyclic hemiacetal is called a **pyranose**. Cyclization leads to the formation of a new chirality center called the **anomeric center** and the production of two diastereomeric hemiacetals called **alpha (α)** and **beta (β) anomers**.

Much of the chemistry of monosaccharides is the familiar chemistry of alcohols and aldehydes/ketones. Thus, the hydroxyl groups of carbohydrates form esters and ethers. The carbonyl group of a monosaccharide can be reduced with $NaBH_4$ to form an **alditol**, oxidized with aqueous Br_2 to form an **aldonic acid**, oxidized with HNO_3 to form an **aldaric acid**, oxidized enzymatically to form a **uronic acid**, or treated with an alcohol in the presence of acid to form a **glycoside**. Monosaccharides can also be chain-lengthened by the multistep **Kiliani-Fischer synthesis** and can be chain-shortened by **Wohl degradation**.

Disaccharides are complex carbohydrates in which simple sugars are linked by a glycoside bond between the **anomeric center** of one unit and a hydroxyl of the second unit. The sugars can be the same, as in maltose and cellobiose, or different, as in lactose and sucrose. The glycosidic bond can be either α (maltose) or β (cellobiose, lactose) and can involve any hydroxyl of the second sugar. A 1 \rightarrow 4 link is most common (cellobiose, maltose), but others such as 1 \rightarrow 2 (sucrose) are also known. **Polysaccharides**, such as cellulose, starch, and glycogen, are used in nature as structural materials, as a means of long-term energy storage, and as cell-surface markers.

Summary of Reactions

Additional Problems

Visualizing Chemistry

PROBLEM Identify the following aldoses, and tell whether each is a D or L sugar:

25-26 (a)

(b)

PROBLEM Draw Fischer projections of the following molecules, placing the carbonyl group at the top in the usual way. Identify each as a D or L sugar.

25-27

(a)

(b)

PROBLEM The following structure is that of an L aldohexose in its pyranose form. Identify it, and tell whether it is an α or β anomer.

25-28

PROBLEM The following model is that of an aldohexose:

25-29

(a) Draw Fischer projections of the sugar, its enantiomer, and a diastereomer.

(b) Is this a D sugar or an L sugar? Explain.

(c) Draw the β anomer of the sugar in its furanose form.

Mechanism Problems

PROBLEM Galactose, one of the eight essential monosaccharides (**Section 25.7**), is biosynthesized from UDP-glucose by galactose 4-epimerase, where UDP = uridylyl diphosphate (a ribonucleotide diphosphate; **Section 28.1**). The enzyme requires NAD^+ for activity (**Section 17.7**), but it is not a stoichiometric reactant, and NADH is not a final reaction product. Propose a mechanism.

25-30

PROBLEM 25-31 Mannose, one of the eight essential monosaccharides (Section 25.7), is biosynthesized as its 6-phosphate derivative from fructose 6-phosphate. No enzyme cofactor is required. Propose a mechanism.

PROBLEM 25-32 Glucosamine, one of the eight essential monosaccharides (Section 25.7), is biosynthesized as its 6-phosphate derivative from fructose 6-phosphate by reaction with ammonia. Propose a mechanism.

PROBLEM 25-33 D-Glucose reacts with acetone in the presence of acid to yield the nonreducing 1,2:5,6-diisopropylidene-D-glucofuranose. Propose a mechanism.

PROBLEM 25-34 One of the steps in the biological pathway for carbohydrate metabolism is the conversion of fructose 1,6-bisphosphate into dihydroxyacetone phosphate and glyceraldehyde 3-phosphate. Propose a mechanism for the transformation.

PROBLEM 25-35 L-Fucose, one of the eight essential monosaccharides (**Section 25.7**), is biosynthesized from GDP-D-mannose by the following three-step reaction sequence, where GDP = guanosine diphosphate (a ribonucleoside diphosphate; **Section 28.1**):

- Step 1 involves an oxidation to a ketone, a dehydration to an enone, and a conjugate reduction. The step requires NADP^+ , but no NADPH is formed as a final reaction product. Propose a mechanism.
- Step 2 accomplishes two epimerizations and utilizes acidic and basic sites in the enzyme but does not require a coenzyme. Propose a mechanism.
- Step 3 requires NADPH as coenzyme. Show the mechanism.

Carbohydrate Structures

PROBLEM 25-36 Classify each of the following sugars. (For example, glucose is an aldohexose.)

PROBLEM 25-37 Write open-chain structures for the following:

- (a)** A ketotetrose **(b)** A ketopentose **(c)** A deoxyaldohexose **(d)** A five-carbon amino sugar

PROBLEM 25-38 What is the stereochemical relationship of D-ribose to L-xylose? What generalizations can you make about the following properties of the two sugars?

- (a)** Melting point **(b)** Solubility in water **(c)** Specific rotation **(d)** Density

PROBLEM Does ascorbic acid (vitamin C) have a D or L configuration?

25-39

PROBLEM Draw the three-dimensional furanose form of ascorbic acid (Problem 25-39), and assign *R* or *S*

25-40 stereochemistry to each chirality center.

PROBLEM Assign *R* or *S* configuration to each chirality center in the following molecules:

25-41 (a)

(b)

(c)

PROBLEM Draw Fischer projections of the following molecules:

25-42 (a) The *S* enantiomer of 2-bromobutane (b) The *R* enantiomer of alanine, $\text{CH}_3\text{CH}(\text{NH}_2)\text{CO}_2\text{H}$
(c) The *R* enantiomer of 2-hydroxypropanoic acid (d) The *S* enantiomer of 3-methylhexane

PROBLEM Draw Fischer projections for the two D aldohexoses whose stereochemistry at C3, C4, C5, and C6 is

25-43 the same as that of D-glucose at C2, C3, C4, and C5.

PROBLEM The following cyclic structure is that of allose. Is this a furanose or pyranose form? Is it an α or a β

25-44 anomer? Is it a D or an L sugar?

PROBLEM What is the complete name of the following sugar?

25-45

PROBLEM Write the following sugars in their open-chain forms:

25-46 (a)

(b)

(c)

PROBLEM Draw D-ribulose in its five-membered cyclic β -hemiacetal form.

25-47

PROBLEM Look up the structure of D-talose in Figure 25.4, and draw the β anomer in its pyranose form.

25-48 Identify the ring substituents as axial or equatorial.

Carbohydrate Reactions

PROBLEM Draw structures for the products you would expect to obtain from reaction of β -D-talopyranose with

25-49 each of the following reagents:

- (a) NaBH_4 in H_2O (b) Warm dilute HNO_3 (c) $\text{Br}_2, \text{H}_2\text{O}$ (d) $\text{CH}_3\text{CH}_2\text{OH}, \text{HCl}$ (e) $\text{CH}_3\text{I}, \text{Ag}_2\text{O}$
 (f) $(\text{CH}_3\text{CO})_2\text{O}$, pyridine

PROBLEM How many D-2-ketohexoses are possible? Draw them.

25-50

PROBLEM One of the D-2-ketohexoses is called *sorbose*. On treatment with NaBH_4 , sorbose yields a mixture of

25-51 gulitol and iditol. What is the structure of sorbose?

PROBLEM Another D-2-ketohexose, *psicose*, yields a mixture of allitol and altritol when reduced with NaBH_4 .

25-52 What is the structure of psicose?

PROBLEM L-Gulose can be prepared from D-glucose by a route that begins with oxidation to D-glucaric acid,

25-53 which cyclizes to form two six-membered-ring lactones. Separating the lactones and reducing them with sodium amalgam gives D-glucose and L-gulose. What are the structures of the two lactones, and which one is reduced to L-gulose?

PROBLEM Gentiobiose, a rare disaccharide found in saffron and gentian, is a reducing sugar and forms only

25-54 D-glucose on hydrolysis with aqueous acid. Reaction of gentiobiose with iodomethane and Ag_2O yields an octamethyl derivative, which can be hydrolyzed with aqueous acid to give 1 equivalent of 2,3,4,6-tetra-*O*-methyl-D-glucopyranose and 1 equivalent of 2,3,4-tri-*O*-methyl-D-glucopyranose. If gentiobiose contains a β -glycoside link, what is its structure?

General Problems

PROBLEM All aldoses exhibit mutarotation. For example, α -D-galactopyranose has $[\alpha]_D = +150.7$, and

25-55 β -D-galactopyranose has $[\alpha]_D = +52.8$. If either anomer is dissolved in water and allowed to reach equilibrium, the specific rotation of the solution is $+80.2$. What are the percentages of each anomer at equilibrium? Draw the pyranose forms of both anomers.

PROBLEM What other D aldohexose gives the same alditol as D-talose?

25-56

PROBLEM Which of the eight D aldohexoses give the same aldaric acids as their L enantiomers?

25-57

PROBLEM Which of the other three D aldopentoses gives the same aldaric acid as D-lyxose?

25-58

PROBLEM Draw the structure of L-galactose, and then answer the following questions:

- 25-59** (a) Which other aldohexose gives the same aldaric acid as L-galactose on oxidation with warm HNO_3 ?
 (b) Is this other aldohexose a D sugar or an L sugar?
 (c) Draw this other aldohexose in its most stable pyranose conformation.

- PROBLEM 25-60** Amygdalin, or laetrile, is a cyanogenic glycoside first isolated in 1830 from almond and apricot seeds. If acidic hydrolysis of amygdalin liberates HCN, along with benzaldehyde cyanohydrin with gentiobiose (Problem 25-54), what is its structure?
- PROBLEM 25-61** Trehalose is a nonreducing disaccharide that is hydrolyzed by aqueous acid to yield 2 equivalents of D-glucose. Methylation followed by hydrolysis yields 2 equivalents of 2,3,4,6-tetra-*O*-methylglucose. How many structures are possible for trehalose?
- PROBLEM 25-62** Trehalose (Problem 25-61) is cleaved by enzymes that hydrolyze α -glycosides but not by enzymes that hydrolyze β -glycosides. What is the structure and systematic name of trehalose?
- PROBLEM 25-63** Isotrehalose and neotrehalose are chemically similar to trehalose (Problems 25-61 and 25-62) except that neotrehalose is hydrolyzed only by β -glycosidase enzymes, whereas isotrehalose is hydrolyzed by both α - and β -glycosidase enzymes. What are the structures of isotrehalose and neotrehalose?
- PROBLEM 25-64** D-Mannose reacts with acetone to give a diisopropylidene derivative (Problem 25-33) that is still reducing toward Tollens' reagent. Propose a likely structure for this derivative.
- PROBLEM 25-65** Glucose and mannose can be interconverted (in low yield) by treatment with dilute aqueous NaOH. Propose a mechanism.
- PROBLEM 25-66** Propose a mechanism to account for the fact that D-gluconic acid and D-mannonic acid are interconverted when either is heated in pyridine solvent.
- PROBLEM 25-67** The *cyclitols* are a group of carbocyclic sugar derivatives having the general formulation 1,2,3,4,5,6-cyclohexanehexol. How many stereoisomeric cyclitols are possible? Draw them in their chair forms.
- PROBLEM 25-68** Compound **A** is a D aldopentose that can be oxidized to an optically inactive aldaric acid **B**. On Kiliani-Fischer chain extension, **A** is converted into **C** and **D**; **C** can be oxidized to an optically active aldaric acid **E**, but **D** is oxidized to an optically inactive aldaric acid **F**. What are the structures of **A-F**?
- PROBLEM 25-69** Simple sugars undergo reaction with phenylhydrazine, PhNH-NH₂, to yield crystalline derivatives called *osazones*. The reaction is a bit complex, however, as shown by the fact that glucose and fructose yield the same osazone.

- (a) Draw the structure of a third sugar that yields the same osazone as glucose and fructose.
- (b) Using glucose as the example, the first step in osazone formation is reaction of the sugar with phenylhydrazine to yield an imine called a *phenylhydrazone*. Draw the structure of the product.
- (c) The second and third steps in osazone formation are tautomerization of the phenylhydrazone to give an enol, followed by elimination of aniline to give a keto imine. Draw the structures of both the enol tautomer and the keto imine.
- (d) The final step is reaction of the keto imine with 2 equivalents of phenylhydrazine to yield the osazone plus ammonia. Propose a mechanism for this step.

PROBLEM When heated to 100 °C, D-idose undergoes a reversible loss of water and exists primarily as
25-70 1,6-anhydro-D-idopyranose.

**D-Idose****1,6-Anhydro-D-idopyranose**

- Draw D-idose in its pyranose form, showing the more stable chair conformation of the ring.
- Which is more stable, α -D-idopyranose or β -D-idopyranose? Explain.
- Draw 1,6-anhydro-D-idopyranose in its most stable conformation.
- When heated to 100 °C under the same conditions as those used for D-idose, D-glucose does not lose water and does not exist in a 1,6-anhydro form. Explain.

PROBLEM Acetyl coenzyme A (acetyl CoA) is the key intermediate in food metabolism. What sugar is present
25-71 in acetyl CoA?

26.11 How Do Enzymes Work? Citrate Synthase

WHY THIS CHAPTER? Continuing our look at the main classes of biomolecules, we'll focus in this chapter on amino acids, the fundamental building blocks from which up to 150,000 or so different proteins in our bodies are made. We'll then see how amino acids are incorporated into proteins and examine the structures of those proteins. Any understanding of biological chemistry would be impossible without this knowledge.

Proteins occur in every living organism, are of many different types, and have many different biological

functions. The keratin of skin and fingernails, the fibroin of silk and spider webs, and the estimated 50,000 or so enzymes that catalyze the biological reactions in our bodies are all proteins. Regardless of their function, all proteins have a fundamentally similar structure and are made up of many *amino acids* linked together in a long chain.

Amino acids, as their name implies, are difunctional. They contain both a basic amino group and an acidic carboxyl group.

Alanine, an amino acid

Their value as building blocks to make proteins stems from the fact that amino acids can join together into long chains by forming amide bonds between the -NH_2 of one amino acid and the $\text{-CO}_2\text{H}$ of another. For classification purposes, chains with fewer than 50 amino acids are often called **peptides**, while the term **protein** is generally used for larger chains.

26.1 Structures of Amino Acids

We saw in [Section 20.3](#) and [Section 24.5](#) that a carboxyl group is deprotonated and exists as the carboxylate anion at a physiological pH of 7.3, while an amino group is protonated and exists as the ammonium cation. Thus, amino acids exist in aqueous solution primarily in the form of a dipolar ion, or **zwitterion** (from the German *zwitter*, meaning “hybrid”).

Alanine

Amino acid zwitterions are internal salts and therefore have many of the physical properties associated with salts. They have large dipole moments, are relatively soluble in water but insoluble in hydrocarbons, and are crystalline with relatively high melting points. In addition, amino acids are *amphiprotic*; they can react either as acids or as bases, depending on the circumstances. In aqueous acid solution, an amino acid zwitterion is a base that accepts a proton onto its -CO_2^- group to yield a cation. In aqueous base solution, the zwitterion is an acid that loses a proton from its -NH_3^+ group to form an anion.

The structures, abbreviations (both three- and one-letter), and pK_a values of the 20 amino acids commonly found in proteins are shown in **TABLE 26.1**. All are **α -amino acids**, meaning that the amino group in each is a substituent on the α carbon—the one next to the carbonyl group. Nineteen of the twenty amino acids are primary amines, RNH_2 , and differ only in the nature of their **side chain**—the substituent attached to the α carbon. Proline is a secondary amine whose nitrogen and α carbon atoms are part of a five-membered pyrrolidine ring.

TABLE 26.1 The 20 Common Amino Acids in Proteins

A primary α -amino acidProline, a secondary
 α -amino acid

In addition to the 20 amino acids commonly found in proteins, 2 others—selenocysteine and pyrrolysine—are found in some organisms, and more than 700 nonprotein amino acids are also found in nature. γ -Aminobutyric acid (GABA), for instance, is found in the brain and acts as a neurotransmitter; homocysteine is found in blood and is linked to coronary heart disease; and thyroxine is found in the thyroid gland, where it acts as a hormone.

Except for glycine, $\text{H}_2\text{NCH}_2\text{CO}_2\text{H}$, the α carbons of amino acids are chirality centers. Two enantiomers of each are therefore possible, but nature uses only one to build proteins. In Fischer projections, naturally occurring amino acids are represented by placing the $-\text{CO}_2^-$ group at the top and pointing the side chain downwards, as if drawing a carbohydrate (Section 25.2) and then placing the $-\text{NH}_3^+$ group on the left. Because of their stereochemical similarity to L sugars (Section 25.3), the naturally occurring α -amino acids are often referred to as L amino acids. The nonnaturally occurring enantiomers are called D amino acids.

The 20 common amino acids can be further classified as neutral, acidic, or basic, depending on the structure of their side chains. Fifteen of the twenty have neutral side chains, two (aspartic acid and glutamic acid) have an extra carboxylic acid function in their side chains, and three (lysine, arginine, and histidine) have basic amino groups in their side chains. Note that both cysteine (a thiol) and tyrosine (a phenol), although usually classified as neutral amino acids, nevertheless have weakly acidic side chains that can be deprotonated in a sufficiently basic solution.

At the physiological pH of 7.3, the side-chain carboxyl groups of aspartic acid and glutamic acid are deprotonated and the basic side-chain nitrogens of lysine and arginine are protonated. Histidine, however, which contains a heterocyclic imidazole ring in its side chain, is not quite basic enough to be protonated at pH 7.3. Note that only the pyridine-like, doubly bonded nitrogen in histidine is basic. The pyrrole-like singly bonded nitrogen is nonbasic because its lone pair of electrons is part of the six- π -electron aromatic imidazole ring (Section 24.9).

Humans are able to biosynthesize only 11 of the 20 protein amino acids, called nonessential amino acids.

The other 9, called essential amino acids, are biosynthesized only in plants and microorganisms and must be obtained in our diet. The division between essential and nonessential amino acids is not clear-cut, however. Tyrosine, for instance, is sometimes considered nonessential because humans can produce it from phenylalanine, but phenylalanine itself is essential and must be obtained in the diet. Arginine can be synthesized by humans, but much of the arginine we need also comes from our diet.

PROBLEM 26-1 How many of the α -amino acids shown in Table 26.1 contain aromatic rings? How many contain sulfur? How many contain alcohol groups? How many contain hydrocarbon side chains?

PROBLEM 26-2 Of the 19 L amino acids, 18 have the *S* configuration at the α carbon. Cysteine is the only L amino acid that has an *R* configuration. Explain.

PROBLEM 26-3 The amino acid threonine, (2*S*,3*R*)-2-amino-3-hydroxybutanoic acid, has two chirality centers.

(a) Draw threonine, using normal, wedged, and dashed lines to show dimensionality.

(b) Draw a diastereomer of threonine, and label its chirality centers as *R* or *S*.

26.2 Amino Acids and the Henderson–Hasselbalch Equation: Isoelectric Points

According to the Henderson–Hasselbalch equation (Section 20.3 and Section 24.5), if we know both the pH of a solution and the pK_a of an acid HA, we can calculate the ratio of $[A^-]$ to $[HA]$ in the solution. Furthermore, when $pH = pK_a$, the two forms A^- and HA are present in equal amounts because $\log 1 = 0$.

$$pH = pK_a + \log \frac{[A^-]}{[HA]} \quad \text{or} \quad \log \frac{[A^-]}{[HA]} = pH - pK_a$$

To apply the Henderson–Hasselbalch equation to an amino acid, let's find out what species are present in a 1.00 M solution of alanine at $pH = 9.00$. According to TABLE 26.1, protonated alanine [$^+H_3NCH(CH_3)CO_2H$] has $pK_{a1} = 2.34$ and neutral zwitterionic alanine [$^+H_3NCH(CH_3)CO_2^-$] has $pK_{a2} = 9.69$:

Because the pH of the solution is much closer to pK_{a2} than to pK_{a1} , we need to use pK_{a2} for the calculation. From the Henderson–Hasselbalch equation, we have:

$$\log \frac{[A^-]}{[HA]} = pH - pK_a = 9.00 - 9.69 = -0.69$$

So

$$\frac{[A^-]}{[HA]} = \text{antilog}(-0.69) = 0.20 \quad \text{and} \quad [A^-] = 0.20[HA]$$

In addition, we know that

$$[A^-] + [HA] = 1.00 \text{ M}$$

Solving the two simultaneous equations gives $[HA] = 0.83$ and $[A^-] = 0.17$. In other words, at $pH = 9.00$, 83% of alanine molecules in a 1.00 M solution are neutral (zwitterionic) and 17% are deprotonated. Similar calculations can be done at other pH values and the results plotted to give the titration curve shown in FIGURE 26.2.

Each leg of the titration curve is calculated separately. The first leg, from pH 1 to 6, corresponds to the dissociation of protonated alanine, H_2A^+ . The second leg, from pH 6 to 11, corresponds to the dissociation of zwitterionic alanine, HA. It's as if we started with H_2A^+ at low pH and then titrated with NaOH. When 0.5

equivalent of NaOH is added, the deprotonation of H_2A^+ is 50% complete; when 1.0 equivalent of NaOH is added, the deprotonation of H_2A^+ is finished and HA predominates; when 1.5 equivalents of NaOH is added, the deprotonation of HA is 50% complete; and when 2.0 equivalents of NaOH is added, the deprotonation of HA is finished.

FIGURE 26.2 A titration curve for alanine, plotted using the Henderson–Hasselbalch equation. Each of the two legs is plotted separately. At $\text{pH} < 1$, alanine is entirely protonated; at $\text{pH} = 2.34$, alanine is a 50 : 50 mix of protonated and neutral forms; at $\text{pH} = 6.01$, alanine is entirely neutral; at $\text{pH} = 9.69$, alanine is a 50 : 50 mix of neutral and deprotonated forms; at $\text{pH} > 11.5$, alanine is entirely deprotonated.

Look carefully at the titration curve in **FIGURE 26.2**. In acid solution, the amino acid is protonated and exists primarily as a cation. In basic solution, the amino acid is deprotonated and exists primarily as an anion. In between the two is an intermediate pH at which the amino acid is exactly balanced between anionic and cationic forms, existing primarily as the neutral, dipolar zwitterion. This pH is called the amino acid's **isoelectric point (pI)** and has a value of 6.01 for alanine.

The isoelectric point of an amino acid depends on its structure, with values for the 20 common amino acids given previously in **TABLE 26.1**. The 15 neutral amino acids have isoelectric points near neutrality, in the pH range 5.0 to 6.5. The two acidic amino acids have isoelectric points at lower pH so that deprotonation of the side-chain $-\text{CO}_2\text{H}$ does not occur at their pI, and the three basic amino acids have isoelectric points at higher pH so that protonation of the side-chain amino group does not occur at their pI.

More specifically, the pI of any amino acid is the average of the two acid-dissociation constants that involve the neutral zwitterion. For the 13 amino acids with a neutral side chain, pI is the average of $\text{pK}_{\text{a}1}$ and $\text{pK}_{\text{a}2}$. For the four amino acids with either a strongly or weakly acidic side chain, pI is the average of the two lowest pK_{a} values. For the three amino acids with a basic side chain, pI is the average of the two highest pK_{a} values.

Just as individual amino acids have isoelectric points, proteins have an overall pI due to the cumulative effect of all the acidic or basic amino acids they may contain. The enzyme lysozyme, for instance, has a preponderance of basic amino acids and thus has a high isoelectric point ($pI = 11.0$). Pepsin, however, has a preponderance of acidic amino acids and a low isoelectric point ($pI \sim 1.0$). Not surprisingly, the solubilities and properties of proteins with different pI 's are strongly affected by the pH of the medium. Solubility in water is usually lowest at the isoelectric point, where the protein has no net charge, and is higher both above and below the pI , where the protein is charged.

We can take advantage of the differences in isoelectric points to separate a mixture of proteins into its pure components. Using a technique known as **electrophoresis**, a mixture of proteins is placed near the center of a strip of paper or gel. The paper or gel is moistened with an aqueous buffer of a given pH, and electrodes are connected to the ends of the strip. When an electric potential is applied, the proteins with negative charges (those that are deprotonated because the pH of the buffer is above their isoelectric point) migrate slowly toward the positive electrode. At the same time, those amino acids with positive charges (those that are protonated because the pH of the buffer is below their isoelectric point) migrate toward the negative electrode.

Different proteins migrate at different rates, depending on their isoelectric points and on the pH of the aqueous buffer, thereby effecting a separation of the mixture into its components. **FIGURE 26.3** illustrates this process for a mixture containing basic, neutral, and acidic components.

FIGURE 26.3 Separation of a protein mixture by electrophoresis. At pH = 6.00, a neutral protein does not migrate, a basic protein is protonated and migrates toward the negative electrode, and an acidic protein is deprotonated and migrates toward the positive electrode.

PROBLEM Hemoglobin has $pI = 6.8$. Does hemoglobin have a net negative charge or net positive charge at pH 26-4 = 5.3? At pH = 7.3?

26.3 Synthesis of Amino Acids

α -Amino acids can be synthesized in the laboratory using some of the reactions discussed in previous chapters. One of the oldest methods of α -amino acid synthesis begins with α bromination of a carboxylic acid by treatment with Br_2 and PBr_3 (the Hell-Volhard-Zelinskii reaction; **Section 22.4**). $\text{S}_{\text{N}}2$ substitution of the α -bromo acid with ammonia then yields an α -amino acid.

PROBLEM Show how you could prepare the following α -amino acids from the appropriate carboxylic acids:

26-5 (a) Phenylalanine **(b)** Valine

The Amidomalonate Synthesis

A more general method for preparation of α -amino acids is the *amidomalonate synthesis*, a straightforward extension of the malonic ester synthesis (Section 22.7). The reaction begins with the conversion of diethyl acetamidomalonate into an enolate ion by treatment with base, followed by S_N2 alkylation with a primary alkyl halide. Hydrolysis of both the amide protecting group and the esters occurs when the alkylated product is warmed with aqueous acid, and decarboxylation then takes place to yield an α -amino acid. For example, aspartic acid can be prepared from ethyl bromoacetate, $\text{BrCH}_2\text{CO}_2\text{Et}$:

PROBLEM What alkyl halides would you use to prepare the following α -amino acids by the amidomalonate method?

26-6

(a) Leucine **(b)** Histidine **(c)** Tryptophan **(d)** Methionine

Reductive Amination of α -Keto Acids

Yet another method for the synthesis of α -amino acids is by reductive amination of an α -keto acid with ammonia and a reducing agent. Alanine, for instance, is prepared by treatment of pyruvic acid with ammonia in the presence of NaBH_4 . As described in Section 24.6, the reaction proceeds through formation of an intermediate imine which is then reduced.

Enantioselective Synthesis

The synthesis of an α -amino acid from an achiral precursor by any of the methods just described yields a racemic mixture, with equal amounts of *S* and *R* enantiomers. To use an amino acid in the laboratory synthesis of a naturally occurring protein, however, the pure *S* enantiomer must be obtained.

Two methods are used in practice to obtain enantiomerically pure amino acids. One way requires resolving the racemic mixture into its pure enantiomers (Section 5.8). A more direct approach, however, is to use an enantioselective synthesis to prepare only the desired *S* enantiomer directly. As discussed in the **Chapter 19 Chemistry Matters**, the idea behind enantioselective synthesis is to find a chiral reaction catalyst that will temporarily hold a substrate molecule in an unsymmetrical, chiral environment. While in that chiral environment, the substrate may be more open to reaction on one side than on another, leading to an excess of one enantiomeric product.

William Knowles at the Monsanto Company discovered in 1968 that α -amino acids can be prepared enantioselectively by hydrogenation of a *Z* enamido acid with a chiral hydrogenation catalyst. (*S*)-Phenylalanine, for instance, is prepared at 98.7% purity, contaminated by only 1.3% of the (*R*) enantiomer, when using a chiral rhodium catalyst. For this discovery, Knowles shared the 2001 Nobel Prize in Chemistry.

The most effective catalysts for enantioselective amino acid synthesis are coordination complexes of rhodium(I) with 1,5-cyclooctadiene (COD) and a chiral diphosphine such as (*R,R*)-1,2-bis(*o*-anisylphenylphosphino)ethane, the so-called DiPAMP ligand. This complex owes its chirality to the presence of trisubstituted phosphorus atoms (Section 5.10).

PROBLEM Show how you could prepare the following amino acid enantioselectively:

26-7

26.4 Peptides and Proteins

Proteins and peptides are amino acid polymers in which the individual amino acids, called **residues**, are linked together by amide bonds, or *peptide bonds*. An amino group from one residue forms an amide bond with the carboxyl of a second residue, the amino group of the second forms an amide bond with the carboxyl of a third, and so on. For example, alanylserine is the dipeptide that results when an amide bond forms between the alanine carboxyl and the serine amino group.

Note that two dipeptides can result from reaction between alanine and serine, depending on which carboxyl group reacts with which amino group. If the alanine amino group reacts with the serine carboxyl, serylalanine results.

The long, repetitive sequence of $-\text{N}-\text{CH}-\text{CO}-$ atoms that makes up a continuous chain is called the protein's **backbone**. By convention, peptides are written with the **N-terminal amino acid** (the one with the free $-\text{NH}_3^+$ group) on the left and the **C-terminal amino acid** (the one with the free $-\text{CO}_2^-$ group) on the right. The name of a peptide is denoted by the abbreviations listed in [TABLE 26.1](#) for each amino acid. Thus, alanylserine is abbreviated Ala-Ser or A-S, and serylalanine is abbreviated Ser-Ala or S-A. The one-letter abbreviations are more convenient, though less immediately recognizable, than the three-letter abbreviations.

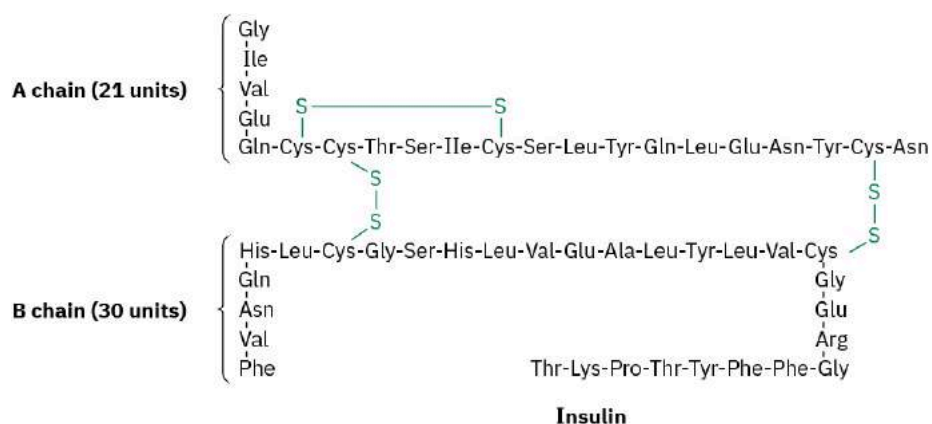

The amide bond that links amino acids together in peptides is no different from any other amide bond ([Section 24.3](#)). An amide nitrogen is nonbasic because its unshared electron pair is delocalized by resonance with the carbonyl group. This overlap of the nitrogen p orbital with the p orbitals of the carbonyl group imparts a certain amount of double-bond character to the $\text{C}-\text{N}$ bond and restricts rotation around it. The amide bond is therefore planar, and the $\text{N}-\text{H}$ is oriented 180° to the $\text{C}=\text{O}$.

A second kind of covalent bonding in peptides occurs when a disulfide linkage, $\text{RS}-\text{SR}$, is formed between two cysteine residues. As we saw in [Section 18.7](#), a disulfide is formed by mild oxidation of a thiol, RSH , and is cleaved by mild reduction.

A disulfide bond between cysteine residues in different peptide chains links the otherwise separate chains together, whereas a disulfide bond between cysteine residues in the same chain forms a loop. Insulin, for instance, is composed of two chains that total 51 amino acids and are linked by two cysteine disulfide bridges.

PROBLEM 26-8 Six isomeric tripeptides contain valine, tyrosine, and glycine. Name them using both three- and one-letter abbreviations.

PROBLEM 26-9 Draw the structure of M-P-V-G, and indicate its amide bonds.

26.5 Amino Acid Analysis of Peptides

To determine the structure of a protein or peptide, we need to answer three questions: What amino acids are present? How much of each is present? In what sequence do the amino acids occur in the peptide chain? The answers to the first two questions are provided by an automated instrument called an amino acid analyzer.

An amino acid analyzer is based on techniques worked out in the 1950s by William Stein and Stanford Moore at the Rockefeller University, who shared the 1972 Nobel Prize in Chemistry for their work. In preparation for analysis, the peptide is broken into its constituent amino acids by reducing all disulfide bonds, capping the $-SH$ groups of cysteine residues by S_N2 reaction with iodoacetic acid, and hydrolyzing the amide bonds by heating with aqueous 6 M HCl at 110 °C for 24 hours. The resultant amino acid mixture is then separated into its components by a technique called *chromatography*, either high-pressure liquid chromatography (HPLC) or ion-exchange chromatography.

In both HPLC and ion-exchange chromatography, the mixture to be separated is dissolved in a solvent, called the *mobile phase*, and passed through a metal tube or glass column that contains an adsorbent material, called the *stationary phase*. Because different compounds adsorb to the stationary phase to different extents, they migrate through the chromatography column at different rates and are separated as they emerge (*elute*) from the end.

In the ion-exchange technique, separated amino acids eluting from the chromatography column mix with a solution of a substance called *ninhydrin* and undergo a rapid reaction that produces an intense purple color. The color is measured by a spectrometer, and a plot of elution time versus spectrometer absorbance is obtained.

Because the time required for a given amino acid to elute from a standard column is reproducible, the identities of the amino acids in a peptide can be determined. The amount of each amino acid in the sample is determined by measuring the intensity of the purple color resulting from its reaction with ninhydrin. **FIGURE 26.4** shows the results of amino acid analysis of a standard equimolar mixture of 17 α -amino acids. Typically, amino acid analysis requires about 100 picomoles (2–3 μg) of sample for a protein containing about 200 residues.

PROBLEM Show the structures of the products obtained on reaction of valine with ninhydrin. **26-11**

26.6 Peptide Sequencing: The Edman Degradation

With the identities and relative amounts of amino acids known, a peptide can then be sequenced to find out in what order the amino acids are linked. Much peptide sequencing is now done by mass spectrometry, using either electrospray ionization (ESI) or matrix-assisted laser desorption ionization (MALDI) linked to a time-of-flight (TOF) mass analyzer, as described in [Section 12.4](#). Also in common use is a chemical method of peptide sequencing called the **Edman degradation**.

The general idea of peptide sequencing by Edman degradation is to cleave one amino acid at a time from an end of the peptide chain. That terminal amino acid is then separated and identified, and the cleavage reactions are repeated on the chain-shortened peptide until the entire peptide sequence is known. Automated protein sequencers are available that allow as many as 50 repetitive sequencing cycles to be carried out before a buildup of unwanted by-products interferes with the results. So efficient are these instruments that sequence information can be obtained from as little as 1 to 5 picomoles of sample—less than $0.1 \mu\text{g}$.

As shown in [FIGURE 26.5](#), Edman degradation involves treatment of a peptide with phenyl isothiocyanate (PITC), $\text{C}_6\text{H}_5\text{-N}=\text{C}=\text{S}$, followed by reaction with trifluoroacetic acid. The first step attaches the PITC to the $-\text{NH}_2$ group of the N-terminal amino acid, and the second step splits the N-terminal residue from the peptide chain, yielding an anilinothiazolinone (ATZ) derivative plus the chain-shortened peptide. Further acid-catalyzed rearrangement of the ATZ derivative with aqueous acid converts it into a phenylthiohydantoin (PTH), which is identified by comparison of its elution time with the known elution times of PTH derivatives of the 20 common amino acids. The chain-shortened peptide is then automatically resubmitted for another round of Edman degradation.

FIGURE 26.5 MECHANISM**Mechanism of the Edman degradation for N-terminal analysis of peptides.**

1 Nucleophilic addition of the peptide terminal amino group to phenyl isothiocyanate (PITC) gives an *N*-phenylthiourea derivative.

2 Acid-catalyzed cyclization of the phenylthiourea yields a tetrahedral intermediate . . .

3 . . . which expels the chain-shortened peptide and forms an anilinothiazolinone (ATZ) derivative.

4 The ATZ rearranges in the presence of aqueous acid to an isomeric *N*-phenylthiohydantoin (PTH) as the final product.

Complete sequencing of large proteins by Edman degradation is impractical because of the buildup of unwanted by-products. To get around this problem, a large peptide chain is first cleaved by partial hydrolysis into a number of smaller fragments, the sequence of each fragment is determined, and the individual fragments are

fitted together by matching their overlapping ends. In this way, protein chains with more than 400 amino acids have been sequenced.

Partial hydrolysis of a peptide can be carried out either chemically with aqueous acid or enzymatically. Acid hydrolysis is unselective and gives a more-or-less random mixture of small fragments, but enzymatic hydrolysis is quite specific. The enzyme trypsin, for instance, catalyzes hydrolysis of peptides only at the carboxyl side of the basic amino acids arginine and lysine; chymotrypsin cleaves only at the carboxyl side of the aryl-substituted amino acids phenylalanine, tyrosine, and tryptophan.

PROBLEM 26-12 The octapeptide angiotensin II has the sequence Asp-Arg-Val-Tyr-Ile-His-Pro-Phe. What fragments would result if angiotensin II were cleaved with trypsin? With chymotrypsin?

PROBLEM 26-13 What is the N-terminal residue on a peptide that gives the following PTH derivative upon Edman degradation?

PROBLEM 26-14 Draw the structure of the PTH derivative that would be formed by Edman degradation of angiotensin II (Problem 26-12).

PROBLEM 26-15 Give the amino acid sequence of hexapeptides that produce the following sets of fragments upon partial acid hydrolysis:

- (a) Arg, Gly, Ile, Leu, Pro, Val gives Pro-Leu-Gly, Arg-Pro, Gly-Ile-Val
 (b) N, L, M, W, V₂ gives V-L, V-M-W, W-N-V

26.7 Peptide Synthesis

Once the structure of a peptide is known, its synthesis can be undertaken—perhaps to obtain a larger amount for biological evaluation. A simple amide might be formed by treating an amine and a carboxylic acid with a carbodiimide (either DCC or EDC; [Section 21.3](#)), but peptide synthesis is a more difficult problem because many different amide bonds must be formed in a specific order, rather than at random.

The solution to the specificity problem is protection ([Section 17.8](#)). If we want to couple alanine with leucine to synthesize Ala-Leu, for instance, we could protect the -NH_2 group of alanine and the $\text{-CO}_2\text{H}$ group of leucine to shield them from reacting, then form the desired Ala-Leu amide bond by reaction with EDC or DCC, and then remove the protecting groups.

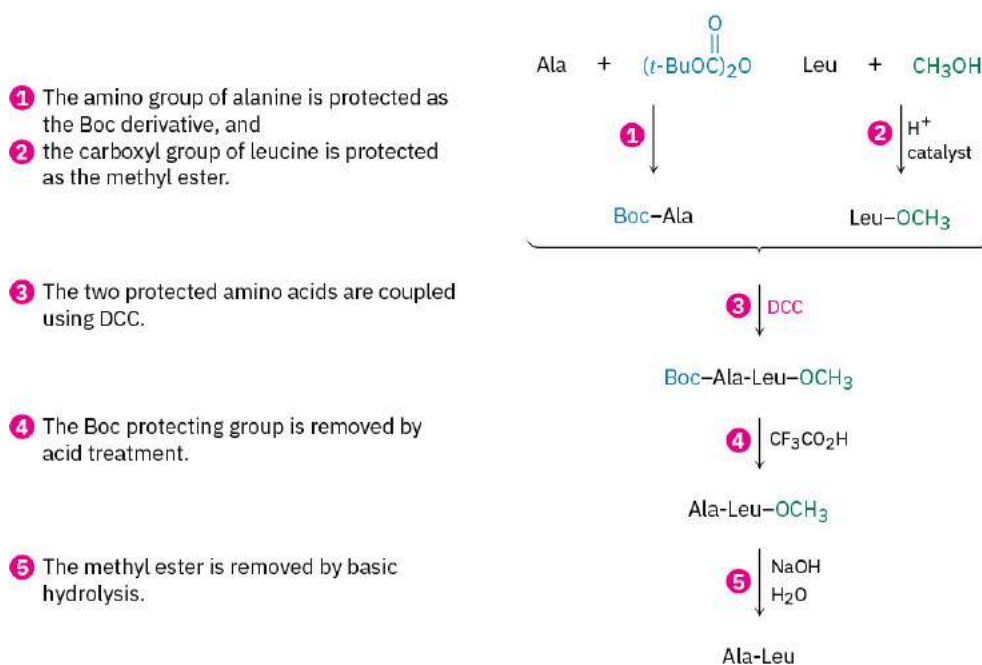

A number of different amino- and carboxyl-protecting groups have been devised, but only a few are used in peptide synthesis. Carboxyl groups are often protected simply by converting them into methyl or benzyl esters. Both groups are easily introduced by standard methods of ester formation (Section 21.6) and are easily removed by mild hydrolysis with aqueous NaOH. Benzyl esters can also be cleaved by catalytic *hydrogenolysis* of the weak benzylic C–O bond ($\text{RCO}_2\text{---CH}_2\text{Ph} + \text{H}_2 \rightarrow \text{RCO}_2\text{H} + \text{PhCH}_3$).

Amino groups are sometimes protected as their *tert*-butyloxycarbonyl amide (Boc) or, more commonly, as their fluorenylmethyloxycarbonyl amide (Fmoc). The Boc protecting group is introduced by reaction of the amino acid with di-*tert*-butyl dicarbonate in a nucleophilic acyl substitution reaction and is removed by brief treatment with a strong acid such as trifluoroacetic acid, $\text{CF}_3\text{CO}_2\text{H}$. The Fmoc protecting group is introduced by reaction with fluorenylmethyloxycarbonyl chloride and is removed by treatment with a 20% solution of the amine piperidine in dimethylformamide as solvent.

Thus, five steps are needed to synthesize a dipeptide such as Ala-Leu:

These steps can be repeated to add one amino acid at a time to the growing chain or to link two peptide chains together. Many remarkable achievements in peptide synthesis have been reported, including a complete synthesis of human insulin. Insulin is composed of two chains totaling 51 amino acids linked by two disulfide bridges. The three-dimensional structure of insulin, shown previously, was determined by Dorothy Crowfoot Hodgkin, a British chemist who received the 1964 Nobel Prize in Chemistry for her work on this and other complex biological molecules.

PROBLEM 26-16 Show the mechanism for formation of a Boc derivative by reaction of an amino acid with di-*tert*-butyl dicarbonate.

PROBLEM 26-17 Write all five steps required for the synthesis of Leu-Ala from alanine and leucine.

26.8 Automated Peptide Synthesis: The Merrifield Solid-Phase Method

As you might imagine, the synthesis of a large peptide chain by sequential addition of one amino acid at a time is a long and arduous process. An immense simplification is possible, however, using methods introduced by R. Bruce Merrifield, who received the 1984 Nobel Prize in Chemistry. In the Merrifield solid-phase method, peptide synthesis is carried out with the growing amino acid chain covalently bonded to small beads of a polymer resin, rather than in solution.

In the original procedure, polystyrene resin was used, prepared so that one of every hundred or so benzene rings contained a chloromethyl ($-\text{CH}_2\text{Cl}$) group. A Boc-protected C-terminal amino acid was then attached to the resin through an ester bond formed by $\text{S}_{\text{N}}2$ reaction.

With the first amino acid bonded to the resin, a repeating series of four steps is then carried out to build a peptide.

1 A Boc-protected amino acid is covalently linked to the polystyrene polymer by formation of an ester bond (S_N2 reaction).

2 The polymer-bonded amino acid is washed free of excess reagent and then treated with trifluoroacetic acid to remove the Boc group.

3 A second Boc-protected amino acid is coupled to the first by reaction with DCC. Excess reagents are removed by washing them from the insoluble polymer.

4 The cycle of deprotection, coupling, and washing is repeated as many times as desired to add amino acid units to the growing chain.

5 After the desired peptide has been made, treatment with anhydrous HF removes the final Boc group and cleaves the ester bond to the polymer, yielding the free peptide.

The steps in the solid-phase procedure have been improved substantially over the years, but the fundamental idea remains the same. A common procedure is use of the Wang resin, developed by Su-Sun Wang, with the Fmoc protecting group. Less common is using the PAM (phenylacetamidomethyl) resin with Boc as the N-protecting group.

Robotic peptide synthesizers are now used to automatically repeat the coupling, washing, and deprotection steps with different amino acids. Each step occurs in high yield, and mechanical losses are minimized because the peptide intermediates are never removed from the insoluble polymer until the final step. Peptides with 20 amino acids can be routinely prepared in a few hours.

26.9 Protein Structure

Proteins are usually classified as either fibrous or globular, according to their three-dimensional shape. **Fibrous proteins**, such as the collagen in tendons and connective tissue and the myosin in muscle tissue, consist of polypeptide chains arranged side by side in long filaments. Because these proteins are tough and insoluble in water, they are used in nature for structural materials. **Globular proteins**, by contrast, are usually coiled into compact, roughly spherical shapes. These proteins are generally soluble in water and are mobile within cells. Most of the more than 3000 or so enzymes that have been characterized are globular proteins, including the 1300 different enzymes in the human body.

Proteins are so large that the word *structure* takes on a broader meaning than with simpler organic compounds. In fact, chemists speak of four different levels of structure when describing proteins.

- The **primary structure** of a protein is simply the amino acid sequence.
- The **secondary structure** of a protein describes how *segments* of the peptide backbone orient into a regular pattern.
- The **tertiary structure** describes how the *entire* protein molecule coils into an overall three-dimensional shape.
- The **quaternary structure** describes how different protein molecules come together to yield large aggregate structures.

Primary structure is determined, as we've seen, by sequencing the protein. Secondary, tertiary, and quaternary structures are determined either by NMR or by X-ray crystallography (**Chapter 12 Chemistry Matters**).

The most common secondary structures are the α helix and the β -pleated sheet. An **α helix** is a right-handed coil of the protein backbone, much like the coil of a spiral staircase (**FIGURE 26.6a**). Each turn of the helix contains 3.6 amino acid residues, with a distance between coils of 540 pm, or 5.4 Å. The structure is stabilized by hydrogen bonds between amide N–H groups and C=O groups four residues away, with an N–H \cdots O distance of 2.8 Å. The α helix is an extremely common secondary structure, and nearly all globular proteins contain many helical segments. Myoglobin, a small globular protein containing 153 amino acid residues in a single chain, is one example (**FIGURE 26.6b**).

A **β -pleated sheet** differs from an α helix in that the peptide chain is fully extended rather than coiled and the hydrogen bonds occur between residues in adjacent chains (**FIGURE 26.7a**). The neighboring chains can run either in the same direction (parallel) or in opposite directions (antiparallel), although the antiparallel arrangement is more common and somewhat more energetically favorable. Concanavalin A, for instance,

consists of two identical chains of 237 residues, with extensive regions of antiparallel β sheets (FIGURE 26.7b).

FIGURE 26.6 (a) The α -helical secondary structure of proteins is stabilized by hydrogen bonds between the N–H group of one residue and the C=O group four residues away. (b) The structure of myoglobin, a globular protein with extensive helical regions that are shown as coiled ribbons in this representation.

FIGURE 26.7 (a) The β -pleated sheet secondary structure of proteins is stabilized by hydrogen bonds between parallel or antiparallel chains. (b) The structure of concanavalin A, a protein with extensive regions of antiparallel β sheets, shown as flat ribbons.

What about tertiary structure? Why does a protein adopt the shape it does? The forces that determine the tertiary structure of a protein are the same forces that act on all molecules, regardless of size, to provide maximum stability. Particularly important are the hydrophilic (water-loving; Section 2.12) interactions of the polar side chains on acidic or basic amino acids and the hydrophobic (water-fearing) interactions of nonpolar

side chains. These acidic or basic amino acids with charged side chains tend to congregate on the exterior of the protein, where they can be solvated by water. Amino acids with neutral, nonpolar side chains tend to congregate on the hydrocarbon-like interior of a protein molecule, away from the aqueous medium.

Also important for stabilizing a protein's tertiary structure are the formation of disulfide bridges between cysteine residues, the formation of hydrogen bonds between nearby amino acid residues, and the presence of ionic attractions, called **salt bridges**, between positively and negatively charged sites on various amino acid side chains within the protein.

Because the tertiary structure of a globular protein is delicately maintained by weak intramolecular attractions, a modest change in temperature or pH is often enough to disrupt that structure and cause the protein to become **denatured**. Denaturation occurs under such mild conditions that the primary structure remains intact, but the tertiary structure unfolds from a specific globular shape to a randomly looped chain (**FIGURE 26.8**).

FIGURE 26.8 A representation of protein denaturation. A globular protein loses its specific three-dimensional shape and becomes randomly looped.

Denaturation is accompanied by changes in both physical and biological properties. Solubility is drastically decreased, as occurs when egg white is cooked and the albumins unfold and coagulate. Most enzymes lose all catalytic activity when denatured, since a precisely defined tertiary structure is required for their action. Although most denaturation is irreversible, some cases are known where spontaneous renaturation of an unfolded protein to its stable tertiary structure occurs, accompanied by a full recovery of biological activity.

26.10 Enzymes and Coenzymes

An **enzyme** is a substance—usually a large protein—that acts as a catalyst for a biological reaction. Like all catalysts, an enzyme doesn't affect the equilibrium constant of a reaction and can't bring about a chemical change that is otherwise unfavorable. An enzyme acts only to lower the activation energy for a reaction, thereby making the reaction take place more rapidly than it otherwise would. Sometimes, in fact, the rate acceleration brought about by enzymes is extraordinary. Millionfold rate increases are common, and the glycosidase enzymes that hydrolyze polysaccharides increase the reaction rate by a factor of more than 10^{17} , changing the time required for the reaction from millions of years to milliseconds!

Unlike many of the catalysts that chemists use in the laboratory, enzymes are usually specific in their action. Often, in fact, an enzyme will catalyze only a single reaction of a single compound, called the enzyme's *substrate*. For example, the enzyme amylase, found in the human digestive tract, catalyzes only the hydrolysis of starch to yield glucose; cellulose and other polysaccharides are untouched by amylase.

Different enzymes have different specificities. Some, such as amylase, are specific for a single substrate, but others operate on a range of substrates. Papain, for instance, a globular protein of 212 amino acids isolated from papaya fruit, catalyzes the hydrolysis of many kinds of peptide bonds. In fact, it's this ability to hydrolyze peptide bonds that makes papain useful as a cleaner for contact lenses.

Enzymes function through a pathway that involves initial formation of an enzyme–substrate complex (E · S), followed by a multistep chemical conversion of the enzyme-bound substrate into enzyme-bound product (E · P)

and final release of product from the complex.

The overall rate constant for conversion of the $E \cdot S$ complex to products $E \cdot P$ is called the **turnover number** because it represents the number of substrate molecules a single enzyme molecule turns over into product per unit time. A value of about 10^3 per second is typical, although carbonic anhydrase can reach a value of up to 600,000.

The extraordinary rate accelerations achieved by enzymes are due to a combination of several factors. One important factor is simple geometry: an enzyme will adjust its shape to hold the substrate, other reactants, and various catalytic sites on acidic or basic residues in the precise geometry needed for reaction. In addition, the wrapping of the enzyme around the substrate can create specialized microenvironments that protect the substrate from the aqueous medium and can dramatically change the behavior of acid–base catalytic residues in the active site. But perhaps most important is that the enzyme stabilizes and thus lowers the energy of the rate-limiting transition state for reaction. That is, it's not the ability of the enzyme to bind the *substrate* that matters but rather its ability to bind and stabilize the *transition state*. Often, in fact, the enzyme binds the transition structure as much as 10^{12} times more tightly than it binds the substrate or products. An energy diagram for an enzyme-catalyzed process might resemble that in **FIGURE 26.9**.

FIGURE 26.9 Energy diagrams for **uncatalyzed** and **enzyme-catalyzed** processes. The enzyme makes available an alternative, lower-energy pathway. Rate enhancement is due to the ability of the enzyme to bind to the transition state for product formation, thereby lowering its energy.

Enzymes are classified into six categories depending on the kind of reaction they catalyze, as shown in **TABLE 26.2**. **Oxidoreductases** catalyze oxidations and reductions; **transferases** catalyze the transfer of a group from one substrate to another; **hydrolases** catalyze hydrolysis reactions of esters, amides, and related substrates; **lyases** catalyze the elimination or addition of a small molecule such as H_2O from or to a substrate; **isomerases** catalyze isomerizations; and **ligases** catalyze the bonding of two molecules, often coupled with the hydrolysis of ATP. The systematic name of an enzyme has two parts, ending with *-ase*. The first part identifies the enzyme's substrate, and the second part identifies its class. Hexose kinase, for example, is a transferase that catalyzes the transfer of a phosphate group from ATP to a hexose sugar.

TABLE 26.2 Classification of Enzymes

Class	Some subclasses	Function
Oxidoreductases	Dehydrogenases	Introduction of double bond
	Oxidases	Oxidation
	Reductases	Reduction
Transferases	Kinases	Transfer of phosphate group
	Transaminases	Transfer of amino group
Hydrolases	Lipases	Hydrolysis of ester
	Nucleases	Hydrolysis of phosphate
	Proteases	Hydrolysis of amide
Lyases	Decarboxylases	Loss of CO ₂
	Dehydrases	Loss of H ₂ O
Isomerases	Epimerases	Isomerization of chirality center
Ligases	Carboxylases	Addition of CO ₂
	Synthetases	Formation of a new bond

In addition to their protein part, most enzymes also contain a small non-protein part called a **cofactor**. A cofactor can be either an inorganic ion, such as Zn²⁺, or a small organic molecule, called a **coenzyme**. A coenzyme is not a catalyst but is a reactant that undergoes chemical change during the reaction and requires an additional step to return to its initial state.

Many coenzymes are derived from vitamins—substances that an organism requires in small amounts for growth but is unable to synthesize and must receive in its diet (**Chapter 20 Chemistry Matters**). Coenzyme A from pantothenate (vitamin B₃), NAD⁺ from niacin, FAD from riboflavin (vitamin B₂), tetrahydrofolate from folic acid, pyridoxal phosphate from pyridoxine (vitamin B₆), and thiamin diphosphate from thiamin (vitamin B₁) are examples. **TABLE 26.3** shows the structures of some common coenzymes.

PROBLEM To what classes do the following enzymes belong?

26-18 (a) Pyruvate decarboxylase **(b)** Chymotrypsin **(c)** Alcohol dehydrogenase

26.11 How Do Enzymes Work? Citrate Synthase

As we saw in the previous section, enzymes work by bringing substrate and other reactant molecules together, holding them in the orientation necessary for reaction, providing any necessary acidic or basic sites to catalyze specific steps, and stabilizing the transition state for reaction. As an example, let's look at citrate synthase, an enzyme that catalyzes the aldol-like addition of acetyl CoA to oxaloacetate to give citrate. This reaction is the first step in the citric acid cycle, in which acetyl groups produced by degradation of food molecules are metabolized to yield CO₂ and H₂O. We'll look at the details of the citric acid cycle in **Section 29.7**.

Citrate synthase is a globular protein of 433 amino acids with a deep cleft lined by an array of functional groups that can bind to the substrate, oxaloacetate. On binding oxaloacetate, the original cleft closes and another opens up nearby to bind acetyl CoA. This second cleft is also lined by appropriate functional groups, including a histidine at position 274 and an aspartic acid at position 375. The two reactants are now held by the enzyme in close proximity and with a suitable orientation for reaction. **FIGURE 26.10** shows the structure of citrate synthase as determined by X-ray crystallography, along with a close-up of the active site.

TABLE 26.3 Structures and Functions of Some Common Coenzymes**Adenosine triphosphate—ATP (phosphorylation)****Coenzyme A (acyl transfer)****Nicotinamide adenine dinucleotide—NAD⁺ (oxidation/reduction)**
(NADP⁺)**Flavin adenine dinucleotide—FAD (oxidation/reduction)**

TABLE 26.3 Structures and Functions of Some Common Coenzymes**Tetrahydrofolate (transfer of C₁ units)****S-Adenosylmethionine (methyl transfer)****Lipoic acid (acyl transfer)****Pyridoxal phosphate (amino acid metabolism)****Thiamin diphosphate (decarboxylation)****Biotin (carboxylation)**

FIGURE 26.10 X-ray crystal structure of citrate synthase. Part (a) is a space-filling model and part (b) is a ribbon model, which emphasizes the α -helical segments of the protein chain and indicates that the enzyme is dimeric; that is, it consists of two identical chains held together by hydrogen bonds and other intermolecular attractions. Part (c) is a close-up of the active site in which oxaloacetate and an unreactive acetyl CoA mimic are bound.

As shown in **FIGURE 26.11**, the first step in the aldol reaction of acetyl CoA and oxaloacetate is generation of the enol of acetyl CoA. The side-chain carboxyl of an aspartate residue acts as base to abstract an acidic α proton, while at the same time the side-chain imidazole ring of a histidine donates H^+ to the carbonyl oxygen. The enol thus produced then performs a nucleophilic addition to the ketone carbonyl group of oxaloacetate. The first histidine acts as a base to remove the $-OH$ hydrogen from the enol, while a second histidine residue simultaneously donates a proton to the oxaloacetate carbonyl group, giving citryl CoA. Water then hydrolyzes the thiol ester group in citryl CoA in a nucleophilic acyl substitution reaction, releasing citrate and coenzyme A as the final products.

FIGURE 26.11 MECHANISM

Mechanism of the addition of acetyl CoA to oxaloacetate to give (S)-citryl CoA, catalyzed by citrate synthase.

- 1 The side-chain carboxylate group of an aspartic acid acts as a base and removes an acidic α proton from acetyl CoA, while the N–H group on the side chain of a histidine acts as an acid and donates a proton to the carbonyl oxygen, giving an enol.
- 2 A histidine deprotonates the acetyl-CoA enol, which adds to the ketone carbonyl group of oxaloacetate in an aldol-like reaction. Simultaneously, an acid N–H proton of another histidine protonates the carbonyl oxygen, producing (S)-citryl CoA.
- 3 The thioester group of citryl CoA is hydrolyzed by a typical nucleophilic acyl substitution reaction to produce citrate plus coenzyme A.

CHEMISTRY MATTERS

The Protein Data Bank

Enzymes are so large, so structurally complex, and so numerous that the use of computer databases and molecular visualization programs has become an essential tool for studying biological chemistry. Of the various databases available online, the Kyoto Encyclopedia of Genes and Genomes (KEGG) database (<http://www.genome.jp/kegg/pathway.html>), maintained by the Kanehisa Laboratory of Kyoto University Bioinformatics Center, is useful for obtaining information on biosynthetic pathways of the sort we'll be describing in Chapter 29. For obtaining information on a specific enzyme, the BRENDA database (<http://www.brenda-enzymes.org>), maintained by the Institute of Biochemistry at the University of Cologne, Germany, is particularly valuable.

Perhaps the most useful of all biological databases is the Protein Data Bank (PDB), operated by the Research Collaboratory for Structural Bioinformatics (RCSB). The PDB is a worldwide repository of X-ray and NMR structural data for biological macromolecules. In mid-2022, data for more than 192,888 structures were available, and more than 7000 new ones were being added yearly. To access the Protein Data Bank, go to www.rcsb.org and a home page like that shown in **FIGURE 26.12** will appear. As with much that is available online, however, the PDB site is changing rapidly, so you may not see quite the same thing.

FIGURE 26.12 The Protein Data Bank home page. (credit: RCSB Protein Data Bank)

To learn how to use the PDB, begin by running the short tutorial listed under Learn on the left side column. After that introduction, start exploring. Let's say you want to view citrate synthase, the enzyme that catalyzes the addition of acetyl CoA to oxaloacetate to give citrate. Type "citrate synthase" (with quotation marks) into the small search box on the top line, click on "Search," and a list of 2,400 or so structures will appear. Scroll down near the end of the list until you find the entry with a PDB code of 5CTS and the title "Proposed Mechanism for the Condensation Reaction of Citrate Synthase: 1.9-Angstroms Structure of the Ternary Complex with Oxaloacetate and Carboxymethyl Coenzyme A." Alternatively, if you know the code of the enzyme you want, you can enter it directly into the search box. Click on the PDB code of entry 5CTS, and a new page containing information about the enzyme will open.

If you choose, you can download the structure file to your computer and open it with any of numerous molecular graphics programs to see an image like that in **FIGURE 26.13**. The biologically active molecule is a dimer of two identical subunits consisting primarily of α -helical regions displayed as coiled ribbons. For now, just select "View in Jmol" under the enzyme image on the right side of the screen to see some of the options for visualizing and further exploring the enzyme.

Summary

Proteins and **peptides** are large biomolecules made of **α -amino acid residues** linked together by amide, or peptide, bonds. Twenty amino acids are commonly found in proteins, and all except glycine have stereochemistry similar to that of L sugars. In neutral solution, amino acids exist as dipolar **zwitterions**.

Amino acids can be synthesized in racemic form by several methods, including ammonolysis of an α -bromo acid, alkylation of diethyl acetamidomalonate, and reductive amination of an α -keto acid. Alternatively, an enantioselective synthesis of amino acids can be carried out using a chiral hydrogenation catalyst.

Determining the structure of a peptide or protein begins with amino acid analysis. The peptide is hydrolyzed to its constituent α -amino acids, which are separated and identified. Next, the peptide is sequenced. **Edman degradation** by treatment with phenyl isothiocyanate (PITC) cleaves one residue from the N terminus of the peptide and forms an easily identifiable phenylthiohydantoin (PTH) derivative of the **N-terminal amino acid**. An automated series of Edman degradations can sequence peptide chains up to 50 residues in length.

Peptide synthesis involves the use of protecting groups. An N-protected amino acid with a free $-\text{CO}_2\text{H}$ group is coupled using DCC or EDC to an O-protected amino acid with a free $-\text{NH}_2$ group. Amide formation occurs, the protecting groups are removed, and the sequence is repeated. Amines are usually protected as their *tert*-butyloxycarbonyl (Boc) or fluorenylmethyloxycarbonyl (Fmoc) derivatives; acids are usually protected as esters. The synthesis is often carried out by the Merrifield solid-phase method, in which the peptide is bonded to insoluble polymer beads.

Proteins have four levels of structure. **Primary structure** describes a protein's amino acid sequence; **secondary structure** describes how segments of the protein chain orient into regular patterns—either **α helix** or **β -pleated sheet**; **tertiary structure** describes how the entire protein molecule coils into an overall three-dimensional shape; and **quaternary structure** describes how individual protein molecules aggregate into larger structures.

Proteins are classified as either globular or fibrous. **Fibrous proteins** such as **α -keratin** are tough, rigid, and water-insoluble; **globular proteins** such as myoglobin are water-soluble and roughly spherical in shape. Many globular proteins are **enzymes**—substances that act as catalysts for biological reactions. Enzymes are grouped into six classes according to the kind of reaction they catalyze. In addition to their protein part, many enzymes contain **cofactors**, which can be either metal ions or small organic molecules called **coenzymes**.

Summary of Reactions

1. Amino acid synthesis (Section 26.3)

a. From α -bromo acids

b. Diethyl acetamidomalonate synthesis

c. Reductive amination of an α -keto acid

d. Enantioselective synthesis

2. Peptide sequencing by Edman degradation (Section 26.6)

3. Peptide synthesis (Section 26.7)

a. Amine protection

b. Carboxyl protection

Additional Problems

Visualizing Chemistry

PROBLEM Identify the following amino acids:

26-19 (a)

(b)

(c)

PROBLEM Give the sequence of the following tetrapeptide (yellow = S):

26-20

PROBLEM Isoleucine and threonine are the only two amino acids with two chirality centers. Assign *R* or *S*

26-21 configuration to the methyl-bearing carbon atom of isoleucine.

PROBLEM Is the following structure a D amino acid or an L amino acid? Identify it.

26-22

PROBLEM Give the sequence of the following tetrapeptide:

26-23

Mechanism Problems

PROBLEM The reaction of ninhydrin with an α -amino acid occurs in several steps.

- 26-24 (a) The first step is formation of an imine by reaction of the amino acid with ninhydrin. Show its structure and the mechanism of its formation.
- (b) The second step is a decarboxylation. Show the structure of the product and the mechanism of the decarboxylation reaction.
- (c) The third step is hydrolysis of an imine to yield an amine and an aldehyde. Show the structures of both products and the mechanism of the hydrolysis reaction.
- (d) The final step is formation of the purple anion. Show the mechanism of the reaction.

PROBLEM The chloromethylated polystyrene resin originally used for Merrifield solid-phase peptide synthesis was prepared by treatment of polystyrene with chloromethyl methyl ether and a Lewis acid catalyst. Propose a mechanism for the reaction.

26-25

PROBLEM An Fmoc protecting group can be removed from an amino acid by treatment with the amine base

26-26 piperidine. Propose a mechanism.

PROBLEM 26-27 Proteins can be cleaved specifically at the amide bond on the carboxyl side of methionine residues by reaction with cyanogen bromide, $\text{BrC}\equiv\text{N}$.

The reaction occurs in several steps:

- The first step is a nucleophilic substitution reaction of the sulfur on the methionine side chain with BrCN to give a cyanosulfonium ion, $[\text{R}_2\text{SCN}]^+$. Show the structure of the product, and propose a mechanism for the reaction.
- The second step is an internal $\text{S}_{\text{N}}2$ reaction, with the carbonyl oxygen of the methionine residue displacing the positively charged sulfur leaving group and forming a five-membered ring product. Show the structure of the product and the mechanism of its formation.
- The third step is a hydrolysis reaction to split the peptide chain. The carboxyl group of the former methionine residue is now part of a lactone (cyclic ester) ring. Show the structure of the lactone product and the mechanism of its formation.
- The final step is a hydrolysis of the lactone to give the product shown. Show the mechanism of the reaction.

PROBLEM 26-28 A clever recent method of peptide synthesis involves formation of an amide bond by reaction of an α -keto acid with an *N*-alkylhydroxylamine:

An α -keto acid **A hydroxylamine** **An amide**

The reaction is thought to occur by nucleophilic addition of the *N*-alkylhydroxylamine to the keto acid as if forming an oxime (Section 19.8), followed by decarboxylation and elimination of water. Show the mechanism.

Amino Acid Structures and Chirality

PROBLEM 26-29 Except for cysteine, only *S* amino acids occur in proteins. Several *R* amino acids are also found in nature, however. (*R*)-Serine is found in earthworms, and (*R*)-alanine is found in insect larvae. Draw Fischer projections of (*R*)-serine and (*R*)-alanine. Are these D or L amino acids?

PROBLEM 26-30 Cysteine is the only amino acid that has L stereochemistry but an *R* configuration. Make up a structure for another L amino acid of your own creation that also has an *R* configuration.

PROBLEM Draw a Fischer projection of (*S*)-proline.

26-31

PROBLEM Show the structures of the following amino acids in their zwitterionic forms:

26-32 (a) Trp (b) Ile (c) Cys (d) His

PROBLEM Proline has $pK_{a1} = 1.99$ and $pK_{a2} = 10.60$. Use the Henderson–Hasselbalch equation to calculate the ratio of protonated and neutral forms at $pH = 2.50$. Calculate the ratio of neutral and deprotonated forms at $pH = 9.70$.

26-33

PROBLEM Using both three- and one-letter codes for amino acids, write the structures of all possible peptides that contain the following amino acids:

26-34

(a) Val, Ser, Leu (b) Ser, Leu₂, Pro

PROBLEM Look at the side chains of the 20 amino acids in Table 26.1, and then think about what is *not* present. None of the 20 contain either an aldehyde or a ketone carbonyl group, for instance. Is this just one of nature's oversights, or is there a likely chemical reason? What complications might an aldehyde or ketone carbonyl group cause?

26-35

Amino Acid Synthesis and Reactions

PROBLEM Show how you could use the acetamidomalonic method to prepare the following amino acids:

26-36 (a) Leucine (b) Tryptophan

PROBLEM Show how you could prepare the following amino acids using a reductive amination:

26-37 (a) Methionine (b) Isoleucine

PROBLEM Show how you could prepare the following amino acids enantioselectively:

26-38 (a) Pro (b) Val

PROBLEM Serine can be synthesized by a simple variation of the amidomalonic method using formaldehyde rather than an alkyl halide. How might this be done?

26-39

PROBLEM Predict the product of the reaction of valine with the following reagents:

26-40 (a) CH_3CH_2OH , acid (b) Di-*tert*-butyl dicarbonate (c) KOH , H_2O
(d) CH_3COCl , pyridine; then H_2O

PROBLEM Draw resonance forms for the purple anion obtained by reaction of ninhydrin with an α -amino acid

26-41 (see Problem 26-24).

Peptides and Enzymes

PROBLEM Write full structures for the following peptides:

26-42 (a) C-H-E-M (b) P-E-P-T-I-D-E

PROBLEM Propose two structures for a tripeptide that gives Leu, Ala, and Phe on hydrolysis but does not react with phenyl isothiocyanate.

26-43

PROBLEM Show the steps involved in a synthesis of Phe-Ala-Val using the Merrifield procedure.

26-44

PROBLEM Draw the structure of the PTH derivative product you would obtain by Edman degradation of the following peptides:

26-45

(a) I-L-P-F (b) D-T-S-G-A

PROBLEM Which amide bonds in the following polypeptide are cleaved by trypsin? By chymotrypsin?

26-46

Phe-Leu-Met-Lys-Tyr-Asp-Gly-Gly-Arg-Val-Ile-Pro-Tyr

PROBLEM What kinds of reactions do the following classes of enzymes catalyze?

26-47 (a) Hydrolases (b) Lyases (c) Transferases

PROBLEM Which of the following amino acids are more likely to be found on the exterior of a globular protein, and which on the interior? Explain.

26-48

- (a) Valine (b) Aspartic acid (c) Phenylalanine (d) Lysine

PROBLEM Leuprolide is a synthetic nonapeptide used to treat both endometriosis in women and prostate cancer in men.

26-49

- (a) Both C-terminal and N-terminal amino acids in leuprolide have been structurally modified. Identify the modifications.
- (b) One of the nine amino acids in leuprolide has D stereochemistry rather than the usual L. Which one?
- (c) Write the structure of leuprolide using both one- and three-letter abbreviations.
- (d) What charge would you expect leuprolide to have at neutral pH?

General Problems

PROBLEM The α -helical parts of myoglobin and other proteins stop whenever a proline residue is encountered in the chain. Why is proline never present in a protein α helix?

26-50

PROBLEM Arginine, the most basic of the 20 common amino acids, contains a *guanidino* functional group in its side chain. Explain, using resonance structures to show how the protonated guanidino group is stabilized.

26-51

PROBLEM Cytochrome *c* is an enzyme found in the cells of all aerobic organisms. Elemental analysis of cytochrome *c* shows that it contains 0.43% iron. What is the minimum molecular weight of this enzyme?

26-52

PROBLEM Evidence for restricted rotation around amide $O=C-N$ bonds comes from NMR studies. At room temperature, the 1H NMR spectrum of *N,N*-dimethylformamide shows three peaks: 2.9 δ (singlet, 3 H), 3.0 δ (singlet, 3 H), and 8.0 δ (singlet, 1 H). As the temperature is raised, however, the two singlets at 2.9 δ and 3.0 δ slowly merge. At 180 $^\circ C$, the 1H NMR spectrum shows only two peaks: 2.95 δ (singlet, 6 H) and 8.0 δ (singlet, 1 H). Explain this temperature-dependent behavior.

26-53

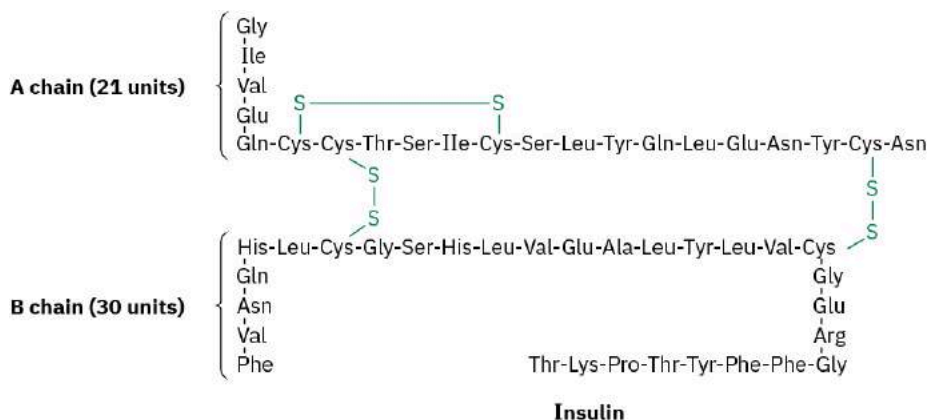

PROBLEM Propose a structure for an octapeptide that shows the composition Asp, Gly₂, Leu, Phe, Pro₂, Val on amino acid analysis. Edman analysis shows a glycine N-terminal group, and leucine is the C-

26-54

terminal group. Acidic hydrolysis gives the following fragments:

Val-Pro-Leu, Gly, Gly-Asp-Phe-Pro, Phe-Pro-Val

PROBLEM 26-55 Look at the structure of human insulin, and indicate where in each chain the molecule is cleaved by trypsin and chymotrypsin.

PROBLEM 26-56 What is the structure of a nonapeptide that gives the following fragments when cleaved?

Trypsin cleavage: Val-Val-Pro-Tyr-Leu-Arg, Ser-Ile-Arg

Chymotrypsin cleavage: Leu-Arg, Ser-Ile-Arg-Val-Val-Pro-Tyr

PROBLEM 26-57 Oxytocin, a nonapeptide hormone secreted by the pituitary gland, functions by stimulating uterine contraction and lactation during childbirth. Its sequence was determined from the following evidence:

- Oxytocin is a cyclic compound containing a disulfide bridge between two cysteine residues.
- When the disulfide bridge is reduced, oxytocin has the constitution Asn, Cys₂, Gln, Gly, Ile, Leu, Pro, Tyr.
- Partial hydrolysis of reduced oxytocin yields seven fragments: Asp-Cys, Ile-Glu, Cys-Tyr, Leu-Gly, Tyr-Ile-Glu, Glu-Asp-Cys, and Cys-Pro-Leu.
- Gly is the C-terminal group.
- Both Glu and Asp are present as their side-chain amides (Gln and Asn) rather than as free side-chain acids.

What is the amino acid sequence of reduced oxytocin? What is the structure of oxytocin itself?

PROBLEM 26-58 *Aspartame*, a nonnutritive sweetener marketed under such trade names as Equal, NutraSweet, and Canderel, is the methyl ester of a simple dipeptide, Asp-Phe-OCH₃.

- Draw the structure of aspartame.
- The isoelectric point of aspartame is 5.9. Draw the principal structure present in aqueous solution at this pH.
- Draw the principal form of aspartame present at physiological pH = 7.3.

PROBLEM 26-59 Refer to Figure 26.5 and propose a mechanism for the final step in Edman degradation—the acid-catalyzed rearrangement of the ATZ derivative to the PTH derivative.

PROBLEM 26-60 Amino acids are metabolized by a transamination reaction in which the -NH₂ group of the amino acid changes places with the keto group of an α-keto acid. The products are a new amino acid and a new α-keto acid. Show the product from transamination of isoleucine.

PROBLEM 26-61 The first step in the biological degradation of histidine is formation of a 4-methylidene-5-imidazolone (MIO) by cyclization of a segment of the peptide chain in the histidine ammonia lyase enzyme. Propose a mechanism.

PROBLEM 26-62 The first step in the biological degradation of lysine is reductive amination with α -ketoglutarate to give saccharopine. Nicotinamide adenine dinucleotide phosphate (NADPH), a relative of NADH, is the reducing agent. Show the mechanism.

CHAPTER 27

Biomolecules: Lipids

FIGURE 27.1 Soap bubbles, so common yet so beautiful, are made from animal fat, a lipid. (credit: “Reflections in soap bubbles” by Image Picture Photography/Flickr, CC BY 2.0)

CHAPTER CONTENTS

27.1 Waxes, Fats, and Oils

27.2 Soap

27.3 Phospholipids

27.4 Prostaglandins and Other Eicosanoids

27.5 Terpenoids

27.6 Steroids

27.7 Biosynthesis of Steroids

WHY THIS CHAPTER? We’ve now covered two of the four major classes of biomolecules—proteins and carbohydrates—and have two remaining. In this chapter, we’ll cover lipids, the largest and most diverse class of biomolecules, looking both at their structure and function and at their metabolism.

Lipids are naturally occurring organic molecules that have limited solubility in water and can be isolated from organisms by extraction with nonpolar organic solvents. Fats, oils, waxes, many vitamins and hormones, and most nonprotein cell-membrane components are some examples. Note that this definition differs from the sort used for carbohydrates and proteins in that lipids are defined by a physical property (solubility) rather than by structure. Of the many kinds of lipids, we’ll be concerned in this chapter with only a few: triacylglycerols, eicosanoids, terpenoids, and steroids.

Lipids are classified into two broad types: those like fats and waxes, which contain ester linkages and can be hydrolyzed, and those like cholesterol and other steroids, which don’t have ester linkages and can’t be hydrolyzed.

27.1 Waxes, Fats, and Oils

Waxes are mixtures of esters of long-chain carboxylic acids with long-chain alcohols. The carboxylic acid usually has an even number of carbons from 16 to 36, while the alcohol has an even number of carbons from 24 to 36. One of the major components of beeswax, for instance, is triacontyl hexadecanoate, the ester of the C₃₀ alcohol (1-triacontanol) and the C₁₆ acid (hexadecanoic acid). The waxy protective coatings on most fruits, berries, leaves, and animal furs have similar structures.

Animal fats and vegetable oils are the most widely occurring lipids. Although they appear different—animal fats like butter and lard are solids, whereas vegetable oils like corn and peanut oil are liquid—their structures are closely related. Chemically, fats and oils are *triglycerides*, or **triacylglycerols**—triesters of glycerol with three long-chain carboxylic acids called **fatty acids**. Animals use fats for long-term energy storage because they are far less highly oxidized than carbohydrates and provide about six times as much energy as an equal weight of stored, hydrated glycogen.

Hydrolysis of a fat or oil with aqueous NaOH yields glycerol and three fatty acids. The fatty acids are generally unbranched and contain an even number of carbon atoms between 12 and 20. If double bonds are present, they have mostly, although not entirely, Z, or cis, geometry. The three fatty acids of a specific triacylglycerol molecule need not be the same, and the fat or oil from a given source is likely to be a complex mixture of many different triacylglycerols. [TABLE 27.1](#) lists some of the commonly occurring fatty acids, and [TABLE 27.2](#) lists the approximate composition of fats and oils from different sources.

TABLE 27.1 Structures of Some Common Fatty Acids

Name	No. of carbons	Melting point (°C)	Structure
Saturated			
Lauric	12	43.2	$\text{CH}_3(\text{CH}_2)_{10}\text{CO}_2\text{H}$
Myristic	14	53.9	$\text{CH}_3(\text{CH}_2)_{12}\text{CO}_2\text{H}$
Palmitic	16	63.1	$\text{CH}_3(\text{CH}_2)_{14}\text{CO}_2\text{H}$
Stearic	18	68.8	$\text{CH}_3(\text{CH}_2)_{16}\text{CO}_2\text{H}$
Arachidic	20	76.5	$\text{CH}_3(\text{CH}_2)_{18}\text{CO}_2\text{H}$
Unsaturated			
Palmitoleic	16	-0.1	(<i>Z</i>)- $\text{CH}_3(\text{CH}_2)_5\text{CH}=\text{CH}(\text{CH}_2)_7\text{CO}_2\text{H}$
Oleic	18	13.4	(<i>Z</i>)- $\text{CH}_3(\text{CH}_2)_7\text{CH}=\text{CH}(\text{CH}_2)_7\text{CO}_2\text{H}$
Linoleic	18	-12	(<i>Z, Z</i>)- $\text{CH}_3(\text{CH}_2)_4(\text{CH}=\text{CHCH}_2)_2(\text{CH}_2)_6\text{CO}_2\text{H}$
Linolenic	18	-11	(all <i>Z</i>)- $\text{CH}_3\text{CH}_2(\text{CH}=\text{CHCH}_2)_3(\text{CH}_2)_6\text{CO}_2\text{H}$
Arachidonic	20	-49.5	(all <i>Z</i>)- $\text{CH}_3(\text{CH}_2)_4(\text{CH}=\text{CHCH}_2)_4\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$

TABLE 27.2 Composition of Some Fats and Oils

Source	Saturated fatty acids (%)				Unsaturated fatty acids (%)	
	C ₁₂ lauric	C ₁₄ myristic	C ₁₆ palmitic	C ₁₈ stearic	C ₁₈ oleic	C ₁₈ linoleic
Animal fat						
Lard	—	1	25	15	50	6
Butter	2	10	25	10	25	5
Human fat	1	3	25	8	46	10
Whale blubber	—	8	12	3	35	10
Vegetable oil						
Coconut	50	18	8	2	6	1
Corn	—	1	10	4	35	45
Olive	—	1	5	5	80	7
Peanut	—	—	7	5	60	20

More than 100 different fatty acids are known and about 40 occur widely. Palmitic acid (C_{16}) and stearic acid (C_{18}) are the most abundant saturated fatty acids; oleic and linoleic acids (both C_{18}) are the most abundant unsaturated ones. Oleic acid is monounsaturated because it has only one double bond, whereas linoleic, linolenic, and arachidonic acids are **polyunsaturated fatty acids** because they have more than one double bond. Linoleic and linolenic acids occur in cream and are essential in the human diet; infants grow poorly and develop skin lesions if fed a diet of nonfat milk for prolonged periods. Linolenic acid, in particular, is an example of an **omega-3 fatty acid**, which has been found to lower blood triglyceride levels and reduce the risk of heart attack. The name omega-3 means that there is a double bond three carbons in from the noncarboxyl end of the chain.

The data in [TABLE 27.1](#) show that unsaturated fatty acids generally have lower melting points than their saturated counterparts, a trend that is also true for triacylglycerols. Since vegetable oils generally have a higher proportion of unsaturated to saturated fatty acids than animal fats ([TABLE 27.2](#)), they have lower melting points. The difference is a consequence of structure. Saturated fats have a uniform shape that allows them to pack together efficiently in a crystal lattice. In unsaturated vegetable oils, however, the $C=C$ bonds introduce bends and kinks into the hydrocarbon chains, making crystal formation more difficult. The more double bonds there are, the harder it is for the molecules to crystallize and the lower the melting point of the oil.

The $C=C$ bonds in vegetable oils can be reduced by catalytic hydrogenation, typically carried out at high temperature using a nickel catalyst, to produce saturated solid or semisolid fats. Prior to 2015, industrially produced margarine and shortening were produced by hydrogenating soybean, peanut, or cottonseed oil until the proper consistency is obtained. As of 2015, trans fats are no longer considered safe by the FDA and have since been phased out of industrially produced foods. Unfortunately, the hydrogenation reaction is accompanied by some cis–trans isomerization of the remaining double bonds, producing fats with about 10% to 15% trans unsaturated fatty acids. Dietary intake of trans fatty acids increases cholesterol levels in the blood, thereby increasing the risk of heart problems. The conversion of linoleic acid into elaidic acid is an example.

PROBLEM 27-1 Carnauba wax, used in floor and furniture polishes, contains an ester of a C_{32} straight-chain alcohol with a C_{20} straight-chain carboxylic acid. Draw its structure.

PROBLEM 27-2 Draw structures of glyceryl tripalmitate and glyceryl trioleate. Which would you expect to have a higher melting point?

27.2 Soap

Soap has been in use for nearly 5000 years. As early as 2800 BC, the Babylonians boiled fats with ashes to create a soap-like substance. Ancient Egyptian medical papyri dating from 1550 BC reveals that Egyptians bathed regularly with soap made from a mixture of animal fats, vegetable oils, and alkaline salts. Chemically, soap is a mixture of the sodium or potassium salts of the long-chain fatty acids produced by hydrolysis (**saponification**) of animal fat with alkali. Wood ash was used as a source of alkali until the early 1800s, when the LeBlanc process for making Na_2CO_3 by heating sodium sulfate with limestone became available.

Crude soap curds contain glycerol and excess alkali as well as soap but can be purified by boiling with water and adding NaCl or KCl to precipitate the pure carboxylate salts. The smooth soap that precipitates is dried, perfumed, and pressed into bars for household use. Dyes are added to make colored soaps, antiseptics are added for medicated soaps, pumice is added for scouring soaps, and air is blown in for soaps that float. Regardless of these extra treatments and regardless of price, though, all soaps are basically the same.

Soaps act as cleansers because the two ends of a soap molecule are so different. The carboxylate end of the long-chain molecule is ionic and therefore hydrophilic (**Section 2.12**), or attracted to water. The long hydrocarbon portion of the molecule, however, is nonpolar and hydrophobic, avoiding water and therefore more soluble in oils. The net effect of these two opposing tendencies is that soaps are attracted to both oils and water and are therefore useful as cleansers.

When soaps are dispersed in water, the long hydrocarbon tails cluster together on the inside of a tangled, hydrophobic ball, while the ionic heads on the surface of the cluster protrude into the water layer. These spherical clusters, called **micelles**, are shown schematically in **FIGURE 27.2**. Grease and oil droplets are solubilized in water when they are coated by the nonpolar, hydrophobic tails of soap molecules in the center of micelles. Once solubilized, the grease and dirt can be rinsed away.

FIGURE 27.2 A soap micelle solubilizing a grease particle in water. An electrostatic potential map of a fatty acid carboxylate shows how the negative charge is located in the head group.

As useful as they are, soaps also have drawbacks. In hard water, which contains metal ions, soluble sodium carboxylates are converted into insoluble magnesium and calcium salts, leaving the familiar ring of scum around bathtubs and a gray tinge on white clothes. Chemists have circumvented this problem by synthesizing a class of synthetic detergents based on salts of long-chain alkylbenzenesulfonic acids. The mechanism of synthetic detergents is the same as that of soaps: the alkylbenzene end of the molecule is attracted to grease, while the anionic sulfonate end is attracted to water. Unlike soaps, though, sulfonate detergents don't form insoluble metal salts in hard water and don't leave an unpleasant scum.

A synthetic detergent
(R = various C₁₂ chains)

PROBLEM Draw the structure of magnesium oleate, a component of bathtub scum.

27-3

PROBLEM Write the saponification reaction of glyceryl dioleate monopalmitate with aqueous NaOH.

27-4

27.3 Phospholipids

Just as waxes, fats, and oils are esters of carboxylic acids, **phospholipids** are esters of phosphoric acid, H₃PO₄.

Phospholipids are of two general types: **glycerophospholipids** and **sphingomyelins**. Glycerophospholipids are based on phosphatidic acid, which contains a glycerol backbone linked by ester bonds to two fatty acids and one phosphoric acid. Although the fatty-acid residues can be any of the C₁₂–C₂₀ units typically present in fats, the acyl group at C1 is usually saturated and the one at C2 is usually unsaturated. The phosphate group at C3 is also

bonded to an amino alcohol such as choline $[\text{HOCH}_2\text{CH}_2\text{N}(\text{CH}_3)_3]^+$, ethanolamine $(\text{HOCH}_2\text{CH}_2\text{NH}_2)$, or serine $[\text{HOCH}_2\text{CH}(\text{NH}_2)\text{CO}_2\text{H}]$. The compounds are chiral and have an *L*, or *R*, configuration at C2.

Sphingomyelins are the second major group of phospholipids. These compounds have sphingosine or a related dihydroxyamine as their backbone and are particularly abundant in brain and nerve tissue, where they are a major constituent of the coating around nerve fibers.

Phospholipids are found widely in both plant and animal tissues and make up approximately 50% to 60% of cell membranes. Because they are like soaps in having a long, nonpolar hydrocarbon tail bound to a polar ionic head, phospholipids in the cell membrane organize into a **lipid bilayer** about 5.0 nm (50 Å) thick. As shown in **FIGURE 27.3**, the nonpolar tails aggregate in the center of the bilayer in much the same way that soap tails aggregate in the center of a micelle. This bilayer serves as an effective barrier to the passage of water, ions, and other components into and out of cells.

FIGURE 27.3 Aggregation of glycerophospholipids into the lipid bilayer that composes cell membranes.

27.4 Prostaglandins and Other Eicosanoids

Prostaglandins are a group of C_{20} lipids that contain a five-membered ring with two long side chains. First isolated in the 1930s by Ulf von Euler at the Karolinska Institute in Sweden, much of the structural and chemical

work on prostaglandins was carried out by Sune Bergström and Bengt Samuelsson. All three shared Nobel Prizes for their work. The name *prostaglandin* derives from the fact that the compounds were first isolated from sheep prostate glands, but they have subsequently been found to be present in small amounts in all body tissues and fluids.

The several dozen known prostaglandins have an extraordinarily wide range of biological effects. Among their many properties, they can lower blood pressure, affect blood platelet aggregation during clotting, lower gastric secretions, control inflammation, affect kidney function, affect reproductive systems, and stimulate uterine contractions during childbirth.

Prostaglandins, together with related compounds called thromboxanes and leukotrienes, make up a class of compounds called **eicosanoids** because they are derived biologically from 5,8,11,14-eicosatetraenoic acid, or arachidonic acid (**FIGURE 27.4**). Prostaglandins (PG) have a cyclopentane ring with two long side chains; thromboxanes (TX) have a six-membered, oxygen-containing ring; and leukotrienes (LT) are acyclic.

FIGURE 27.4 Structures of some representative eicosanoids. All are derived biologically from arachidonic acid.

Eicosanoids are named based on their ring system (PG, TX, or LT), substitution pattern, and number of double bonds. The various substitution patterns on the ring are indicated by letter as in **FIGURE 27.5**, and the number of double bonds is indicated by a subscript. Thus, PGE₁ is a prostaglandin with the “E” substitution pattern and one double bond. The numbering of the atoms in the various eicosanoids is the same as in arachidonic acid, starting with the $-\text{CO}_2\text{H}$ carbon as C1, continuing around the ring, and ending with the $-\text{CH}_3$ carbon at the other end of the chain as C20.

FIGURE 27.5 The naming system for eicosanoids.

Eicosanoid biosynthesis begins with the conversion of arachidonic acid to PGH_2 , catalyzed by the multifunctional PGH synthase (PGHS), also called cyclooxygenase (COX). There are two distinct enzymes, PGHS-1 and PGHS-2 (or COX-1 and COX-2), both of which accomplish the same reaction but appear to function independently. COX-1 carries out the normal physiological production of prostaglandins, and COX-2 produces additional prostaglandin in response to arthritis or other inflammatory conditions. Vioxx, Bextra, and several other drugs selectively inhibit the COX-2 enzyme but cause potentially serious heart and gastrointestinal problems in weakened patients. (See the [Chapter 15 Chemistry Matters](#).)

PGHS accomplishes two transformations, an initial reaction of arachidonic acid with O_2 to yield PGG_2 and a subsequent reduction of the hydroperoxide group ($-\text{OOH}$) to the alcohol PGH_2 . The sequence of steps involved in these transformations was shown in [FIGURE 8.12](#).

Further processing of PGH_2 leads to other eicosanoids. PGE_2 , for instance, arises by an isomerization of PGH_2 catalyzed by PGE synthase (PGES) ([FIGURE 27.6](#)).

FIGURE 27.6 Mechanism of the conversion of PGH₂ into PGE₂.

PROBLEM Assign *R* or *S* configuration to each chirality center in prostaglandin E₂ (Figure 27.6), the most abundant and biologically potent of mammalian prostaglandins.

27.5 Terpenoids

We saw in the **Chapter 8 Chemistry Matters** that **terpenoids** are a vast and diverse group of lipids found in all living organisms. Despite their apparent structural differences, all terpenoids contain a multiple of five carbons and are derived biosynthetically from the five-carbon precursor isopentenyl diphosphate (**FIGURE 27.7**). Although formally a *terpenoid* contains oxygen, while a hydrocarbon is called a *terpene*, we'll use the term *terpenoid* to refer to both for simplicity.

FIGURE 27.7 Structures of some representative terpenoids.

You might recall from the chapter on **Alkenes: Reactions and Synthesis** that terpenoids are classified according to the number of five-carbon multiples they contain. *Monoterpenoids* contain 10 carbons and are derived from two isopentenyl diphosphates, *sesquiterpenoids* contain 15 carbons and are derived from three isopentenyl diphosphates, diterpenoids contain 20 carbons and are derived from four isopentenyl diphosphates, and so on, up to triterpenoids (C₃₀) and tetraterpenoids (C₄₀). Lanosterol, for instance, is a triterpene from which steroid hormones are made, and β-carotene is a tetraterpene that serves as a dietary source of vitamin A (**FIGURE 27.7**).

The terpenoid precursor isopentenyl diphosphate, formerly called isopentenyl pyrophosphate and thus abbreviated IPP, is biosynthesized by two different pathways, depending on the organism and the structure of the final product. In animals and higher plants, sesquiterpenoids and triterpenoids arise primarily from the *mevalonate* pathway, whereas monoterpenoids, diterpenoids, and tetraterpenoids are biosynthesized by the *1-deoxyxylulose 5-phosphate (DXP)* pathway, also called the methylerythritol phosphate, or MEP, pathway. In bacteria, both pathways are used. We'll look only at the mevalonate pathway, which is more common and better understood at present.

The Mevalonate Pathway to Isopentenyl Diphosphate

As shown in **FIGURE 27.8**, the mevalonate pathway begins with the conversion of acetate to acetyl CoA, followed by Claisen condensation to yield acetoacetyl CoA. A second carbonyl condensation reaction with a third molecule of acetyl CoA, this one an aldol-like process, then yields the six-carbon compound 3-hydroxy-3-methylglutaryl CoA, which is reduced to give mevalonate. Phosphorylation, followed by loss of CO_2 and phosphate ion, completes the process.

Step 1 of FIGURE 27.8: Claisen Condensation

The first step in mevalonate biosynthesis is a Claisen condensation to yield acetoacetyl CoA, a reaction catalyzed by acetoacetyl-CoA acetyltransferase. An acetyl group is first bound to the enzyme by a nucleophilic acyl substitution reaction with a cysteine $-\text{SH}$ group. Formation of an enolate ion from a second molecule of acetyl CoA, followed by Claisen condensation, then yields the product.

Step 2 of FIGURE 27.8: Aldol Condensation

Acetoacetyl CoA next undergoes an aldol-like addition of an acetyl CoA enolate ion in a reaction catalyzed by 3-hydroxy-3-methylglutaryl-CoA synthase. The reaction occurs by initial binding of the substrate to a cysteine $-\text{SH}$ group in the enzyme, followed by enolate-ion addition and subsequent hydrolysis to give (3*S*)-3-hydroxy-3-methylglutaryl CoA (HMG-CoA).

FIGURE 27.8 MECHANISM

The mevalonate pathway for the biosynthesis of isopentenyl diphosphate from three molecules of acetyl CoA. Individual steps are explained in the text.

- 1 Claisen condensation of two molecules of acetyl CoA gives acetoacetyl CoA.

- 2 Aldol-like condensation of acetoacetyl CoA with a third molecule of acetyl CoA, followed by hydrolysis, gives (3S)-3-hydroxy-3-methylglutaryl CoA.

- 3 Reduction of the thioester group by 2 equivalents of NADPH gives (R)-mevalonate, a dihydroxy acid.

- 4 Phosphorylation of the tertiary hydroxyl and diphosphorylation of the primary hydroxyl, followed by decarboxylation and simultaneous expulsion of phosphate, gives isopentenyl diphosphate, the precursor of terpenoids.

Step 3 of FIGURE 27.8: Reduction

Reduction of HMG-CoA to give (*R*)-mevalonate is catalyzed by 3-hydroxy-3-methylglutaryl-CoA reductase and requires 2 equivalents of reduced nicotinamide adenine dinucleotide phosphate (NADPH), a close relative of NADH (Section 19.12). The reaction occurs in two steps and proceeds through an aldehyde intermediate. The first step is a nucleophilic acyl substitution reaction involving hydride transfer from NADPH to the thioester carbonyl group of HMG-CoA. Following expulsion of HSCoA as leaving group, the aldehyde intermediate undergoes a second hydride addition to give mevalonate.

Step 4 of FIGURE 27.8: Phosphorylation and Decarboxylation

Three additional reactions are needed to convert mevalonate to isopentenyl diphosphate. The first two are straightforward phosphorylations by ATP that occur through nucleophilic substitution reactions on the terminal phosphorus. Mevalonate is first converted to mevalonate 5-phosphate (phosphomevalonate) by reaction with ATP; mevalonate 5-phosphate then reacts with a second ATP to give mevalonate 5-diphosphate (diphosphomevalonate). The third reaction results in phosphorylation of the tertiary hydroxyl group, followed by decarboxylation and loss of phosphate ion.

The final decarboxylation of mevalonate 5-diphosphate seems unusual because decarboxylations of acids do not typically occur except in β -keto acids and malonic acids, in which the carboxylate group is two atoms away from an additional carbonyl group. As discussed in [Section 22.7](#), the function of this second carbonyl group is to act as an electron acceptor and stabilize the charge resulting from loss of CO_2 . In fact, though, the decarboxylation of a β -keto acid and the decarboxylation of mevalonate 5-diphosphate are closely related.

Catalyzed by mevalonate-5-diphosphate decarboxylase, the substrate is first phosphorylated on the free $-\text{OH}$ group by reaction with ATP to give a tertiary phosphate, which undergoes spontaneous $\text{S}_{\text{N}}1$ -like dissociation to give a tertiary carbocation. The positive charge then acts as an electron acceptor to facilitate decarboxylation in the same way a β carbonyl group does, giving isopentenyl diphosphate. (In the following structures, the diphosphate group is abbreviated OPP.)

PROBLEM 27-6 The conversion of mevalonate 5-phosphate to isopentenyl diphosphate occurs with the following result. Which hydrogen, pro-*R* or pro-*S*, ends up cis to the methyl group, and which ends up trans?

Conversion of Isopentenyl Diphosphate to Terpenoids

The conversion of isopentenyl diphosphate (IPP) to terpenoids begins with its isomerization to dimethylallyl diphosphate, abbreviated DMAPP and formerly called dimethylallyl pyrophosphate. These two C_5 building blocks then combine to give the C_{10} unit geranyl diphosphate (GPP). The corresponding alcohol, geraniol, is itself a fragrant terpenoid that occurs in rose oil.

Further combination of GPP with another IPP gives the C_{15} unit farnesyl diphosphate (FPP), and so on, up to C_{25} .

Terpenoids with more than 25 carbons—that is, triterpenoids (C_{30}) and tetraterpenoids (C_{40})—are synthesized by dimerization of C_{15} and C_{20} units, respectively (FIGURE 27.9). Triterpenoids and steroids, in particular, arise from dimerization of farnesyl diphosphate to give squalene.

FIGURE 27.9 An overview of terpenoid biosynthesis from isopentenyl diphosphate.

The isomerization of isopentenyl diphosphate to dimethylallyl diphosphate is catalyzed by IPP isomerase and occurs through a carbocation pathway. Protonation of the IPP double bond by a hydrogen-bonded cysteine residue in the enzyme gives a tertiary carbocation intermediate, which is deprotonated by a glutamate residue as base to yield DMAPP. X-ray structural studies on the enzyme show that it holds the substrate in an unusually deep, well-protected pocket to shield the highly reactive carbocation from reaction with solvent or other external substances.

Both the initial coupling of DMAPP with IPP to give geranyl diphosphate and the subsequent coupling of GPP with a second molecule of IPP to give farnesyl diphosphate are catalyzed by farnesyl diphosphate synthase. The process requires Mg^{2+} ion, and the key step is a nucleophilic substitution reaction in which the double bond of IPP behaves as a nucleophile in displacing diphosphate ion leaving group (PP_i) or DMAPP. Evidence suggests that the DMAPP develops a considerable cationic character and that spontaneous dissociation of the

allylic diphosphate ion in an S_N1 -like pathway probably occurs (FIGURE 27.10).

FIGURE 27.10 Mechanism of the coupling reaction of dimethylallyl diphosphate (DMAPP) and isopentenyl diphosphate (IPP), to give geranyl diphosphate (GPP).

Further conversion of geranyl diphosphate into monoterpenoids typically involves carbocation intermediates and multistep reaction pathways that are catalyzed by terpene cyclases. Monoterpene cyclases function by first isomerizing geranyl diphosphate to its allylic isomer linalyl diphosphate (LPP), a process that occurs by spontaneous S_N1 -like dissociation to an allylic carbocation, followed by recombination. The effect of this isomerization is to convert the C2–C3 double bond of GPP into a single bond, thereby making cyclization possible and allowing *E/Z* isomerization of the double bond.

Further dissociation and cyclization by electrophilic addition of the cationic carbon to the terminal double bond then gives a cyclic cation, which might either rearrange, undergo a hydride shift, be captured by a nucleophile, or be deprotonated to give any of the several hundred known monoterpenoids. As just one example, limonene, a monoterpenoid found in many citrus oils, arises by the biosynthetic pathway shown in FIGURE 27.11.

FIGURE 27.11 Mechanism for the formation of the monoterpene limonene from geranyl diphosphate.

WORKED EXAMPLE 27.1

Proposing a Terpenoid Biosynthesis Pathway

Propose a mechanistic pathway for the biosynthesis of α -terpineol from geranyl diphosphate.

Strategy

α -Terpineol, a monoterpene, must be derived biologically from geranyl diphosphate through its isomer linalyl diphosphate. Draw the precursor in a conformation that approximates the structure of the target molecule, and then carry out a cationic cyclization, using the appropriate double bond to displace the diphosphate leaving group. Since the target is an alcohol, the carbocation resulting from cyclization evidently reacts with water.

Solution

PROBLEM 27-7 Propose mechanistic pathways for the biosynthetic formation of the following terpenoids:

27.6 Steroids

In addition to fats, phospholipids, eicosanoids, and terpenoids, the lipid extracts of plants and animals also contain **steroids**, molecules that are derived from the triterpenoid lanosterol (FIGURE 27.7) and whose structures are based on a tetracyclic ring system. The four rings are designated A, B, C, and D, beginning at the lower left. The three 6-membered rings (A, B, and C) adopt chair conformations but are prevented by their rigid geometry from undergoing the usual cyclohexane ring-flips (Section 4.6).

Two cyclohexane rings can be joined in either a *cis* or a *trans* manner. With *cis* fusion to give *cis*-decalin, both groups at the ring-junction positions (the *angular* groups) are on the same side of the two rings. With *trans* fusion to give *trans*-decalin, the groups at the ring junctions are on opposite sides.

As shown in FIGURE 27.12, steroids can have either a *cis* or a *trans* fusion of the A and B rings, but the other ring fusions (B–C and C–D) are usually *trans*.

An A–B trans steroid

An A–B cis steroid

FIGURE 27.12 Steroid conformations. The three 6-membered rings have chair conformations but are unable to undergo ring-flips. The A and B rings can be either cis-fused or trans-fused.

Substituent groups on the steroid ring system can be either axial or equatorial. As with simple cyclohexanes, equatorial substitution is generally more favorable than axial substitution for steric reasons. The hydroxyl group of cholesterol, for example, has the more stable equatorial orientation.

Cholesterol

PROBLEM Draw the following molecules in chair conformations, and tell whether the ring substituents are axial or equatorial:

27-8

(a)

(b)

PROBLEM Lithocholic acid is an A–B cis steroid found in human bile. Draw lithocholic acid showing chair conformations, as in Figure 27.12, and tell whether the hydroxyl group at C3 is axial or equatorial.

Lithocholic acid

Steroid Hormones

In humans, most steroids function as **hormones**, chemical messengers that are secreted by endocrine glands

and carried through the bloodstream to target tissues. There are two main classes of steroid hormones: the *sex hormones*, which control maturation, tissue growth, and reproduction, and the *adrenocortical hormones*, which regulate a variety of metabolic processes.

Sex Hormones

Testosterone and androsterone are the two most important male sex hormones, or **androgens**. Androgens are responsible for the development of male secondary sex characteristics during puberty and for promoting tissue and muscle growth. Both are synthesized in the testes from cholesterol. Androstenedione is another minor hormone that has received particular attention because of its use by prominent athletes.

Estrone and estradiol are the two most important female sex hormones, or **estrogens**. Synthesized in the ovaries from testosterone, estrogenic hormones are responsible for the development of female secondary sex characteristics and for regulation of the menstrual cycle. Note that both have a benzene-like aromatic A ring. In addition, another kind of sex hormone called a **progestin** is essential in preparing the uterus for implantation of a fertilized ovum during pregnancy. Progesterone is the most important progestin.

Adrenocortical Hormones

Adrenocortical steroids are secreted by the adrenal glands, small organs located near the upper end of each kidney. There are two types of adrenocortical steroids, called **mineralocorticoids** and **glucocorticoids**. Mineralocorticoids, such as aldosterone, control tissue swelling by regulating cellular salt balance between Na^+ and K^+ . Glucocorticoids, such as hydrocortisone, are involved in the regulation of glucose metabolism and in the control of inflammation. Glucocorticoid ointments are widely used to bring down the swelling from exposure to poison oak or poison ivy.

Synthetic Steroids

In addition to the hundreds of steroids isolated from plants and animals, many more have been synthesized in pharmaceutical laboratories in the search for new drugs. Among the best-known synthetic steroids are oral contraceptives and anabolic agents. Most birth control pills are a mixture of two compounds, a synthetic estrogen, such as ethynylestradiol, and a synthetic progestin, such as norethindrone. **Anabolic steroids**, such as methandrostenolone (Dianabol), are synthetic androgens that mimic the tissue-building effects of natural testosterone.

27.7 Biosynthesis of Steroids

Steroids are heavily modified triterpenoids that are biosynthesized in living organisms from farnesyl diphosphate (C_{15}). A reductive dimerization first converts farnesyl diphosphate to the acyclic hydrocarbon squalene (C_{30}), which is converted into lanosterol (FIGURE 27.13). Further rearrangements and degradations then take place to yield various steroids. The conversion of squalene to lanosterol is among the most intensively studied of biosynthetic transformations. Starting from an achiral, open-chain polyene, the entire process requires only two enzymes and results in the formation of six carbon-carbon bonds, four rings, and seven chirality centers.

FIGURE 27.13 An overview of steroid biosynthesis from farnesyl diphosphate.

Lanosterol biosynthesis begins with the selective epoxidation of squalene to give (3*S*)-2,3-oxidosqualene, catalyzed by squalene epoxidase. Molecular O_2 provides the epoxide oxygen atom, and NADPH is required,

along with a flavin coenzyme. The proposed mechanism involves reaction of FADH_2 with O_2 to produce a flavin hydroperoxide intermediate (ROOH), which transfers an oxygen to squalene in a pathway initiated by nucleophilic attack of the squalene double bond on the terminal hydroperoxide oxygen (**FIGURE 27.14**). The flavin alcohol formed as a by-product loses H_2O to give FAD , which is reduced back to FADH_2 by NADPH . As noted in **Section 8.7**, this biological epoxidation mechanism is closely analogous to the mechanism by which peroxyacids (RCO_3H) react with alkenes to give epoxides in the laboratory.

The second part of lanosterol biosynthesis is catalyzed by oxidosqualene-lanosterol cyclase and occurs as shown in **FIGURE 27.15**. Squalene is folded by the enzyme into a conformation that aligns the various double bonds for a cascade of successive intramolecular electrophilic additions, followed by a series of hydride and methyl migrations. Except for the initial epoxide protonation/cyclization, the process is probably stepwise and appears to involve discrete carbocation intermediates that are stabilized by electrostatic interactions with electron-rich aromatic amino acids in the enzyme.

FIGURE 27.14 Proposed mechanism of the oxidation of squalene by flavin hydroperoxide.

Steps 1, 2 of **FIGURE 27.15**: Epoxide Opening and Initial Cyclizations

Cyclization begins in step **1** with protonation of the epoxide ring by an aspartic acid residue in the enzyme. Nucleophilic opening of the protonated epoxide by the nearby 5,10 double bond (steroid numbering; **Section 27.6**) then yields a tertiary carbocation at C10. Further addition of C10 to the 8,9 double bond in step **2** next gives a bicyclic tertiary cation at C8.

Step 3 of FIGURE 27.15: Third Cyclization

The third cationic cyclization is somewhat unusual because it occurs with non-Markovnikov regiochemistry and gives a secondary cation at C13 rather than the alternative tertiary cation at C14. There is growing evidence, however, that the tertiary carbocation may in fact be formed initially and that the secondary cation arises by subsequent rearrangement. The secondary cation is probably stabilized in the enzyme pocket by the proximity of an electron-rich aromatic ring.

FIGURE 27.15 MECHANISM

Mechanism of the conversion of 2,3-oxidosqualene to lanosterol. Four cationic cyclizations are followed by four rearrangements and a final loss of H^+ from C9. The steroid numbering system is used for referring to specific positions in the intermediates (Section 27.6). Individual steps are explained in the text.

- 1 Protonation on oxygen opens the epoxide ring and gives a tertiary carbocation at C4. Intramolecular electrophilic addition of C4 to the 5,10 double bond then yields a tertiary monocyclic carbocation at C10.

- 2 The C10 carbocation adds to the 8,9 double bond, giving a C8 tertiary bicyclic carbocation.

- 3 Further intramolecular addition of the C8 carbocation to the 13,14 double bond occurs with non-Markovnikov regiochemistry and gives a tricyclic secondary carbocation at C13.

- 4 The fourth and final cyclization occurs by addition of the C13 cation to the 17,20 double bond, giving the protosteryl cation with 17β stereochemistry.

- 5 Hydride migration from C17 to C20 occurs, establishing R stereochemistry at C20.

FIGURE 27.16

(Continued)

Step 4 of FIGURE 27.15: Final Cyclization

The fourth and last cyclization occurs in step 4 by addition of the cationic center at C13 to the 17,20 double bond, giving what is known as the *protosteryl* cation. The side-chain alkyl group at C17 has β (up) stereochemistry, although this stereochemistry is lost in step 5 and then reset in step 6.

Steps 5–9 of FIGURE 27.15: Carbocation Rearrangements

Once the tetracyclic carbon skeleton of lanosterol has been formed, a series of carbocation rearrangements occur (Section 7.11). The first rearrangement, hydride migration from C17 to C20, occurs in step 5 and results in establishment of *R* stereochemistry at C20 in the side chain. In step 6, a second hydride migration occurs from C13 to C17 on the α (bottom) face of the ring and reestablishes the 17β orientation of the side chain. Finally, two methyl migrations, the first from C14 to C13 on the top (β) face and the second from C8 to C14 on the bottom (α) face, place the positive charge at C8. A basic histidine residue in the enzyme then removes the neighboring β proton from C9 to give lanosterol.

From lanosterol, the pathway for steroid biosynthesis continues on to yield cholesterol. Cholesterol then becomes a branch point, serving as the common precursor from which all other steroids are derived.

PROBLEM Compare the structures of lanosterol and cholesterol, and catalog the changes needed for the 27-10 transformation shown.

CHEMISTRY MATTERS

Saturated Fats, Cholesterol, and Heart Disease

We hear a lot these days about the relationship between saturated fats, cholesterol, and heart disease. What are the facts? It's well established that a diet rich in saturated animal fats often leads to an increase in blood serum cholesterol, particularly in sedentary, overweight individuals. Conversely, a diet lower in saturated fats and higher in polyunsaturated fats leads to a lower serum cholesterol level. Studies have shown that a serum cholesterol level greater than 240 mg/dL (a desirable value is < 200 mg/dL) is correlated with an increased incidence of coronary artery disease, in which cholesterol deposits build up on the inner walls of coronary arteries, blocking the flow of blood to the heart muscles.

A better indication of a person's risk of heart disease comes from a measurement of blood lipoprotein levels. **Lipoproteins** are complex molecules with both lipid and protein components that transport lipids through the body. They can be divided into three types according to density, as shown in [TABLE 27.3](#). Very-low-density lipoproteins (VLDLs) act primarily as carriers of triglycerides from the intestines to peripheral tissues, whereas low-density lipoproteins (LDLs) and high-density lipoproteins (HDLs) act as carriers of cholesterol to and from the liver.

FIGURE 27.17 It's hard to resist, but a high intake of saturated animal fat doesn't do much for your cholesterol level. (credit: modification of work "food-chicken-meat-outdoors" by www.pixel.la/Flickr, Public Domain)

Evidence suggests that LDLs transport cholesterol as its fatty-acid ester to peripheral tissues, whereas HDLs remove cholesterol as its stearate ester from dying cells. If LDLs deliver more cholesterol than is needed, and if insufficient HDLs are present to remove it, the excess is deposited in arteries. Thus, a *low* level of *low*-density lipoproteins is good because it means that less cholesterol is being transported, and a *high* level of *high*-density lipoproteins is good because it means that more cholesterol is being removed. In addition, HDL contains an enzyme that has antioxidant properties, offering further protection against heart disease.

As a rule of thumb, a person's risk drops about 25% for each increase of 5 mg/dL in HDL concentration. Normal values are >40 mg/dL for men and <50 mg/dL for women, perhaps explaining why premenopausal women appear to be somewhat less susceptible than men to heart disease.

TABLE 27.3 Serum Lipoproteins

Name	Density (g/mL)	% Lipid	% Protein	Optimal (mg/dL)	Poor (mg/dL)
VLDL	0.930–1.006	90	10	–	–
LDL	1.019–1.063	75	25	<100	>130
HDL	1.063–1.210	67	33	>60	<40

Not surprisingly, the most important factor in gaining high HDL levels is a generally healthful lifestyle. Obesity, smoking, and lack of exercise lead to low HDL levels, whereas regular exercise and a sensible diet lead to high HDL levels. Distance runners and other endurance athletes have HDL levels nearly 50% higher than the general population. Failing that—some of us, but not everyone, wants to run 30 miles or bike 80 miles per week—diet is also important. Diets high in cold-water fish, like salmon and whitefish, raise HDL and lower blood cholesterol because these fish contain almost entirely polyunsaturated fat, including a large percentage of omega-3 fatty acids. Animal fat from red meat and cooking fats should be minimized because saturated fats and monounsaturated trans fats raise blood cholesterol.

Key Terms

- **wax**

Summary

Lipids are the naturally occurring materials isolated from plants and animals by extraction with a nonpolar organic solvent. Animal fats and vegetable oils are the most widely occurring lipids. Both are **triacylglycerols**—triesters of glycerol with long-chain **fatty acids**. Animal fats are usually saturated, whereas vegetable oils usually have unsaturated fatty acid residues.

Phospholipids are important constituents of cell membranes and are of two kinds. *Glycerophospholipids*, such as phosphatidylcholine and phosphatidylethanolamine, are closely related to fats in that they have a glycerol backbone esterified to two fatty acids (one saturated and one unsaturated) and to one phosphate ester. *Sphingomyelins* have the amino alcohol sphingosine for their backbone.

Eicosanoids and **terpenoids** are still other classes of lipids. Eicosanoids, of which prostaglandins are the most abundant kind, are derived biosynthetically from arachidonic acid, are found in all body tissues, and have a wide range of physiological activity. Terpenoids are often isolated from the essential oils of plants, have an immense diversity of structure, and are produced biosynthetically from the five-carbon precursor isopentenyl diphosphate (IPP). Isopentenyl diphosphate is itself biosynthesized from 3 equivalents of acetate in the mevalonate pathway.

Steroids are plant and animal lipids with a characteristic tetracyclic carbon skeleton. Like the eicosanoids, steroids occur widely in body tissues and have a large variety of physiological activities. Steroids are closely related to terpenoids and arise biosynthetically from the triterpenoid lanosterol. Lanosterol, in turn, arises from cationic cyclization of the acyclic hydrocarbon squalene.

Additional Problems

Visualizing Chemistry

PROBLEM 27-11 The following model is that of cholic acid, a constituent of human bile. Locate the three hydroxyl groups, and identify each as axial or equatorial. Is cholic acid an A–B trans steroid or an A–B cis steroid?

PROBLEM 27-12 Propose a biosynthetic pathway for the sesquiterpenoid helminthogermacrene from farnesyl diphosphate.

PROBLEM 27-13 Identify the following fatty acid, and tell whether it is more likely to be found in peanut oil or in red meat:

Mechanism Problems

PROBLEM 27-14 Propose a mechanistic pathway for the biosynthesis of caryophyllene, a substance found in clove oil.

PROBLEM 27-15 Suggest a mechanism by which ψ -ionone is transformed into β -ionone on treatment with acid.

PROBLEM 27-16 Isoborneol is converted into camphene on treatment with dilute sulfuric acid. Propose a mechanism for the reaction, which involves a carbocation rearrangement.

Fats, Oils, and Related Lipids

PROBLEM 27-17 Fatty fish like salmon and albacore are rich in *omega*-3 fatty acids, which have a double bond three carbons in from the noncarboxyl end of the chain and have been shown to lower blood cholesterol levels. Draw the structure of 5,8,11,14,17-eicosapentaenoic acid, a common example. (Eicosane = $\text{C}_{20}\text{H}_{42}$.)

PROBLEM 27-18 Fats can be either optically active or optically inactive, depending on their structure. Draw the structure of an optically active fat that yields 2 equivalents of stearic acid and 1 equivalent of oleic acid on hydrolysis. Draw the structure of an optically inactive fat that yields the same products.

PROBLEM 27-19 Spermaceti, a fragrant substance from sperm whales, was widely used in cosmetics until it was banned in 1976 to protect whales from extinction. Chemically, spermaceti is cetyl palmitate, the ester of cetyl alcohol ($n\text{-C}_{16}\text{H}_{33}\text{OH}$) with palmitic acid. Draw its structure.

PROBLEM 27-20 Show the products you would expect to obtain from reaction of glyceryl trioleate with the following reagents:

- (a) Excess Br_2 in CH_2Cl_2 (b) H_2/Pd (c) $\text{NaOH}/\text{H}_2\text{O}$ (d) O_3 , then $\text{Zn}/\text{CH}_3\text{CO}_2\text{H}$
 (e) LiAlH_4 , then H_3O^+ (f) CH_3MgBr , then H_3O^+

PROBLEM 27-21 How would you convert oleic acid into the following substances?

- (a) Methyl oleate (b) Methyl stearate (c) Nonanal (d) Nonanedioic acid
 (e) 9-Octadecynoic acid (stearolic acid) (f) 2-Bromostearic acid
 (g) 18-Pentatriacontanone, $\text{CH}_3(\text{CH}_2)_{16}\text{CO}(\text{CH}_2)_{16}\text{CH}_3$

PROBLEM 27-22 *Plasmalogens* are a group of lipids found in nerve and muscle cells. How do plasmalogens differ from fats?

PROBLEM 27-23 What products would you obtain from hydrolysis of a plasmalogen (Problem 27-22) with aqueous NaOH ? With H_3O^+ ?

PROBLEM 27-24 *Cardiolipins* are a group of lipids found in heart muscles. What products would be formed if all ester

bonds, including phosphates, were saponified by treatment with aqueous NaOH?

PROBLEM 27-25 Stearic acid, $C_{18}H_{32}O_2$, yields stearic acid on catalytic hydrogenation and undergoes oxidative cleavage with ozone to yield nonanoic acid and nonanedioic acid. What is the structure of stearic acid?

PROBLEM 27-26 How would you synthesize stearic acid (Problem 27-25) from 1-decyne and 1-chloro-7-iodoheptane?

Terpenoids and Steroids

PROBLEM 27-27 Without proposing an entire biosynthetic pathway, draw the appropriate precursor, either geranyl diphosphate or farnesyl diphosphate, in a conformation that shows a likeness to each of the following terpenoids:

PROBLEM 27-28 Indicate by asterisks the chirality centers present in each of the terpenoids shown in Problem 27-27. What is the maximum possible number of stereoisomers for each?

PROBLEM 27-29 Assume that the three terpenoids in Problem 27-27 are derived biosynthetically from isopentenyl diphosphate and dimethylallyl diphosphate, each of which was isotopically labeled at the diphosphate-bearing carbon atom (C1). At what positions would the terpenoids be isotopically labeled?

PROBLEM 27-30 Assume that acetyl CoA containing a ^{14}C isotopic label in the carboxyl carbon atom is used as starting material for the biosynthesis of mevalonate, as shown in Figure 27.8. At what positions in mevalonate would the isotopic label appear?

PROBLEM 27-31 Assume that acetyl CoA containing a ^{14}C isotopic label in the carboxyl carbon atom is used as starting material and that the mevalonate pathway is followed. Identify the positions in α -cadinol where the label would appear.

PROBLEM 27-32 Assume that acetyl CoA containing a ^{14}C isotopic label in the carboxyl carbon atom is used as starting material and that the mevalonate pathway is followed. Identify the positions in squalene

where the label would appear.

Squalene

PROBLEM 27-33 Assume that acetyl CoA containing a ^{14}C isotopic label in the carboxyl carbon atom is used as starting material and that the mevalonate pathway is followed. Identify the positions in lanosterol where the label would appear.

Lanosterol

General Problems

PROBLEM 27-34 Flexibilene, a compound isolated from marine coral, is the first known terpenoid to contain a 15-membered ring. What is the structure of the acyclic biosynthetic precursor of flexibilene? Show the mechanistic pathway for the biosynthesis.

Flexibilene

PROBLEM 27-35 Draw the most stable chair conformation of dihydrocarvone.

Dihydrocarvone

PROBLEM 27-36 Draw the most stable chair conformation of menthol, and label each substituent as axial or equatorial.

Menthol (from peppermint oil)

PROBLEM 27-37 As a general rule, equatorial alcohols are esterified more readily than axial alcohols. What product would you expect to obtain from reaction of the following two compounds with 1 equivalent of acetic anhydride?

PROBLEM 27-38 Propose a mechanistic pathway for the biosynthesis of isoborneol. A carbocation rearrangement is needed at one point in the scheme.

PROBLEM 27-39 Digitoxigenin is a heart stimulant obtained from the purple foxglove *Digitalis purpurea* and used in the treatment of heart disease. Draw the three-dimensional conformation of digitoxigenin, and identify the two -OH groups as axial or equatorial.

PROBLEM 27-40 What product would you obtain by reduction of digitoxigenin (Problem 27-39) with LiAlH_4 ? By oxidation with the Dess–Martin periodinane?

PROBLEM 27-41 Vaccenic acid, $\text{C}_{18}\text{H}_{34}\text{O}_2$, is a rare fatty acid that gives heptanal and 11-oxoundecanoic acid $[\text{OHC}(\text{CH}_2)_9\text{CO}_2\text{H}]$ on ozonolysis followed by zinc treatment. When allowed to react with $\text{CH}_2\text{I}_2/\text{Zn}(\text{Cu})$, vaccenic acid is converted into lactobacillic acid. What are the structures of vaccenic and lactobacillic acids?

PROBLEM 27-42 Eleostearic acid, $\text{C}_{18}\text{H}_{30}\text{O}_2$, is a rare fatty acid found in the tung oil used for finishing furniture. On ozonolysis followed by treatment with zinc, eleostearic acid furnishes one part pentanal, two parts glyoxal ($\text{OHC}-\text{CHO}$), and one part 9-oxononanoic acid $[\text{OHC}(\text{CH}_2)_7\text{CO}_2\text{H}]$. What is the structure of eleostearic acid?

PROBLEM 27-43 Diterpenoids are derived biosynthetically from geranylgeranyl diphosphate (GGPP), which is itself biosynthesized by reaction of farnesyl diphosphate with isopentenyl diphosphate. Show the structure of GGPP, and propose a mechanism for its biosynthesis from FPP and IPP.

PROBLEM 27-44 Diethylstilbestrol (DES) has estrogenic activity even though it is structurally unrelated to steroids. Once used as an additive in animal feed, DES has been implicated as a causative agent in several types of cancer. Show how DES can be drawn so that it is sterically similar to estradiol.

PROBLEM 27-45 Cembrene, $C_{20}H_{32}$, a diterpenoid hydrocarbon isolated from pine resin, has a UV absorption at 245 nm, but dihydrocembrene ($C_{20}H_{34}$), the product of hydrogenation with 1 equivalent of H_2 , has no UV absorption. On exhaustive hydrogenation, 4 equivalents of H_2 react, and octahydrocembrene, $C_{20}H_{40}$, is produced. On ozonolysis of cembrene, followed by treatment of the ozonide with zinc, four carbonyl-containing products are obtained:

Propose a structure for cembrene that is consistent with its formation from geranylgeranyl diphosphate.

PROBLEM 27-46 α -Fenchone is a pleasant-smelling terpenoid isolated from oil of lavender. Propose a pathway for the formation of α -fenchone from geranyl diphosphate. A carbocation rearrangement is required.

PROBLEM 27-47 Fatty acids are synthesized by a multistep route that starts with acetate. The first step is a reaction between protein-bound acetyl and malonyl units to give a protein-bound 3-ketobutyryl unit. Show the mechanism, and tell what kind of reaction is occurring.

PROBLEM 27-48 Propose a mechanism for the biosynthesis of the sesquiterpenoid trichodiene from farnesyl diphosphate. The process involves cyclization to give an intermediate secondary carbocation, followed by several carbocation rearrangements.

WHY THIS CHAPTER? Nucleic acids are the last of the four major classes of biomolecules we'll consider. So much has been written and spoken about DNA in the media that the basics of DNA replication and transcription are probably known to you. Thus, we'll move fairly quickly through the fundamentals and then look more closely at the chemical details of DNA sequencing, synthesis, and metabolism. This field is moving rapidly, and there's a lot you may not be familiar with.

The nucleic acids, **deoxyribonucleic acid (DNA)** and **ribonucleic acid (RNA)**, are the chemical carriers of a cell's genetic information. Coded in a cell's DNA is the information that determines the nature of the cell, controls its growth and division, and directs biosynthesis of the enzymes and other proteins required for cellular functions.

In addition to nucleic acids themselves, nucleic acid derivatives such as ATP are involved as phosphorylating agents in many biochemical pathways, and several important coenzymes, including NAD^+ , FAD, and coenzyme A, have nucleic acid components. See [TABLE 26.3](#) for their structures.

28.1 Nucleotides and Nucleic Acids

Just as proteins are biopolymers made of amino acids, the nucleic acids are biopolymers made of **nucleotides**, joined together to form a long chain. Each nucleotide is composed of a **nucleoside** bonded to a phosphate group, and each nucleoside is composed of an aldopentose sugar linked through its anomeric carbon to the nitrogen atom of a heterocyclic purine or pyrimidine base.

The sugar component in RNA is ribose, and the sugar in DNA is 2'-deoxyribose. (In naming and numbering nucleotides, numbers with a prime superscript refer to positions on the sugar and numbers without a prime superscript refer to positions on the heterocyclic base. Thus, the prefix 2'-deoxy indicates that oxygen is missing from C2' of ribose.) DNA contains four different amine bases: two substituted purines (**A**, adenine, and **G**, guanine) and two substituted pyrimidines (**C**, cytosine, and **T**, thymine). Adenine, guanine, and cytosine also occur in RNA, but thymine is replaced in RNA by a closely related pyrimidine base called **U**, uracil.

The structures of the four deoxyribonucleotides and the four ribonucleotides are shown in [FIGURE 28.2](#). Although similar chemically, DNA and RNA differ dramatically in size. Molecules of DNA are enormous, containing as many as 245 million nucleotides and having molecular weights as high as 75 billion. Molecules of RNA, by contrast, are much smaller, containing as few as 21 nucleotides and having molecular weights as low as 7000.

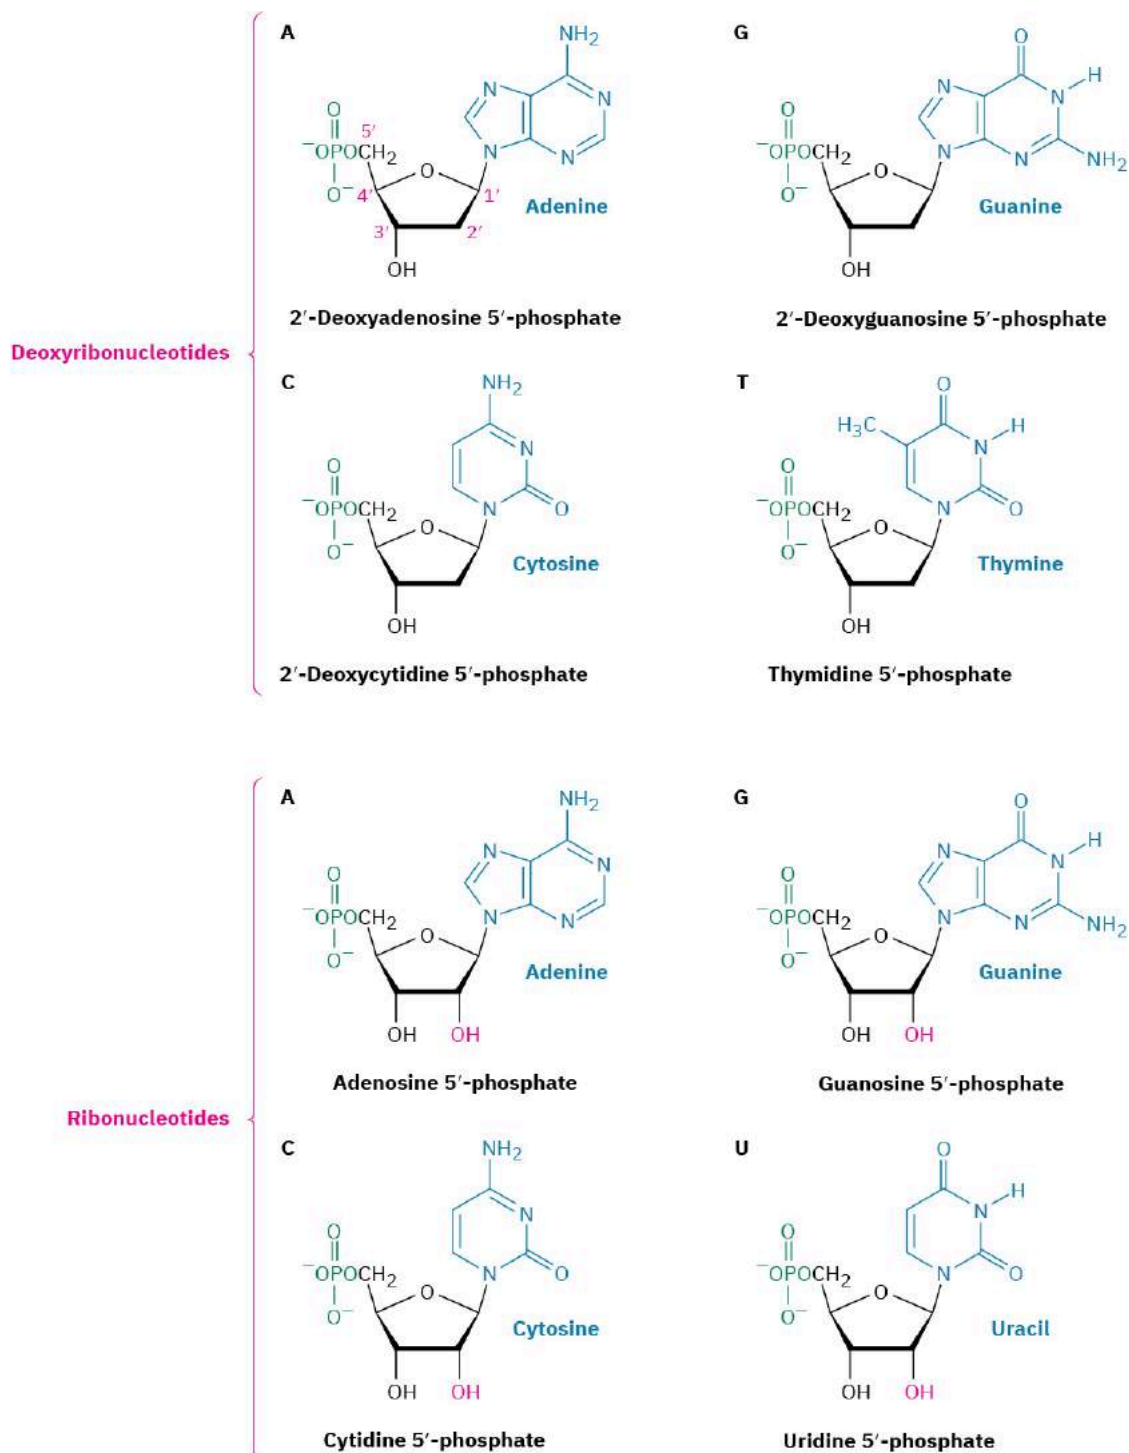

FIGURE 28.2 Structures of the four deoxyribonucleotides and the four ribonucleotides.

Nucleotides are linked together in DNA and RNA by *phosphodiester* bonds [RO-(PO₂⁻)-OR'] between phosphate, the 5'-hydroxyl group on one nucleoside, and the 3'-hydroxyl group on another nucleoside. One end of the nucleic acid polymer has a free hydroxyl at C3' (the **3' end**), and the other end has a phosphate at C5' (the **5' end**). The sequence of nucleotides in a chain is described by starting at the 5' end and identifying the bases in order of occurrence, using the abbreviations G, C, A, T (or U in RNA). Thus, a typical DNA sequence might be written as TAGGCT.

PROBLEM Draw the full structure of the DNA dinucleotide AG.

28-1

PROBLEM Draw the full structure of the RNA dinucleotide UA.

28-2

28.2 Base Pairing in DNA

Samples of DNA isolated from different tissues of the same species have the same proportions of heterocyclic bases, but samples from different species often have greatly differing proportions of bases. Human DNA, for example, contains about 30% each of adenine and thymine and about 20% each of guanine and cytosine. The bacterium *Clostridium perfringens*, however, contains about 37% each of adenine and thymine and only 13% each of guanine and cytosine. Note that in both examples the bases occur in pairs. Adenine and thymine are present in equal amounts, as are cytosine and guanine. Why?

In 1953, Rosalind Franklin, Maurice Wilkins, James Watson, and Francis Crick published scientific reports describing the secondary structure of DNA. According to their model, DNA under physiological conditions consists of two polynucleotide strands, running in opposite directions and coiled around each other in a **double helix** like the handrails on a spiral staircase. The two strands are complementary rather than identical and are held together by hydrogen bonds between specific pairs of bases, A with T and C with G. That is, whenever an A base occurs in one strand, a T base occurs opposite it in the other strand; when a C base occurs in one, a G occurs in the other (**FIGURE 28.3**). This complementary base-pairing thus explains why A and T are always found in equal amounts, as are G and C.

FIGURE 28.3 Hydrogen-bonding between base pairs in the DNA double helix. Electrostatic potential maps show that the faces of the bases are relatively **neutral**, while the edges have **positive** and **negative** regions. Pairing G with C and A with T brings together oppositely charged regions.

A full turn of a DNA double helix is shown in **FIGURE 28.4**. The helix is 20 Å wide, there are 10 base pairs per turn, and each turn is 34 Å in length. Notice in **FIGURE 28.4** that the two strands of the double helix coil in such a way that two kinds of “grooves” result, a *major groove* 12 Å wide and a *minor groove* 6 Å wide. The major groove is slightly deeper than the minor groove, and both are lined by flat heterocyclic bases. As a result, a variety of other polycyclic aromatic molecules are able to slip sideways, or *intercalate*, between the stacked bases. Many cancer-causing and cancer-preventing agents function by interacting with DNA in this way.

FIGURE 28.4 A turn of the DNA double helix in both space-filling and wire-frame formats. The sugar–phosphate backbone runs along the outside of the helix, and the amine bases hydrogen bond to one another on the inside. Both major and minor grooves are visible.

An organism’s genetic information is stored as a sequence of deoxyribonucleotides strung together in the DNA chain. For the information to be preserved and passed on to future generations, a mechanism must exist for

copying DNA. For the information to be used, a mechanism must exist for decoding the DNA message and implementing the instructions it contains.

What Crick called the “central dogma of molecular genetics” says that the function of DNA is to store information and pass it on to RNA. The function of RNA, in turn, is to read, decode, and use the information received from DNA to make proteins. This view is greatly oversimplified but is nevertheless a good place to start. Three fundamental processes take place.

- **Replication** is the process by which identical copies of DNA are made so that information can be preserved and handed down to offspring.
- **Transcription** is the process by which genetic messages are read and carried out of the cell nucleus to ribosomes, where protein synthesis occurs.
- **Translation** is the process by which the genetic messages are decoded and used to synthesize proteins.

WORKED EXAMPLE 28.1

Predicting the Complementary Base Sequence in Double-Stranded DNA

What sequence of bases on one strand of DNA is complementary to the sequence TATGCAT on another strand?

Strategy

Remember that A and G form complementary pairs with T and C, respectively, and then go through the sequence replacing A by T, G by C, T by A, and C by G. Remember also that the 5' end is on the left and the 3' end is on the right in the original strand.

Solution

Original: (5') TATGCAT (3')

Complement: (3') ATACGTA (5') or (5') ATGCATA (3')

PROBLEM What sequence of bases on one strand of DNA is complementary to the following sequence on **28-3** another strand?

(5') GGCTAATCCGT (3')

28.3 Replication of DNA

DNA **replication** is an enzyme-catalyzed process that begins with a partial unwinding of the double helix at various points along the chain, brought about by enzymes called *helicases*. Hydrogen bonds are broken, the two strands separate to form a “bubble,” and bases are exposed. New nucleotides then line up on each strand in a complementary manner, A to T and G to C, and two new strands begin to grow from the ends of the bubble, called the **replication forks**. Each new strand is complementary to its old template strand, so two identical DNA double helices are produced (**FIGURE 28.5**). Because each of the new DNA molecules contains one old strand and one new strand, the process is described as *semiconservative* replication.

is faithfully copied during replication. The entire copying process takes only a few hours and, after proofreading and repair, an error gets through only about once per 10 to 100 billion bases. In fact, only about 60 of these random mutations are passed on from parent to child per human generation.

28.4 Transcription of DNA

As noted previously, RNA is structurally similar to DNA but contains ribose rather than deoxyribose and uracil rather than thymine. RNA has three major types, each of which serves a specific purpose. In addition, there are a number of small RNAs that appear to control a wide variety of important cellular functions. All RNA molecules are much smaller than DNA, and all remain single-stranded rather than double-stranded.

- **Messenger RNA (mRNA)** carries genetic messages from DNA to ribosomes, small granular particles in the cytoplasm of a cell where protein synthesis takes place.
- **Ribosomal RNA (rRNA)** complexed with protein provides the physical makeup of the ribosomes.
- **Transfer RNA (tRNA)** transports amino acids to the ribosomes, where they are joined together to make proteins.
- **Small RNAs**, also called **functional RNAs**, have a variety of functions within the cell, including silencing transcription and catalyzing chemical modifications of other RNA molecules.

The genetic information in DNA is contained in segments called **genes**, each of which consists of a specific nucleotide sequence that encodes a specific protein. The conversion of that information from DNA into proteins begins in the nucleus of cells with the synthesis of mRNA by **transcription** of DNA. In bacteria, the process begins when RNA polymerase recognizes and binds to a *promoter sequence* on DNA, typically consisting of around 40 base pairs located upstream (5') of the transcription start site. Within the promoter are two hexameric *consensus sequences*, one located 10 base pairs upstream of the start and the second located 35 base pairs upstream.

Following formation of the polymerase–promoter complex, several turns of the DNA double helix untwist, forming a bubble and exposing 14 or so base pairs of the two strands. Appropriate ribonucleotides then line up by hydrogen-bonding to their complementary bases on DNA, bond formation occurs in the 5' → 3' direction, the RNA polymerase moves along the DNA chain, and the growing RNA molecule unwinds from DNA (**FIGURE 28.6**). At any one time, about 12 base pairs of the growing RNA remain hydrogen-bonded to the DNA template.

FIGURE 28.6 Biosynthesis of RNA using a DNA segment as a template.

Unlike what happens in DNA replication, where both strands are copied, only one of the two DNA strands is transcribed into mRNA. The DNA strand that contains the gene is often called the **sense strand**, or *coding strand*, and the DNA strand that gets transcribed to give RNA is called the **antisense strand**, or *noncoding strand*. Because the sense strand and the antisense strand in DNA are complementary, and because the DNA antisense strand and the newly formed RNA strand are also complementary, the RNA molecule produced during transcription is a copy of the DNA sense strand. That is, the complement of the complement is the same as the original. The only difference is that the RNA molecule has a U everywhere that the DNA sense strand has a T.

Another part of the picture in vertebrates and flowering plants is that genes are often not continuous segments of the DNA chain. Instead, a gene will begin in one small section of DNA called an *exon*, then be interrupted

by a noncoding section called an *intron*, and then take up again farther down the chain in another exon. The final mRNA molecule results only after the noncoded sections are cut out of the transcribed mRNA and the remaining pieces are joined together by spliceosome enzymes. The gene for triose phosphate isomerase in maize, for instance, contains eight noncoding introns accounting for approximately 70% of the DNA base pairs and nine coding exons accounting for only 30% of the base pairs.

PROBLEM Show how uracil can form strong hydrogen bonds to adenine.

28.5 Translation of RNA: Protein Biosynthesis

The primary cellular function of mRNA is to direct the biosynthesis of the thousands of diverse peptides and proteins required by an organism—as many as 150,000 in a human. The mechanics of protein biosynthesis take place on ribosomes, small granular particles in the cytoplasm of a cell that consist of about 60% ribosomal RNA and 40% protein.

The specific ribonucleotide sequence in mRNA forms a message that determines the order in which amino acid residues are to be joined. Each “word,” or **codon**, along the mRNA chain consists of a sequence of three ribonucleotides that is specific for a given amino acid. For example, the series UUC on mRNA is a codon directing incorporation of the amino acid phenylalanine into the growing protein. Of the $4^3 = 64$ possible triplets of the four bases in RNA, 61 code for specific amino acids and 3 code for chain termination. **TABLE 28.1** shows the meaning of each codon.

TABLE 28.1 Codon Assignments of Base Triplets

First base (5' end)	Second base	Third base (3' end)			
		U	C	A	G
U	U	Phe	Phe	Leu	Leu
	C	Ser	Ser	Ser	Ser
	A	Tyr	Tyr	Stop	Stop
	G	Cys	Cys	Stop	Trp
C	U	Leu	Leu	Leu	Leu
	C	Pro	Pro	Pro	Pro
	A	His	His	Gln	Gln
	G	Arg	Arg	Arg	Arg
A	U	Ile	Ile	Ile	Met
	C	Thr	Thr	Thr	Thr

TABLE 28.1 Codon Assignments of Base Triplets

First base (5' end)	Second base	Third base (3' end)			
		U	C	A	G
	A	Asn	Asn	Lys	Lys
	G	Ser	Ser	Arg	Arg
G	U	Val	Val	Val	Val
	C	Ala	Ala	Ala	Ala
	A	Asp	Asp	Glu	Glu
	G	Gly	Gly	Gly	Gly

The message embedded in mRNA is read by transfer RNA (tRNA) in a process called **translation**. There are 61 different tRNAs, one for each of the 61 codons that specify an amino acid. A typical tRNA is single-stranded and has roughly the shape of a cloverleaf, as shown in **FIGURE 28.7**. It consists of about 70 to 100 ribonucleotides and is bonded to a specific amino acid by an ester linkage through the 3' hydroxyl on ribose at the 3' end of the tRNA. Each tRNA also contains on its middle leaf a segment called an **anticodon**, a sequence of three ribonucleotides complementary to the codon sequence. For example, the codon sequence UUC present on mRNA is read by a phenylalanine-bearing tRNA having the complementary anticodon base sequence GAA. [Remember that nucleotide sequences are written in the 5' → 3' direction, so the sequence in an anticodon must be reversed. That is, the complement to (5')-UUC-(3') is (3')-AAG-(5'), which is written as (5')-GAA-(3').]

FIGURE 28.7 Structure of a tRNA molecule. The tRNA is a roughly cloverleaf-shaped molecule containing an anticodon triplet on one “leaf” and an amino acid unit attached covalently at its 3' end. The example shown is a yeast tRNA that codes for phenylalanine. The

nucleotides not specifically identified are chemically modified analogs of the four common nucleotides.

As each successive codon on mRNA is read, different tRNAs bring the correct amino acids into position for enzyme-mediated transfer to the growing peptide. When synthesis of the proper protein is completed, a “stop” codon signals the end, and the protein is released from the ribosome. This process is illustrated in **FIGURE 28.8**.

FIGURE 28.8 A representation of protein biosynthesis. The codon base sequences on mRNA are read by tRNAs containing complementary anticodon base sequences. Transfer RNAs assemble the proper amino acids into position for incorporation into the growing peptide.

WORKED EXAMPLE 28.2

Predicting the Amino Acid Sequence Transcribed from DNA

What amino acid sequence is coded by the following segment of a DNA coding strand (sense strand)?

Strategy

The mRNA produced during translation is a copy of the DNA coding strand, with each T replaced by U. Thus, the mRNA has the sequence

Each set of three bases forms a codon, whose meaning can be found in **TABLE 28.1**.

Solution

Leu-Thr-Ser-Gly-Ser-Pro.

PROBLEM List codon sequences for the following amino acids:

28-7 (a) Ala (b) Phe (c) Leu (d) Tyr

PROBLEM List anticodon sequences on the tRNAs carrying the following amino acids.

28-8 (a) Ala (b) Phe (c) Leu (d) Tyr

PROBLEM What amino acid sequence is coded by the following mRNA base sequence?

28-9

CUU-AUG-GCU-UGG-CCC-UAA

PROBLEM What is the base sequence in the original DNA strand on which the mRNA sequence in Problem 28-10 28-9 was made?

28.6 DNA Sequencing

A scientific revolution is now under way in molecular biology, as scientists learn how to manipulate and harness the genetic machinery of organisms. None of the extraordinary advances of the past several decades would have been possible, however, were it not for the discovery in 1977 of methods for sequencing immense DNA chains.

The first step in DNA sequencing is to cleave the enormous chain at known points to produce smaller, more manageable pieces, a task accomplished by the use of **restriction endonucleases**, or *restriction enzymes*. Each different restriction enzyme, of which more than 4000 are known and approximately 600 are commercially available, cleaves a DNA molecule at a point in the chain where a specific base sequence occurs. For example, the restriction enzyme *AluI* cleaves between G and C in the four-base sequence AG-CT. Note that the sequence is a *palindrome*, meaning that the sequence (5')-AGCT-(3') is the same as its complement (3')-TCGA-(5') when both are read in the same 5' → 3' direction. The same is true for other restriction endonucleases.

If the original DNA molecule is cut with another restriction enzyme having a different specificity for cleavage, still other segments are produced whose sequences partially overlap those produced by the first enzyme. Sequencing all the segments, followed by identification of the overlapping regions, allows for complete DNA sequencing.

A dozen or so different methods of DNA sequencing are now available, and many others are under development. The **Sanger dideoxy method** is among the most frequently used and was the method responsible for first sequencing the entire human genome of 3.0 billion base pairs. In commercial sequencing instruments, the dideoxy method begins with a mixture of the following:

- The restriction fragment to be sequenced
- A small piece of DNA called a *primer*, whose sequence is complementary to that on the 3' end of the restriction fragment
- The four 2'-deoxyribonucleoside triphosphates (dNTPs)
- Very small amounts of the four 2',3'-dideoxyribonucleoside triphosphates (ddNTPs), each of which is labeled with a fluorescent dye of a different color (A 2',3'-*dideoxyribonucleoside* triphosphate is one in which both 2' and 3' -OH groups are missing from ribose.)

DNA polymerase is added to the mixture, and a strand of DNA complementary to the restriction fragment begins to grow from the end of the primer. Most of the time, only normal deoxyribonucleotides are incorporated into the growing chain because of their much higher concentration in the mixture, but every so often, a dideoxyribonucleotide is incorporated. When that happens, DNA synthesis stops because the chain end no longer has a 3'-hydroxyl group for adding further nucleotides.

When reaction is complete, the product consists of a mixture of DNA fragments of all possible lengths, each terminated by one of the four dye-labeled dideoxyribonucleotides. This product mixture is then separated according to the size of the pieces by gel electrophoresis (Section 26.2), and the identity of the terminal dideoxyribonucleotide in each piece—and thus the sequence of the restriction fragment—is determined by

noting the color with which the attached dye fluoresces. **FIGURE 28.9** shows a typical result.

FIGURE 28.9 The sequence of a restriction fragment determined by the Sanger dideoxy method can be read simply by noting the colors of the dye attached to each of the various terminal nucleotides.

So efficient is the automated dideoxy method that sequences up to 1100 nucleotides in length, with a throughput of up to 19,000 bases per hour, can be sequenced with 98% accuracy. After a decade of work and a cost of about \$500 million, preliminary sequence information for the entire human genome of 3.0 billion base pairs was announced early in 2001 and complete information was released in 2003. More recently, the genome sequencing of individuals, including that of James Watson, one of the discoverers of the double helix, has been accomplished. The sequencing price per genome is dropping rapidly and is currently less than \$1,000, meaning that the routine sequencing of individuals is within reach.

Remarkably, our genome appears to contain only about 21,000 genes, less than one-fourth the previously predicted number and only about twice the number found in the common roundworm. It's also interesting to note that the number of genes in a human (21,000) is much smaller than the number of kinds of proteins (perhaps 500,000). This discrepancy arises because most proteins are modified in various ways after translation (*posttranslational modifications*), so a single gene can ultimately give many different proteins.

28.7 DNA Synthesis

The ongoing revolution in molecular biology has brought with it an increased demand for the efficient chemical synthesis of short DNA segments, called *oligonucleotides*, or simply *oligos*. The problems of DNA synthesis are similar to those of peptide synthesis (**Section 26.7**) but are more difficult because of the complexity of the nucleotide monomers. Each nucleotide has multiple reactive sites that must be selectively protected and deprotected at specific times, and coupling of the four nucleotides must be carried out in the proper sequence. Automated DNA synthesizers are available, however, that allow the fast and reliable synthesis of DNA segments up to 200 nucleotides in length.

DNA synthesizers operate on a principle similar to that of the Merrifield solid-phase peptide synthesizer (**Section 26.8**). In essence, a protected nucleotide is covalently bonded to a solid support, and one nucleotide at a time is added to the growing chain by the use of a coupling reagent. After the final nucleotide has been added, all the protecting groups are removed and the synthetic DNA is cleaved from the solid support. Five steps are needed:

STEP 1

The first step in DNA synthesis is to attach a protected deoxynucleoside to a silica (SiO_2) support by an ester linkage to the 3' -OH group of the deoxynucleoside. Both the 5' -OH group on the sugar and free -NH₂ groups on the heterocyclic bases must be protected. Adenine and cytosine bases are protected by benzoyl groups, guanine is protected by an isobutyryl group, and thymine requires no protection. The deoxyribose 5' -OH is protected as its *p*-dimethoxytrityl (DMT) ether.

**STEP 2**

The second step is removal of the DMT protecting group by treatment with dichloroacetic acid in CH_2Cl_2 . The reaction occurs by an $\text{S}_{\text{N}}1$ mechanism and proceeds rapidly because of the stability of the tertiary, benzylic dimethoxytrityl cation.

**STEP 3**

The third step is the coupling of the polymer-bonded deoxynucleoside with a protected deoxynucleoside containing a *phosphoramidite* group $[\text{R}_2\text{NP}(\text{OR})_2]$ at its 3' position. The coupling reaction takes place in the polar aprotic solvent acetonitrile, requires catalysis by the heterocyclic amine tetrazole, and yields a *phosphite*, $\text{P}(\text{OR})_3$, as product. Note that one of the phosphorus oxygen atoms is protected by a β -cyanoethyl group, $-\text{OCH}_2\text{CH}_2\text{C}\equiv\text{N}$. The coupling step takes place with better than 99% yield.

**STEP 4**

With the coupling accomplished, the phosphite product is oxidized to a phosphate by treatment with iodine in aqueous tetrahydrofuran in the presence of 2,6-dimethylpyridine. The cycle of (1) deprotection, (2) coupling, and (3) oxidation is then repeated until an oligonucleotide chain of the desired sequence has been constructed.

**STEP 5**

The final step is removal of all protecting groups and cleavage of the ester bond holding the DNA to the silica. All these reactions are done at the same time by treatment with aqueous NH_3 . Purification by electrophoresis then yields the synthetic DNA.

PROBLEM 28-11 *p*-Dimethoxytrityl (DMT) ethers are easily cleaved by mild acid treatment. Show the mechanism of the cleavage reaction.

PROBLEM 28-12 Propose a mechanism to account for cleavage of the β -cyanoethyl protecting group from the phosphate groups on treatment with aqueous ammonia. (Acrylonitrile, $\text{H}_2\text{C}=\text{CHCN}$, is a by-product.) What kind of reaction is occurring?

28.8 The Polymerase Chain Reaction

It often happens that only a tiny amount of DNA can be obtained directly, as might occur at a crime scene, so methods for obtaining larger amounts are sometimes needed to carry out sequencing and characterization. The invention of the **polymerase chain reaction (PCR)** by Kary Mullis in 1986 has been described as being to genes what Gutenberg's invention of the printing press was to the written word. Just as the printing press produces multiple copies of a book, PCR produces multiple copies of a given DNA sequence. Starting from less than 1 picogram (pg) of DNA with a chain length of 10,000 nucleotides ($1 \text{ pg} = 10^{-12} \text{ g}$; about 10^5 molecules), PCR makes it possible to obtain several micrograms ($1 \mu\text{g} = 10^{-6} \text{ g}$; about 10^{11} molecules) in just a few hours.

The key to the polymerase chain reaction is *Taq* DNA polymerase, a heat-stable enzyme isolated from the thermophilic bacterium *Thermus aquaticus* found in a hot spring in Yellowstone National Park. *Taq* polymerase is able to take a single strand of DNA having a short, primer segment of complementary chain at one end and then finish constructing the entire complementary strand. The overall process takes three steps, as shown in **FIGURE 28.10**. More recently, improved heat-stable DNA polymerases have become available, including Vent polymerase and *Pfu* polymerase, both isolated from bacteria growing near geothermal vents in the ocean floor. The error rate of both enzymes is substantially less than that of *Taq*.

FIGURE 28.10 The polymerase chain reaction. Details are explained in the text.

STEP 1

The double-stranded DNA to be amplified is heated in the presence of *Taq* polymerase, Mg²⁺ ion, the four deoxynucleotide triphosphate monomers (dNTPs), and a large excess of two short oligonucleotide primers of about 20 bases each. Each primer is complementary to the sequence at the end of one of the target DNA segments. At a temperature of 95 °C, double-stranded DNA denatures, spontaneously breaking apart into two single strands.

STEP 2

The temperature is lowered to between 37 and 50 °C, allowing the primers, because of their relatively high concentration, to anneal by hydrogen-bonding to their complementary sequence at the end of each target strand.

STEP 3

The temperature is then raised to 72 °C, and *Taq* polymerase catalyzes the addition of further nucleotides to the two primed DNA strands. When replication of each strand is complete, two copies of the original DNA now exist. Repeating the denature–anneal–synthesize cycle a second time yields four DNA copies, repeating a third time yields eight copies, and so on, in an exponential series.

PCR has been automated, and 30 or so cycles can be carried out in an hour, resulting in a theoretical amplification factor of 2^{30} ($\sim 10^9$). In practice, however, the efficiency of each cycle is less than 100%, and an experimental amplification of about 10^6 to 10^8 is routinely achieved for 30 cycles.

CHEMISTRY MATTERS

DNA Fingerprinting

The invention of DNA sequencing has affected society in many ways, few more dramatic than those stemming from the development of *DNA fingerprinting*. DNA fingerprinting arose from the discovery in 1984 that human genes contain short, repeating sequences of noncoding DNA, called *short tandem repeat* (STR) loci. Furthermore, the STR loci are slightly different for everyone except identical twins. By sequencing these loci, a pattern unique to each person can be obtained.

Perhaps the most common and well-publicized use of DNA fingerprinting is that carried out by crime laboratories to link suspects to biological evidence—blood, hair follicles, skin, or semen—found at a crime scene. Many thousands of court cases have been decided based on DNA evidence.

For use in criminal cases, forensic laboratories in the United States have agreed on 13 core STR loci that are most accurate for the identification of an individual. Based on these 13 loci, a Combined DNA Index System (CODIS) has been established to serve as a registry of convicted offenders. When a DNA sample is obtained from a crime scene, the sample is subjected to cleavage with restriction endonucleases to cut out fragments containing the STR loci, the fragments are amplified using the polymerase chain reaction, and the sequences of the fragments are determined.

If the profile of sequences from a known individual and the profile from DNA obtained at a crime scene match, the probability is approximately 82 billion to 1 that the DNA is from the same individual. In paternity cases, where the DNA of male parent and offspring are related but not fully identical, the identity of the male parent can be established with a probability of around 100,000 to 1. Even after several generations, paternity can still be inferred from DNA analysis of the Y chromosome of direct male-line descendants. The most well-known such case is that of Thomas Jefferson, one of the nation's founders, who likely impregnated enslaved person Sally Hemings. Although Jefferson himself has no male-line descendants, DNA analysis of the male-line descendants of Jefferson's paternal uncle contained the same Y chromosome as a male-line descendant of Eston Hemings, the youngest son of Sally Hemings. Thus, a mixing of the two genomes is clear, although the male individual responsible for that mixing can't be identified with 100% certainty.

Among its many other applications, DNA fingerprinting is widely used for the diagnosis of genetic disorders, both prenatally and in newborns. Cystic fibrosis, hemophilia, Huntington's disease, Tay–Sachs disease, sickle cell anemia, and thalassemia are among the many diseases that can be detected, enabling early treatment of an affected child. Furthermore, by studying the DNA fingerprints of relatives with a history of a particular disorder, it's possible to identify DNA patterns associated with the disease and perhaps obtain clues for an eventual cure. In addition, the U.S. Department of Defense requires blood and saliva samples from all military personnel. The samples are stored, and DNA is extracted if the need for identification of a casualty arises.

Summary

DNA (deoxyribonucleic acid) and **RNA (ribonucleic acid)** are biological polymers that act as chemical carriers of an organism's genetic information. Enzyme-catalyzed hydrolysis of nucleic acids yields **nucleotides**, the monomer units from which RNA and DNA are constructed. Further enzyme-catalyzed hydrolysis of the nucleotides yields **nucleosides** plus phosphate. Nucleosides, in turn, consist of a purine or pyrimidine base linked to the C1 of an aldopentose sugar—ribose in RNA and 2-deoxyribose in DNA. The nucleotides are joined by phosphate links between the 5' phosphate of one nucleotide and the 3' hydroxyl on the sugar of another nucleotide.

Molecules of DNA consist of two complementary polynucleotide strands held together by hydrogen bonds between heterocyclic bases on the different strands and coiled into a **double helix**. Adenine and thymine form hydrogen bonds to each other, as do cytosine and guanine.

Three processes take place in deciphering the genetic information of DNA:

- **Replication** of DNA is the process by which identical DNA copies are made. The DNA double helix unwinds, complementary deoxyribonucleotides line up in order, and two new DNA molecules are produced.
- **Transcription** is the process by which RNA is produced to carry genetic information from the nucleus to the ribosomes. A short segment of the DNA double helix unwinds, and complementary ribonucleotides line up to produce **messenger RNA (mRNA)**.
- **Translation** is the process by which mRNA directs protein synthesis. Each mRNA is divided into **codons**, ribonucleotide triplets that are recognized by small amino acid-carrying molecules of **transfer RNA (tRNA)**, which deliver the appropriate amino acids needed for protein synthesis.

Sequencing of DNA is carried out by the **Sanger dideoxy method**, and small DNA segments can be synthesized in the laboratory by automated instruments. Small amounts of DNA can be amplified by factors of 10^6 using the **polymerase chain reaction (PCR)**.

Additional Problems

Visualizing Chemistry

PROBLEM Identify the following bases, and tell whether each is found in DNA, RNA, or both:

28-13 (a)

(b)

(c)

PROBLEM Identify the following nucleotide, and tell how it is used:

28-14

PROBLEM 28-15 Amine bases in nucleic acids can react with alkylating agents in typical S_N2 reactions. Look at the following electrostatic potential maps, and tell which is the better nucleophile, guanine or adenine. The reactive positions in each are indicated.

Mechanism Problems

PROBLEM 28-16 The final step in DNA synthesis is deprotection by treatment with aqueous ammonia. Show the mechanisms by which deprotection occurs at the points indicated in the following structure:

PROBLEM 28-17 The final step in the metabolic degradation of uracil is the oxidation of malonic semialdehyde to give malonyl CoA. Propose a mechanism.

PROBLEM 28-18 One of the steps in the biosynthesis of a nucleotide called inosine monophosphate is the formation of aminoimidazole ribonucleotide from formylglycinamide ribonucleotide. Propose a mechanism.

PROBLEM Which of the following base sequences would most likely be recognized by a restriction endonuclease? Explain.

28-25

(a) GAATTC (b) GATTACA (c) CTCGAG

PROBLEM For what amino acids do the following ribonucleotide triplets code?

28-26 (a) AAU (b) GAG (c) UCC (d) CAU

PROBLEM From what DNA sequences were each of the mRNA codons in Problem 28-26 transcribed?

28-27

PROBLEM What anticodon sequences of tRNAs are coded for by the codons in Problem 28-26?

28-28

PROBLEM Draw the complete structure of the ribonucleotide codon UAC. For what amino acid does this sequence code?

28-29

PROBLEM Draw the complete structure of the deoxyribonucleotide sequence from which the mRNA codon in Problem 28-29 was transcribed.

28-30

PROBLEM Give an mRNA sequence that will code for the synthesis of met-enkephalin.

28-31

Tyr-Gly-Gly-Phe-Met

PROBLEM Give an mRNA sequence that will code for the synthesis of angiotensin II.

28-32

Asp-Arg-Val-Tyr-Ile-His-Pro-Phe

PROBLEM What amino acid sequence is coded for by the following DNA coding strand (sense strand)?

28-33

(5') CTT-CGA-CCA-GAC-AGC-TTT (3')

PROBLEM What amino acid sequence is coded for by the following mRNA base sequence?

28-34

(5') CUA-GAC-CGU-UCC-AAG-UGA (3')

PROBLEM If the DNA coding sequence -CAA-CCG-GAT- were miscopied during replication and became -CGA-CCG-GAT-, what effect would there be on the sequence of the protein produced?

28-35

PROBLEM Show the steps involved in a laboratory synthesis of the DNA fragment with the sequence CTAG.

28-36

PROBLEM Draw the structure of cyclic adenosine monophosphate (cAMP), a messenger involved in the regulation of glucose production in the body. Cyclic AMP has a phosphate ring connecting the 3'- and 5'-hydroxyl groups on adenosine.

28-37

PROBLEM Valganciclovir, marketed as Valcyte, is an antiviral agent used for the treatment of cytomegalovirus. Called a *prodrug*, valganciclovir is inactive by itself but is rapidly converted in the intestine by hydrolysis of its ester bond to produce an active drug, called ganciclovir, along with an amino acid.

28-38

(a) What amino acid is produced by hydrolysis of the ester bond in valganciclovir?

(b) What is the structure of ganciclovir?

(c) What atoms present in the nucleotide deoxyguanine are missing from ganciclovir?

- (d) What role do the atoms missing from deoxyguanine play in DNA replication?
- (e) How might valganciclovir interfere with DNA synthesis?

29.10 Some Conclusions about Biological Chemistry

WHY THIS CHAPTER? In this chapter, we'll look at some of the pathways by which organisms carry out their chemistry, focusing primarily on how they metabolize fats and carbohydrates. The treatment will be far from complete, but it should give you an idea of the kinds of processes that occur.

Anyone who wants to understand or contribute to the revolution now taking place in the biological sciences must first understand life processes at the molecular level. This understanding, in turn, must be based on a detailed knowledge of the chemical reactions and pathways used by living organisms. Just knowing what occurs is not enough; it's also necessary to understand how and why organisms use the chemistry they do.

Biochemical reactions are not mysterious. Even though the biological reactions that take place in living organisms often appear complicated, they follow the same rules of reactivity as laboratory reactions and they operate by the same mechanisms.

Some of the molecules we'll be encountering are substantially larger and more complex than those we've been dealing with thus far. But don't be intimidated; keep your focus on the parts of the molecules where changes occur, and ignore the parts where nothing changes. The reactions themselves are exactly the same additions, eliminations, substitutions, carbonyl condensations, and so forth, that we've been dealing with all along. By the end of this chapter, it should be clear that the chemistry of living organisms *is* organic chemistry.

29.1 An Overview of Metabolism and Biochemical Energy

The many reactions that occur in the cells of living organisms are collectively called **metabolism**. The pathways that break down larger molecules into smaller ones are called **catabolism**, and the pathways that synthesize larger biomolecules from smaller ones are known as **anabolism**. Catabolic reaction pathways are usually exergonic and release energy, while anabolic pathways are often endergonic and absorb energy. Catabolism can be divided into the four stages shown in **FIGURE 29.2**.

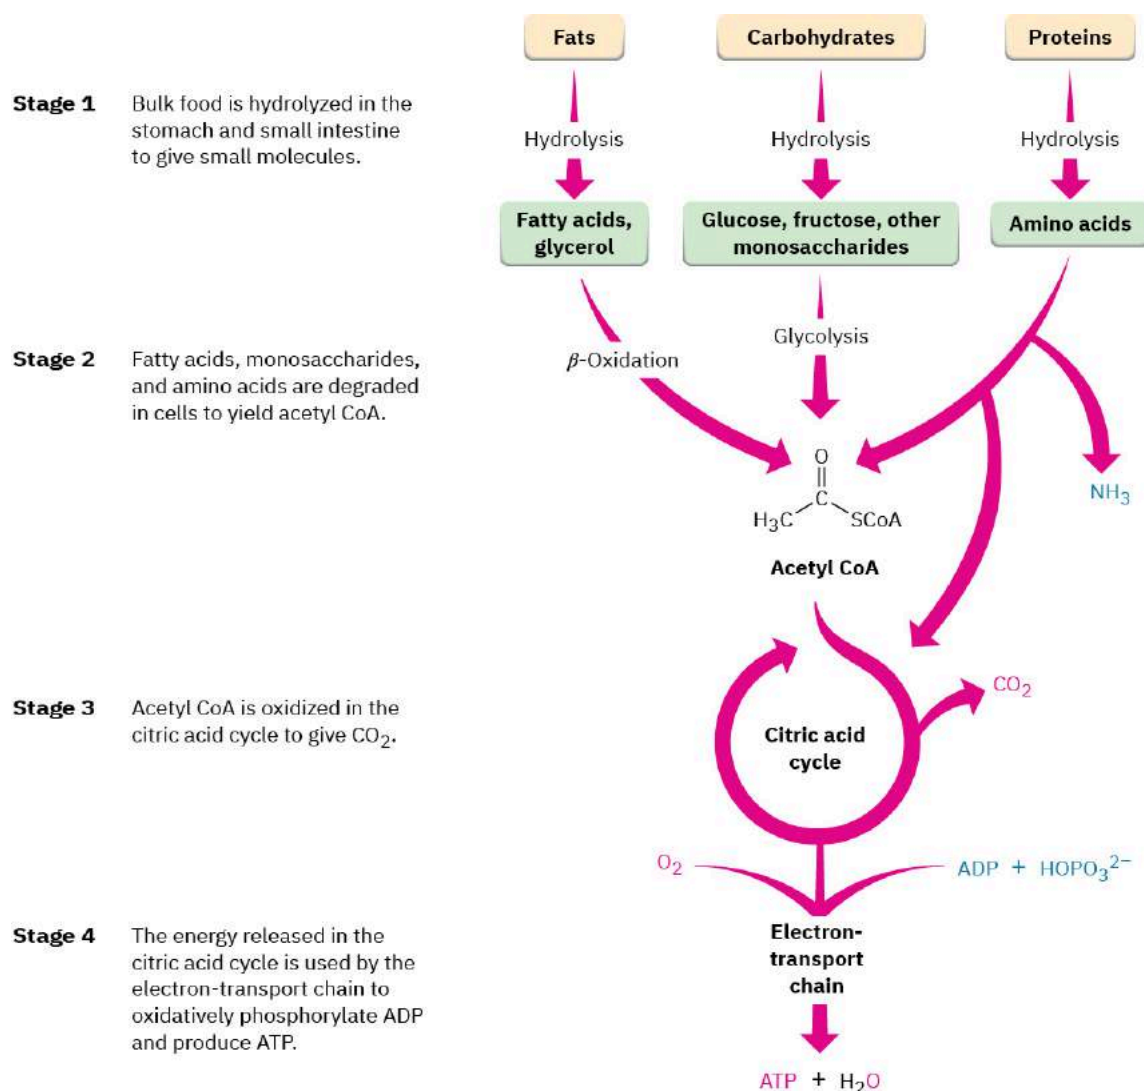

FIGURE 29.2 An overview of catabolic pathways for the degradation of food and the production of biochemical energy. The ultimate products of food catabolism are CO_2 and H_2O , with the energy released in the citric acid cycle used to drive the endergonic synthesis of adenosine triphosphate (ATP) from adenosine diphosphate (ADP) plus hydrogen phosphate ion, HOPO_3^{2-} .

In the first catabolic stage, commonly called *digestion*, food is broken down in the mouth, stomach, and small intestine by hydrolysis of ester, acetal (glycoside), and amide (peptide) bonds to yield fatty acids, simple sugars,

and amino acids. These smaller molecules are then absorbed and further degraded in the second stage of catabolism to yield acetyl groups attached by a thioester bond to the large carrier molecule, coenzyme A. The resultant compound, acetyl coenzyme A (acetyl CoA), is a key substance in the metabolism of food molecules and in many other biological pathways. As noted in [Section 21.8](#), the acetyl group in acetyl CoA is linked to the sulfur atom of phosphopantetheine, which is itself linked to adenosine 3',5'-bisphosphate.

Acetyl CoA—a thioester

Acetyl groups are oxidized inside cellular mitochondria in the third stage of catabolism, the *citric acid cycle*, to yield CO_2 . (We'll see the details of the process in [Section 29.7](#).) Like most oxidations, this stage releases a large amount of energy, which is used in the fourth stage, the *electron-transport chain*, to accomplish the endergonic phosphorylation of adenosine diphosphate (ADP) with hydrogen phosphate ion (HOPO_3^{2-} , abbreviated P_i) to give adenosine triphosphate (ATP).

As the final result of food catabolism, ATP has been called the “energy currency” of the cell. Catabolic reactions “buy” ATP with the energy they release to synthesize it from ADP and hydrogen phosphate ion. Anabolic reactions then spend the ATP by transferring a phosphate group to another molecule, thereby regenerating ADP. Energy production and use in living organisms thus revolves around the $\text{ATP} \rightleftharpoons \text{ADP}$ interconversion.

ADP and ATP are both *phosphoric acid anhydrides*, which contain $\text{-P(=O)(O}^-\text{)-O-P(=O)(O}^-\text{)-}$ linkages analogous to the -C(=O)-O-C(=O)- linkage in carboxylic acid anhydrides. Just as carboxylic acid anhydrides react with alcohols by breaking a C–O bond and forming a carboxylic ester, ROCOR' ([Section 21.5](#)), phosphoric acid anhydrides react with alcohols by breaking a P–O bond and forming a phosphate ester, ROPO_3^{2-} . The reaction is, in effect, a nucleophilic acyl substitution at phosphorus. Note that phosphorylation reactions with ATP generally require the presence of a divalent metal cation in the enzyme, usually Mg^{2+} , to form a Lewis acid–base complex with the phosphate oxygen atoms and to neutralize negative charge.

How does the body use ATP? Recall from [Section 6.7](#) that the free-energy change ΔG must be negative and energy must be released for a reaction to be energetically favorable and occur spontaneously. If ΔG is positive, the reaction is energetically unfavorable and the process can't occur spontaneously.

For an energetically unfavorable reaction to occur, it must be “coupled” to an energetically favorable reaction so that the overall free-energy change for the two reactions together is favorable. To understand what it means for reactions to be coupled, imagine that reaction 1 does not occur to any reasonable extent because it has a small equilibrium constant and is energetically unfavorable; that is, the reaction has $\Delta G > 0$.

where **A** and **B** are the biochemically “important” substances while *m* and *n* are enzyme cofactors, H_2O , or other small molecules.

Imagine also that product *n* can react with substance *o* to yield *p* and *q* in a second, highly favorable reaction that has a large equilibrium constant and $\Delta G \ll 0$.

Taking the two reactions together, they share, or are coupled through, the common intermediate *n*, which is a product in the first reaction and a reactant in the second. When even a tiny amount of *n* is formed in reaction 1, it undergoes essentially complete conversion in reaction 2, thereby removing it from the first equilibrium and forcing reaction 1 to continually replenish *n* until reactant **A** is gone. That is, the two reactions added together have a favorable $\Delta G < 0$, and we say that the favorable reaction 2 “drives” the unfavorable reaction 1. Because the two reactions are coupled through *n*, the transformation of **A** to **B** becomes favorable.

For an example of two reactions that are coupled, look at the phosphorylation reaction of glucose to yield glucose 6-phosphate plus water, an important step in the breakdown of dietary carbohydrates.

The reaction of glucose with HOPO_3^{2-} does not occur spontaneously because it is energetically unfavorable, with $\Delta G^{\circ'} = 13.8 \text{ kJ/mol}$. (The standard free-energy change for a biological reaction is denoted $\Delta G^{\circ'}$ and refers to a process in which reactants and products have a concentration of 1.0 M in a solution with $\text{pH} = 7$.) At the same time, however, the reaction of water with ATP to yield ADP plus HOPO_3^{2-} is strongly favorable, with $\Delta G^{\circ'}$

= -30.5 kJ/mol. When the two reactions are coupled, glucose reacts with ATP to yield glucose 6-phosphate plus ADP in a reaction that is favorable by about 16.7 kJ/mol (4.0 kcal/mol). That is, ATP drives the phosphorylation reaction of glucose.

It's this ability to drive otherwise unfavorable phosphorylation reactions that makes ATP so useful. The resultant phosphates are much more reactive as leaving groups in nucleophilic substitutions and eliminations than the alcohols they're derived from and are therefore more chemically useful.

PROBLEM One of the steps in fat metabolism is the reaction of glycerol (1,2,3-propanetriol) with ATP to yield **29-1** glycerol 1-phosphate. Write the reaction, and draw the structure of glycerol 1-phosphate.

29.2 Catabolism of Triacylglycerols: The Fate of Glycerol

The metabolic breakdown of triacylglycerols begins with their hydrolysis in the stomach and small intestine to yield glycerol plus fatty acids. The reaction is catalyzed by a lipase, whose mechanism is shown in **FIGURE 29.3**. The active site of the enzyme contains a catalytic triad of aspartic acid, histidine, and serine residues, which act cooperatively to provide the necessary acid and base catalysis for the individual steps. Hydrolysis is accomplished by two sequential nucleophilic acyl substitution reactions, one that covalently binds an acyl group to the side chain -OH of a serine residue on the enzyme and a second that frees the fatty acid from the enzyme.

FIGURE 29.3 MECHANISM

Mechanism for the action of lipase. The active site of the enzyme contains a catalytic triad of aspartic acid, histidine, and serine, which react cooperatively to carry out two nucleophilic acyl substitution reactions. Individual steps are explained in the text.

- 1** The enzyme active site contains an aspartic acid, a histidine, and a serine. First, histidine acts as a base to deprotonate the $-OH$ group of serine, with the negatively charged carboxylate of aspartic acid stabilizing the nearby histidine cation that results. Serine then adds to the carbonyl group of the triacylglycerol, yielding a tetrahedral intermediate.

- 2** This intermediate expels a diacylglycerol as leaving group in a nucleophilic acyl substitution reaction, giving an acyl enzyme. The diacylglycerol is protonated by the histidine cation.

- 3** Histidine deprotonates a water molecule, which adds to the acyl group. A tetrahedral intermediate is again formed, and the histidine cation is again stabilized by the nearby carboxylate.

- 4** The tetrahedral intermediate expels the serine as leaving group in a second nucleophilic acyl substitution reaction, yielding a free fatty acid. The serine accepts a proton from histidine, and the enzyme has now returned to its starting structure.

Steps 1–2 of FIGURE 29.3: Acyl Enzyme Formation

The first nucleophilic acyl substitution step—reaction of the triacylglycerol with the active-site serine to give an acyl enzyme—begins with deprotonation of the serine alcohol by histidine to form the more strongly nucleophilic alkoxide ion. This proton transfer is facilitated by a nearby side-chain carboxylate anion of aspartic acid, which makes the histidine more basic and stabilizes the resultant histidine cation by electrostatic interactions. The deprotonated serine adds to a carbonyl group of a triacylglycerol to give a tetrahedral intermediate, which expels a diacylglycerol as a leaving group and produces an acyl enzyme. This step is catalyzed by a proton transfer from histidine to make the leaving group a neutral alcohol.

Steps 3–4 of FIGURE 29.3: Hydrolysis

The second nucleophilic acyl substitution step hydrolyzes the acyl enzyme and gives the free fatty acid by a mechanism analogous to that of the first two steps. Water is deprotonated by histidine to give hydroxide ion, which adds to the enzyme-bound acyl group. The tetrahedral intermediate then expels the neutral serine residue as the leaving group, freeing the fatty acid and returning the enzyme to its active form.

The fatty acids released on triacylglycerol hydrolysis are transported to mitochondria and degraded to acetyl CoA, while the glycerol is carried to the liver for further metabolism. In the liver, glycerol is first phosphorylated by reaction with ATP and then oxidized by NAD⁺. The resulting dihydroxyacetone phosphate (DHAP) enters the carbohydrate glycolysis pathway, which we'll discuss in [Section 29.5](#).

You might note that C2 of glycerol is a prochiral center (Section 5.11) with two identical “arms.” As is typical for enzyme-catalyzed reactions, the phosphorylation of glycerol is selective. Only the *pro-R* arm undergoes reaction, although this can’t be predicted in advance.

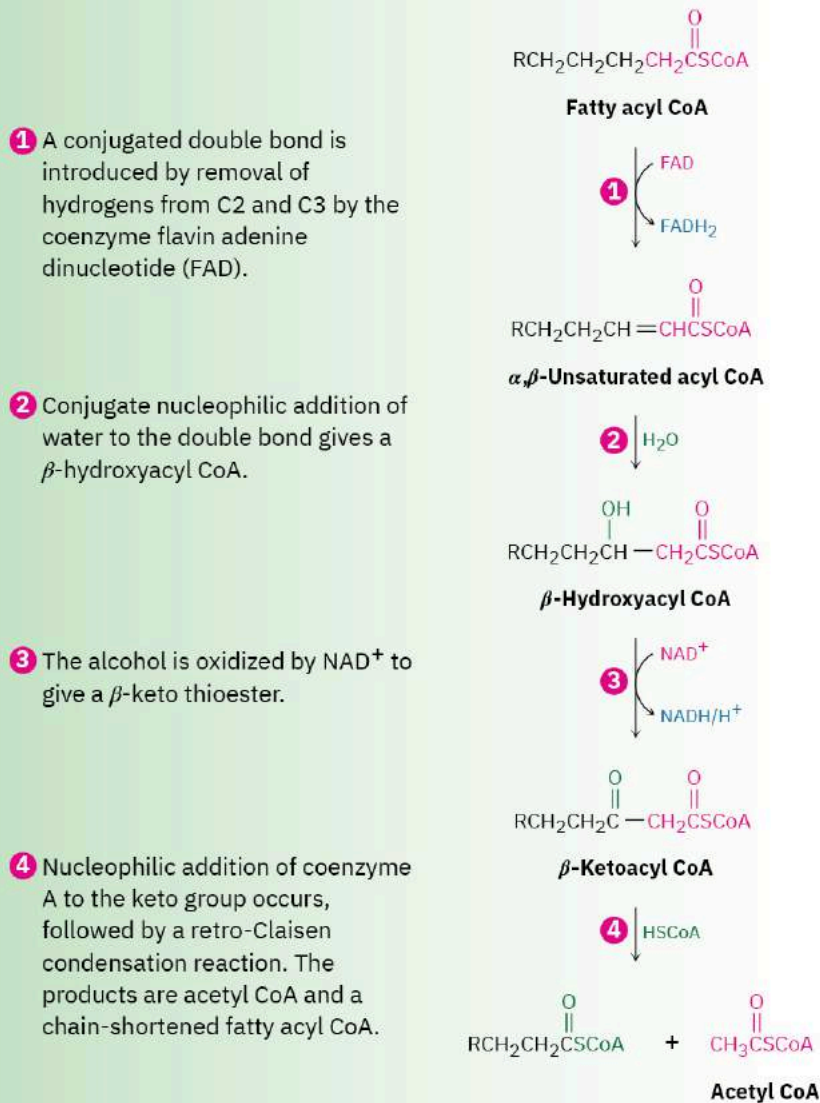

Note also that the phosphorylation product is named *sn*-glycerol 3-phosphate, where the *sn*- prefix means “stereospecific numbering.” In this convention, the molecule is drawn as a Fischer projection with the –OH group at C2 pointing to the left and the glycerol carbon atoms numbered from the top.

29.3 Catabolism of Triacylglycerols: β -Oxidation

The fatty acids that result from triacylglycerol hydrolysis are converted into thioesters with coenzyme A and then catabolized by a repetitive four-step sequence of reactions called the **β -oxidation pathway**, shown in **FIGURE 29.4**. Each passage along the pathway results in the cleavage of an acetyl group from the end of the fatty-acid chain, until the entire molecule is ultimately degraded. As each acetyl group is produced, it enters the citric acid cycle and is further degraded to CO₂, as we’ll see in **Section 29.7**.

FIGURE 29.4 MECHANISM

The four steps of the β -oxidation pathway, resulting in the cleavage of an acetyl group from the end of the fatty-acid chain. The key chain-shortening step is a retro-Claisen reaction of a β -keto thioester. Individual steps are explained in the text.

Step 1 of FIGURE 29.4: Introduction of a Double Bond

The β -oxidation pathway begins when two hydrogen atoms are removed from C2 and C3 of the fatty acyl CoA by one of a family of acyl-CoA dehydrogenases to yield an α,β -unsaturated acyl CoA. This kind of oxidation—the introduction of a conjugated double bond into a carbonyl compound—occurs frequently in biochemical pathways and usually involves the coenzyme flavin adenine dinucleotide (FAD). Reduced FADH_2 is the by-product.

The mechanisms of FAD-catalyzed reactions are often difficult to establish because flavin coenzymes can follow both two-electron (polar) and one-electron (radical) pathways. As a result, extensive studies of the family of acyl-CoA dehydrogenases have not yet provided a clear picture of how these enzymes function. What is known is that: (1) The first step is abstraction of the pro-*R* hydrogen from the acidic α position of the acyl CoA to give a thioester enolate ion. Hydrogen-bonding between the acyl carbonyl group and the ribitol hydroxyls of FAD increases the acidity of the acyl group. (2) The pro-*R* hydrogen at the β position is transferred to FAD. (3) The α,β -unsaturated acyl CoA that results has a trans double bond.

One suggested mechanism has the reaction taking place by a conjugate nucleophilic addition of hydride, analogous to what occurs during alcohol oxidations with NAD^+ . Electrons on the enolate ion might expel a β hydride ion, which could add to the doubly bonded N5 nitrogen on FAD. Protonation of the intermediate at N1 would give the product.

Step 2 of FIGURE 29.4: Conjugate Addition of Water

The α,β -unsaturated acyl CoA produced in step 1 reacts with water by a conjugate addition pathway (Section 19.13) to yield a β -hydroxyacyl CoA in a process catalyzed by enoyl CoA hydratase. Water as nucleophile adds to the β carbon of the double bond, yielding an intermediate thioester enolate ion that is protonated on the α position.

**Step 3 of FIGURE 29.4: Alcohol Oxidation**

The β -hydroxyacyl CoA from step 2 is oxidized to a β -ketoacyl CoA in a reaction catalyzed by one of a family of L-3-hydroxyacyl-CoA dehydrogenases, which differ in substrate specificity according to the chain length of the acyl group. As in the oxidation of *sn*-glycerol 3-phosphate to dihydroxyacetone phosphate mentioned at the end of Section 29.2, this alcohol oxidation requires NAD^+ as a coenzyme and yields reduced NADH/H^+ as by-product. Deprotonation of the hydroxyl group is carried out by a histidine residue at the active site.

**Step 4 of FIGURE 29.4: Chain Cleavage**

Acetyl CoA is split off from the chain in the final step of β -oxidation, leaving an acyl CoA that is two carbon atoms shorter than the original. The reaction is catalyzed by β -ketoacyl-CoA thiolase and is mechanistically the reverse of a Claisen condensation reaction (Section 23.7). In the forward direction, a Claisen condensation joins two esters together to form a β -keto ester product. In the reverse direction, a retro-Claisen reaction splits apart a β -keto ester (or β -keto thioester in this case) to form two esters (or two thioesters).

The retro-Claisen reaction occurs by nucleophilic addition of a cysteine $-\text{SH}$ group on the enzyme to the keto group of the β -ketoacyl CoA to yield an alkoxide ion intermediate. Cleavage of the C2–C3 bond then follows, with the expulsion of an acetyl CoA enolate ion that is immediately protonated. The enzyme-bound acyl group then undergoes nucleophilic acyl substitution by reaction with a molecule of coenzyme A, and the chain-shortened acyl CoA that results re-enters the β -oxidation pathway for further degradation.

Look at the catabolism of myristic acid shown in **FIGURE 29.5** to see the overall results of the β -oxidation pathway. The first passage converts the 14-carbon myristoyl CoA into the 12-carbon lauroyl CoA plus acetyl CoA, the second passage converts lauroyl CoA into the 10-carbon caproyl CoA plus acetyl CoA, the third passage converts caproyl CoA into the 8-carbon capryloyl CoA, and so on. Note that the final passage produces two molecules of acetyl CoA because the precursor has four carbons.

FIGURE 29.5 Catabolism of the 14-carbon myristic acid by the β -oxidation pathway yields seven molecules of acetyl CoA after six passages.

Most fatty acids have an even number of carbon atoms, so none are left over after β -oxidation. Those fatty acids with an odd number of carbon atoms yield the three-carbon propionyl CoA in the final β -oxidation. Propionyl CoA is then converted to succinate by a multistep radical pathway, and succinate enters the citric acid cycle (**Section 29.7**). Note that the three-carbon propionyl group should technically be called *propanoyl*, but biochemists generally use the nonsystematic name.

PROBLEM 29-2 Write the equations for the remaining passages of the β -oxidation pathway following those shown in Figure 29.5.

PROBLEM 29-3 How many molecules of acetyl CoA are produced by catabolism of the following fatty acids, and how many passages of the β -oxidation pathway are needed?

- (a) Palmitic acid, $\text{CH}_3(\text{CH}_2)_{14}\text{CO}_2\text{H}$ (b) Arachidic acid, $\text{CH}_3(\text{CH}_2)_{18}\text{CO}_2\text{H}$

29.4 Biosynthesis of Fatty Acids

One of the most striking features of the common fatty acids is that they have an even number of carbon atoms (TABLE 27.1). This occurs because all fatty acids are derived biosynthetically from acetyl CoA by sequential addition of two-carbon units to a growing chain. The acetyl CoA, in turn, arises primarily from the metabolic breakdown of carbohydrates in the glycolysis pathway, which we'll see in Section 29.5. Thus, dietary carbohydrates consumed in excess of immediate energy needs are turned into fats for storage.

As a general rule in biological chemistry, the anabolic pathway by which a substance is made is not the reverse of the catabolic pathway by which the same substance is degraded. The two paths must differ in some respects for both to be energetically favorable. Thus, the β -oxidation pathway for converting fatty acids into acetyl CoA and the biosynthesis of fatty acids from acetyl CoA are related but are not exact opposites. Differences include the identity of the acyl-group carrier, the stereochemistry of the β -hydroxyacyl reaction intermediate, and the identity of the redox coenzyme. FAD is used to introduce a double bond in β -oxidation, while NADPH is used to reduce the double bond in fatty-acid biosynthesis.

In bacteria, each step in fatty-acid synthesis is catalyzed by a separate enzyme. In vertebrates, however, fatty-acid synthesis is catalyzed by an immense, multienzyme complex called a *synthase* that contains two identical subunits of 2505 amino acids each and catalyzes all steps in the pathway. In fact, for an 18-carbon fatty acid, the synthase catalyzes 42 separate steps! An overview of fatty-acid biosynthesis is shown in FIGURE 29.6.

Steps 1–2 of FIGURE 29.6: Acyl Transfers

The starting material for fatty-acid biosynthesis is the thioester acetyl CoA, the final product of carbohydrate breakdown, as we'll see in Section 29.6. The pathway begins with several *priming reactions*, which transport acetyl CoA and convert it into more reactive species. The first priming reaction is a nucleophilic acyl substitution reaction that converts acetyl CoA into acetyl ACP (acyl carrier protein).

Notice that the mechanism of the nucleophilic acyl substitution in **step 1** can be given in an abbreviated form that saves space by not explicitly showing the tetrahedral reaction intermediate. Instead, electron movement is shown as a heart-shaped path around the carbonyl oxygen to imply the two steps of the full mechanism. Biochemists commonly use this kind of abbreviated format, and we'll also use it on occasion through the rest of this chapter.

FIGURE 29.6 MECHANISM

The pathway for fatty-acid biosynthesis from the two-carbon precursor, acetyl CoA. Individual steps are explained in the text.

1 An acetyl group is transferred from CoA to ACP (acyl carrier protein).

2 The acetyl group is transferred again, from ACP to a synthase enzyme.

5 Claisen-like condensation of malonyl ACP with acetyl synthase occurs, followed by decarboxylation to yield acetoacetyl ACP, a β -keto thioester.

6 Reduction of the ketone by NADPH yields the corresponding β -hydroxy thioester.

7 Dehydration of β -hydroxybutyryl ACP gives crotonyl ACP, an α, β -unsaturated thioester.

8 Reduction of the double bond yields the saturated, chain-elongated butyryl ACP.

3 Acetyl CoA is carboxylated to give malonyl CoA.

4 The malonyl group is transferred from CoA to ACP.

In bacteria, ACP is a small protein of 77 residues that transports an acyl group from one enzyme to another. In vertebrates, however, ACP appears to be a long arm on a multienzyme synthase complex, whose apparent function is to shepherd an acyl group from site to site within the complex. As in acetyl CoA, the acyl group in acetyl ACP is linked by a thioester bond to the sulfur atom of phosphopantetheine. The phosphopantetheine is in turn linked to ACP through the side-chain -OH group of a serine residue in the enzyme.

Acetyl ACP

Step 2, another priming reaction, involves a further exchange of thioester linkages by another nucleophilic acyl substitution and results in covalent bonding of the acetyl group to a cysteine residue in the synthase complex that catalyzes the upcoming condensation step.

Steps 3–4 of FIGURE 29.6: Carboxylation and Acyl Transfer

Step 3 is a *loading* reaction in which acetyl CoA is carboxylated by reaction with HCO_3^- and ATP to yield malonyl CoA plus ADP. This step requires the coenzyme biotin, which is bonded to the lysine residue of acetyl CoA carboxylase and acts as a carrier of CO_2 . Biotin first reacts with bicarbonate ion to give *N*-carboxybiotin, which then reacts with the enolate ion of acetyl CoA and transfers the CO_2 group. Thus, biotin acts as a carrier of CO_2 , binding it in one step and releasing it in another.

The mechanism of the CO_2 transfer reaction with acetyl CoA to give malonyl CoA is thought to involve CO_2 as the reactive species. One proposal is that the loss of CO_2 is favored by hydrogen-bond formation between the *N*-carboxybiotin carbonyl group and a nearby acidic site in the enzyme. Simultaneous deprotonation of acetyl CoA by a basic site in the enzyme gives a thioester enolate ion that can react with CO_2 as it forms (FIGURE 29.7).

FIGURE 29.7 MECHANISM

Mechanism of step 3 in FIGURE 29.6, the biotin-dependent carboxylation of acetyl CoA to yield malonyl CoA.

Following the formation of malonyl CoA, another nucleophilic acyl substitution reaction occurs in **step 4** to form the more reactive malonyl ACP, thereby binding the malonyl group to an ACP arm of the multienzyme synthase. At this point, both acetyl and malonyl groups are bound to the enzyme, and the stage is set for their condensation.

Step 5 of FIGURE 29.6: Condensation

The key carbon-carbon bond-forming reaction that builds the fatty-acid chain occurs in **step 5**. This step is simply a Claisen condensation between acetyl synthase as the electrophilic acceptor and malonyl ACP as the nucleophilic donor. The mechanism of the condensation is thought to involve decarboxylation of malonyl ACP to give an enolate ion, followed by immediate nucleophilic addition of the enolate ion to the carbonyl group of acetyl synthase. Breakdown of the tetrahedral intermediate then gives the four-carbon condensation product acetoacetyl ACP and frees the synthase binding site for attachment of the chain-elongated acyl group at the end of the sequence.

Steps 6–8 of FIGURE 29.6: Reduction and Dehydration

The ketone carbonyl group in acetoacetyl ACP is next reduced to the alcohol β -hydroxybutyryl ACP by β -keto thioester reductase and NADPH, a reducing coenzyme closely related to NADH. *R* stereochemistry results at the newly formed chirality center in the β -hydroxy thioester product. (Note that the systematic name of a butyryl group is *butanoyl*.)

Subsequent dehydration of β -hydroxybutyryl ACP by an E1cB reaction in **step 7** yields *trans*-crotonyl ACP, and the carbon–carbon double bond of crotonyl ACP is reduced by NADPH in **step 8** to yield butyryl ACP. The double-bond reduction occurs by conjugate nucleophilic addition of a hydride ion from NADPH to the β carbon of *trans*-crotonyl ACP. In vertebrates, this reduction occurs by an overall *syn* addition, but other organisms carry out similar chemistry with different stereochemistry.

The net effect of the eight steps in the fatty-acid biosynthesis pathway is to take two 2-carbon acetyl groups and combine them into a 4-carbon butyryl group. Further condensation of the butyryl group with another malonyl ACP yields a 6-carbon unit, and still further repetitions add two carbon atoms at a time until the 16-carbon palmitoyl ACP is produced.

Further chain elongation of palmitic acid occurs by reactions similar to those just described, but CoA rather than ACP acts as the carrier group, and separate enzymes are needed for each step rather than a multienzyme synthase complex.

PROBLEM Write a mechanism for the dehydration reaction of β -hydroxybutyryl ACP to yield crotonyl ACP in step 7 of fatty-acid synthesis.

PROBLEM Evidence for the role of acetate in fatty-acid biosynthesis comes from isotope-labeling experiments.

29-5 If acetate labeled with ^{13}C in the methyl group ($^{13}\text{CH}_3\text{CO}_2\text{H}$) were incorporated into fatty acids, at what positions in the fatty-acid chain would you expect the ^{13}C label to appear?

PROBLEM Does the reduction of acetoacetyl ACP in **step 6** occur on the Re face or the Si face of the molecule?

29-6

29.5 Catabolism of Carbohydrates: Glycolysis

Glucose is the body's primary short-term energy source. Its catabolism begins with **glycolysis**, a series of ten enzyme-catalyzed reactions that break down glucose into 2 equivalents of pyruvate, $\text{CH}_3\text{COCO}_2^-$. The steps of glycolysis, also called the *Embden–Meyerhoff pathway* after its discoverers, are summarized in **FIGURE 29.8**.

FIGURE 29.8 MECHANISM

The ten-step glycolysis pathway for catabolizing glucose to two molecules of pyruvate. Individual steps are described in the text.

FIGURE 29.9 MECHANISM**(Continued)****Steps 1–2 of FIGURE 29.8: Phosphorylation and Isomerization**

Glucose, produced by the digestion of dietary carbohydrates, is phosphorylated at the C6 hydroxyl group by reaction with ATP in a process catalyzed by hexokinase. As noted in [Section 29.1](#), the reaction requires Mg^{2+} as a cofactor to complex with the negatively charged phosphate oxygens. The glucose 6-phosphate that results is then isomerized by glucose 6-phosphate isomerase to give fructose 6-phosphate. This isomerization takes place by initial opening of the glucose hemiacetal ring to its open-chain form, followed by keto–enol tautomerization to a cis enediol, $\text{HO}-\text{C}=\text{C}-\text{OH}$. But because glucose and fructose share a common enediol, further tautomerization to a different keto form produces open-chain fructose, and cyclization completes the process ([FIGURE 29.10](#)).

FIGURE 29.10 Mechanism of step 2 in glycolysis, the isomerization of glucose 6-phosphate to fructose 6-phosphate.

Step 3 of FIGURE 29.8: Phosphorylation

Fructose 6-phosphate is converted in **step 3** to fructose 1,6-bisphosphate (FBP) by a phosphofructokinase-catalyzed reaction with ATP (recall that the prefix *bis-* means two). The mechanism is similar to that in step 1, with Mg^{2+} ion again required as cofactor. Interestingly, the product of step 2 is the α anomer of fructose 6-phosphate, but it is the β anomer that is phosphorylated in step 3, implying that the two anomers equilibrate rapidly through the open-chain form. The result is a molecule ready to be split into the two three-carbon intermediates that will ultimately become two molecules of pyruvate.

Step 4 of FIGURE 29.8: Cleavage

Fructose 1,6-bisphosphate is cleaved in **step 4** into two 3-carbon pieces, dihydroxyacetone phosphate (DHAP) and glyceraldehyde 3-phosphate (GAP). The bond between C3 and C4 of fructose 1,6-bisphosphate breaks, and a $C=O$ group is formed at C4. Mechanistically, the cleavage is the reverse of an aldol reaction (Section 23.1) and is catalyzed by an aldolase. A forward aldol reaction joins two aldehydes or ketones to give a β -hydroxy carbonyl compound, while a retro-aldol reaction, as in this case, cleaves a β -hydroxy carbonyl compound into two aldehydes or ketones.

Two classes of aldolases are used by organisms for catalysis of the retro-aldol reaction. In fungi, algae, and some bacteria, the retro-aldol reaction is catalyzed by class II aldolases, which function by coordination of the fructose carbonyl group with Zn^{2+} as Lewis acid. In plants and animals, the reaction is catalyzed by class I aldolases and does not take place on the free ketone. Instead, fructose 1,6-bisphosphate undergoes reaction with the side-chain $-\text{NH}_2$ group of a lysine residue on the aldolase to yield a protonated enzyme-bound imine (Section 19.8), which is often called a **Schiff base** in biochemistry.

Because of its positive charge, the iminium ion is a better electron acceptor than a ketone carbonyl group. Retro-aldol reaction ensues, giving glyceraldehyde 3-phosphate and an enamine, which is protonated to give another iminium ion that is hydrolyzed to yield dihydroxyacetone phosphate (FIGURE 29.11).

FIGURE 29.11 Mechanism of step 4 in FIGURE 29.8, the cleavage of fructose 1,6-bisphosphate to yield glyceraldehyde 3-phosphate and dihydroxyacetone phosphate. The reaction occurs through an iminium ion formed by reaction with a lysine residue in the enzyme.

Step 5 of FIGURE 29.8: Isomerization

Dihydroxyacetone phosphate is isomerized in **step 5** by triose phosphate isomerase to form a second equivalent of glyceraldehyde 3-phosphate. As in the conversion of glucose 6-phosphate to fructose 6-phosphate in **step 2**, the isomerization takes place by keto–enol tautomerization through a common enediol intermediate. A base deprotonates C1 and then reprotonates C2 using the same hydrogen. The net result of **steps 4 and 5** together is the production of two glyceraldehyde 3-phosphate molecules, both of which pass down the rest of the pathway. Thus, each of the remaining five steps of glycolysis takes place twice for every glucose molecule entering at step 1.

Steps 6–7 of FIGURE 29.9: Oxidation, Phosphorylation, and Dephosphorylation

Glyceraldehyde 3-phosphate is oxidized and phosphorylated in **step 6** to give 1,3-bisphosphoglycerate (FIGURE 29.12). The reaction is catalyzed by glyceraldehyde 3-phosphate dehydrogenase and begins by nucleophilic addition of the $-SH$ group of a cysteine residue in the enzyme to the aldehyde carbonyl group to yield a *hemithioacetal* (Section 19.10), the sulfur analog of a hemiacetal. Oxidation of the hemithioacetal $-OH$ group by NAD^+ then yields a thioester, which reacts with phosphate ion in a nucleophilic acyl substitution step to yield 1,3-bisphosphoglycerate, a mixed anhydride derived from a carboxylic acid and a phosphoric acid.

FIGURE 29.12 Mechanism of step 6 in FIGURE 29.9, the oxidation and phosphorylation of glyceraldehyde 3-phosphate to give 1,3-bisphosphoglycerate. The process occurs through initial formation of a hemiacetal that is oxidized to a thioester and converted into an acyl phosphate.

Like all anhydrides (Section 21.5), the mixed carboxylic–phosphoric anhydride is a reactive substrate in nucleophilic acyl (or phosphoryl) substitution reactions. Reaction of 1,3-bisphosphoglycerate with ADP occurs in **step 7** by substitution on phosphorus, resulting in transfer of a phosphate group to ADP and giving ATP plus 3-phosphoglycerate. The process is catalyzed by phosphoglycerate kinase and requires Mg^{2+} as cofactor. Together, steps 6 and 7 accomplish the oxidation of an aldehyde to a carboxylic acid.

Step 8 of FIGURE 29.9: Isomerization

3-Phosphoglycerate isomerizes to 2-phosphoglycerate in a step catalyzed by phosphoglycerate mutase. In

plants, 3-phosphoglycerate transfers its phosphoryl group from its C3 oxygen to a histidine residue on the enzyme in one step and then accepts the same phosphoryl group back onto the C2 oxygen in a second step. In animals and yeast, however, the enzyme contains a phosphorylated histidine, which transfers its phosphoryl group to the C2 oxygen of 3-phosphoglycerate and forms 2,3-bisphosphoglycerate as intermediate. The same histidine then accepts a phosphoryl group from the C3 oxygen to yield the isomerized product plus the regenerated enzyme. As explained in [Section 29.4](#), we'll occasionally use an abbreviated mechanism for nucleophilic acyl substitution reactions to save space.

Steps 9–10 of [FIGURE 29.9](#): Dehydration and Dephosphorylation

Like most β -hydroxy carbonyl compounds, 2-phosphoglycerate undergoes a ready dehydration in [step 9](#) by an E1cB mechanism ([Section 23.3](#)). The process is catalyzed by enolase, and the product is phosphoenolpyruvate, abbreviated PEP. Two Mg^{2+} ions are associated with the 2-phosphoglycerate to neutralize the negative charges.

Transfer of the phosphoryl group to ADP in [step 10](#) then generates ATP and gives enolpyruvate, which tautomerizes to pyruvate. The reaction is catalyzed by pyruvate kinase and requires that a molecule of fructose 1,6-bisphosphate also be present, as well as 2 equivalents of Mg^{2+} . One Mg^{2+} ion coordinates to ADP, and the other increases the acidity of a water molecule necessary for protonation of the enolate ion.

The overall result of glycolysis can be summarized by the following equation:

PROBLEM Identify the two steps of glycolysis in which ATP is produced.

29-7

PROBLEM Look at the entire glycolysis pathway, and make a list of the kinds of organic reactions that take place—nucleophilic acyl substitutions, aldol reactions, E1cB reactions, and so forth.

29-8

29.6 Conversion of Pyruvate to Acetyl CoA

Pyruvate, produced by catabolism of glucose (and by degradation of several amino acids), can undergo several further transformations depending on the conditions and on the organism. In the absence of oxygen, pyruvate can either be reduced by NADH to yield lactate [$\text{CH}_3\text{CH}(\text{OH})\text{CO}_2^-$] or, in yeast, fermented to give ethanol. Under typical aerobic conditions in mammals, however, pyruvate is converted by a process called *oxidative decarboxylation* to give acetyl CoA plus CO_2 . (*Oxidative* because the oxidation state of the carbonyl carbon rises from that of a ketone to that of a thioester.)

The conversion occurs through a multistep sequence of reactions catalyzed by a complex of enzymes and cofactors called the *pyruvate dehydrogenase complex*. The process occurs in three stages, each catalyzed by one of the enzymes in the complex, as outlined in **FIGURE 29.13**. Acetyl CoA, the ultimate product, then acts as fuel for the final stage of catabolism, the citric acid cycle.

Step 1 of FIGURE 29.13: Addition of Thiamin Diphosphate

The conversion of pyruvate to acetyl CoA begins by reaction of pyruvate with thiamin diphosphate, a derivative of vitamin B₁. Formerly called thiamin *pyrophosphate*, thiamin diphosphate is usually abbreviated as TPP. The spelling *thiamine* is also correct and frequently used.

The key structural element in thiamin diphosphate is the thiazolium ring—a five-membered, unsaturated heterocycle containing a sulfur atom and a positively charged nitrogen atom. The thiazolium ring is weakly acidic, with a $\text{p}K_a$ of approximately 18 for the ring hydrogen between N and S. Bases can therefore deprotonate thiamin diphosphate, leading to formation of an ylide much like the phosphonium ylides used in Wittig reactions (**Section 19.11**). As in the Wittig reaction, the TPP ylide is a nucleophile and adds to the ketone carbonyl group of pyruvate to yield an alcohol addition product.

FIGURE 29.13 MECHANISM

Mechanism for the conversion of pyruvate to acetyl CoA through a multistep sequence of reactions that requires three different enzymes and four different coenzymes. The individual steps are explained in the text.

- 1 Nucleophilic addition of thiamin diphosphate (TPP) ylide to pyruvate gives an alcohol addition product.

- 2 Decarboxylation occurs in a step analogous to the loss of CO_2 from a β -keto acid, yielding the enamine hydroxyethylthiamin diphosphate (HETPP).

- 3 The enamine double bond attacks a sulfur atom of lipoamide and carries out an $\text{S}_{\text{N}}2$ -like displacement of the second sulfur to yield a hemithioacetal.

- 4 Elimination of thiamin diphosphate ylide from the hemithioacetal intermediate yields acetyl dihydrolipoamide . . .

- 5 . . . which reacts with coenzyme A in a nucleophilic acyl substitution reaction to exchange one thioester for another and give acetyl CoA plus dihydrolipoamide.

Step 2 of FIGURE 29.13: Decarboxylation

The TPP addition product, which contains an iminium ion β to a carboxylate anion, undergoes decarboxylation in much the same way that a β -keto acid decarboxylates in the acetoacetic ester synthesis (Section 22.7). The $C=N^+$ bond of the pyruvate addition product acts like the $C=O$ bond of a β -keto acid to accept electrons as CO_2 leaves, giving hydroxyethylthiamin diphosphate (HETPP).

**Step 3 of FIGURE 29.13: Reaction with Lipoamide**

Hydroxyethylthiamin diphosphate is an enamine ($R_2N-C=C$), which, like all enamines, is nucleophilic (Section 23.11). It therefore reacts with the enzyme-bound disulfide lipoamide by nucleophilic attack on a sulfur atom, displacing the second sulfur in an S_N2 -like process.

**Step 4 of FIGURE 29.13: Elimination of Thiamin Diphosphate**

The product of the HETPP reaction with lipoamide is a hemithioacetal, which eliminates thiamin diphosphate ylide. This elimination is the reverse of the ketone addition in **step 1** and generates acetyl dihydrolipoamide.

**Step 5 of FIGURE 29.13: Acyl Transfer**

Acetyl dihydrolipoamide, a thioester, undergoes a nucleophilic acyl substitution reaction with coenzyme A to yield acetyl CoA plus dihydrolipoamide. The dihydrolipoamide is then oxidized back to lipoamide by FAD (Section 29.3), and the $FADH_2$ that results is in turn oxidized back to FAD by NAD^+ , completing the catalytic cycle.

PROBLEM Which carbon atoms in glucose end up as $-\text{CH}_3$ carbons in acetyl CoA? Which carbons end up as **29-9** CO_2 ?

29.7 The Citric Acid Cycle

The initial stages of catabolism result in the conversion of both fats and carbohydrates into acetyl groups that are bonded through a thioester link to coenzyme A. Acetyl CoA then enters the next stage of catabolism—the **citric acid cycle**, also called the *tricarboxylic acid (TCA) cycle*, or *Krebs cycle*, after Hans Krebs, who unraveled its complexities in 1937. The overall result of the cycle is the conversion of an acetyl group into two molecules of CO_2 plus reduced coenzymes by the eight-step reaction sequence shown in **FIGURE 29.14**.

As its name implies, the citric acid *cycle* is a closed loop of reactions in which the product of the final step (oxaloacetate) is a reactant in the first step. The intermediates are constantly regenerated, flowing continuously through the cycle, which operates as long as the oxidizing coenzymes NAD^+ and FAD are available. To meet this condition, the reduced coenzymes NADH and FADH_2 must be reoxidized via the electron-transport chain, which in turn relies on oxygen as the ultimate electron acceptor. Thus, the cycle is dependent on the availability of oxygen and on the operation of the electron-transport chain.

FIGURE 29.14 MECHANISM

The citric acid cycle is an eight-step series of reactions that results in the conversion of an acetyl group into two molecules of CO_2 plus reduced coenzymes. Individual steps are explained in the text.

Step 1 of FIGURE 29.14: Addition to Oxaloacetate

Acetyl CoA enters the citric acid cycle in **step 1** by nucleophilic addition to the oxaloacetate carbonyl group, to give (S)-citryl CoA. This addition is an aldol reaction and is catalyzed by citrate synthase, as discussed in **Section 26.11**. (S)-Citryl CoA is then hydrolyzed to citrate by a typical nucleophilic acyl substitution reaction with water, catalyzed by the same citrate synthase enzyme.

Note that the hydroxyl-bearing carbon of citrate is a prochirality center and contains two identical arms. Because the initial aldol reaction of acetyl CoA to oxaloacetate occurs specifically from the Si face of the

ketone carbonyl group, the pro-*S* arm of citrate is derived from acetyl CoA and the pro-*R* arm is derived from oxaloacetate.

Step 2 of FIGURE 29.14: Isomerization

Citrate, a prochiral tertiary alcohol, is next converted into its isomer, (2*R*,3*S*)-isocitrate, a chiral secondary alcohol. The isomerization occurs in two steps, both of which are catalyzed by the same aconitase enzyme. The initial step is an E1cB dehydration of a β -hydroxy acid to give *cis*-aconitate, the same sort of reaction that occurs in step 9 of glycolysis (FIGURE 29.8). The second step is a conjugate nucleophilic addition of water to the C=C bond (Section 19.13). The dehydration of citrate takes place specifically on the pro-*R* arm—the one derived from oxaloacetate—rather than on the pro-*S* arm derived from acetyl CoA.

Step 3 of FIGURE 29.14: Oxidation and Decarboxylation

(2*R*,3*S*)-Isocitrate, a secondary alcohol, is oxidized by NAD⁺ in step 3 to give the ketone oxalosuccinate, which loses CO₂ to give α -ketoglutarate. Catalyzed by isocitrate dehydrogenase, the decarboxylation is a typical reaction of a β -keto acid, just like that in the acetoacetic ester synthesis (Section 22.7). The enzyme requires a divalent cation as a cofactor to polarize the ketone carbonyl group and make it a better electron acceptor.

Step 4 of FIGURE 29.14: Oxidative Decarboxylation

The transformation of α -ketoglutarate to succinyl CoA in **step 4** is a multistep process just like the transformation of pyruvate to acetyl CoA that we saw in **FIGURE 29.13**. In both cases, an α -keto acid loses CO_2 and is oxidized to a thioester in a series of steps catalyzed by a multienzyme dehydrogenase complex. As in the conversion of pyruvate to acetyl CoA, the reaction involves an initial nucleophilic addition reaction of thiamin diphosphate ylide to α -ketoglutarate, followed by decarboxylation. Reaction with lipoamide, elimination of TPP ylide, and finally a transesterification of the dihydrolipoamide thioester with coenzyme A yields succinyl CoA.

Step 5 of FIGURE 29.14: Acyl CoA Cleavage

Succinyl CoA is converted to succinate in **step 5**. This reaction is catalyzed by succinyl CoA synthetase and is coupled with phosphorylation of guanosine diphosphate (GDP) to give guanosine triphosphate (GTP). The overall transformation is similar to that of steps 6 through 8 in glycolysis (**FIGURE 29.8**), in which a thioester is converted into an acyl phosphate and a phosphate group is then transferred to ADP. The overall result is a “hydrolysis” of the thioester group without involvement of water.

Step 6 of FIGURE 29.14: Dehydrogenation

Succinate is dehydrogenated in **step 6** by the FAD-dependent succinate dehydrogenase to give fumarate. This process is analogous to what occurs during the β -oxidation pathway of fatty-acid catabolism (**Section 29.3**). The reaction is stereospecific, removing the pro-*S* hydrogen from one carbon and the pro-*R* hydrogen from the other.

Steps 7–8 of FIGURE 29.14: Hydration and Oxidation

The final two steps in the citric acid cycle are the conjugate nucleophilic addition of water to fumarate to yield (*S*)-malate and the oxidation of (*S*)-malate by NAD^+ to give oxaloacetate. The addition is catalyzed by fumarase and is mechanistically similar to the addition of water to *cis*-aconitate in step 2. This reaction occurs through an enolate-ion intermediate, which is protonated on the side opposite the OH, leading to a net anti addition.

The final step is the oxidation of (S)-malate by NAD^+ to give oxaloacetate, a reaction catalyzed by malate dehydrogenase. The citric acid cycle has now returned to its starting point, ready to revolve again. The overall result of the cycle is

PROBLEM 29-10 Which of the substances in the citric acid cycle are tricarboxylic acids, thus giving the cycle its alternative name?

PROBLEM 29-11 Write mechanisms for step 2 of the citric acid cycle, the dehydration of citrate and the addition of water to aconitate.

PROBLEM 29-12 Is the pro-*R* or pro-*S* hydrogen removed from citrate during the dehydration in step 2 of the citric acid cycle? Does the elimination reaction occur with syn or anti geometry?

29.8 Carbohydrate Biosynthesis: Gluconeogenesis

Glucose is the body's primary fuel when food is plentiful, but in times of fasting or prolonged exercise, glucose stores can become depleted. Most tissues then begin metabolizing fats as their source of acetyl CoA, but the brain is different. The brain relies almost entirely on glucose for fuel and is dependent on receiving a continuous supply in the blood. When the supply of glucose fails, even for a brief time, irreversible damage can occur. Thus, a pathway for synthesizing glucose from simple precursors is crucial.

Higher organisms are not able to synthesize glucose from acetyl CoA but must instead use one of the three-carbon precursors lactate, glycerol, or alanine, all of which are readily converted into pyruvate.

Pyruvate then becomes the starting point for **gluconeogenesis**, the 11-step biosynthetic pathway by which organisms make glucose (**FIGURE 29.15**). The gluconeogenesis pathway is not the reverse of the glycolysis pathway by which glucose is degraded. As with the catabolic and anabolic pathways for fatty acids (**Section 29.3** and **Section 29.4**), the catabolic and anabolic pathways for carbohydrates differ in some details so that both are energetically favorable.

FIGURE 29.15 MECHANISM

The **gluconeogenesis pathway for the biosynthesis of glucose from pyruvate**. Individual steps are explained in the text.

FIGURE 29.16 MECHANISM**(Continued)****Step 1 of FIGURE 29.15: Carboxylation**

Gluconeogenesis begins with the carboxylation of pyruvate to yield oxaloacetate. The reaction is catalyzed by pyruvate carboxylase and requires ATP, bicarbonate ion, and the coenzyme biotin, which acts as a carrier to transport CO_2 to the enzyme active site. The mechanism is analogous to that of step 3 in fatty-acid biosynthesis (FIGURE 29.6), in which acetyl CoA is carboxylated to yield malonyl CoA.

Step 2 of FIGURE 29.15: Decarboxylation and Phosphorylation

Decarboxylation of oxaloacetate, a β -keto acid, occurs by the typical retro-aldol mechanism like that in step 3 in the citric acid cycle (FIGURE 29.14), and phosphorylation of the resultant pyruvate enolate ion by GTP occurs concurrently to give phosphoenolpyruvate. This reaction is catalyzed by phosphoenolpyruvate carboxykinase.

Steps 3–4 of FIGURE 29.15: Hydration and Isomerization

Conjugate nucleophilic addition of water to the double bond of phosphoenolpyruvate gives 2-phosphoglycerate by a process similar to that of step 7 in the citric acid cycle. Phosphorylation of C3 and dephosphorylation of C2 then yields 3-phosphoglycerate. Mechanistically, these steps are the reverse of steps 9 and 8 in glycolysis (FIGURE 29.8), which have equilibrium constants near 1 so that substantial amounts of reactant and product are both present.

Steps 5–7 of FIGURE 29.15: Phosphorylation, Reduction, and Tautomerization

Reaction of 3-phosphoglycerate with ATP generates the corresponding acyl phosphate, 1,3-bisphosphoglycerate, which binds to the glyceraldehyde 3-phosphate dehydrogenase by a thioester bond to a cysteine residue. Reduction of the thioester by NADH/ H^+ yields the corresponding aldehyde, and keto–enol tautomerization of the aldehyde gives dihydroxyacetone phosphate. All three steps comprise a mechanistic reversal of the corresponding steps 7, 6, and 5 of glycolysis and have equilibrium constants near 1.

Step 8 of FIGURE 29.16: Aldol Reaction

Dihydroxyacetone phosphate and glyceraldehyde 3-phosphate, the two 3-carbon units produced in step 7, join by an aldol reaction to give fructose 1,6-bisphosphate, the reverse of step 4 in glycolysis (FIGURE 29.11). As in glycolysis, the reaction is catalyzed in plants and animals by a class I aldolase and takes place on an iminium ion formed by reaction of dihydroxyacetone phosphate with a side-chain lysine $-\text{NH}_2$ group on the enzyme. Loss of a proton from the neighboring carbon then generates an enamine, an aldol-like reaction ensues, and the product is hydrolyzed.

Steps 9–10 of FIGURE 29.16: Hydrolysis and Isomerization

Hydrolysis of the phosphate group at C1 of fructose 1,6-bisphosphate gives fructose 6-phosphate. Although the result of the reaction is the exact opposite of step 3 in glycolysis, the mechanism is not. In glycolysis, phosphorylation is accomplished by reaction of fructose with ATP, with formation of ADP as by-product. The reverse of that process, however—the reaction of fructose 1,6-bisphosphate with ADP to give fructose 6-phosphate and ATP—is energetically unfavorable because ATP is too high in energy. Thus, an alternative pathway is used in which the C1 phosphate group is removed by a direct hydrolysis reaction, catalyzed by fructose 1,6-bisphosphatase.

Following hydrolysis, keto–enol tautomerization of the carbonyl group from C2 to C1 gives glucose 6-phosphate. The isomerization is the reverse of step 2 in glycolysis.

Step 11 of FIGURE 29.16: Hydrolysis

The final step in gluconeogenesis is the conversion of glucose 6-phosphate to glucose by a second phosphatase-catalyzed hydrolysis reaction. As just discussed for the hydrolysis of fructose 1,6-bisphosphate in step 9, and for the same energetic reasons, the mechanism of the glucose 6-phosphate hydrolysis is not the exact opposite

of the corresponding step 1 in glycolysis.

Interestingly, however, the mechanisms of the two phosphate hydrolysis reactions in steps 9 and 11 are not the same. In step 9, water is the nucleophile, but in the glucose 6-phosphate reaction of step 11, a histidine residue on the enzyme attacks phosphorus, giving a phosphoryl enzyme intermediate that subsequently reacts with water.

The overall result of gluconeogenesis is summarized by the following equation:

PROBLEM 29-13 Write a mechanism for step 6 of gluconeogenesis, the reduction of 3-phosphoglyceryl phosphate with NADH/H^+ to yield glyceraldehyde 3-phosphate.

29.9 Catabolism of Proteins: Deamination

The catabolism of proteins is much more complex than that of fats and carbohydrates because each of the 20 α -amino acids is degraded through its own unique pathway. The general idea, however, is that (1) the α amino group is first removed as ammonia by a **deamination** process, (2) the ammonia is converted into urea, and (3) the remaining amino acid carbon skeleton (usually an α -keto acid) is converted into a compound that enters the citric acid cycle.

Transamination

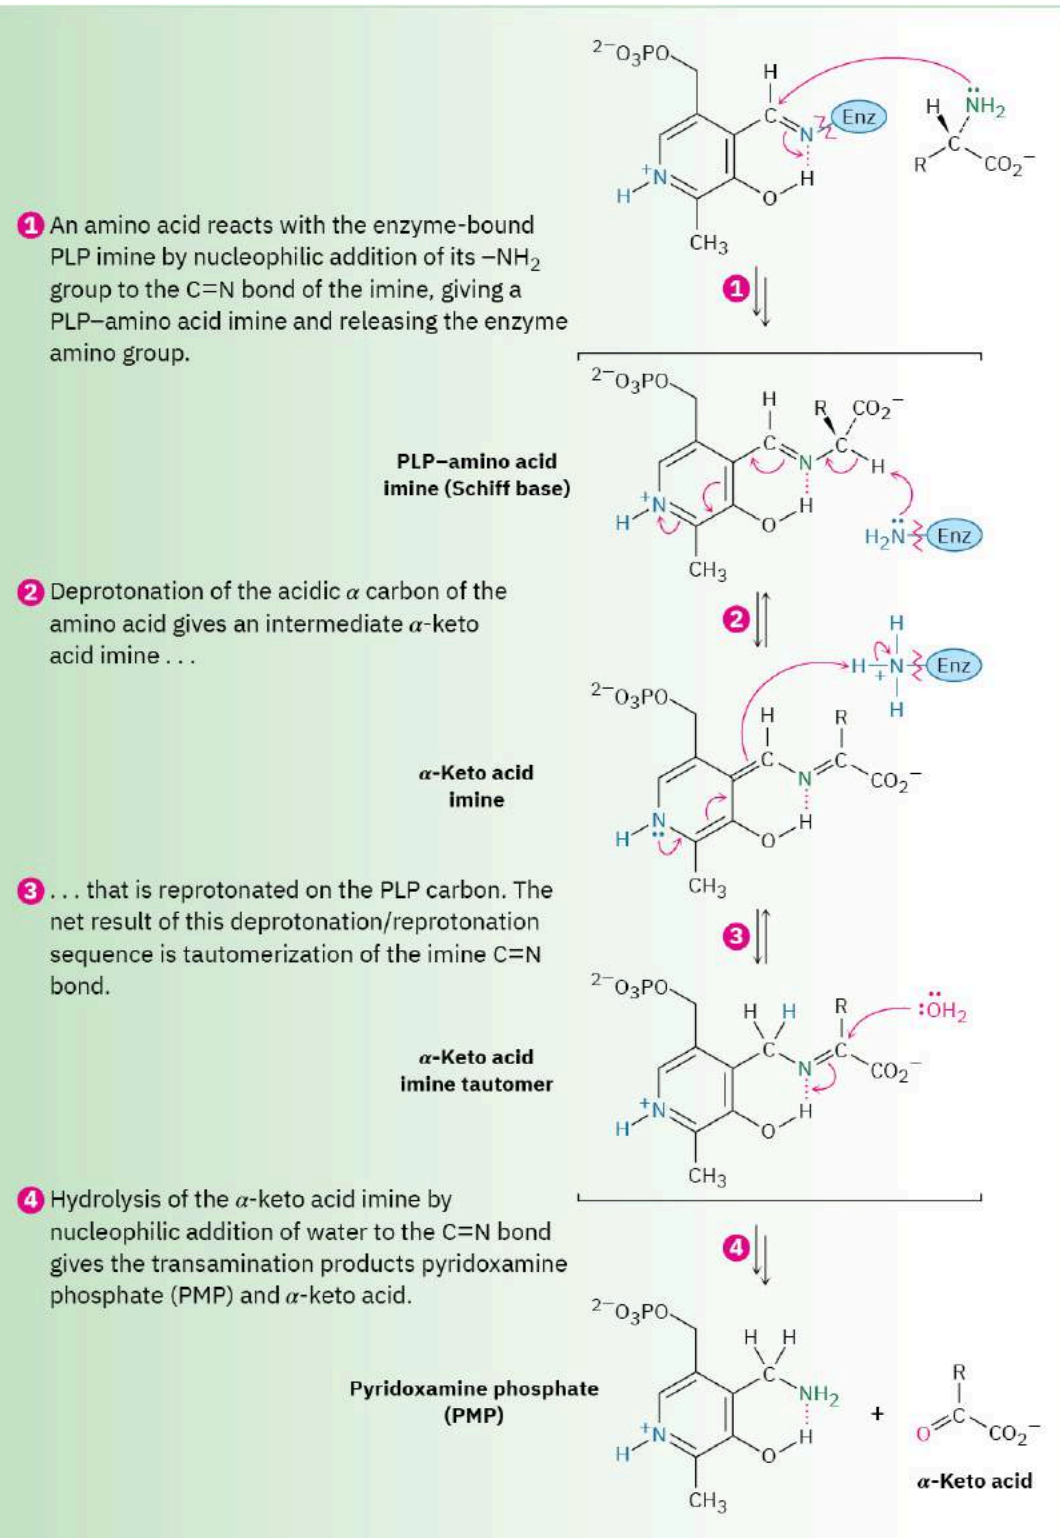

Deamination is usually accomplished by a **transamination** reaction in which the $-\text{NH}_2$ group of the amino acid is exchanged with the keto group of α -ketoglutarate, forming a new α -keto acid plus glutamate. The overall process occurs in two parts, is catalyzed by aminotransferases, and involves participation of the coenzyme pyridoxal phosphate, abbreviated PLP, a derivative of pyridoxine (vitamin B_6). The aminotransferases differ in their specificity for amino acids, but the mechanism remains the same.

The mechanism of the first part of transamination is shown in **FIGURE 29.17**. The process begins with reaction between the α -amino acid and pyridoxal phosphate, which is covalently bonded to the aminotransferase by an imine linkage between the side-chain $-NH_2$ group of a lysine residue in the enzyme and the PLP aldehyde group. Deprotonation/reprotonation of the PLP–amino acid imine effects tautomerization of the imine $C=N$ bond, and hydrolysis of the tautomerized imine gives an α -keto acid plus pyridoxamine phosphate (PMP).

FIGURE 29.17 MECHANISM

Mechanism for the enzyme-catalyzed, PLP-dependent transamination of an α -amino acid to give an α -keto acid. Individual steps are explained in the text.

Step 1 of FIGURE 29.17: Transamination

The first step in *transamination* is *transimination*—the reaction of the PLP–enzyme imine with an α -amino acid

to give a PLP–amino acid imine plus expelled enzyme as the leaving group. The reaction occurs by nucleophilic addition of the amino acid -NH_2 group to the $\text{C}=\text{N}$ bond of the PLP imine, much as an amine adds to the $\text{C}=\text{O}$ bond of a ketone or aldehyde in a nucleophilic addition reaction (Section 19.8). The protonated diamine intermediate undergoes a proton transfer and expels the lysine amino group in the enzyme to complete the step.

Steps 2–4 of FIGURE 29.17: Tautomerization and Hydrolysis

Following formation of the PLP–amino acid imine in **step 1**, a tautomerization of the $\text{C}=\text{N}$ bond occurs in **step 2**. The basic lysine residue in the enzyme that was expelled as a leaving group during transamination deprotonates the acidic α position of the amino acid, with the protonated pyridine ring of PLP acting as the electron acceptor. Reprotonation occurs on the carbon atom next to the ring, generating a tautomeric product that is the imine of an α -keto acid with pyridoxamine phosphate, abbreviated PMP.

Hydrolysis of this PMP– α -keto acid imine then completes the first part of the transamination reaction. This is the mechanistic reverse of imine formation and occurs by nucleophilic addition of water to the imine, followed by proton transfer and expulsion of PMP as leaving group.

Regeneration of PLP from PMP

With PLP plus the α -amino acid now converted into PMP plus an α -keto acid, PMP must be transformed back into PLP to complete the catalytic cycle. The conversion occurs by another transamination reaction, this one between PMP and an α -keto acid, usually α -ketoglutarate. The products are PLP plus glutamate, and the mechanism is the exact reverse of that shown in **FIGURE 29.17**. That is, PMP and α -ketoglutarate give an imine; the PMP- α -ketoglutarate imine undergoes tautomerization of the C=N bond to give a PLP-glutamate imine; and the PLP-glutamate imine reacts with a lysine residue on the enzyme in a transamination process to yield PLP-enzyme imine plus glutamate.

PROBLEM 29-14 Write all the steps in the transamination reaction of PMP with α -ketoglutarate plus a lysine residue in the enzyme to give the PLP-enzyme imine plus glutamate.

PROBLEM 29-15 What α -keto acid is formed on transamination of leucine?

PROBLEM 29-16 From what amino acid is the following α -keto acid derived?

29.10 Some Conclusions about Biological Chemistry

As promised in the chapter introduction, the past few sections have been a fast-paced tour of a large number of reactions. Following it all undoubtedly required a lot of work and a lot of page-turning to look at earlier sections.

After examining the various metabolic pathways, perhaps the main conclusion about biological chemistry is the remarkable similarity between the mechanisms of biological reactions and the mechanisms of laboratory reactions. If you were to look at the steps of vitamin B₁₂ biosynthesis, you would see the same kinds of reactions we've been seeing throughout the text—nucleophilic substitutions, eliminations, aldol reactions, nucleophilic acyl substitutions, and so forth. There are, of course, some complexities, but the fundamental mechanisms of organic chemistry remain the same, whether in the laboratory with smaller molecules or in organisms with larger molecules.

So what is there to be learned from studying metabolism? One good answer is given in the following *Chemistry Matters*, which relates the story of how knowledge of a biosynthetic pathway led to the design of new drugs that have saved millions of lives.

CHEMISTRY MATTERS

Statin Drugs

Coronary heart disease—the buildup of cholesterol-containing plaques on the walls of heart arteries—is the leading cause of death for people older than 20 in industrialized countries. It's estimated that up to one-third of women and one-half of men will develop the disease at some point in their lives.

The onset of coronary heart disease is directly correlated with blood cholesterol levels (see the **Chapter 27 Chemistry Matters**), and the first step in disease prevention is to lower those levels. It turns out that only about 25% of your blood cholesterol comes from what you eat; the remaining 75%—about 1 gram each day—is biosynthesized in your liver from dietary fats and carbohydrates. Thus, any effective plan for lowering your cholesterol level means limiting the amount that your body makes, which is where a detailed chemical knowledge of cholesterol biosynthesis comes in.

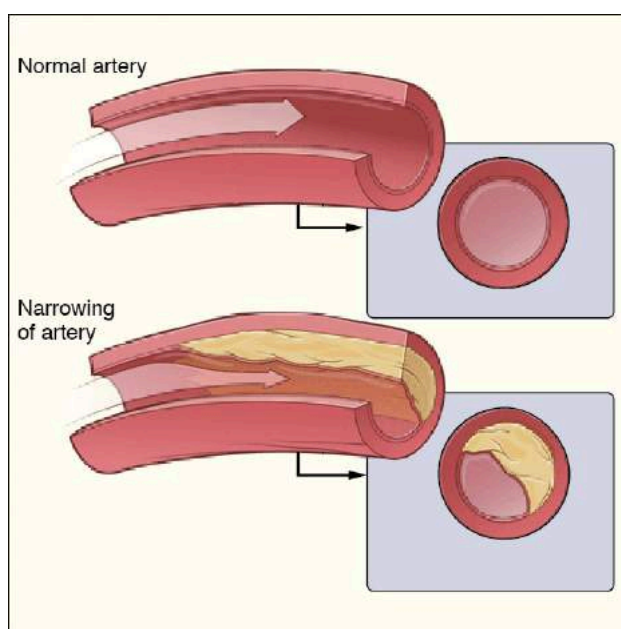

FIGURE 29.18 The buildup of cholesterol deposits inside arteries can cause coronary heart disease, a leading cause of death for adults in industrialized nations.

We saw in **Section 27.5** and **Section 27.7** that all steroids, including cholesterol, are biosynthesized from the triterpenoid lanosterol, which in turn comes from acetyl CoA through isopentenyl diphosphate. If you knew all the mechanisms for all the chemical steps in cholesterol biosynthesis, you might be able to devise a drug that would block one of those steps, thereby short-circuiting the biosynthetic process and controlling the amount of cholesterol produced.

But we do know those mechanisms! Look back at the pathway for the biosynthesis of isopentenyl diphosphate from acetyl CoA, shown in **FIGURE 27.8**. It turns out that the rate-limiting step in the pathway is the reduction of 3-hydroxy-3-methylglutaryl CoA (abbreviated HMG-CoA) to mevalonate, brought about by the enzyme HMG-CoA reductase. If that enzyme could be stopped from functioning, cholesterol biosynthesis would also be stopped.

To find a drug that blocks HMG-CoA reductase, chemists did two simultaneous experiments on a large number of potential drug candidates isolated from soil microbes. In one experiment, the drug candidate and mevalonate were added to liver extract; in the second experiment, only the drug candidate was added without mevalonate. If cholesterol was produced only in the presence of added mevalonate but not in the absence of mevalonate, the drug candidate must have blocked the enzyme for mevalonate synthesis.

The drugs that block HMG-CoA reductase, and thus control cholesterol synthesis in the body, are called *statins*. In just the 10-year period following their introduction in 1994, the death rate from coronary heart disease decreased by 33% in the United States.

Like many drugs, statins don't come without risks and have some serious side effects that people considering their use should be aware of, but approaching 30 years later, they remain among the most widely prescribed drugs in the world, with estimated annual sales of \$14 billion. Atorvastatin (Lipitor), simvastatin (Zocor), rosuvastatin (Crestor), pravastatin (Pravachol), and lovastatin (Mevacor) are some examples. An X-ray crystal structure of the active site in the HMG-CoA reductase enzyme is shown in the accompanying graphic, along with a molecule of atorvastatin (purple) that is tightly bound in the active site and stops the enzyme from functioning. A good understanding of organic chemistry certainly paid off in this instance.

Atorvastatin (Lipitor)

- **transamination**

Summary

Metabolism is the sum of all chemical reactions in the body. Reactions that break down large molecules into

smaller fragments are called **catabolism**, and those that build up large molecules from small pieces are called **anabolism**. Although the details of specific biochemical pathways are sometimes complex, all the reactions that occur follow the normal rules of organic chemical reactivity.

The catabolism of fats begins with digestion, in which ester bonds are hydrolyzed to give glycerol and fatty acids. The fatty acids are degraded in the four-step **β -oxidation pathway** by removal of two carbons at a time, yielding acetyl CoA. Catabolism of carbohydrates begins with the hydrolysis of glycoside bonds to give glucose, which is degraded in the ten-step **glycolysis** pathway. Pyruvate, the initial product of glycolysis, is then converted into acetyl CoA. Acetyl CoA next enters the eight-step **citric acid cycle**, where it is further degraded into CO_2 . The cycle is a closed loop of reactions in which the product of the final step (oxaloacetate) is a reactant in the first step.

Catabolism of proteins is more complex than that of fats or carbohydrates because each of the 20 different amino acids is degraded by its own unique pathway. In general, though, the amino nitrogen atoms are removed and the substances that remain are converted into compounds that enter the citric acid cycle. Most amino acids lose their nitrogen atom by **transamination**, a reaction in which the $-\text{NH}_2$ group of the amino acid trades places with the keto group of an α -keto acid such as α -ketoglutarate. The products are a new α -keto acid and glutamate.

The energy released in catabolic pathways is used in the *electron-transport chain* to make molecules of adenosine triphosphate, ATP. ATP, the final result of food catabolism, couples to and drives many otherwise unfavorable reactions.

Biomolecules are synthesized as well as degraded, but the pathways for anabolism and catabolism are not the exact reverse of one another. Fatty acids are biosynthesized from acetate by an 8-step pathway, and carbohydrates are made from pyruvate by the 11-step **gluconeogenesis** pathway.

Additional Problems

Visualizing Chemistry

PROBLEM Identify the amino acid that is a catabolic precursor of each of the following α -keto acids:

29-17 (a)

(b)

PROBLEM Identify the following intermediate in the citric acid cycle, and tell whether it has *R* or *S* stereochemistry:

29-18

PROBLEM The following compound is an intermediate in the biosynthesis of one of the 20 common α -amino acids. Which one is it likely to be, and what kind of chemical change must take place to complete the biosynthesis?

29-19

PROBLEM 29-20 The following compound is an intermediate in the pentose phosphate pathway, an alternative route for glucose metabolism. Identify the sugar it is derived from.

Mechanism Problems

PROBLEM 29-21 In the *pentose phosphate* pathway for degrading sugars, ribulose 5-phosphate is converted to ribose 5-phosphate. Propose a mechanism for the isomerization.

Ribulose 5-phosphate

Ribose 5-phosphate

PROBLEM 29-22 Another step in the pentose phosphate pathway for degrading sugars (see Problem 29-21) is the conversion of ribose 5-phosphate to glyceraldehyde 3-phosphate. What kind of organic process is occurring? Propose a mechanism for the conversion.

Ribose 5-phosphate

Glyceraldehyde 3-phosphate

PROBLEM 29-23 One of the steps in the pentose phosphate pathway for glucose catabolism is the reaction of sedoheptulose 7-phosphate with glyceraldehyde 3-phosphate in the presence of a transaldolase to yield erythrose 4-phosphate and fructose 6-phosphate.

- (a) The first part of the reaction is the formation of a protonated Schiff base of sedoheptulose 7-phosphate with a lysine residue in the enzyme followed by a retro-aldol cleavage to give an enamine plus erythrose 4-phosphate. Show the structure of the enamine and the mechanism by which it is formed.
- (b) The second part of the reaction is a nucleophilic addition of the enamine to glyceraldehyde 3-phosphate followed by hydrolysis of the Schiff base to give fructose 6-phosphate. Show the mechanism.

PROBLEM 29-24 One of the steps in the pentose phosphate pathway for glucose catabolism is the reaction of xylulose 5-phosphate with ribose 5-phosphate in the presence of a transketolase to give glyceraldehyde 3-phosphate and sedoheptulose 7-phosphate.

- (a) The first part of the reaction is nucleophilic addition of thiamin diphosphate (TPP) ylide to xylulose 5-phosphate, followed by a retro-aldol cleavage to give glyceraldehyde 3-phosphate and a TPP-containing enamine. Show the structure of the enamine and the mechanism by which it is formed.
- (b) The second part of the reaction is addition of the enamine to ribose 5-phosphate followed by loss of TPP ylide to give sedoheptulose 7-phosphate. Show the mechanism.

PROBLEM 29-25 The amino acid tyrosine is biologically degraded by a series of steps that include the following transformations:

The double-bond isomerization of maleoylacetate to fumaroylacetate is catalyzed by practically any nucleophile, :Nu^- . Propose a mechanism.

PROBLEM 29-26 Propose a mechanism for the conversion of fumaroylacetate to fumarate plus acetoacetate (see Problem 29-25).

PROBLEM 29-27 Propose a mechanism for the conversion of acetoacetate to acetyl CoA (see Problem 29-25).

PROBLEM 29-28 Design your own degradative pathway. You know the rules (organic mechanisms), and you've seen the kinds of reactions that occur in the biological degradation of fats and carbohydrates into acetyl CoA. If you were Mother Nature, what series of steps would you use to degrade the amino acid serine into acetyl CoA?

PROBLEM 29-29 The amino acid serine is biosynthesized by a route that involves reaction of 3-phosphohydroxypyruvate with glutamate to give 3-phosphoserine. Propose a mechanism.

PROBLEM 29-30 The amino acid leucine is biosynthesized from α -ketoisocaproate, which is itself prepared from α -ketoisovalerate by a multistep route that involves (1) reaction with acetyl CoA, (2) hydrolysis, (3) dehydration, (4) hydration, (5) oxidation, and (6) decarboxylation. Show the steps in the transformation, and propose a mechanism for each.

PROBLEM 29-31 The amino acid cysteine, $\text{C}_3\text{H}_7\text{NO}_2\text{S}$, is biosynthesized from a substance called cystathionine by a multistep pathway.

- The first step is a transamination. What is the product?
- The second step is an E1cB reaction. Show the products and the mechanism of the reaction.
- The final step is a double-bond reduction. What organic cofactor is required for this reaction, and what is the product represented by the question mark in the equation?

Enzymes and Coenzymes

PROBLEM 29-32 What chemical events occur during the digestion of food?

PROBLEM What is the difference between digestion and metabolism?

29-33

PROBLEM What is the difference between anabolism and catabolism?

29-34

PROBLEM Draw the structure of adenosine 5'-monophosphate (AMP), an intermediate in some biochemical pathways.

29-35

PROBLEM Cyclic adenosine monophosphate (cyclic AMP), a modulator of hormone action, is related to AMP (Problem 29-35) but has its phosphate group linked to *two* hydroxyl groups at C3' and C5' of the sugar. Draw the structure of cyclic AMP.

29-36

PROBLEM What general kind of reaction does ATP carry out?

29-37

PROBLEM What general kind of reaction does NAD^+ carry out?

29-38

PROBLEM What general kind of reaction does FAD carry out?

29-39

PROBLEM What enzyme cofactor is associated with each of the following kinds of reactions?

29-40 (a) Transamination (b) Carboxylation of a ketone (c) Decarboxylation of an α -keto acid

PROBLEM Lactate, a product of glucose catabolism in oxygen-starved muscles, can be converted into pyruvate by oxidation. What coenzyme do you think is needed? Write the equation in the normal biochemical format using a curved arrow.

29-41

Metabolism

PROBLEM Write the equation for the final step in the β -oxidation pathway of any fatty acid with an even number of carbon atoms.

29-42

PROBLEM Show the products of each of the following reactions:

29-43

PROBLEM Why aren't the glycolysis and gluconeogenesis pathways the exact reverse of each other?

29-44

PROBLEM How many moles of acetyl CoA are produced by catabolism of the following substances?

29-45 (a) 1.0 mol of glucose (b) 1.0 mol of palmitic acid (c) 1.0 mol of maltose

PROBLEM How many grams of acetyl CoA (MW = 809.6 amu) are produced by catabolism of the following substances? Which substance is the most efficient precursor of acetyl CoA on a weight basis?

29-46

(a) 100.0 g of glucose (b) 100.0 g of palmitic acid (c) 100.0 g of maltose

PROBLEM What is the structure of the α -keto acid formed by transamination of each of the following amino acids?

29-47

(a) Threonine (b) Phenylalanine (c) Asparagine

PROBLEM 29-48 The glycolysis pathway shown in Figure 29.8 has a number of intermediates that contain phosphate groups. Why can 3-phosphoglyceryl phosphate and phosphoenolpyruvate transfer a phosphate group to ADP while glucose 6-phosphate cannot?

PROBLEM 29-49 Write a mechanism for the conversion of α -ketoglutarate to succinyl CoA in step 4 of the citric acid cycle (Figure 29.14).

PROBLEM 29-50 In step 2 of the citric acid cycle (Figure 29.14), *cis*-aconitate reacts with water to give (2*R*,3*S*)-isocitrate. Does $-\text{OH}$ add from the *Re* face of the double bond or from the *Si* face? What about $-\text{H}$? Does the addition of water occur with *syn* or *anti* geometry?

General Problems

PROBLEM 29-51 In glycerol metabolism, the oxidation of *sn*-glycerol 3-phosphate to give dihydroxyacetone phosphate is catalyzed by *sn*-glycerol-3-phosphate dehydrogenase, with NAD^+ as cofactor. The reaction is stereospecific, occurring exclusively on the *Re* face of the nicotinamide ring.

Which hydrogen in the NADH product comes from *sn*-glycerol 3-phosphate? Does it have *pro-R* or *pro-S* stereochemistry?

PROBLEM 29-52 The primary fate of acetyl CoA under normal metabolic conditions is degradation in the citric acid cycle to yield CO_2 . When the body is stressed by prolonged starvation, however, acetyl CoA is converted into compounds called *ketone bodies*, which can be used by the brain as a temporary fuel. Fill in the missing information indicated by the four question marks in the following biochemical pathway for the synthesis of ketone bodies from acetyl CoA:

PROBLEM 29-53 The initial reaction in Problem 29-52, conversion of two molecules of acetyl CoA to one molecule of acetoacetyl CoA, is a Claisen reaction. Assuming that there is a base present, show the mechanism

of the reaction.

PROBLEM In step 6 of fatty-acid biosynthesis (Figure 29.6), acetoacetyl ACP is reduced stereospecifically by
29-54 NADPH to yield an alcohol. Does hydride ion add to the Si face or the Re face of acetoacetyl ACP?

PROBLEM In step 7 of fatty-acid biosynthesis (Figure 29.6), dehydration of a β -hydroxy thioester occurs to give
29-55 *trans*-crotonyl ACP. Is the dehydration a syn elimination or an anti elimination?

PROBLEM In step 8 of fatty-acid biosynthesis (Figure 29.6), reduction of *trans*-crotonyl ACP gives butyryl ACP.
29-56 A hydride from NADPH adds to C3 of the crotonyl group from the Re face, and protonation on C2 occurs on the Si face. Is the reduction a syn addition or an anti addition?

30.9 A Summary of Rules for Pericyclic Reactions

WHY THIS CHAPTER? Broad outlines of both polar and radical reactions have been in place for more than a century, but our understanding of pericyclic reactions has emerged more recently. Prior to the mid-1960s, in fact, they were even occasionally referred to as “no-mechanism reactions.” They occur largely in the laboratory rather than in biological processes, but a knowledge of them is necessary, both for completeness in studying organic chemistry and in understanding biological pathways where they do occur.

Most organic reactions take place by polar mechanisms, in which a nucleophile donates two electrons to an electrophile in forming a new bond. Other reactions take place by radical mechanisms, in which each of two reactants donates one electron in forming a new bond. Both kinds of reactions occur frequently in the laboratory and in living organisms. Less common, however, is the third major class of organic reactions—*pericyclic reactions*.

A **pericyclic reaction** is one that occurs by a concerted process through a cyclic transition state. A *concerted reaction* is one in which all bonding changes occur simultaneously; no intermediates are involved. Rather than try to expand this definition now, we'll begin by briefly reviewing some of the ideas of molecular orbital theory introduced in the chapters on **Structure and Bonding** and **Conjugated Compounds and Ultraviolet Spectroscopy** and then looking individually at the three main classes of pericyclic reactions: *electrocyclic reactions*, *cycloadditions*, and *sigmatropic rearrangements*.

30.1 Molecular Orbitals of Conjugated Pi Systems

A conjugated polyene, as we saw in **Section 14.1**, is one with alternating double and single bonds. According to molecular orbital (MO) theory, the p orbitals on the sp^2 -hybridized carbons of a conjugated polyene interact to form a set of π molecular orbitals whose energies depend on the number of nodes they have between nuclei. Molecular orbitals with fewer nodes are lower in energy than isolated p atomic orbitals and are bonding MOs; molecular orbitals with more nodes are higher in energy than isolated p orbitals and are antibonding MOs. Pi molecular orbitals of ethylene and 1,3-butadiene are shown in **FIGURE 30.2**.

FIGURE 30.2 Pi molecular orbitals of (a) ethylene and (b) 1,3-butadiene.

A similar sort of molecular orbital description can be derived for any conjugated π electron system. 1,3,5-Hexatriene, for example, has three double bonds and six π MOs, as shown in **FIGURE 30.3**. In the ground state, only the three bonding orbitals, ψ_1 , ψ_2 , and ψ_3 , are filled. On irradiation with ultraviolet light, however, an electron is promoted from the highest-energy filled orbital (ψ_3) to the lowest-energy unfilled orbital (ψ_4^*) to give an excited state (**Section 14.7**), in which ψ_3 and ψ_4^* are each half-filled. (An asterisk denotes an antibonding orbital.)

What do molecular orbitals and their nodes have to do with pericyclic reactions? The answer is, *everything*. According to a series of rules formulated in the mid-1960s by R. B. Woodward and Roald Hoffmann at Harvard University, a pericyclic reaction can take place only if the symmetries of the reactant MOs are the same as the symmetries of the product MOs. In other words, the lobes of reactant MOs must be of the correct algebraic sign for bonding to occur in the transition state leading to product.

If the symmetries of reactant and product orbitals match up, or *correlate*, the reaction is said to be **symmetry-allowed**. If the symmetries of reactant and product orbitals don't correlate, the reaction is **symmetry-disallowed**. Symmetry-allowed reactions often occur under relatively mild conditions, but symmetry-disallowed reactions can't occur by concerted paths. They either take place by nonconcerted, higher-energy

pathways, or they don't take place at all.

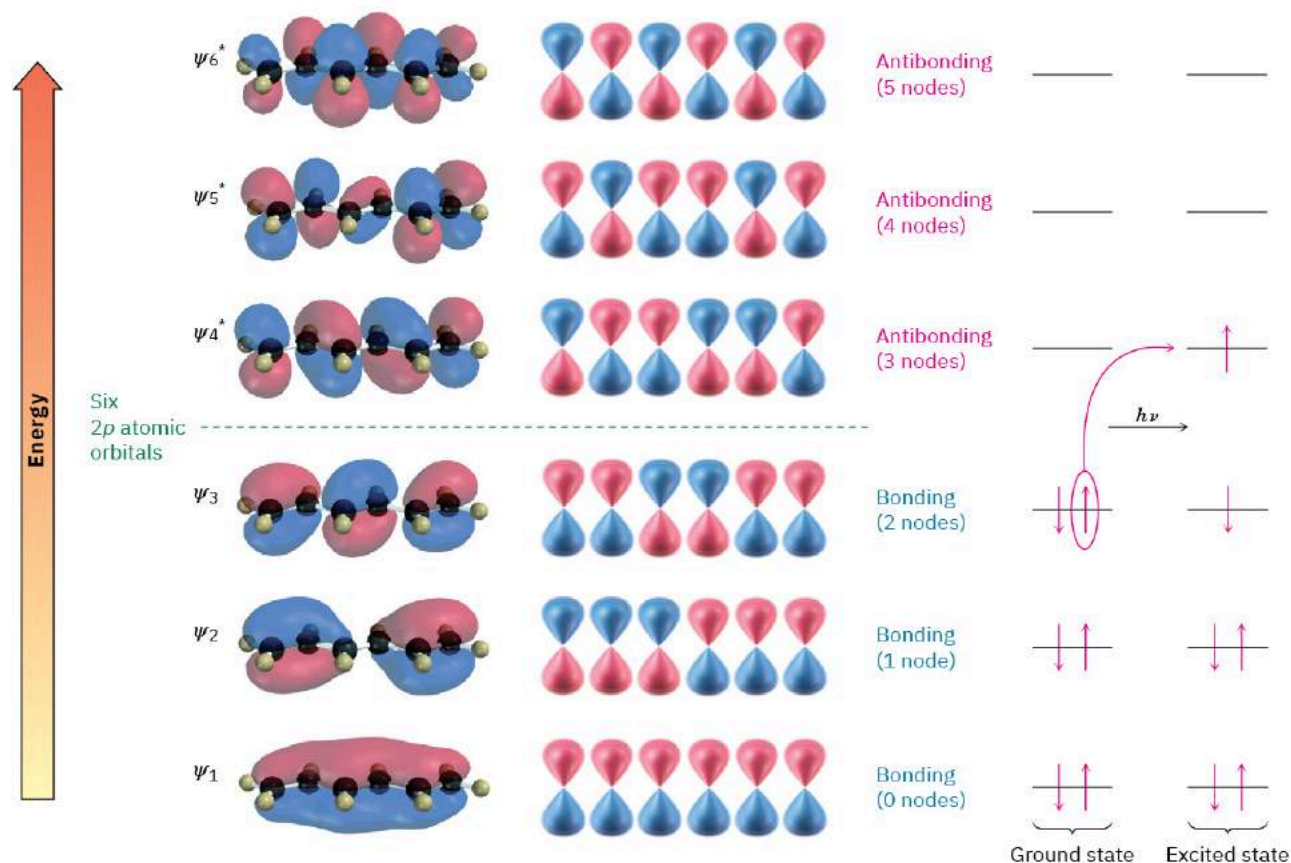

FIGURE 30.3 The six π molecular orbitals of 1,3,5-hexatriene. In the ground state, the three bonding MOs, ψ_1 , ψ_2 , and ψ_3 , are filled. In the excited state, ψ_3 and ψ_4^* are both half-filled.

The Woodward–Hoffmann rules for pericyclic reactions require an analysis of all reactant and product molecular orbitals, but Kenichi Fukui at Kyoto Imperial University in Japan introduced a simplified version. Hoffman and Fukui shared a Nobel Prize for their work, and Woodward would have joined them (for his second Nobel Prize) had he not passed away before the award was made. According to Fukui's simplified version, we need to consider only two molecular orbitals, called the **frontier orbitals**. These frontier orbitals are the **highest occupied molecular orbital (HOMO)** and the **lowest unoccupied molecular orbital (LUMO)**. In ground-state 1,3,5-hexatriene, for example, ψ_3 is the HOMO and ψ_4^* is the LUMO (FIGURE 30.3). In excited-state 1,3,5-hexatriene, however, ψ_4^* is the HOMO and ψ_5^* is the LUMO.

PROBLEM Look at Figure 30.2, and tell which molecular orbital is the HOMO and which is the LUMO for both
30-1 ground and excited states of ethylene and 1,3-butadiene.

30.2 Electrocyclic Reactions

The best way to understand how orbital symmetry affects pericyclic reactions is to look at some examples. Let's look first at a group of polyene rearrangements called *electrocyclic reactions*. An **electrocyclic reaction** is a pericyclic process that involves the cyclization of a conjugated acyclic polyene. One π bond is broken, the other π bonds change position, a new σ bond is formed, and a cyclic compound results. For example, a conjugated triene can be converted into a cyclohexadiene, and a conjugated diene can be converted into a cyclobutene.

Pericyclic reactions are reversible, and the position of the equilibrium depends on the specific case. In general, the triene \rightleftharpoons cyclohexadiene equilibrium favors the cyclic product, whereas the diene \rightleftharpoons cyclobutene equilibrium favors the less strained open-chain product.

The most striking feature of electrocyclic reactions is their stereochemistry. For example, (2*E*,4*Z*,6*E*)-2,4,6-octatriene yields only *cis*-5,6-dimethyl-1,3-cyclohexadiene when heated, and (2*E*,4*Z*,6*Z*)-2,4,6-octatriene yields only *trans*-5,6-dimethyl-1,3-cyclohexadiene. Remarkably, however, the stereochemical results change completely when the reactions are carried out under what are called *photochemical*, rather than *thermal*, conditions. Irradiation of (2*E*,4*Z*,6*E*)-2,4,6-octatriene with ultraviolet light (denoted $h\nu$) yields *trans*-5,6-dimethyl-1,3-cyclohexadiene (**FIGURE 30.4**).

FIGURE 30.4 Electrocyclic interconversions of 2,4,6-octatriene isomers and 5,6-dimethyl-1,3-cyclohexadiene isomers.

A similar result is obtained for the thermal electrocyclic ring-opening of 3,4-dimethylcyclobutene. The *trans* isomer yields only (2*E*,4*E*)-2,4-hexadiene when heated, and the *cis* isomer yields only (2*E*,4*Z*)-2,4-hexadiene. On UV irradiation, however, the results are opposite. Cyclization of the 2*E*,4*E* isomer under photochemical conditions yields *cis* product (**FIGURE 30.5**).

FIGURE 30.5 Electrocyclic interconversions of 2,4-hexadiene isomers and 3,4-dimethylcyclobutene isomers.

To account for these results, we need to look at the two outermost lobes of the polyene MOs—the lobes that interact when cyclization occurs. There are two possibilities: lobes of like sign can be either on the same side of the molecule or on opposite sides.

For a bond to form, the outermost π lobes must rotate so that favorable bonding interaction is achieved—a positive lobe with a positive lobe or a negative lobe with a negative lobe. If two lobes of like sign are on the same side of the molecule, the two orbitals must rotate in *opposite* directions—one clockwise and one counterclockwise. This kind of motion is referred to as **disrotatory**.

Conversely, if lobes of like sign are on opposite sides of the molecule, both orbitals must rotate in the *same* direction, either both clockwise or both counterclockwise. This kind of motion is called **conrotatory**.

30.3 Stereochemistry of Thermal Electrocyclic Reactions

How can we predict whether conrotatory or disrotatory motion will occur in a given case? According to frontier orbital theory, the stereochemistry of an electrocyclic reaction is determined by the symmetry of the polyene HOMO. The electrons in the HOMO are the highest-energy, most loosely held electrons and are therefore most easily moved during reaction. For thermal reactions, the ground-state electron configuration is used to identify the HOMO; for **photochemical reactions**, the excited-state electron configuration is used.

Let's look again at the thermal ring-closure of conjugated trienes. According to **FIGURE 30.3**, the HOMO of a conjugated triene in its ground state has lobes of like sign on the same side of the molecule, a symmetry that predicts disrotatory ring-closure. This disrotatory cyclization is precisely what is observed in the thermal cyclization of 2,4,6-octatriene. The *2E,4Z,6E* isomer yields *cis* product; the *2E,4Z,6Z* isomer yields *trans* product (**FIGURE 30.6**).

FIGURE 30.6 Thermal cyclizations of 2,4,6-octatrienes occur by disrotatory ring-closures.

In the same way, the ground-state HOMO of conjugated dienes (**FIGURE 30.2**) has a symmetry that predicts conrotatory ring-closure. In practice, however, the conjugated diene reaction can be observed only in the reverse direction (cyclobutene → diene) because of the position of the equilibrium. We therefore find that the 3,4-dimethylcyclobutene ring *opens* in a conrotatory fashion. *cis*-3,4-Dimethylcyclobutene yields (*2E,4Z*)-2,4-hexadiene, and *trans*-3,4-dimethylcyclobutene yields (*2E,4E*)-2,4-hexadiene by conrotatory opening (**FIGURE 30.7**).

FIGURE 30.7 Thermal ring-openings of *cis*- and *trans*-dimethylcyclobutene occur by conrotatory paths.

Note that a conjugated diene and a conjugated triene react with opposite stereochemistry. The diene opens and closes by a conrotatory path, whereas the triene opens and closes by a disrotatory path. This is due to the different symmetries of the diene and triene HOMOs.

It turns out that there is an alternating relationship between the number of electron pairs (double bonds) undergoing bond reorganization and the stereochemistry of ring-opening or -closure. Polyenes with an even number of electron pairs undergo thermal electrocyclic reactions in a conrotatory sense, whereas polyenes with an odd number of electron pairs undergo the same reactions in a disrotatory sense.

PROBLEM Draw the products you would expect from conrotatory and disrotatory cyclizations of **30-2** (2*Z*,4*Z*,6*Z*)-2,4,6-octatriene. Which of the two paths would you expect the thermal reaction to follow?

PROBLEM *trans*-3,4-Dimethylcyclobutene can open by two conrotatory paths to give either **30-3** (2*E*,4*E*)-2,4-hexadiene or (2*Z*,4*Z*)-2,4-hexadiene. Explain why both products are symmetry-allowed, and then account for the fact that only the 2*E*,4*E* isomer is obtained in practice.

30.4 Photochemical Electrocyclic Reactions

We noted previously that photochemical electrocyclic reactions take a different stereochemical course than their thermal counterparts, and we can now explain this difference. Ultraviolet irradiation of a polyene causes an excitation of one electron from the ground-state HOMO to the ground-state LUMO, thus changing their symmetries. But because electronic excitation changes the symmetries of HOMO and LUMO, it also changes the reaction stereochemistry. (2*E*,4*E*)-2,4-Hexadiene, for instance, undergoes photochemical cyclization by a disrotatory path, whereas the thermal reaction is conrotatory. Similarly, (2*E*,4*Z*,6*E*)-2,4,6-octatriene undergoes photochemical cyclization by a conrotatory path, whereas the thermal reaction is disrotatory (**FIGURE 30.8**).

FIGURE 30.8 Photochemical cyclizations of conjugated dienes and trienes. The two processes occur with different stereochemistry because of their different orbital symmetries.

Thermal and photochemical electrocyclic reactions always take place with opposite stereochemistry because the symmetries of the frontier orbitals are always different. TABLE 30.1 gives some simple rules that make it possible to predict the stereochemistry of electrocyclic reactions.

TABLE 30.1 Stereochemical Rules for Electrocyclic Reactions

Electron pairs (double bonds)	Thermal reaction	Photochemical reaction
Even number	Conrotatory	Disrotatory
Odd number	Disrotatory	Conrotatory

PROBLEM What product would you expect to obtain from the photochemical cyclization of **30-4** (*2E,4Z,6E*)-2,4,6-octatriene? Of (*2E,4Z,6Z*)-2,4,6-octatriene?

30.5 Cycloaddition Reactions

A **cycloaddition reaction** is one in which two unsaturated molecules add to one another to yield a cyclic product. As with electrocyclic reactions, cycloadditions are governed by the orbital symmetry of the reactants. Symmetry-allowed processes often take place readily, but symmetry-disallowed processes take place with difficulty, if at all, and then only by nonconcerted pathways. Let's look at two examples to see how they differ.

As we saw in Section 14.4, the Diels–Alder cycloaddition reaction is a pericyclic process that takes place between a diene (four π electrons) and a dienophile (two π electrons) to yield a cyclohexene product. Many thousands of Diels–Alder reactions are known. They often take place easily at room temperature or slightly above, and they are stereospecific with respect to substituents. For example, room-temperature reaction between 1,3-butadiene and diethyl maleate (*cis*) exclusively yields the *cis*-disubstituted cyclohexene product. A similar reaction between 1,3-butadiene and diethyl fumarate (*trans*) exclusively yields the *trans*-disubstituted product.

In contrast to the $[4 + 2]$ - π -electron Diels–Alder reaction, the $[2 + 2]$ - π -electron cycloaddition between two alkenes does not occur thermally. The $[2 + 2]$ cycloaddition takes place only on irradiation, yielding cyclobutane products.

For a successful cycloaddition, the terminal π lobes of the two reactants must have the correct symmetry for bonding to occur. This can happen in either of two ways, called *suprafacial* and *antarafacial*. **Suprafacial** cycloadditions take place when a bonding interaction occurs between lobes on the same face of one reactant and lobes on the same face of the other reactant. **Antarafacial** cycloadditions take place when a bonding interaction occurs between lobes on the same face of one reactant and lobes on opposite faces of the other reactant (FIGURE 30.9).

FIGURE 30.9 (a) Suprafacial cycloaddition occurs when there is bonding between lobes on the same face of one reactant and lobes on the same face of the other reactant. (b) Antarafacial cycloaddition occurs when there is bonding between lobes on the same face of one reactant and lobes on opposite faces of the other, which requires a twist in one π system.

Note that both suprafacial and antarafacial cycloadditions are symmetry-allowed. Geometric constraints often make antarafacial reactions difficult, however, because there must be a twisting of the π orbital system in one of the reactants. Thus, suprafacial cycloadditions are much more common for small π systems.

30.6 Stereochemistry of Cycloadditions

How can we predict whether a given cycloaddition reaction will occur with suprafacial or with antarafacial geometry? According to frontier orbital theory, a cycloaddition reaction takes place when a bonding interaction occurs between the HOMO of one reactant and the LUMO of the other. An intuitive explanation of this rule is to imagine that one reactant donates electrons to the other. As with electrocyclic reactions, it's the electrons in the HOMO of the first reactant that are least tightly held and most likely to be donated. Of course when the second reactant accepts those electrons, they must go into a vacant, unoccupied orbital—the LUMO.

For a [4 + 2] cycloaddition (Diels–Alder reaction), let's arbitrarily select the diene LUMO and the alkene HOMO. The symmetries of the two ground-state orbitals are such that bonding of the terminal lobes can occur with suprafacial geometry (FIGURE 30.10), so the Diels–Alder reaction takes place readily under thermal conditions. Note that, as with electrocyclic reactions, we need be concerned only with the terminal lobes. For purposes of prediction, interactions among the interior lobes need not be considered.

FIGURE 30.10 Interaction of diene LUMO and alkene HOMO in a suprafacial [4 + 2] cycloaddition reaction (Diels–Alder reaction).

In contrast with the thermal [4 + 2] Diels–Alder reaction, the [2 + 2] cycloaddition of two alkenes to yield a cyclobutane can only occur photochemically. The explanation for this follows from orbital-symmetry arguments. Looking at the ground-state HOMO of one alkene and the LUMO of the second alkene, it's apparent that a thermal [2 + 2] cycloaddition must take place by an antarafacial pathway (**FIGURE 30.11a**). Geometric constraints make the antarafacial transition state difficult, however, and so concerted thermal [2 + 2] cycloadditions are not observed.

In contrast with the thermal process, photochemical [2 + 2] cycloadditions *are* observed. Irradiation of an alkene with UV light excites an electron from ψ_1 , the ground-state HOMO, to ψ_2^* , which becomes the excited-state HOMO. Interaction between the excited-state HOMO of one alkene and the LUMO of the second alkene allows a photochemical [2 + 2] cycloaddition reaction to occur by a suprafacial pathway (**FIGURE 30.11b**).

FIGURE 30.11 (a) Interaction of a ground-state HOMO and a ground-state LUMO in a potential [2 + 2] cycloaddition does not occur thermally because the antarafacial geometry is too strained. (b) Interaction of an excited-state HOMO and a ground-state LUMO in a photochemical [2 + 2] cycloaddition reaction is less strained, however, and occurs with suprafacial geometry.

The photochemical [2 + 2] cycloaddition reaction occurs smoothly, particularly with α,β -unsaturated carbonyl compounds, and represents one of the best methods known for synthesizing cyclobutane rings. For example:

Thermal and photochemical cycloaddition reactions always take place with opposite stereochemistry. As with electrocyclic reactions, we can categorize cycloadditions according to the total number of electron pairs (double bonds) involved in the rearrangement. Thus, a thermal [4 + 2] Diels–Alder reaction between a diene and a dienophile involves an odd number (three) of electron pairs and takes place by a suprafacial pathway. A thermal [2 + 2] reaction between two alkenes involves an even number (two) of electron pairs and must take place by an antarafacial pathway. For photochemical cyclizations, these selectivities are reversed. These general rules are given in [TABLE 30.2](#).

TABLE 30.2 Stereochemical Rules for Cycloaddition Reactions

Electron pairs (double bonds)	Thermal reaction	Photochemical reaction
Even number	Antarafacial	Suprafacial
Odd number	Suprafacial	Antarafacial

PROBLEM 30-5 What stereochemistry would you expect for the product of the Diels–Alder reaction between (2*E*,4*E*)-2,4-hexadiene and ethylene? What stereochemistry would you expect if (2*E*,4*Z*)-2,4-hexadiene were used instead?

PROBLEM 30-6 1,3-Cyclopentadiene reacts with cycloheptatrienone to give the product shown. Tell what kind of reaction is involved, and explain the observed result. Is the reaction suprafacial or antarafacial?

30.7 Sigmatropic Rearrangements

A **sigmatropic rearrangement**, the third general kind of pericyclic reaction, is a process in which a σ -bonded substituent atom or group migrates across a π electron system from one position to another. A σ bond is broken in the reactant, the π bonds move, and a new σ bond is formed in the product. The σ -bonded group can be either at the end or in the middle of the π system, as the following [1,5] and [3,3] rearrangements illustrate:

A [1,5] sigmatropic rearrangement**A [3,3] sigmatropic rearrangement**

The notations [1,5] and [3,3] describe the kind of rearrangement that is occurring. The numbers refer to the two groups connected by the σ bond in the reactant and designate the positions in those groups to which migration occurs. For example, in the [1,5] sigmatropic rearrangement of a 1,3-diene, the two groups connected by the σ bond are a hydrogen atom and a pentadienyl group. Migration occurs to position 1 of the H group (the only possibility) and to position 5 of the pentadienyl group. In the [3,3] rearrangement of an allylic vinylic ether, the two groups connected by the σ bond are an allylic group and the vinylic ether. Migration occurs to position 3 of the allylic group and also to position 3 of the vinylic ether.

Like electrocyclic reactions and cycloadditions, sigmatropic rearrangements are controlled by orbital symmetries. There are two possible modes of reaction: migration of a group across the same face of the π system is suprafacial, and migration of a group from one face of the π system to the other face is antarafacial (**FIGURE 30.12**).

FIGURE 30.12 Suprafacial and antarafacial sigmatropic rearrangements.

Both suprafacial and antarafacial sigmatropic rearrangements are symmetry-allowed, but suprafacial rearrangements are often easier for geometric reasons. The rules for sigmatropic rearrangements are identical to those for cycloaddition reactions (TABLE 30.3).

TABLE 30.3 Stereochemical Rules for Sigmatropic Rearrangements

Electron pairs (double bonds)	Thermal reaction	Photochemical reaction
Even number	Antarafacial	Suprafacial
Odd number	Suprafacial	Antarafacial

PROBLEM Classify the following sigmatropic reaction by order $[x,y]$, and tell whether it will proceed with
30-7 suprafacial or antarafacial stereochemistry:

30.8 Some Examples of Sigmatropic Rearrangements

Because a [1,5] sigmatropic rearrangement involves three electron pairs (two π bonds and one σ bond), the orbital-symmetry rules in TABLE 30.3 predict a suprafacial reaction. In fact, the [1,5] suprafacial shift of a hydrogen atom across two double bonds of a π system is a commonly observed sigmatropic rearrangement. For example, 5-methyl-1,3-cyclopentadiene rapidly rearranges at room temperature to yield a mixture of 1-methyl-, 2-methyl-, and 5-methyl-isomers.

As another example, heating 5,5,5-trideuterio-(3*Z*)-1,3-pentadiene causes scrambling of deuterium between

positions 1 and 5.

Both these [1,5] hydrogen shifts occur by a symmetry-allowed suprafacial pathway, as illustrated in **FIGURE 30.13**. In contrast with these thermal [1,5] sigmatropic hydrogen shifts, however, thermal [1,3] hydrogen shifts are unknown. If they were to occur, they would have to proceed by a strained antarafacial reaction pathway.

FIGURE 30.13 An orbital view of a suprafacial [1,5] hydrogen shift.

Two other important sigmatropic reactions are the **Claisen rearrangement** of either an allyl aryl ether ($\text{H}_2\text{C}=\text{CHCH}_2\text{—O—Ar}$) or an allyl vinyl ($\text{H}_2\text{C}=\text{CHCH}_2\text{—O—CH}=\text{CH}_2$) ether, and the **Cope rearrangement** of a 1,5 hexadiene to an isomeric 1,5-diene. These two rearrangements, along with the Diels–Alder reaction, are among the most generally useful pericyclic reactions for organic synthesis. Thousands of examples of all three are known.

Like the Diels–Alder reaction discussed in **Section 14.4** and **Section 14.5**, the Claisen rearrangement takes place in a single step through a pericyclic mechanism in which a reorganization of bonding electrons occurs in a six-membered, cyclic transition state. The 6-allyl-2,4-cyclohexadienone intermediate then isomerizes to *o*-allylphenol (**FIGURE 30.14**).

FIGURE 30.14 Mechanism of Claisen rearrangement. C–O bond-breaking and C–C bond-making occur simultaneously.

Evidence for this mechanism comes from the observation that the rearrangement takes place with transposition of the allyl group. That is, allyl phenyl ether containing a ^{14}C label on the allyl *ether* carbon atom yields *o*-allylphenol in which the label is on the *terminal* vinylic carbon (green in **FIGURE 30.14**).

PROBLEM Draw a curved-arrow mechanism for the Cope arrangement just shown.

The Cope rearrangement that converts a 1,5-diene to an isomeric 1,5-diene is somewhat limited but a modification called the **Oxy Cope Rearrangement** is wider in scope. As shown in the following example, a 1-5 diene with an –OH next to the double bond can be converted into an oxy-anion by reaction with a strong base such as potassium hydride (KH). A Cope rearrangement then occurs, and reaction with aqueous acid gives an enol that tautomerizes to an aldehyde.

Although biological examples of pericyclic reactions are relatively rare, a much-studied example occurs in bacteria during biosynthesis of the essential amino acid phenylalanine. Phenylalanine arises from the precursor chorismate through a Claisen rearrangement to prephenate, followed by decarboxylation to phenylpyruvate and reductive amination (**FIGURE 30.16**). You might note that the reductive amination of phenylpyruvate is the exact reverse of the transamination process shown in **FIGURE 29.17**, by which amino acids are deaminated. In addition, the reductive amination of ketones is a standard method for preparing amines in the laboratory, as we saw in **Section 24.6**.

FIGURE 30.15 Suprafacial [3,3] (a) Cope and (b) Claisen rearrangements.

FIGURE 30.16 Pathway for the bacterial biosynthesis of phenylalanine from chorismate, involving a Claisen rearrangement.

PROBLEM 30-9 Propose a mechanism to account for the fact that heating 1-deuterioindene scrambles the isotope label to all three positions on the five-membered ring.

PROBLEM 30-10 What product would you expect from Claisen rearrangement of 2-butenyl phenyl ether?

**2-Butenyl phenyl ether**

PROBLEM When a 2,6-disubstituted allyl phenyl ether is heated in an attempted Claisen rearrangement, migration occurs to give the *p*-allyl product as the result of two sequential pericyclic reactions. Explain.

30.9 A Summary of Rules for Pericyclic Reactions

How can you keep straight all the rules about pericyclic reactions? The summary in [TABLE 30.1](#), [TABLE 30.2](#), and [TABLE 30.3](#) can be distilled into a mnemonic phrase that provides an easy way to predict the stereochemical outcome of any pericyclic reaction:

The Electrons Circle Around (**TECA**)

Thermal reactions with an **E**ven number of electron pairs are **C**onrotatory or **A**ntarafacial.

A change either from thermal to photochemical or from an even to an odd number of electron pairs changes the outcome from conrotatory/antarafacial to disrotatory/suprafacial. A change from both thermal and even to photochemical and odd causes no change because two negatives make a positive.

These selection rules are summarized in [TABLE 30.4](#); knowing them gives you the ability to predict the stereochemistry of literally thousands of pericyclic reactions.

TABLE 30.4 Stereochemical Rules for Pericyclic Reactions

Electronic state	Electron pairs	Stereochemistry
Ground state (thermal)	Even number	Antara-con
	Odd number	Supra-dis
Excited state (photochemical)	Even number	Supra-dis
	Odd number	Antara-con

PROBLEM Predict the stereochemistry of the following pericyclic reactions:

- 30-12** (a) The thermal cyclization of a conjugated tetraene
 (b) The photochemical cyclization of a conjugated tetraene
 (c) A photochemical [4 + 4] cycloaddition
 (d) A thermal [2 + 6] cycloaddition
 (e) A photochemical [3,5] sigmatropic rearrangement

CHEMISTRY MATTERS

Vitamin D, the Sunshine Vitamin

Vitamin D, discovered in 1918, is a general name for two related compounds, **cholecalciferol** (vitamin D₃) and **ergocalciferol** (vitamin D₂). Both are derived from steroids (Section 27.6) and differ only in the nature of the hydrocarbon side chain attached to the five-membered ring. Cholecalciferol comes primarily from dairy products and fish; ergocalciferol comes from some vegetables.

FIGURE 30.17 Here are the sunbathers, again, with their chemical work complete. (credit: "Tanning" by Meraj Chhaya/Flickr, CC BY 2.0)

The function of vitamin D in the body is to control the calcification of bones by increasing intestinal absorption of calcium. When sufficient vitamin D is present, approximately 30% of ingested calcium is absorbed, but in the absence of vitamin D, calcium absorption falls to about 10%. A deficiency of vitamin D thus leads to poor bone growth and to the diseases *rickets* in children and *osteoporosis* in adults.

Actually, neither vitamin D₂ nor D₃ is present in foods. Rather, foods contain the precursor molecules 7-dehydrocholesterol and ergosterol. In the presence of sunlight, both precursors are converted in the outer, epidermal layer of skin to the active vitamins, hence the nickname for vitamin D, the "sunshine vitamin."

Pericyclic reactions are unusual in living organisms, and the photochemical synthesis of vitamin D is one of only a few well-studied examples. The reaction takes place in two steps, an electrocyclic ring-opening of a cyclohexadiene to yield an open-chain hexatriene, followed by a sigmatropic [1,7] H shift to yield an isomeric hexatriene. Only the initial electrocyclic ring-opening requires irradiation by so-called UVB light of 295 to 300 nm wavelength. The subsequent sigmatropic [1,7] H shift occurs spontaneously by a thermal isomerization.

Following synthesis under the skin, further metabolic processing of cholecalciferol and ergocalciferol in the liver and kidney introduces two additional $-\text{OH}$ groups to give the active forms of the vitamin, calcitriol and ergocalcitril.

- **suprafacial**
- **symmetry-allowed**
- **symmetry-disallowed**

Summary

A **pericyclic reaction** takes place in a single step through a cyclic transition state without intermediates. There are three major classes of pericyclic processes: electrocyclic reactions, cycloaddition reactions, and sigmatropic rearrangements. The stereochemistry of these reactions is controlled by the symmetry of the orbitals involved in bond reorganization.

Electrocyclic reactions involve the cyclization of conjugated acyclic polyenes. For example, 1,3,5-hexatriene cyclizes to 1,3-cyclohexadiene on heating. Electrocyclic reactions can occur by either **conrotatory** or **disrotatory** pathways, depending on the symmetry of the terminal lobes of the π system. Conrotatory cyclization requires that both lobes rotate in the same direction, whereas disrotatory cyclization requires that the lobes rotate in opposite directions. The reaction course in a specific case can be found by looking at the symmetry of the **highest occupied molecular orbital (HOMO)**.

Cycloaddition reactions are those in which two unsaturated molecules add together to yield a cyclic product. For example, Diels–Alder reaction between a diene (four π electrons) and a dienophile (two π electrons) yields a cyclohexene. Cycloadditions can take place either by **suprafacial** or **antarafacial** pathways. Suprafacial cycloaddition involves interaction between lobes on the same face of one component and on the same face of the second component. Antarafacial cycloaddition involves interaction between lobes on the same face of one component and on opposite faces of the other component. The reaction course in a specific case can be found by looking at the symmetry of the HOMO of one component and the **lowest unoccupied molecular orbital (LUMO)** of the other.

Sigmatropic rearrangements involve the migration of a σ -bonded group across a π electron system. For example, Claisen rearrangement of an allylic vinylic ether yields an unsaturated carbonyl compound, and Cope rearrangement of a 1,5-hexadiene yields an isomeric 1,5-hexadiene. Sigmatropic rearrangements can occur with either suprafacial or antarafacial stereochemistry; the selection rules for a given case are the same as those for cycloaddition reactions.

The stereochemistry of any pericyclic reaction can be predicted by counting the total number of electron pairs (bonds) involved in bond reorganization and then applying the mnemonic “**The Electrons Circle Around.**” That is, **thermal** (ground-state) reactions involving an even number of electron pairs occur with either conrotatory or antarafacial stereochemistry. Exactly the opposite rules apply to **photochemical** (excited-state) reactions.

Additional Problems

Visualizing Chemistry

PROBLEM Predict the product obtained when the following substance is heated:

30-13

would you complete the synthesis?

PROBLEM 30-19 The following thermal rearrangement involves two pericyclic reactions in sequence. Identify them, and propose a mechanism to account for the observed result.

Electrocyclic Reactions

PROBLEM 30-20 Do the following electrocyclic reactions take place in a conrotatory or disrotatory manner? Under what conditions, thermal or photochemical, would you carry out each reaction?

PROBLEM 30-21 The following thermal isomerization occurs under relatively mild conditions. Identify the pericyclic reactions involved, and show how the rearrangement occurs.

PROBLEM 30-22 Would you expect the following reaction to proceed in a conrotatory or disrotatory manner? Show the stereochemistry of the cyclobutene product, and explain your answer.

PROBLEM Heating (1*Z*,3*Z*,5*Z*)-1,3,5-cyclononatriene to 100 °C causes cyclization and formation of a bicyclic product. Is the reaction conrotatory or disrotatory? What is the stereochemical relationship of the two hydrogens at the ring junctions, cis or trans?

30-23

(1*Z*,3*Z*,5*Z*)-1,3,5-Cyclononatriene

PROBLEM (2*E*,4*Z*,6*Z*,8*E*)-2,4,6,8-Decatetraene has been cyclized to give 7,8-dimethyl-1,3,5-cyclooctatriene.

30-24

Predict the manner of ring-closure—conrotatory or disrotatory—for both thermal and photochemical reactions, and predict the stereochemistry of the product in each case.

PROBLEM Answer Problem 30-24 for the thermal and photochemical cyclizations of **30-25** (2*E*,4*Z*,6*Z*,8*Z*)-2,4,6,8-decatetraene.

PROBLEM The cyclohexadecaoctaene shown isomerizes to two different isomers, depending on reaction conditions. Explain the observed results, and indicate whether each reaction is conrotatory or disrotatory.

30-26

Cycloaddition Reactions

PROBLEM Which of the following reactions is more likely to occur? Explain.

30-27

PROBLEM The following reaction takes place in two steps, one of which is a cycloaddition while the other is a reverse cycloaddition. Identify the two pericyclic reactions, and show how they occur.

30-28

PROBLEM 30-29 Two sequential pericyclic reactions are involved in the following furan synthesis. Identify them, and propose a mechanism for the transformation.

Sigmatropic Rearrangements

PROBLEM 30-30 Predict the product of the following pericyclic reaction. Is this [5,5] shift a suprafacial or an antarafacial process?

PROBLEM 30-31 Propose a pericyclic mechanism to account for the following transformation:

PROBLEM 30-32 Vinyl-substituted cyclopropanes undergo thermal rearrangement to yield cyclopentenes. Propose a mechanism for the reaction, and identify the pericyclic process involved.

PROBLEM 30-33 The following synthesis of dienones occurs readily. Propose a mechanism to account for the results, and identify the kind of pericyclic reaction involved.

PROBLEM 30-34 Karahanaenone, a terpenoid isolated from oil of hops, has been synthesized by the thermal reaction shown. Identify the kind of pericyclic reaction, and explain how karahanaenone is formed.

General Problems

PROBLEM 30-35 What stereochemistry—antarafacial or suprafacial—would you expect to observe in the following reactions?

- (a) A photochemical [1,5] sigmatropic rearrangement (b) A thermal [4 + 6] cycloaddition
 (c) A thermal [1,7] sigmatropic rearrangement (d) A photochemical [2 + 6] cycloaddition

PROBLEM 30-36 Bicyclohexadiene, also known as *Dewar benzene*, is extremely stable despite the fact that its

rearrangement to benzene is energetically favored. Explain why the rearrangement is so slow.

PROBLEM 30-37 Ring-opening of the *trans*-cyclobutene isomer shown takes place at much lower temperature than a similar ring-opening of the *cis*-cyclobutene isomer. Explain the temperature effect, and identify the stereochemistry of each reaction as either conrotatory or disrotatory.

PROBLEM 30-38 Photolysis of the *cis*-cyclobutene isomer in Problem 30-37 yields *cis*-cyclododecaen-7-yne, but photolysis of the *trans* isomer yields *trans*-cyclododecaen-7-yne. Explain these results, and identify the type and stereochemistry of the pericyclic reaction.

PROBLEM 30-39 The ^1H NMR spectrum of bullvalene at 100 °C consists only of a single peak at 4.22 δ . Explain.

PROBLEM 30-40 The following rearrangement was devised and carried out to prove the stereochemistry of [1,5] sigmatropic hydrogen shifts. Explain how the observed result confirms the predictions of orbital symmetry.

PROBLEM 30-41 The following reaction is an example of a [2,3] sigmatropic rearrangement. Would you expect the reaction to be suprafacial or antarafacial? Explain.

PROBLEM 30-42 When the compound having a cyclobutene fused to a five-membered ring is heated, (1*Z*,3*Z*)-1,3-cycloheptadiene is formed. When the related compound having a cyclobutene fused to an eight-membered ring is heated, however, (1*E*,3*Z*)-1,3-cyclodecadiene is formed. Explain these results, and suggest a reason why opening of the eight-membered ring occurs at a lower

temperature.

PROBLEM 30-43 In light of your answer to Problem 30-42, explain why a mixture of products occurs in the following reaction:

PROBLEM 30-44 In nature, the enzyme chorismate mutase catalyzes a Claisen rearrangement of chorismate that involves both the terminal double bond and the double bond with the highlighted carbon. What is the structure of prephenate, the biological precursor to the amino acids phenylalanine and tyrosine?

PROBLEM 30-45 Predict the product(s) if the starting materials underwent a Claisen rearrangement. Draw arrows to illustrate the rearrangement of electrons.

31.7 Polymer Structure and Physical Properties

WHY THIS CHAPTER? Our treatment of polymers has thus far been dispersed over several chapters, but it’s also important to take a comprehensive view. In the present chapter, we’ll look further at how polymers are made, and we’ll see how polymer structure correlates with physical properties. No course in organic chemistry would be complete without a look at polymers.

Polymers are a fundamental part of the modern world, used in everything from coffee cups to cars to clothing. In medicine, too, their importance is growing, with uses as diverse as cardiac pacemakers, artificial heart valves, and biodegradable sutures.

We’ve seen on several occasions in previous chapters that a **polymer**, whether synthetic or biological, is a large molecule built up by repetitive bonding of many smaller units, or **monomers**. Polyethylene, for instance, is a synthetic polymer made from ethylene ([Section 8.10](#)), nylon is a synthetic polyamide made from a diacid and a diamine ([Section 21.9](#)), and proteins are biological polyamides made from amino acids. Note that polymers are

often drawn by indicating their repeating unit in parentheses. The repeating unit in polystyrene, for example, comes from the monomer styrene.

31.1 Chain-Growth Polymers

Synthetic polymers are classified by their method of synthesis as either *chain-growth* or *step-growth*. These categories are somewhat imprecise but nevertheless provide a useful distinction. **Chain-growth polymers** are produced by chain-reaction polymerization in which an initiator adds to the carbon-carbon double bond of an unsaturated substrate (a *vinyl monomer*) to yield a reactive intermediate. This intermediate reacts with a second molecule of monomer to yield a new intermediate, which reacts with a third monomer unit, and so on.

The initiator can be a radical, an acid, or a base. Historically, as we saw in [Section 8.10](#), radical polymerization was the most common method because it can be carried out with practically any vinyl monomer.

Acid-catalyzed (cationic) polymerization, by contrast, is effective only with vinyl monomers that contain an electron-donating group (EDG) capable of stabilizing the chain-carrying carbocation intermediate.

where **EDG** = an electron-donating group

Isobutylene (2-methylpropene) is a good example of a monomer that polymerizes rapidly under cationic conditions. The reaction is carried out commercially at -80°C , using BF_3 and a small amount of water to generate $\text{BF}_3\text{OH}^- \text{H}^+$ catalyst. The product is used in the manufacture of truck and bicycle inner tubes.

Vinyl monomers with electron-withdrawing groups (EWG) can be polymerized by basic (anionic) catalysts. The chain-carrying step is a conjugate nucleophilic addition of an anion to the unsaturated monomer ([Section 19.13](#)).

where **EWG** = an electron-withdrawing group

Acrylonitrile ($\text{H}_2\text{C}=\text{CHCN}$), methyl methacrylate [$\text{H}_2\text{C}=\text{C}(\text{CH}_3)\text{CO}_2\text{CH}_3$], and styrene ($\text{H}_2\text{C}=\text{CHC}_6\text{H}_5$) can all be polymerized anionically. The polystyrene used in foam coffee cups, for example, is prepared by anionic

polymerization of styrene using butyllithium as catalyst.

An interesting example of anionic polymerization accounts for the remarkable properties of “super glue,” one drop of which can support up to 2000 lb. Super glue is simply a solution of pure methyl α -cyanoacrylate, which has two electron-withdrawing groups that make anionic addition particularly easy. Trace amounts of water or bases on the surface of an object are sufficient to initiate polymerization of the cyanoacrylate and bind articles together. Skin is a good source of the necessary basic initiators, and many people have found their fingers stuck together after inadvertently touching super glue. So good is super glue at binding tissues that related cyanoacrylate esters such as Dermabond are often used in place of sutures to close wounds.

PROBLEM 31-1 Order the following monomers with respect to their expected reactivity toward cationic polymerization, and explain your answer:

PROBLEM 31-2 Order the following monomers with respect to their expected reactivity toward anionic polymerization, and explain your answer:

PROBLEM 31-3 Polystyrene is produced commercially by reaction of styrene with butyllithium as an anionic initiator. Using resonance structures, explain how the chain-carrying intermediate is stabilized.

31.2 Stereochemistry of Polymerization: Ziegler–Natta Catalysts

Although we didn't point it out when discussing chain-growth polymers in [Section 8.10](#), the polymerization of a substituted vinyl monomer can lead to a polymer with numerous chirality centers in its chain. Propylene, for example, might polymerize with any of the three stereochemical outcomes shown in [FIGURE 31.2](#). A polymer with all methyl groups on the same side of the zigzag backbone is called **isotactic**, one in which the methyl groups alternate regularly on opposite sides of the backbone is called **syndiotactic**, and one with its methyl groups randomly oriented is called **atactic**.

FIGURE 31.2 Isotactic, syndiotactic, and atactic forms of polypropylene.

The three different stereochemical forms of polypropylene all have somewhat different properties, and all can be made by using the right polymerization catalyst. Propylene polymerization using radical initiators does not work well, but polymerization using *Ziegler–Natta catalysts* allows preparation of isotactic, syndiotactic, and atactic polypropylene.

Ziegler–Natta catalysts—there are many different formulations—are organometallic transition-metal complexes prepared by treatment of an alkylaluminum with a titanium compound. Triethylaluminum with titanium tetrachloride is a typical preparation.

Following their introduction in 1953, Ziegler–Natta catalysts revolutionized the field of polymer chemistry because of two advantages: first, the resultant polymers are linear, with practically no chain branching, and second, they are stereochemically controllable. Isotactic, syndiotactic, and atactic forms can all be produced, depending on the catalyst system used.

The active form of a Ziegler–Natta catalyst is an alkyltitanium intermediate with a vacant coordination site on the metal. Coordination of alkene monomer to the titanium occurs, and the coordinated alkene then inserts into the carbon–titanium bond to extend the alkyl chain. A new coordination site opens up during the insertion step, so the process repeats indefinitely.

The linear polyethylene produced by the Ziegler–Natta process, called *high-density polyethylene*, is a highly crystalline polymer with 4000 to 7000 ethylene units per chain and molecular weights in the range 100,000 to 200,000 amu. High-density polyethylene has greater strength and heat resistance than the branched product of radical-induced polymerization, called *low-density polyethylene*, and is used to produce plastic squeeze bottles and molded housewares.

Polyethylenes of even higher molecular weights are produced for specialty applications. So-called high-molecular-weight (HMW) polyethylene contains 10,000 to 18,000 monomer units per chain and molecular weights in the range of 300,000–500,000. It is used for underground pipes and large containers. Ultrahigh-molecular-weight (UHMW) polyethylene contains more than 100,000 monomer units per chain and has molecular weights ranging from 3,000,000 to 6,000,000 amu. It is used in bearings, conveyor belts, and bulletproof vests, among other applications requiring exceptional wear resistance.

PROBLEM Vinylidene chloride, $\text{H}_2\text{C}=\text{CCl}_2$, does not polymerize in isotactic, syndiotactic, and atactic forms.

31-4 Explain.

PROBLEM Polymers such as polypropylene contain a large number of chirality centers. Would you therefore

31-5 expect samples of isotactic, syndiotactic, or atactic polypropylene to rotate plane-polarized light? Explain.

31.3 Copolymers

Up to this point we've discussed only **homopolymers**—polymers that are made up of identical repeating units. In practice, however, *copolymers* are more important commercially. **Copolymers** are obtained when two or more different monomers are allowed to polymerize together. For example, copolymerization of vinyl chloride with vinylidene chloride (1,1-dichloroethylene) in a 1 : 4 ratio leads to the polymer Saran.

Copolymerization of monomer mixtures often leads to materials with properties quite different from those of either corresponding homopolymer, giving the polymer chemist a vast flexibility for devising new materials.

TABLE 31.1 lists some common copolymers and their commercial applications.

TABLE 31.1 Some Common Copolymers and Their Uses

Monomers	Structures	Trade name	Uses
Vinyl chloride Vinylidene chloride	$ \begin{array}{c} \text{H} & & \text{Cl} \\ & \diagdown & / \\ & \text{C}=\text{C} \\ & / & \diagdown \\ \text{H} & & \text{H} \end{array} + \begin{array}{c} \text{H} & & \text{Cl} \\ & \diagdown & / \\ & \text{C}=\text{C} \\ & / & \diagdown \\ \text{H} & & \text{Cl} \end{array} $	Saran	Fibers, food packaging
Styrene 1,3-Butadiene	$ \begin{array}{c} \text{H} & & \text{C}_6\text{H}_5 \\ & \diagdown & / \\ & \text{C}=\text{C} \\ & / & \diagdown \\ \text{H} & & \text{H} \end{array} + \begin{array}{c} \text{H} & & \text{H} \\ & \diagdown & / \\ & \text{C}=\text{C} \\ & / & \diagdown \\ \text{H} & & \text{H} \end{array} $	SBR (styrene–butadiene rubber)	Tires, rubber articles
Hexafluoropropene Vinylidene fluoride	$ \begin{array}{c} \text{F} & & \text{CF}_3 \\ & \diagdown & / \\ & \text{C}=\text{C} \\ & / & \diagdown \\ \text{F} & & \text{F} \end{array} + \begin{array}{c} \text{H} & & \text{F} \\ & \diagdown & / \\ & \text{C}=\text{C} \\ & / & \diagdown \\ \text{H} & & \text{F} \end{array} $	Viton	Gaskets, seals
Acrylonitrile 1,3-Butadiene	$ \begin{array}{c} \text{H} & & \text{CN} \\ & \diagdown & / \\ & \text{C}=\text{C} \\ & / & \diagdown \\ \text{H} & & \text{H} \end{array} + \begin{array}{c} \text{H} & & \text{H} \\ & \diagdown & / \\ & \text{C}=\text{C} \\ & / & \diagdown \\ \text{H} & & \text{H} \end{array} $	Nitrile rubber	Adhesives, hoses

TABLE 31.1 Some Common Copolymers and Their Uses

Monomers	Structures	Trade name	Uses
Isobutylene Isoprene		Butyl rubber	Inner tubes
Acrylonitrile 1,3-Butadiene Styrene		ABS (monomer initials)	Pipes, high-impact applications

Several different types of copolymers can be defined, depending on the distribution of monomer units in the chain. If monomer A is copolymerized with monomer B, for instance, the resultant product might have a random distribution of the two units throughout the chain, or it might have an alternating distribution.

Random copolymer

Alternating copolymer

The exact distribution of monomer units depends on the initial proportions of the two reactant monomers and their relative reactivities. In practice, neither perfectly random nor perfectly alternating copolymers are usually found. Most copolymers have many random imperfections.

Two other forms of copolymers that can be prepared under certain conditions are called *block copolymers* and *graft copolymers*. **Block copolymers** are those in which different blocks of identical monomer units alternate with each other; **graft copolymers** are those in which homopolymer branches of one monomer unit are “grafted” onto a homopolymer chain of another monomer unit.

Block copolymers are prepared by initiating the polymerization of one monomer as if growing a homopolymer chain and then adding an excess of the second monomer to the still-active reaction mix. Graft copolymers are made by gamma irradiation of a completed homopolymer chain in the presence of the second monomer. The high-energy irradiation knocks hydrogen atoms off the homopolymer chain at random points, thus generating new radical sites that can initiate polymerization of the added monomer.

PROBLEM 31-6 Draw the structure of an alternating segment of butyl rubber, a copolymer of isoprene (2-methyl-1,3-butadiene) and isobutylene (2-methylpropene) prepared using a cationic initiator.

PROBLEM 31-7 Irradiation of poly(1,3-butadiene), followed by addition of styrene, yields a graft copolymer that is used to make rubber soles for shoes. Draw the structure of a representative segment of this styrene-butadiene graft copolymer.

31.4 Step-Growth Polymers

Step-growth polymers are produced by reactions in which each bond in the polymer is formed stepwise, independently of the other bonds. Like the polyamides (nylons) and polyesters that we saw in [Section 21.9](#), most step-growth polymers are produced by reaction between two difunctional reactants. The polymer Nylon 66, for instance, is made by reaction between the six-carbon adipic acid and the six-carbon hexamethylenediamine (1,6-hexanediamine). Alternatively, a single reactant with two different functional groups can polymerize. Nylon 6 is made by polymerization of the six-carbon caprolactam. The reaction is initiated by adding a small amount of water, which hydrolyzes some caprolactam to 6-aminohexanoic acid. Nucleophilic addition of the amino group to caprolactam then propagates the polymerization.

Polycarbonates

Polycarbonates are like polyesters, but their carbonyl group is linked to two $-\text{OR}$ groups, $[\text{O}=\text{C}(\text{OR})_2]$. Lexan, for instance, is a polycarbonate prepared from diphenyl carbonate and a diphenol called bisphenol A. Lexan has unusually high impact strength, making it valuable for use in machinery housings, telephones, bicycle safety helmets, and bulletproof glass.

Polyurethanes

A **urethane** is a carbonyl-containing functional group in which the carbonyl carbon is bonded to both an $-\text{OR}$ group and an $-\text{NR}_2$ group. As such, a urethane is halfway between a carbonate and a urea.

A urethane is typically prepared by nucleophilic addition reaction of an alcohol with an isocyanate ($\text{R}-\text{N}=\text{C}=\text{O}$), so a **polyurethane** is prepared by reaction of a diol with a diisocyanate. The diol is usually a low-molecular-weight polymer (MW \approx 1000 amu) with hydroxyl end-groups; the diisocyanate is often toluene-2,4-diisocyanate.

Several different kinds of polyurethanes can be produced, depending on the nature of the polymeric alcohol used. One major use of polyurethane is in the stretchable spandex fibers used for bathing suits and athletic gear. These polyurethanes have a fairly low degree of cross-linking so that the resultant polymer is soft and elastic. A second major use of polyurethanes is in the foams used for insulation. Foaming occurs when a small amount of water is added during polymerization, giving a carbamic acid intermediate that spontaneously loses bubbles of CO_2 .

Polyurethane foams are generally made using a *polyalcohol* rather than a diol as the monomer so that the polymer has a high amount of three-dimensional cross-linking. The result is a rigid but very light foam suitable for use as thermal insulation in building construction and portable ice chests.

PROBLEM Poly(ethylene terephthalate), or PET, is a polyester used to make soft-drink bottles. It is prepared **31-8** by reaction of ethylene glycol with 1,4-benzenedicarboxylic acid (terephthalic acid). Draw the structure of PET.

PROBLEM Show the mechanism of the nucleophilic addition reaction of an alcohol with an isocyanate to yield **31-9** a urethane.

31.5 Olefin Metathesis Polymerization

Perhaps the most important advance in polymer synthesis in recent years has been the development of **olefin metathesis polymerization** by Yves Chauvin of the Institut Français du Pétrole, Robert H. Grubbs of CalTech, and Richard R. Schrock of MIT who shared the 2005 Nobel Prize in Chemistry for their work. At its simplest, an olefin metathesis reaction is two olefins (alkenes) exchanging substituents on their double bonds.

An olefin metathesis reaction

Olefin metathesis catalysts, such as the Grubbs catalyst now in common use, contain a carbon–metal double

bond (usually to ruthenium, Ru) and have the general structure $M=CH-R$. They function by reacting reversibly with an alkene to form a four-membered, metal-containing intermediate called a *metallacycle*, which immediately opens to give a different catalyst and a different alkene. The mechanism is shown in **FIGURE 31.3**.

FIGURE 31.3 Mechanism of the olefin metathesis reaction. The process is initiated by a two-step sequence that involves (1) reaction of the catalyst and olefin 1 to give a four-membered metallacycle intermediate, followed by (2) ring-opening to give a different form of catalyst that contains part of olefin 1. (3) Reaction of this new catalyst with olefin 2 gives another metallacycle intermediate, (4) which opens to give metathesis product and another form of catalyst. (5, 6) The repeating ring-forming and ring-opening steps then continue.

There are several methods for implementing the olefin metathesis reaction to prepare polymers. One method, called *ring-opening metathesis polymerization*, or **ROMP**, involves the use of a moderately strained cycloalkene, such as cyclopentene. The strain of the ring favors ring-opening, thereby driving formation of the open-chain product. The polymer that results has double bonds spaced regularly along the chain, allowing for either hydrogenation or further functionalization if desired.

Ring-opening metathesis polymerization (ROMP)

A second method of using olefin metathesis to prepare polymers is by *acyclic diene metathesis*, or **ADMET**. As the name suggests, ADMET involves olefin metathesis of an open-chain substrate with two double bonds at the ends of a long chain, such as 1,8-nonadiene. As the reaction proceeds, the gaseous ethylene by-product

escapes, thereby driving the equilibrium toward polymer product. So efficient is this reaction that polymers with molecular weights as high as 80,000 amu have been prepared.

Acyclic diene metathesis (ADMET)

The ROMP and ADMET procedures are particularly valuable because the metathesis reaction is compatible with the presence in the olefin monomer of many different functional groups. In addition, the double bonds in the polymers provide still more flexibility for further manipulations. Among the commercial polymers produced by olefin metathesis are Vestenamer, used in the manufacture of tires and other molded rubber objects, and Norsorex, used in the automobile industry as a sealing material.

PROBLEM 31-10 Look at the structures of Vestenamer and Norsorex and show how they might be made by olefin metathesis polymerization.

31.6 Intramolecular Olefin Metathesis

The olefin metathesis reaction has been used primarily as an intermolecular process for polymer synthesis, but it is also finding increased usage in complex organic synthesis as an intramolecular process in what is called ring-closing metathesis (RCM). The optimum catalyst is an Ru(II) complex, and cyclic alkenes with up to 30 atoms in ring size are easily produced.

31.7 Polymer Structure and Physical Properties

Polymers aren't really that different from other organic molecules. They're much larger, of course, but their chemistry is similar to that of analogous small molecules. Thus, the alkane chains of polyethylene undergo radical-initiated halogenation, the aromatic rings of polystyrene undergo typical electrophilic aromatic substitution reactions, and the amide linkages of nylon are hydrolyzed by aqueous base.

The major difference between small and large organic molecules is in their physical properties. For instance, their large size means that polymers experience substantially greater van der Waals forces than do small molecules (Section 2.12). But because van der Waals forces operate only at close distances, they are strongest in polymers like high-density polyethylene, in which chains can pack together closely in a regular way. Many

polymers, in fact, have regions that are essentially crystalline. These regions, called **crystallites**, consist of highly ordered portions in which the zigzag polymer chains are held together by van der Waals forces (**FIGURE 31.4**).

FIGURE 31.4 Crystallites in linear polyethylene. The long polymer chains are arranged in parallel lines in the crystallite regions.

As you might expect, polymer crystallinity is strongly affected by the steric requirements of substituent groups on the chains. Linear polyethylene is highly crystalline, but poly(methyl methacrylate) is noncrystalline because the chains can't pack closely together in a regular way. Polymers with a high degree of crystallinity are generally hard and durable. When heated, the crystalline regions melt at the **melt transition temperature, T_m** , to give an amorphous material.

Noncrystalline, amorphous polymers like poly(methyl methacrylate), sold under the trade name Plexiglas, have little or no long-range ordering among chains but can nevertheless be very hard at room temperature. When heated, the hard amorphous polymer becomes soft and flexible at a point called the **glass transition temperature, T_g** . Much of the art in polymer synthesis lies in finding methods for controlling the degree of crystallinity and the glass transition temperature, thereby imparting useful properties to the polymer.

In general, polymers can be divided into four major categories, depending on their physical behavior: *thermoplastics*, *fibers*, *elastomers*, and *thermosetting resins*. **Thermoplastics** are the polymers most people think of when the word *plastic* is mentioned. These polymers have a high glass transition temperature and are therefore hard at room temperature but become soft and viscous when heated. As a result, they can be molded into toys, beads, telephone housings, or any of a thousand other items. Because thermoplastics have little or no cross-linking, the individual chains can slip past one another in the melt. Some thermoplastic polymers, such as poly(methyl methacrylate) and polystyrene, are amorphous and noncrystalline; others, such as polyethylene and nylon, are partially crystalline. Among the better-known thermoplastics is poly(ethylene terephthalate), or PET, used for making plastic soft-drink bottles.

Plasticizers—small organic molecules that act as lubricants between chains—are usually added to thermoplastics to keep them from becoming brittle at room temperature. An example is poly(vinyl chloride), which is brittle when pure but becomes supple and pliable when a plasticizer is added. In fact, most drip bags used in hospitals to deliver intravenous saline solutions are made of poly(vinyl chloride), although replacements such as polypropylene are appearing.

Dialkyl phthalates such as di(2-ethylhexyl) phthalate (generally called dioctyl phthalate) are commonly used as plasticizers, although questions about their safety have been raised. The U.S. Food and Drug Administration

(FDA) has advised the use of alternative materials in compromised patients and infants but has found no evidence of toxicity for healthy individuals. In addition, children's toys that contain phthalates have been banned in the United States.

Fibers are thin threads produced by extruding a molten polymer through small holes in a die, or spinneret. The fibers are then cooled and drawn out, which orients the crystallite regions along the axis of the fiber and adds considerable tensile strength **FIGURE 31.5**. Nylon, Dacron, and polyethylene all have the semicrystalline structure necessary for being drawn into oriented fibers.

FIGURE 31.5 Oriented crystallite regions in a polymer fiber.

Elastomers are amorphous polymers that have the ability to stretch out and spring back to their original shapes. These polymers must have low glass transition temperatures and a small amount of cross-linking to prevent the chains from slipping over one another. In addition, the chains must have an irregular shape to prevent crystallite formation. When stretched, the randomly coiled chains straighten out and orient along the direction of the pull. Van der Waals forces are too weak and too few to maintain this orientation, however, and the elastomer therefore reverts to its random coiled state when the stretching force is released (**FIGURE 31.6**).

FIGURE 31.6 Unstretched and stretched forms of an elastomer.

Natural rubber (**Section 14.6**) is the most common example of an elastomer. Rubber has the long chains and occasional cross-links needed for elasticity, but its irregular geometry prevents close packing of the chains into crystallites. Gutta-percha, by contrast, is highly crystalline and is not an elastomer (**FIGURE 31.7**).

FIGURE 31.7 (a) Natural rubber is elastic and noncrystalline because of its cis double-bond geometry, but (b) gutta-percha is nonelastic and crystalline because its geometry allows for better packing together of chains.

Thermosetting resins are polymers that become highly cross-linked and solidify into a hard, insoluble mass when heated. Bakelite, a thermosetting resin first produced in 1907, has been in commercial use longer than any other synthetic polymer. It is widely used for molded parts, adhesives, coatings, and even high-temperature applications such as missile nose cones.

Chemically, Bakelite is a *phenolic resin*, produced by reaction of phenol and formaldehyde. On heating, water is eliminated, many cross-links form, and the polymer sets into a rocklike mass. The cross-linking in Bakelite and other thermosetting resins is three-dimensional and is so extensive that we can't really speak of polymer "chains." A piece of Bakelite is essentially one large molecule.

PROBLEM 31-11 What product would you expect to obtain from catalytic hydrogenation of natural rubber? Would the product be syndiotactic, atactic, or isotactic?

PROBLEM 31-12 Propose a mechanism to account for the formation of Bakelite from acid-catalyzed polymerization of phenol and formaldehyde.

CHEMISTRY MATTERS

Degradable Polymers

The high chemical stability of many polymers is both a blessing and a curse. Heat resistance, wear resistance, and long life are valuable characteristics of clothing fibers, bicycle helmets, underground pipes, food wrappers, and many other items. Yet when these items outlive their usefulness, disposal becomes a problem.

FIGURE 31.8 What happens to the plastics that end up here? (credit: modification of work “King of the trash hill” by Alan Levine/Flickr, CC BY 2.0)

Recycling of unwanted polymers is the best solution, and six types of plastics in common use are frequently stamped with identifying codes assigned by the Society of the Plastics Industry **TABLE 31.2**. After being sorted by type, the items to be recycled are shredded into small chips, washed, dried, and melted for reuse. Soft-drink bottles, for instance, are made from recycled poly(ethylene terephthalate), trash bags are made from recycled low-density polyethylene, and garden furniture is made from recycled polypropylene and mixed plastics.

TABLE 31.2 Recyclable Plastics

Polymer	Recycling code	Use
Poly(ethylene terephthalate)	1—PET	Soft-drink bottles
High-density polyethylene	2—HDPE	Bottles
Poly(vinyl chloride)	3—V	Floor mats
Low-density polyethylene	4—LDPE	Grocery bags
Polypropylene	5—PP	Furniture
Polystyrene	6—PS	Molded articles
Mixed plastics	7	Benches, plastic lumber

Frequently, however, plastics are simply thrown away rather than recycled, and much work has therefore been carried out on developing biodegradable polymers, which can be broken down by soil microorganisms. Among the most common biodegradable polymers are polyglycolic acid (PGA), polylactic acid (PLA), and polyhydroxybutyrate (PHB). All are polyesters and are therefore susceptible to hydrolysis of their ester links. Copolymers of PGA with PLA have found a particularly wide range of uses. A 90/10 copolymer of polyglycolic acid with polylactic acid is used to make absorbable sutures that are degraded and absorbed by the body within 90 days after surgery.

Biodegradation is important, but even better than the breakdown of a small group of specialized polymers would be the development of a generalized method of breakdown that could be used on any polymer, including even hydrocarbon polymers such as polyethylene and polypropylene. Such a method has recently been reported by chemists at the University of Delaware, using hydrogen at 200 °C and 2 atm pressure in the presence of an organozirconium catalyst to turn polyethylene into simple hydrocarbons. The method uses a large amount of hydrogen at present, but it is an impressive start.

- **plasticizer**
- **polycarbonate**
- **polymer**
- **polyurethane**
- **syndiotactic polymer**
- **thermoplastic**
- **thermosetting resin**
- **urethane**
- **Ziegler–Natta catalyst**

Summary

Synthetic polymers can be classified as either chain-growth or step-growth. Chain-growth polymers are prepared by chain-reaction polymerization of vinyl monomers in the presence of a radical, an anion, or a cation initiator. Radical polymerization is sometimes used, but alkenes such as 2-methylpropene that have electron-donating substituents on the double bond polymerize easily by a cationic route through carbocation intermediates. Similarly, monomers such as methyl α -cyanoacrylate that have electron-withdrawing substituents on the double bond polymerize by an anionic, conjugate addition pathway.

Copolymerization of two monomers gives a product with properties different from those of either homopolymer. **Graft copolymers** and **block copolymers** are two examples.

Alkene polymerization can be carried out in a controlled manner using a **Ziegler–Natta catalyst**. Ziegler–Natta polymerization minimizes the amount of chain branching in the polymer and leads to stereoregular chains—either **isotactic** (substituents on the same side of the chain) or **syndiotactic** (substituents on alternate sides of the chain), rather than **atactic** (substituents randomly disposed).

Step-growth polymers, the second major class of polymers, are prepared by reactions between difunctional molecules, with individual bonds in the polymer formed independently of one another. **Polycarbonates** are formed from a diester and a diol, and **polyurethanes** are formed from a diisocyanate and a diol.

The chemistry of synthetic polymers is similar to the chemistry of small molecules with the same functional groups, but the physical properties of polymers are greatly affected by size. Polymers can be classified by physical property into four groups: **thermoplastics**, **fibers**, **elastomers**, and **thermosetting resins**. The properties of each group can be accounted for by the structure, the degree of crystallinity, and the amount of cross-linking they contain.

Additional Problems

Visualizing Chemistry

PROBLEM Identify the structural class to which the following polymer belongs, and show the structure of the monomer units used to make it:
31-13

PROBLEM Show the structures of the polymers that could be made from the following monomers (green = Cl):

31-14 (a)

(b)

Mechanism Problems

PROBLEM Poly(ethylene glycol), or Carbowax, is made by anionic polymerization of ethylene oxide using
31-15 NaOH as catalyst. Propose a mechanism.

PROBLEM The polyurethane foam used for home insulation uses methanediphenyldiisocyanate (MDI) as
31-16 monomer. The MDI is prepared by acid-catalyzed reaction of aniline with formaldehyde, followed by treatment with phosgene, COCl_2 . Propose mechanisms for both steps.

PROBLEM Write the structure of a representative segment of polyurethane prepared by reaction of ethylene
31-17 glycol with MDI (Problem 31-16).

PROBLEM The polymeric resin used for Merrifield solid-phase peptide synthesis (Section 26.8) is prepared
31-18 by treating polystyrene with *N*-(hydroxymethyl)phthalimide and trifluoromethanesulfonic acid, followed by reaction with hydrazine. Propose a mechanism for both steps.

PROBLEM 31-19 Polydicyclopentadiene (PDCPD), marketed as Telene or Metton, is a highly cross-linked thermosetting resin used for molding such impact-resistant parts as cabs for large trucks and earth-moving equipment. PDCPD is prepared by ring-opening metathesis polymerization of dicyclopentadiene, which is itself prepared from 1,3-cyclopentadiene. The polymerization occurs by initial metathesis of the more highly strained double bond in the bicyclo[2.2.1]heptane part of the molecule (Section 4.9) to give a linear polymer, followed by cross-linking of different chains in a second metathesis of the remaining cyclopentene double bond.

- Show the mechanism of the formation of dicyclopentadiene from cyclopentadiene.
- Draw the structure of a representative sample of the initially formed linear polymer containing three monomer units.
- Draw the structure of a representative sample of PDCPD that shows how cross-linking of the linear chains takes place.

General Problems

PROBLEM 31-20 Identify the monomer units from which each of the following polymers is made, and tell whether each is a chain-growth or a step-growth polymer:

PROBLEM 31-21 Draw a three-dimensional representation of segments of the following polymers:

- Syndiotactic polyacrylonitrile
- Atactic poly(methyl methacrylate)
- Isotactic poly(vinyl chloride)

PROBLEM 31-22 Draw the structure of Kodel, a polyester prepared by heating dimethyl 1,4-benzenedicarboxylate with 1,4-bis(hydroxymethyl)cyclohexane.

PROBLEM Show the structure of the polymer that results from heating the following diepoxide and diamine:

31-23

PROBLEM Nomex, a polyamide used in such applications as fire-retardant clothing, is prepared by reaction of
31-24 1,3-benzenediamine with 1,3-benzenedicarbonyl chloride. Show the structure of Nomex.

PROBLEM Nylon 10,10 is an extremely tough, strong polymer used to make reinforcing rods for concrete.
31-25 Draw a segment of nylon 10,10, and show its monomer units.

PROBLEM 1,3-Cyclopentadiene undergoes thermal polymerization to yield a polymer that has no double
31-26 bonds in the chain. Upon strong heating, the polymer breaks down to regenerate cyclopentadiene. Propose a structure for the polymer.

PROBLEM When styrene, $C_6H_5CH=CH_2$, is copolymerized in the presence of a few percent *p*-divinylbenzene,
31-27 a hard, insoluble, cross-linked polymer is obtained. Show how this cross-linking of polystyrene chains occurs.

PROBLEM Nitroethylene, $H_2C=CHNO_2$, is a sensitive compound that must be prepared with great care.
31-28 Attempted purification of nitroethylene by distillation often results in low recovery of product and a white coating on the inner walls of the distillation apparatus. Explain.

PROBLEM Poly(vinyl butyral) is used as the plastic laminate in the preparation of automobile windshield safety
31-29 glass. How would you synthesize this polymer?

PROBLEM What is the structure of the polymer produced by anionic polymerization of β -propiolactone using
31-30 NaOH as catalyst?

PROBLEM Glyptal is a highly cross-linked thermosetting resin produced by heating glycerol and phthalic
31-31 anhydride (1,2-benzenedicarboxylic acid anhydride). Show the structure of a representative segment of glyptal.

PROBLEM Melmac, a thermosetting resin often used to make plastic dishes, is prepared by heating melamine
31-32 with formaldehyde. Look at the structure of Bakelite shown in Section 31.7, and then propose a structure for Melmac.

PROBLEM Epoxy adhesives are cross-linked resins prepared in two steps. The first step involves S_N2 reaction
31-33

of the disodium salt of bisphenol A with epichlorohydrin to form a low-molecular-weight prepolymer. This prepolymer is then “cured” into a cross-linked resin by treatment with a triamine such as $\text{H}_2\text{NCH}_2\text{CH}_2\text{NHCH}_2\text{CH}_2\text{NH}_2$.

- (a) What is the structure of the prepolymer?
 (b) How does addition of the triamine to the prepolymer result in cross-linking?

PROBLEM The smoking salons of the Hindenburg and other hydrogen-filled dirigibles of the 1930s were insulated with urea-formaldehyde polymer foams. The structure of this polymer is highly cross-linked, like that of Bakelite (Section 31.7). Propose a structure.

PROBLEM 2-Ethyl-1-hexanol, used in the synthesis of di(2-ethylhexyl) phthalate plasticizer, is made commercially from butanal. Show the likely synthesis route.

APPENDIX A

Nomenclature of Polyfunctional Organic Compounds

With more than 40 million organic compounds now known and thousands more being created daily, naming them all is a real problem. Part of the problem is due to the sheer complexity of organic structures, but part is also due to the fact that chemical names have more than one purpose. For the Chemical Abstracts Service (CAS), which catalogs and indexes the worldwide chemical literature, each compound must have only one correct name. It would be chaos if half the entries for CH_3Br were indexed under “M” for methyl bromide and half under “B” for bromomethane. Furthermore, a CAS name must be strictly systematic so that it can be assigned and interpreted by computers; common names are not allowed.

People, however, have different requirements than computers. For people—which is to say students and professional chemists in their spoken and written communications—it’s best that a chemical name be pronounceable and as easy as possible to assign and interpret. Furthermore, it’s convenient if names follow historical precedents, even if that means a particularly well-known compound might have more than one name. People can readily understand that bromomethane and methyl bromide both refer to CH_3Br .

As noted in the text, chemists overwhelmingly use the nomenclature system devised and maintained by the International Union of Pure and Applied Chemistry, or IUPAC. Rules for naming monofunctional compounds were given throughout the text as each new functional group was introduced, and a list of where these rules can be found is given in **TABLE A1**.

TABLE A1 Nomenclature Rules for Functional Groups

Functional group	Text section
Acid anhydrides	21-1
Acid halides	21-1
Acyl phosphates	21-1
Alcohols	17-1
Aldehydes	19-1
Alkanes	3-4
Alkenes	7-3
Alkyl halides	10-1
Alkynes	9-1
Amides	21-1
Amines	24-1
Aromatic compounds	15-1

TABLE A1 Nomenclature Rules for Functional Groups

Functional group	Text section
Carboxylic acids	20-1
Cycloalkanes	4-1
Esters	21-1
Ethers	18-1
Ketones	19-1
Nitriles	20-1
Phenols	17-1
Sulfides	18-7
Thiols	18-7
Thioesters	21-1

Naming a monofunctional compound is reasonably straightforward, but even experienced chemists often encounter problems when faced with naming a complex polyfunctional compound. Take the following compound, for instance. It has three functional groups, ester, ketone, and C=C, but how should it be named? As an ester with an *-oate* ending, a ketone with an *-one* ending, or an alkene with an *-ene* ending? It's actually named methyl 3-(2-oxo-6-cyclohexenyl)propanoate.

The name of a polyfunctional organic molecule has four parts—suffix, parent, prefixes, and locants—which must be identified and expressed in the proper order and format. Let's look at each of the four.

Name Part 1. The Suffix: Functional-Group Precedence

Although a polyfunctional organic molecule might contain several different functional groups, we must choose just one suffix for nomenclature purposes. It's not correct to use two suffixes. Thus, keto ester **1** must be named either as a ketone with an *-one* suffix or as an ester with an *-oate* suffix, but it can't be named as an *-onoate*. Similarly, amino alcohol **2** must be named either as an alcohol (*-ol*) or as an amine (*-amine*), but it can't be named as an *-olamine* or *-aminol*.

The only exception to the rule requiring a single suffix is when naming compounds that have double or triple bonds. Thus, the unsaturated acid $\text{H}_2\text{C}=\text{CHCH}_2\text{CO}_2\text{H}$ is 3-butenoic acid, and the acetylenic alcohol $\text{HC}\equiv\text{CCH}_2\text{CH}_2\text{CH}_2\text{OH}$ is 5-pentyn-1-ol.

How do we choose which suffix to use? Functional groups are divided into two classes, **principal groups** and **subordinate groups**, as shown in **TABLE A2**. Principal groups can be cited either as prefixes or as suffixes, while subordinate groups are cited only as prefixes. Within the principal groups, an order of priority has been

established: the proper suffix for a given compound is determined by choosing the principal group of highest priority. For example, **TABLE A2** indicates that keto ester **1** should be named as an ester rather than as a ketone because an ester functional group is higher in priority than a ketone. Similarly, amino alcohol **2** should be named as an alcohol rather than as an amine. Thus, the name for **1** is methyl 4-oxopentanoate and the name for **2** is 5-amino-2-pentanol. Further examples are shown:

TABLE A2 Classification of Functional Groups ^a

Functional group	Name as suffix	Name as prefix
Principal groups		
Carboxylic acids	-oic acid	carboxy
	-carboxylic acid	
Acid anhydrides	-oic anhydride	—
	-carboxylic anhydride	
Esters	-oate	alkoxycarbonyl
	-carboxylate	
Thioesters	-thioate	alkylthiocarbonyl
	-carbothioate	
Acid halides	-oyl halide	halocarbonyl
	-carbonyl halide	
Amides	-amide	carbamoyl
	-carboxamide	
Nitriles	-nitrile	cyano
	-carbonitrile	
Aldehydes	-al	oxo
	-carbaldehyde	
Ketones	-one	oxo
Alcohols	-ol	hydroxy
Phenols	-ol	hydroxy
Thiols	-thiol	mercapto

^aPrincipal groups are listed in order of decreasing priority; subordinate groups have no priority order.

TABLE A2 Classification of Functional Groups^a

Functional group	Name as suffix	Name as prefix
Amines	-amine	amino
Imines	-imine	imino
Ethers	ether	alkoxy
Sulfides	sulfide	alkylthio
Disulfides	disulfide	—
Alkenes	-ene	—
Alkynes	-yne	—
Alkanes	-ane	—
Subordinate groups		
Azides	—	azido
Halides	—	halo
Nitro compounds	—	nitro

^aPrincipal groups are listed in order of decreasing priority; subordinate groups have no priority order.

1. Methyl 4-oxopentanoate
(an ester with a ketone group)

2. 5-Amino-2-pentanol
(an alcohol with an amine group)

3. Methyl 5-methyl-6-oxohexanoate
(an ester with an aldehyde group)

4. 5-Carbamoyl-4-hydroxypentanoic acid
(a carboxylic acid with amide and alcohol groups)

5. 3-Oxocyclohexanecarbaldehyde
(an aldehyde with a ketone group)

Name Part 2. The Parent: Selecting the Main Chain or Ring

The parent, or base, name of a polyfunctional organic compound is usually easy to identify. If the principal group of highest priority is part of an open chain, the parent name is that of the longest chain containing the largest number of principal groups. For example, compounds **6** and **7** are isomeric aldehyde amides, which must be named as amides rather than as aldehydes according to TABLE A2. The longest chain in compound

6 has six carbons, and the substance is named 5-methyl-6-oxohexanamide. Compound **7** also has a chain of six carbons, but the longest chain that contains both principal functional groups has only four carbons. Thus, compound **7** is named 4-oxo-3-propylbutanamide.

6. 5-Methyl-6-oxohexanamide

7. 4-Oxo-3-propylbutanamide

If the highest-priority principal group is attached to a ring, the parent name is that of the ring system. Compounds **8** and **9**, for instance, are isomeric keto nitriles and must both be named as nitriles according to **TABLE A2**. Substance **8** is named as a benzonitrile because the $-\text{CN}$ functional group is a substituent on the aromatic ring, but substance **9** is named as an acetonitrile because the $-\text{CN}$ functional group is on an open chain. Thus, their names are 2-acetyl-(4-bromomethyl)benzonitrile (**8**) and (2-acetyl-4-bromophenyl)acetonitrile (**9**). As further examples, compounds **10** and **11** are both keto acids and must be named as acids, but the parent name in **10** is that of a ring system (cyclohexanecarboxylic acid) and the parent name in **11** is that of an open chain (propanoic acid). Thus, their names are *trans*-2-(3-oxopropyl)cyclohexanecarboxylic acid (**10**) and 3-(2-oxocyclohexyl)propanoic acid (**11**).

8. 2-Acetyl-(4-bromomethyl)benzonitrile

9. (2-Acetyl-4-bromophenyl)acetonitrile

10. *trans*-2-(3-oxopropyl)cyclohexanecarboxylic acid

11. 3-(2-Oxocyclohexyl)propanoic acid

Name Parts 3 and 4. The Prefixes and Locants

With the parent name and the suffix established, the next step is to identify and give numbers, or *locants*, to all substituents on the parent chain or ring. The substituents include all alkyl groups and all functional groups other than the one cited in the suffix. For example, compound **12** contains three different functional groups (carboxyl, keto, and double bond). Because the carboxyl group is highest in priority and the longest chain containing the functional groups has seven carbons, compound **12** is a heptenoic acid. In addition, the parent chain has a keto (oxo) substituent and three methyl groups. Numbering from the end nearer the highest-priority functional group gives the name (*E*)-2,5,5-trimethyl-4-oxo-2-heptenoic acid. Look back at some of the other compounds we've named to see other examples of how prefixes and locants are assigned.

12. (*E*)-2,5,5-Trimethyl-4-oxo-2-heptenoic acid

Writing the Name

With the name parts established, the entire name can be written out. Several additional rules apply:

- Order of prefixes.** When the substituents have been identified, the parent chain has been numbered, and the proper multipliers such as *di-* and *tri-* have been assigned, the name is written with the substituents listed in alphabetical, rather than numerical, order. Multipliers such as *di-* and *tri-* are not used for

alphabetization, but the italicized prefixes *iso-* and *sec-* are used.

2. **Use of hyphens; single- and multiple-word names.** The general rule is to determine whether the parent is itself an element or compound. If it is, then the name is written as a single word; if it isn't, then the name is written as multiple words. Methylbenzene is written as one word, for instance, because the parent—benzene—is a compound. Diethyl ether, however, is written as two words because the parent—ether—is a class name rather than a compound name. Some further examples follow:

14. Dimethylmagnesium
(one word, because magnesium is an element)

15. Isopropyl 3-hydroxypropanoate
(two words, because "propanoate" is not a compound)

16. 4-(Dimethylamino)pyridine
(one word, because pyridine is a compound)

17. Methyl cyclopentanecarbothioate
(two words, because "cyclopentanecarbothioate" is not a compound)

3. **Parentheses.** Parentheses are used to denote complex substituents when ambiguity would otherwise arise. For example, chloromethylbenzene has two substituents on a benzene ring, but (chloromethyl)benzene has only one complex substituent. Note that the expression in parentheses is not set off by hyphens from the rest of the name.

18. p-Chloromethylbenzene

19. (Chloromethyl)benzene

20. 2-(1-Methylpropyl)pentanedioic acid

Additional Reading

Further explanations of the rules of organic nomenclature can be found online at **ACD Labs** (<https://www.acdlabs.com/iupac/nomenclature/>) (accessed May 2023) and in the following references:

APPENDIX C

Glossary

- Absolute configuration** (Section 5.5): The exact three-dimensional structure of a chiral molecule. Absolute configurations are specified verbally by the Cahn–Ingold–Prelog *R,S* convention.
- Absorbance (A)** (Section 14.7): In optical spectroscopy, the logarithm of the intensity of the incident light divided by the intensity of the light transmitted through a sample; $A = \log I_0/I$.
- Absorption spectrum** (Section 12.5): A plot of wavelength of incident light versus amount of light absorbed. Organic molecules show absorption spectra in both the infrared and the ultraviolet regions of the electromagnetic spectrum.
- Acetals, R₂C(OR')₂** (Section 19.10): A type of functional group consisting of two –OR groups bonded to the same carbon, R₂C(OR')₂. Acetals are often used as protecting groups for ketones and aldehydes.
- Acetoacetic ester synthesis** (Section 22.7): The synthesis of a methyl ketone by alkylation of an alkyl halide with ethyl acetoacetate, followed by hydrolysis and decarboxylation.
- Acetyl group** (Section 19.1): The CH₃CO– group.
- Acetylide anion** (Section 9.7): The anion formed by removal of a proton from a terminal alkyne, R–C≡C:[−].
- Achiral** (Section 5.2): Having a lack of handedness. A molecule is achiral if it has a plane of symmetry and is thus superimposable on its mirror image.
- Acid anhydrides** (Chapter 21 Introduction): A type of functional group with two acyl groups bonded to a common oxygen atom, RCO₂COR'.
- Acid halides** (Chapter 21 Introduction): A type of functional group with an acyl group bonded to a halogen atom, RCOX.
- Acidity constant, K_a** (Section 2.8): A measure of acid strength. For any acid HA, the acidity constant is given by the expression
$$K_a = \frac{[H_3O^+][A^-]}{[HA]}$$
- Activating groups** (Section 16.4): Electron-donating groups such as hydroxyl (–OH) or amino (–NH₂) that increase the reactivity of an aromatic ring toward electrophilic aromatic substitution.
- Activation energy** (Section 6.9): The difference in energy between ground state and transition state in a reaction. The amount of activation energy determines the rate at which the reaction proceeds. Most organic reactions have activation energies of 40–100 kJ/mol.
- Active site** (Section 6.11, Section 26.11): The pocket in an enzyme where a substrate is bound and undergoes reaction.
- Acyclic diene metathesis (ADMET)** (Section 31.5): A method of polymer synthesis that uses the olefin metathesis reaction of an open-chain diene.
- Acyl group** (Section 16.3, Section 19.1): A –COR group.
- Acyl phosphates** (Chapter 21 Introduction): A type of functional group with an acyl group bonded to a phosphate, RCO₂PO₃^{2−}.
- Acylation** (Section 16.3, Section 24.7): The introduction of an acyl group, –COR, onto a molecule. For example, acylation of an alcohol yields an ester, acylation of an amine yields an amide, and acylation of an aromatic ring yields an alkyl aryl ketone.
- Acylium ion** (Section 16.3): A resonance-stabilized carbocation in which the positive charge is located at a carbonyl-group carbon, R–C=O⁺ ↔ R–C≡O⁺. Acylium ions are intermediates in Friedel–Crafts acylation reactions.
- Adams' catalyst** (Section 6.11): The PtO₂ catalyst used for alkene hydrogenations.
- 1,2-Addition** (Section 14.2, Section 19.13): Addition of a reactant to the two ends of a double bond.
- 1,4-Addition** (Section 14.2, Section 19.13): Addition of a reactant to the ends of a conjugated π system. Conjugated dienes yield 1,4 adducts when treated with electrophiles such as HCl. Conjugated enones yield 1,4 adducts when treated with nucleophiles such as amines.
- Addition reactions** (Section 6.1): Occur when two reactants add together to form a single product with no atoms left over.
- Adrenocortical hormones** (Section 27.6): Steroid hormones secreted by the adrenal glands. There are two types of these hormones: mineralocorticoids and glucocorticoids.
- Alcohols** (Section 3.1, Chapter 17 Introduction): A class of compounds with an –OH group bonded to a saturated, sp³-hybridized carbon, ROH.
- Aldaric acid** (Section 25.6): The dicarboxylic acid resulting from oxidation of an aldose.
- Aldehydes (RCHO)** (Section 3.1, Chapter 19 Introduction): A class of compounds containing the –CHO functional group.
- Alditol** (Section 25.6): The polyalcohol resulting from reduction of the carbonyl group of a sugar.
- Aldol reaction** (Section 23.1): The carbonyl condensation reaction of an aldehyde or ketone to give a β-hydroxy carbonyl compound.
- Aldonic acids** (Section 25.6): Monocarboxylic acids resulting from oxidation of the –CHO group of an aldose.
- Aldoses** (Section 25.1): A type of carbohydrate with an aldehyde functional group.
- Alicyclic** (Section 4.1): A nonaromatic cyclic hydrocarbon such as a cycloalkane or cycloalkene.
- Aliphatic** (Section 3.2): A nonaromatic hydrocarbon such as a simple alkane, alkene, or alkyne.

- Alkaloids (Chapter 2 Chemistry Matters):** Naturally occurring organic bases, such as morphine.
- Alkanes (Section 3.2):** A class of compounds of carbon and hydrogen that contains only single bonds.
- Alkene (Section 3.1, Chapter 7 Introduction):** A hydrocarbon that contains a carbon–carbon double bond, $R_2C=CR_2$.
- Alkoxide ion, RO^- (Section 17.2):** The anion formed by deprotonation of an alcohol.
- Alkoxymercuration (Section 18.2):** A method for synthesizing ethers by mercuric-ion catalyzed addition of an alcohol to an alkene followed by demercuration on treatment with $NaBH_4$.
- Alkyl group (Section 3.3):** The partial structure that remains when a hydrogen atom is removed from an alkane.
- Alkyl halide (Section 3.1, Chapter 10 Introduction):** A compound with a halogen atom bonded to a saturated, sp^3 -hybridized carbon atom.
- Alkylamines (Section 24.1):** Amino-substituted alkanes RNH_2 , R_2NH , or R_3N .
- Alkylation (Section 9.8, Section 16.3, Section 18.2, Section 22.7):** Introduction of an alkyl group onto a molecule. For example, aromatic rings can be alkylated to yield arenes, and enolate anions can be alkylated to yield α -substituted carbonyl compounds.
- Alkyne (Section 3.1, Chapter 9 Introduction):** A hydrocarbon that contains a carbon–carbon triple bond, $RC\equiv CR$.
- Allyl group (Section 7.3):** A $H_2C=CHCH_2-$ substituent.
- Allylic (Section 10.3):** The position next to a double bond. For example, $H_2C=CHCH_2Br$ is an allylic bromide.
- α -Amino acids (Section 26.1):** A type of difunctional compound with an amino group on the carbon atom next to a carboxyl group, $RCH(NH_2)CO_2H$.
- α Anomer (Section 25.5):** The cyclic hemiacetal form of a sugar that has the hemiacetal $-OH$ group cis to the $-OH$ at the lowest chirality center in a Fischer projection.
- α Helix (Section 26.9):** The coiled secondary structure of a protein.
- α Position (Chapter 22 Introduction):** The position next to a carbonyl group.
- α -Substitution reaction (Chapter 22 Introduction):** The substitution of the α hydrogen atom of a carbonyl compound by reaction with an electrophile.
- Amides (Section 3.1, Chapter 21 Introduction):** A class of compounds containing the $-CONR_2$ functional group.
- Amidomalonate synthesis (Section 26.3):** A method for preparing α -amino acids by alkylation of diethyl amidomalonate with an alkyl halide followed by deprotection and decarboxylation.
- Amines (Section 3.1, Chapter 24 Introduction):** A class of compounds containing one or more organic substituents bonded to a nitrogen atom, RNH_2 , R_2NH , or R_3N .
- Amino acid (Section 26.1):** See α -Amino acid.
- Amino sugar (Section 25.7):** A sugar with one of its $-OH$ groups replaced by $-NH_2$.
- Amphiprotic (Section 26.1):** Capable of acting either as an acid or as a base. Amino acids are amphiprotic.
- Amplitude (Section 12.5):** The height of a wave measured from the midpoint to the maximum. The intensity of radiant energy is proportional to the square of the wave's amplitude.
- Anabolic steroids (Section 27.6):** Synthetic androgens that mimic the tissue-building effects of natural testosterone.
- Anabolism (Section 29.1):** The group of metabolic pathways that build up larger molecules from smaller ones.
- Androgen (Section 27.6):** A male steroid sex hormone.
- Angle strain (Section 4.3):** The strain introduced into a molecule when a bond angle is deformed from its ideal value. Angle strain is particularly important in small-ring cycloalkanes, where it results from compression of bond angles to less than their ideal tetrahedral values.
- Annulation (Section 23.12):** The building of a new ring onto an existing molecule.
- Anomeric center (Section 25.5):** The hemiacetal carbon atom in the cyclic pyranose or furanose form of a sugar.
- Anomers (Section 25.5):** Cyclic stereoisomers of sugars that differ only in their configuration at the hemiacetal (anomeric) carbon.
- Antarafacial (Section 30.5):** A pericyclic reaction that takes place on opposite faces of the two ends of a π electron system.
- Anti conformation (Section 3.7):** The geometric arrangement around a carbon–carbon single bond in which the two largest substituents are 180° apart as viewed in a Newman projection.
- Anti periplanar (Section 11.8):** Describing the stereochemical relationship in which two bonds on adjacent carbons lie in the same plane at an angle of 180° .
- Anti stereochemistry (Section 8.2):** The opposite of syn. An anti addition reaction is one in which the two ends of the double bond are attacked from different sides. An anti elimination reaction is one in which the two groups leave from opposite sides of the molecule.
- Antiaromatic (Section 15.3):** Referring to a planar, conjugated molecule with $4n$ π electrons. Delocalization of the π electrons leads to an increase in energy.
- Antibonding MO (Section 1.11):** A molecular orbital that is higher in energy than the atomic orbitals from which it is formed.
- Anticodon (Section 28.5):** A sequence of three bases on tRNA that reads the codons on mRNA and brings the correct amino acids into position for protein synthesis.
- Antisense strand (Section 28.4):** The template, noncoding strand of double-helical DNA that does not contain the gene.
- Arene (Section 15.1):** An alkyl-substituted benzene.
- Arenediazonium salt (Section 24.8):** An aromatic compound $Ar-\overset{+}{N}\equiv N X^-$; used in the Sandmeyer reaction.
- Aromaticity (Chapter 15 Introduction):** The special characteristics of cyclic conjugated molecules, including unusual stability and a tendency to undergo substitution reactions rather than addition reactions on treatment with

electrophiles. Aromatic molecules are planar, cyclic, conjugated species with $4n + 2\pi$ electrons.

Arylamines (Section 24.1): Amino-substituted aromatic compounds, ArNH_2 .

Atactic (Section 31.2): A chain-growth polymer in which the stereochemistry of the substituents is oriented randomly along the backbone.

Atomic mass (Section 1.1): The weighted average mass of an element's naturally occurring isotopes.

Atomic number, Z (Section 1.1): The number of protons in the nucleus of an atom.

ATZ Derivative (Section 26.6): An anilinothiazolinone, formed from an amino acid during Edman degradation of a peptide.

Aufbau principle (Section 1.3): The rules for determining the electron configuration of an atom.

Axial bonds (Section 4.6): Bonds or positions in chair cyclohexane that lie along the ring axis, perpendicular to the rough plane of the ring.

Azide synthesis (Section 24.6): A method for preparing amines by $\text{S}_{\text{N}}2$ reaction of an alkyl halide with azide ion, followed by reduction.

Azo compounds (Section 24.8): A class of compounds with the general structure $\text{R}-\text{N}=\text{N}-\text{R}'$.

Backbone (Section 26.4): The continuous chain of atoms running the length of a protein or other polymer.

Base peak (Section 12.1): The most intense peak in a mass spectrum.

Basicity constant, K_{b} (Section 24.3): A measure of base strength in water. For any base B, the basicity constant is given

Bent bonds (Section 4.4): The bonds in small rings such as cyclopropane that bend away from the internuclear line and overlap at a slight angle, rather than head-on. Bent bonds are highly strained and highly reactive.

Benzoyl (Section 19.1): The $\text{C}_6\text{H}_5\text{CO}-$ group.

Benzyl (Section 15.1): The $\text{C}_6\text{H}_5\text{CH}_2-$ group.

Benzylic (Section 11.5): The position next to an aromatic ring.

Benzynes (Section 16.7): An unstable compound having a triple bond in a benzene ring.

β Anomer (Section 25.5): The cyclic hemiacetal form of a sugar that has the hemiacetal $-\text{OH}$ group trans to the $-\text{OH}$ at the lowest chirality center in a Fischer projection.

β Diketone (Section 22.5): A 1,3-diketone.

β -Keto ester (Section 22.5): A 3-oxoester.

β Lactam (Chapter 21 *Chemistry Matters*): A four-membered lactam, or cyclic amide. Penicillin and cephalosporin antibiotics contain β -lactam rings.

β -Oxidation pathway (Section 29.3): The metabolic pathway for degrading fatty acids.

β -Pleated sheet (Section 26.9): A type of secondary structure of a protein.

Betaine (Section 19.11): A neutral dipolar molecule with

nonadjacent positive and negative charges. For example, the adduct of a Wittig reagent with a carbonyl compound is a betaine.

Bicycloalkane (Section 4.9): A cycloalkane that contains two rings.

Bimolecular reaction (Section 11.2): A reaction whose rate-limiting step occurs between two reactants.

Block copolymers (Section 31.3): Polymers in which different blocks of identical monomer units alternate with one another.

Boat cyclohexane (Section 4.5): A conformation of cyclohexane that bears a slight resemblance to a boat. Boat cyclohexane has no angle strain but has a large number of eclipsing interactions that make it less stable than chair cyclohexane.

Boc derivative (Section 26.7): A butyloxycarbonyl N-protected amino acid.

Bond angle (Section 1.6): The angle formed between two adjacent bonds.

Bond dissociation energy, D (Section 6.8): The amount of energy needed to break a bond and produce two radical fragments.

Bond length (Section 1.5): The equilibrium distance between the nuclei of two atoms that are bonded to each other.

Bond strength (Section 1.5): An alternative name for bond dissociation energy.

Bonding MO (Section 1.11): A molecular orbital that is lower in energy than the atomic orbitals from which it is formed.

Branched-chain alkanes (Section 3.2): Alkanes that contain a branching connection of carbons as opposed to straight-chain alkanes.

Bridgehead (Section 4.9): An atom that is shared by more than one ring in a polycyclic molecule.

Bromohydrin (Section 8.3): A 1,2-bromoalcohol; obtained by addition of HOBr to an alkene.

Bromonium ion (Section 8.2): A species with a divalent, positively charged bromine, R_2Br^+ .

Brønsted-Lowry acid (Section 2.7): A substance that donates a hydrogen ion (proton; H^+) to a base.

Brønsted-Lowry base (Section 2.7): A substance that accepts H^+ from an acid.

C-terminal amino acid (Section 26.4): The amino acid with a free $-\text{CO}_2\text{H}$ group at the end of a protein chain.

Cahn-Ingold-Prelog sequence rules (Section 5.5, Section 7.5): A series of rules for assigning relative rankings to substituent groups on a chirality center or a double-bond carbon atom.

Cannizzaro reaction (Section 19.12): The disproportionation reaction of an aldehyde on treatment with base to yield an alcohol and a carboxylic acid.

Carbanion (Section 10.6, Section 19.7): A carbon anion, or substance that contains a trivalent, negatively charged carbon atom (R_3C^-). Alkyl carbanions are sp^3 -hybridized and have eight electrons in the outer shell of the negatively charged carbon.

Carbene, R_2C (Section 8.9): A neutral substance that contains a divalent carbon atom having only six electrons in its outer shell ($R_2C:$).

Carbinolamine (Section 19.8): A molecule that contains the $R_2C(OH)NH_2$ functional group. Carbinolamines are produced as intermediates during the nucleophilic addition of amines to carbonyl compounds.

Carbocation (Section 6.4, Section 7.9): A carbon cation, or substance that contains a trivalent, positively charged carbon atom having six electrons in its outer shell (R_3C^+).

Carbohydrates (Chapter 25 Introduction): Polyhydroxy aldehydes or ketones. Carbohydrates can be either simple sugars, such as glucose, or complex sugars, such as cellulose.

Carbonyl condensation reactions (Section 23.1): A type of reaction that joins two carbonyl compounds together by a combination of α -substitution and nucleophilic addition reactions.

Carbonyl group (Section 3.1, Preview of Carbonyl Chemistry): The $C=O$ functional group.

Carboxyl group (Section 20.1): The $-CO_2H$ functional group.

Carboxylation (Section 20.5): The addition of CO_2 to a molecule.

Carboxylic acids, RCO_2H (Section 3.1, Chapter 20 Introduction): Compounds containing the $-CO_2H$ functional group.

Carboxylic acid derivative (Chapter 21 Introduction): A compound in which an acyl group is bonded to an electronegative atom or substituent that can act as a leaving group in a substitution reaction. Esters, amides, and acid halides are examples.

Catabolism (Section 29.1): The group of metabolic pathways that break down larger molecules into smaller ones.

Catalyst (Section 6.11): A substance that increases the rate of a chemical transformation by providing an alternative mechanism but is not itself changed in the reaction.

Cation radical (Section 12.1): A reactive species, typically formed in a mass spectrometer by loss of an electron from a neutral molecule and having both a positive charge and an odd number of electrons.

Chain-growth polymers (Section 8.10, Section 21.9, Section 31.1): Polymers whose bonds are produced by chain reaction mechanisms. Polyethylene and other alkene polymers are examples.

Chain reaction (Section 6.6): A reaction that, once initiated, sustains itself in an endlessly repeating cycle of propagation steps. The radical chlorination of alkanes is an example of a chain reaction that is initiated by irradiation with light and then continues in a series of propagation steps.

Chair conformation (Section 4.5): A three-dimensional conformation of cyclohexane that resembles the rough shape of a chair. The chair form of cyclohexane is the lowest-energy conformation of the molecule.

Chemical shift (Section 13.3): The position on the NMR chart

where a nucleus absorbs. By convention, the chemical shift of tetramethylsilane (TMS) is set at zero, and all other absorptions usually occur downfield (to the left on the chart). Chemical shifts are expressed in delta units (δ), where 1 δ equals 1 ppm of the spectrometer operating frequency.

Chiral (Section 5.2): Having handedness. Chiral molecules are those that do not have a plane of symmetry and are therefore not superimposable on their mirror image. A chiral molecule thus exists in two forms, one right-handed and one left-handed. The most common cause of chirality in a molecule is the presence of a carbon atom that is bonded to four different substituents.

Chiral environment (Section 5.12): The chiral surroundings or conditions in which a molecule resides.

Chirality center (Section 5.2): An atom (usually carbon) that is bonded to four different groups.

Chlorohydrin (Section 8.3): A 1,2-chloroalcohol; obtained by addition of $HOCl$ to an alkene.

Chromatography (Section 26.5): A technique for separating a mixture of compounds into pure components. Different compounds adsorb to a stationary support phase and are then carried along it at different rates by a mobile phase.

Cis-trans isomers (Section 4.2, Section 7.4): Stereoisomers that differ in their stereochemistry about a ring or double bond.

Citric acid cycle (Section 29.7): The metabolic pathway by which acetyl CoA is degraded to CO_2 .

Claisen condensation reaction (Section 23.7): The carbonyl condensation reaction of two ester molecules to give a β -keto ester product.

Claisen rearrangement (Section 30.8): The pericyclic conversion of an allyl phenyl ether to an *o*-allylphenol or an allyl vinyl ether to a γ,δ -unsaturated ketone by heating.

Coding strand (Section 28.4): The sense strand of double-helical DNA that contains the gene.

Codon (Section 28.5): A three-base sequence on a messenger RNA chain that encodes the genetic information necessary to cause a specific amino acid to be incorporated into a protein. Codons on mRNA are read by complementary anticodons on tRNA.

Coenzyme (Section 26.10): A small organic molecule that acts as a cofactor in a biological reaction.

Cofactor (Section 26.10): A small nonprotein part of an enzyme that is necessary for biological activity.

Combinatorial chemistry (Chapter 16 Chemistry Matters): A procedure in which anywhere from a few dozen to several hundred thousand substances are prepared simultaneously.

Complex carbohydrates (Section 25.1): Carbohydrates that are made of two or more simple sugars linked together by glycoside bonds.

Concerted reaction (Chapter 30 Introduction): A reaction that takes place in a single step without intermediates. For example, the Diels-Alder cycloaddition reaction is a concerted process.

Condensed structures (Section 1.12): A shorthand way of

writing structures in which carbon–hydrogen and carbon–carbon bonds are understood rather than shown explicitly. Propane, for example, has the condensed structure $\text{CH}_3\text{CH}_2\text{CH}_3$.

- Configuration (Section 5.5):** The three-dimensional arrangement of atoms bonded to a chirality center.
- Conformations (Section 3.6):** The three-dimensional shape of a molecule at any given instant, assuming that rotation around single bonds is frozen.
- Conformational analysis (Section 4.8):** A means of assessing the energy of a substituted cycloalkane by totaling the steric interactions present in the molecule.
- Conformers (Section 3.6):** Conformational isomers.
- Conjugate acid (Section 2.7):** The product that results from protonation of a Brønsted–Lowry base.
- Conjugate addition (Section 19.13):** Addition of a nucleophile to the β carbon atom of an α,β -unsaturated carbonyl compound.
- Conjugate base (Section 2.7):** The product that results from deprotonation of a Brønsted–Lowry acid.
- Conjugation (Chapter 14 Introduction):** A series of overlapping p orbitals, usually in alternating single and multiple bonds. For example, 1,3-butadiene is a conjugated diene, 3-buten-2-one is a conjugated enone, and benzene is a cyclic conjugated triene.
- Conrotatory (Section 30.2):** A term used to indicate that p orbitals must rotate in the same direction during electrocyclic ring-opening or ring-closure.
- Constitutional isomers (Section 3.2, Section 3.6, Section 5.9):** Isomers that have their atoms connected in a different order. For example, butane and 2-methylpropane are constitutional isomers.
- Cope rearrangement (Section 30.8):** The sigmatropic rearrangement of a 1,5-hexadiene.
- Copolymers (Section 31.3):** Polymers obtained when two or more different monomers are allowed to polymerize together.
- Coupled reactions (Section 29.1):** Two reactions that share a common intermediate so that the energy released in the favorable step allows the unfavorable step to occur.
- Coupling constant, J (Section 13.6):** The magnitude (expressed in hertz) of the interaction between nuclei whose spins are coupled.
- Covalent bond (Section 1.4, Section 1.5):** A bond formed by sharing electrons between atoms.
- Cracking (Chapter 3 Chemistry Matters):** A process used in petroleum refining in which large alkanes are thermally cracked into smaller fragments.
- Crown ethers (Section 18.6):** Large-ring polyethers; used as phase-transfer catalysts.
- Crystallites (Section 31.7):** Highly ordered crystal-like regions within a long polymer chain.
- Curtius rearrangement (Section 24.6):** The conversion of an acid chloride into an amine by reaction with azide ion, followed by heating with water.
- Cyanohydrins (Section 19.6):** A class of compounds with an $-\text{OH}$ group and a $-\text{CN}$ group bonded to the same carbon atom; formed by addition of HCN to an aldehyde or ketone.
- Cycloaddition reaction (Section 14.4, Section 30.5):** A pericyclic reaction in which two reactants add together in a single step to yield a cyclic product. The Diels–Alder reaction between a diene and a dienophile to give a cyclohexene is an example.
- Cycloalkane (Section 4.1):** An alkane that contains a ring of carbons.
- D Sugars (Section 25.3):** Sugars whose hydroxyl group at the chirality center farthest from the carbonyl group has the same configuration as D-glyceraldehyde and points to the right when drawn in Fischer projection.
- d,l* form (Section 5.8):** The racemic mixture of a chiral compound.
- Deactivating groups (Section 16.4):** Electron-withdrawing substituents that decrease the reactivity of an aromatic ring toward electrophilic aromatic substitution.
- Deamination (Section 29.9):** The removal of an amino group from a molecule, as occurs with amino acids during metabolic degradation.
- Debyes (D) (Section 2.2):** Units for measuring dipole moments; $1 \text{ D} = 3.336 \times 10^{-30}$ coulomb meter ($\text{C} \cdot \text{m}$).
- Decarboxylation (Section 22.7):** The loss of carbon dioxide from a molecule. β -Keto acids decarboxylate readily on heating.
- Degenerate orbitals (Section 15.2):** Two or more orbitals that have the same energy level.
- Degree of unsaturation (Section 7.2):** The number of rings and/or multiple bonds in a molecule.
- Dehydration (Section 8.1, Section 12.3, Section 17.6):** The loss of water from an alcohol to yield an alkene.
- Dehydrohalogenation (Section 8.1, Section 9.2):** The loss of HX from an alkyl halide. Alkyl halides undergo dehydrohalogenation to yield alkenes on treatment with strong base.
- Delocalization (Section 10.4, Section 15.2):** A spreading out of electron density over a conjugated π electron system. For example, allylic cations and allylic anions are delocalized because their charges are spread out over the entire π electron system. Aromatic compounds have $4n + 2$ π electrons delocalized over their ring.
- Delta (δ) scale (Section 13.3):** An arbitrary scale used to calibrate NMR charts. One delta unit (δ) is equal to 1 part per million (ppm) of the spectrometer operating frequency.
- Denatured (Section 26.9):** The physical changes that occur in a protein when secondary and tertiary structures are disrupted.
- Deoxy sugar (Section 25.7):** A sugar with one of its $-\text{OH}$ groups replaced by an $-\text{H}$.
- Deoxyribonucleic acid (DNA) (Chapter 28 Introduction):** The biopolymer consisting of deoxyribonucleotide units linked together through phosphate–sugar bonds. Found in the nucleus of cells, DNA contains an organism's genetic

information.

DEPT-NMR (Section 13.12): An NMR method for distinguishing among signals due to CH_3 , CH_2 , CH , and quaternary carbons. That is, the number of hydrogens attached to each carbon can be determined.

Deshielding (Section 13.2): An effect observed in NMR that causes a nucleus to absorb toward the left (downfield) side of the chart. Deshielding is caused by a withdrawal of electron density from the nucleus.

Dess–Martin periodinane (Section 17.7): An iodine-based reagent commonly used for the laboratory oxidation of a primary alcohol to an aldehyde or a secondary alcohol to a ketone.

Deuterium isotope effect (Section 11.8): A tool used in mechanistic investigations to establish whether a C–H bond is broken in the rate-limiting step of a reaction.

Dextrorotatory (Section 5.3): A word used to describe an optically active substance that rotates the plane of polarization of plane-polarized light in a right-handed (clockwise) direction.

Diastereomers (Section 5.6): Non-mirror-image stereoisomers; diastereomers have the same configuration at one or more chirality centers but differ at other chirality centers.

Diastereotopic (Section 13.7): Hydrogens in a molecule whose replacement by some other group leads to different diastereomers.

1,3-Diaxial interaction (Section 4.7): The strain energy caused by a steric interaction between axial groups three carbon atoms apart in chair cyclohexane.

Diazonium salts (Section 24.8): A type of compound with the general structure $\text{RN}_2^+ \text{X}^-$.

Diazotization (Section 24.8): The conversion of a primary amine, RNH_2 , into a diazonium ion, RN_2^+ , by treatment with nitrous acid.

Dieckmann cyclization reaction (Section 23.9): An intramolecular Claisen condensation reaction of a diester to give a cyclic β -keto ester.

Diels–Alder reaction (Section 14.4, Section 30.5): The cycloaddition reaction of a diene with a dienophile to yield a cyclohexene.

Dienophile (Section 14.5): A compound containing a double bond that can take part in the Diels–Alder cycloaddition reaction. The most reactive dienophiles are those that have electron-withdrawing groups on the double bond.

Digestion (Section 29.1): The first stage of catabolism, in which food is broken down by hydrolysis of ester, glycoside (acetal), and peptide (amide) bonds to yield fatty acids, simple sugars, and amino acids.

Dihedral angle (Section 3.6): The angle between two bonds on adjacent carbons as viewed along the C–C bond.

Dipole moment, μ (Section 2.2): A measure of the net polarity of a molecule. A dipole moment arises when the centers of mass of positive and negative charges within a molecule do not

coincide.

Dipole–dipole forces (Section 2.12): Noncovalent electrostatic interactions between dipolar molecules.

Disaccharide (Section 25.8): A carbohydrate formed by linking two simple sugars through an acetal bond.

Dispersion forces (Section 2.12): Noncovalent interactions between molecules that arise because of constantly changing electron distributions within the molecules.

Disrotatory (Section 30.2): A term used to indicate that p orbitals rotate in opposite directions during electrocyclic ring-opening or ring-closing reactions.

Disulfides (RSSR') (Section 18.7): A class of compounds of the general structure RSSR' .

Deoxyribonucleic acid (DNA) (Chapter 28 Introduction): Chemical carriers of a cell's genetic information.

Double bond (Section 1.8): A covalent bond formed by sharing two electron pairs between atoms.

Double helix (Section 28.2): The structure of DNA in which two polynucleotide strands coil around each other.

Doublet (Section 13.6): A two-line NMR absorption caused by spin–spin splitting when the spin of the nucleus under observation couples with the spin of a neighboring magnetic nucleus.

Downfield (Section 13.3): Referring to the left-hand portion of the NMR chart.

E geometry (Section 7.5): A term used to describe the stereochemistry of a carbon–carbon double bond. The two groups on each carbon are ranked according to the Cahn–Ingold–Prelog sequence rules, and the two carbons are compared. If the higher-ranked groups on each carbon are on opposite sides of the double bond, the bond has *E* geometry.

E1 reaction (Section 11.10): A unimolecular elimination reaction in which the substrate spontaneously dissociates to give a carbocation intermediate, which loses a proton in a separate step.

E1cB reaction (Section 11.10): A unimolecular elimination reaction in which a proton is first removed to give a carbanion intermediate, which then expels the leaving group in a separate step.

E2 reaction (Section 11.8): A bimolecular elimination reaction in which C–H and C–X bond cleavages are simultaneous.

Eclipsed conformation (Section 3.6): The geometric arrangement around a carbon–carbon single bond in which the bonds to substituents on one carbon are parallel to the bonds to substituents on the neighboring carbon as viewed in a Newman projection.

Eclipsing strain (Section 3.6): The strain energy in a molecule caused by electron repulsions between eclipsed bonds. Eclipsing strain is also called torsional strain.

Edman degradation (Section 26.6): A method for N-terminal sequencing of peptide chains by treatment with *N*-phenylisothiocyanate.

Eicosanoid (Section 27.4): A lipid derived biologically from

- 5,8,11,14-eicosatetraenoic acid, or arachidonic acid. Prostaglandins, thromboxanes, and leukotrienes are examples.
- Elastomer (Section 31.7):** An amorphous polymer that has the ability to stretch out and spring back to its original shape.
- Electrocyclic reaction (Section 30.2):** A unimolecular pericyclic reaction in which a ring is formed or broken by a concerted reorganization of electrons through a cyclic transition state. For example, the cyclization of 1,3,5-hexatriene to yield 1,3-cyclohexadiene is an electrocyclic reaction.
- Electromagnetic spectrum (Section 12.5):** The range of electromagnetic energy, including infrared, ultraviolet, and visible radiation.
- Electron configuration (Section 1.3):** A list of the orbitals occupied by electrons in an atom.
- Electron-dot structure (Section 1.4):** A representation of a molecule showing valence electrons as dots.
- Electron shells (Section 1.2):** A group of an atom's electrons with the same principal quantum number.
- Electron-transport chain (Section 29.1):** The final stage of catabolism in which ATP is produced.
- Electronegativity (EN) (Section 2.1):** The ability of an atom to attract electrons in a covalent bond. Electronegativity increases across the periodic table from left to right and from bottom to top.
- Electrophile (Section 6.3, Section 6.4):** An "electron-lover," or substance that accepts an electron pair from a nucleophile in a polar bond-forming reaction.
- Electrophilic addition reactions (Section 7.7):** Addition of an electrophile to a carbon-carbon double bond to yield a saturated product.
- Electrophilic aromatic substitution reaction (Chapter 16 Introduction):** A reaction in which an electrophile (E^+) reacts with an aromatic ring and substitutes for one of the ring hydrogens.
- Electrophoresis (Section 26.2, Section 28.6):** A technique used for separating charged organic molecules, particularly proteins and DNA fragments. The mixture to be separated is placed on a buffered gel or paper, and an electric potential is applied across the ends of the apparatus. Negatively charged molecules migrate toward the positive electrode, and positively charged molecules migrate toward the negative electrode.
- Electrostatic potential maps (Section 2.1):** Molecular representations that use color to indicate the charge distribution in molecules as derived from quantum-mechanical calculations.
- Elimination reactions (Section 6.1):** What occurs when a single reactant splits into two products.
- Elution (Section 26.5):** The passage of a substance from a chromatography column.
- Emden-Meyerhof pathway (Section 29.5):** An alternative name for glycolysis.
- Enamines (Section 19.8):** Compounds with the $R_2N-CR=CR_2$ functional group.
- Enantiomers (Section 5.1):** Stereoisomers of a chiral substance that have a mirror-image relationship. Enantiomers have opposite configurations at all chirality centers.
- Enantioselective synthesis (Chapter 19 Chemistry Matters):** A reaction method that yields only a single enantiomer of a chiral product starting from an achiral reactant.
- Enantiotopic (Section 13.7):** Hydrogens in a molecule whose replacement by some other group leads to different enantiomers.
- 3' End (Section 28.1):** The end of a nucleic acid chain with a free hydroxyl group at C3'.
- 5' End (Section 28.1):** The end of a nucleic acid chain with a free hydroxyl group at C5'.
- Endergonic (Section 6.7):** A reaction that has a positive free-energy change and is therefore nonspontaneous. In an energy diagram, the product of an endergonic reaction has a higher energy level than the reactants.
- Endo (Section 14.5):** A term indicating the stereochemistry of a substituent in a bridged bicycloalkane. An endo substituent is syn to the larger of the two bridges.
- Endothermic (Section 6.7):** A reaction that absorbs heat and therefore has a positive enthalpy change.
- Energy diagram (Section 6.9):** A representation of the course of a reaction, in which free energy is plotted as a function of reaction progress. Reactants, transition states, intermediates, and products are represented, and their appropriate energy levels are indicated.
- Enol (Section 9.4, Section 22.1):** A vinylic alcohol that is in equilibrium with a carbonyl compound, $C=C-OH$.
- Enolate ion (Section 22.1):** The anion of an enol, $C=C-O^-$.
- Enthalpy change (ΔH) (Section 6.7):** The heat of reaction. The enthalpy change that occurs during a reaction is a measure of the difference in total bond energy between reactants and products.
- Entropy change (ΔS) (Section 6.7):** The change in amount of molecular randomness. The entropy change that occurs during a reaction is a measure of the difference in randomness between reactants and products.
- Enzyme (Section 6.11, Section 26.10):** A biological catalyst. Enzymes are large proteins that catalyze specific biochemical reactions.
- Epimers (Section 5.6):** Diastereomers that differ in configuration at only one chirality center but are the same at all others.
- Epoxyde (Section 8.7):** A three-membered-ring ether functional group.
- Equatorial bonds (Section 4.6):** Bonds or positions in chair cyclohexane that lie along the rough equator of the ring.
- ESI (Section 12.4):** Electrospray ionization; a "soft" ionization method used for mass spectrometry of biological samples of very high molecular weight.
- Essential amino acid (Section 26.1):** One of nine amino acids

that are biosynthesized only in plants and microorganisms and must be obtained by humans in the diet.

Essential monosaccharide (Section 25.7): One of eight simple sugars that is best obtained in the diet rather than by biosynthesis.

Essential oil (Chapter 8 Chemistry Matters): The volatile oil obtained by steam distillation of a plant extract.

Esters (Section 3.1, Chapter 21 Introduction): A class of compounds containing the $-\text{CO}_2\text{R}$ functional group.

Estrogens (Section 27.6): Female steroid sex hormones.

Ethers (Section 3.1, Chapter 18 Introduction): A class of compounds that has two organic substituents bonded to the same oxygen atom, ROR' .

Exergonic (Section 6.7): A reaction that has a negative free-energy change and is therefore spontaneous. On an energy diagram, the product of an exergonic reaction has a lower energy level than that of the reactants.

Exo (Section 14.5): A term indicating the stereochemistry of a substituent in a bridged bicycloalkane. An exo substituent is anti to the larger of the two bridges.

Exon (Section 28.4): A section of DNA that contains genetic information.

Exothermic (Section 6.7): A reaction that releases heat and therefore has a negative enthalpy change.

Fats (Section 27.1): Solid triacylglycerols derived from an animal source.

Fatty acids (Section 27.1): A long, straight-chain carboxylic acid found in fats and oils.

Fiber (Section 31.7): A thin thread produced by extruding a molten polymer through small holes in a die.

Fibrous proteins (Section 26.9): A type of protein that consists of polypeptide chains arranged side by side in long threads. Such proteins are tough, insoluble in water, and used in nature for structural materials such as hair, hooves, and fingernails.

Fingerprint region (Section 12.7): The complex region of the infrared spectrum from $1500\text{--}400\text{ cm}^{-1}$.

First-order reaction (Section 11.4): Designates a reaction whose rate-limiting step is unimolecular and whose kinetics therefore depend on the concentration of only one reactant.

Fischer esterification reaction (Section 21.3): The acid-catalyzed nucleophilic acyl substitution reaction of a carboxylic acid with an alcohol to yield an ester.

Fischer projections (Section 25.2): A means of depicting the absolute configuration of a chiral molecule on a flat page. A Fischer projection uses a cross to represent the chirality center. The horizontal arms of the cross represent bonds coming out of the plane of the page, and the vertical arms of the cross represent bonds going back into the plane of the page.

Fmoc derivative (Section 26.7): A fluorenylmethyloxycarbonyl N-protected amino acid.

Formal charges (Section 2.3): The difference in the number of electrons owned by an atom in a molecule and by the same atom in its elemental state.

Formyl (Section 19.1): A $-\text{CHO}$ group.

Frequency, ν (Section 12.5): The number of electromagnetic wave cycles that travel past a fixed point in a given unit of time. Frequencies are expressed in units of cycles per second, or hertz.

Friedel–Crafts reaction (Section 16.3): An electrophilic aromatic substitution reaction to alkylate or acylate an aromatic ring.

Frontier orbitals (Section 30.1): The highest occupied (HOMO) and lowest unoccupied (LUMO) molecular orbitals.

FT-NMR (Section 13.10): Fourier-transform NMR; a rapid technique for recording NMR spectra in which all magnetic nuclei absorb at the same time.

Functional (Section 3.1): An atom or group of atoms that is part of a larger molecule and has a characteristic chemical reactivity.

Functional RNAs (Section 28.4): An alternative name for small RNAs.

Furanose (Section 25.5): The five-membered-ring form of a simple sugar.

Gabriel amine synthesis (Section 24.6): A method for preparing an amine by $\text{S}_{\text{N}}2$ reaction of an alkyl halide with potassium phthalimide, followed by hydrolysis.

Gauche conformation (Section 3.7): The conformation of butane in which the two methyl groups lie 60° apart as viewed in a Newman projection. This conformation has 3.8 kJ/mol steric strain.

Geminal (Section 19.5): Referring to two groups attached to the same carbon atom. For example, the hydrate formed by nucleophilic addition of water to an aldehyde or ketone is a geminal diol.

Gibbs free-energy change (ΔG) (Section 6.7): The free-energy change that occurs during a reaction, given by the equation $\Delta G = \Delta H - T\Delta S$. A reaction with a negative free-energy change is spontaneous, and a reaction with a positive free-energy change is nonspontaneous.

Gilman reagent (LiR_2Cu) (Section 10.7): A diorganocopper reagent.

Glass transition temperature, T_g (Section 31.7): The temperature at which a hard, amorphous polymer becomes soft and flexible.

Globular proteins (Section 26.9): A type of protein that is coiled into a compact, nearly spherical shape. Globular proteins, which are generally water-soluble and mobile within the cell, are the structural class to which enzymes belong.

Gluconeogenesis (Section 29.8): The anabolic pathway by which organisms make glucose from simple three-carbon precursors.

Glycal (Section 25.9): An unsaturated sugar with a $\text{C1}\text{--}\text{C2}$ double bond.

Glycal assembly method (Section 25.9): A method for linking monosaccharides together to synthesize polysaccharides.

Glycerophospholipids (Section 27.3): Lipids that contain a

glycerol backbone linked to two fatty acids and a phosphoric acid.

Glycoconjugate (Section 25.6): A molecule in which a carbohydrate is linked through its anomeric center to another biological molecule such as a lipid or protein.

Glycol (Section 8.7): A diol, such as ethylene glycol, HOCH₂CH₂OH.

Glycolipid (Section 25.6): A biological molecule in which a carbohydrate is linked through a glycoside bond to a lipid.

Glycolysis (Section 29.5): A series of ten enzyme-catalyzed reactions that break down glucose into 2 equivalents of pyruvate, CH₃COCO₂⁻.

Glycoprotein (Section 25.6): A biological molecule in which a carbohydrate is linked through a glycoside bond to a protein.

Glycoside (Section 25.6): A cyclic acetal formed by reaction of a sugar with another alcohol.

Graft copolymers (Section 31.3): Copolymers in which homopolymer branches of one monomer unit are “grafted” onto a homopolymer chain of another monomer unit.

Green chemistry (Chapter 11 *Chemistry Matters*, Chapter 24 *Chemistry Matters*): The design and implementation of chemical products and processes that reduce waste and minimize or eliminate the generation of hazardous substances.

Grignard reagent (RMgX) (Section 10.6): An organomagnesium halide.

Ground-state electron configuration (Section 1.3): The most stable, lowest-energy electron configuration of a molecule or atom.

Haloform reaction (Section 22.6): The reaction of a methyl ketone with halogen and base to yield a haloform (CHX₃) and a carboxylic acid.

Halogenation (Section 8.2, Section 16.1): The reaction of halogen with an alkene to yield a 1,2-dihalide addition product or with an aromatic compound to yield a substitution product.

Halohydrin (Section 8.3): A 1,2-haloalcohol, such as that obtained on addition of HOBr to an alkene.

Halonium ion (Section 8.2): A species containing a positively charged, divalent halogen. Three-membered-ring bromonium ions are intermediates in the electrophilic addition of Br₂ to alkenes.

Hammond postulate (Section 7.10): A postulate stating that we can get a picture of what a given transition state looks like by looking at the structure of the nearest stable species. Exergonic reactions have transition states that resemble reactant; endergonic reactions have transition states that resemble product.

Heat of combustion (Section 4.3): The amount of heat released when a compound burns completely in oxygen.

Heat of hydrogenation (Section 7.6): The amount of heat released when a carbon-carbon double bond is hydrogenated.

Heat of reaction (Section 6.7): An alternative name for the enthalpy change in a reaction, ΔH .

Hell-Volhard-Zelinskii (HVZ) reaction (Section 22.4): The

reaction of a carboxylic acid with Br₂ and phosphorus to give an α -bromo carboxylic acid.

Hemiacetal (Section 19.10): A functional group having one -OR and one -OH group bonded to the same carbon.

Henderson-Hasselbalch equation (Section 20.3, Section 24.5, Section 26.2): An equation for determining the extent of dissociation of a weak acid at various pH values.

Hertz, Hz (Section 12.5): A unit of measure of electromagnetic frequency, the number of waves that pass by a fixed point per second.

Heterocycle (Section 15.5, Section 24.9): A cyclic molecule whose ring contains more than one kind of atom. For example, pyridine is a heterocycle that contains five carbon atoms and one nitrogen atom in its ring.

Heterolytic bond breakage (Section 6.2): The kind of bond-breaking that occurs in polar reactions when one fragment leaves with both of the bonding electrons: A : B → A⁺ + B:⁻.

Hofmann elimination reaction (Section 24.7): The elimination reaction of an amine to yield an alkene by reaction with iodomethane followed by heating with Ag₂O.

Hofmann rearrangement (Section 24.6): The conversion of an amide into an amine by reaction with Br₂ and base.

Highest occupied molecular orbital (HOMO) (Section 14.7, Section 30.1): The symmetries of the HOMO and LUMO are important in pericyclic reactions.

Homolytic bond breakage (Section 6.2): The kind of bond-breaking that occurs in radical reactions when each fragment leaves with one bonding electron: A : B → A[•] + B:[•].

Homopolymers (Section 31.3): A polymer made up of identical repeating units.

Homotopic (Section 13.7): Hydrogens in a molecule that give the identical structure on replacement by X and thus show identical NMR absorptions.

Hormones (Section 27.6): Chemical messengers that are secreted by an endocrine gland and carried through the bloodstream to a target tissue.

HPLC (Section 26.5): High-pressure liquid chromatography; a variant of column chromatography using high pressure to force solvent through very small absorbent particles.

Hückel 4n + 2 rule (Section 15.3): A rule stating that monocyclic conjugated molecules having 4n + 2 π electrons (n = an integer) are aromatic.

Hund's rule (Section 1.3): If two or more empty orbitals of equal energy are available, one electron occupies each, with their spins parallel, until all are half-full.

Hybrid orbital (Section 1.6): An orbital derived from a combination of atomic orbitals. Hybrid orbitals, such as the sp³, sp², and sp hybrids of carbon, are strongly directed and form stronger bonds than atomic orbitals do.

Hydration (Section 8.4): Addition of water to a molecule, such as occurs when alkenes are treated with aqueous sulfuric acid to give alcohols.

Hydride shift (Section 7.11): The shift of a hydrogen atom and

its electron pair to a nearby cationic center.

Hydroboration (Section 8.5): Addition of borane (BH_3) or an alkylborane to an alkene. The resultant trialkylborane products can be oxidized to yield alcohols.

Hydrocarbons (Section 3.2): A class of compounds that contain only carbon and hydrogen.

Hydrogen bond (Section 2.12): A weak attraction between a hydrogen atom bonded to an electronegative atom and an electron lone pair on another electronegative atom.

Hydrogenated (Section 6.11): Addition of hydrogen to a double or triple bond to yield a saturated product.

Hydrogenolysis (Section 26.7): Cleavage of a bond by reaction with hydrogen. Benzylic ethers and esters, for instance, are cleaved by hydrogenolysis.

Hydrophilic (Section 2.12): Water-loving; attracted to water.

Hydrophobic (Section 2.12): Water-fearing; repelled by water.

Hydroquinones (Section 17.10): 1,4-dihydroxybenzene.

Hydroxylation (Section 8.7): Addition of two $-\text{OH}$ groups to a double bond.

Hyperconjugation (Section 7.6, Section 7.9): An electronic interaction that results from overlap of a vacant p orbital on one atom with a neighboring $\text{C}-\text{H}$ σ bond. Hyperconjugation is important in stabilizing carbocations and substituted alkenes.

Imide (Section 24.6): A compound with the $-\text{CONHCO}-$ functional group.

Imines (Section 19.8): A class of compounds with the $\text{R}_2\text{C}=\text{NR}$ functional group.

Inductive effect (Section 2.1, Section 7.9, Section 16.4): The electron-attracting or electron-withdrawing effect transmitted through σ bonds. Electronegative elements have an electron-withdrawing inductive effect.

Infrared (IR) spectroscopy (Section 12.6): A kind of optical spectroscopy that uses infrared energy. IR spectroscopy is particularly useful in organic chemistry for determining the kinds of functional groups present in molecules.

Initiator (Section 8.10, Section 31.1): A substance that is used to initiate a radical chain reaction or polymerization. For example, radical chlorination of alkanes is initiated when light energy breaks the weak $\text{Cl}-\text{Cl}$ bond to form $\text{Cl}\cdot$ radicals.

Integrating (Section 13.5): A technique for measuring the area under an NMR peak to determine the relative number of each kind of proton in a molecule.

Intermediate (Section 6.10): A species that is formed during the course of a multistep reaction but is not the final product. Intermediates are more stable than transition states but may or may not be stable enough to isolate.

Intramolecular, intermolecular (Section 23.6): A reaction that occurs within the same molecule is intramolecular; a reaction that occurs between two molecules is intermolecular.

Intron (Section 28.4): A section of DNA that does not contain genetic information.

Ion pairs (Section 11.4): A loose association between two ions in solution. Ion pairs are implicated as intermediates in $\text{S}_{\text{N}}1$

reactions to account for the partial retention of stereochemistry that is often observed.

Ionic bond (Section 1.4): The electrostatic attraction between ions of unlike charge.

Isoelectric point (pI) (Section 26.2): The pH at which the number of positive charges and the number of negative charges on a protein or an amino acid are equal.

Isomers (Section 3.2, Section 5.9): Compounds that have the same molecular formula but different structures.

Isoprene rule (Chapter 8 Chemistry Matters): An observation to the effect that terpenoids appear to be made up of isoprene (2-methyl-1,3-butadiene) units connected head-to-tail.

Isotactic (Section 31.2): A chain-growth polymer in which the stereochemistry of the substituents is oriented regularly along the backbone.

Isotopes (Section 1.1): Atoms of the same element that have different mass numbers.

IUPAC system of nomenclature (Section 3.4): Rules for naming compounds, devised by the International Union of Pure and Applied Chemistry.

Kekulé structure (Section 1.4): An alternative name for a line-bond structure, which represents a molecule by showing covalent bonds as lines between atoms.

Ketals (Section 19.10): An alternative name for acetals derived from a ketone rather than an aldehyde and consisting of two $-\text{OR}$ groups bonded to the same carbon, $\text{R}_2\text{C}(\text{OR})_2$. Ketals are often used as protecting groups for ketones.

Keto-enol tautomerism (Section 9.4, Section 22.1): The equilibration between a carbonyl form and vinylic alcohol form of a molecule.

Ketones (R_2CO) (Section 3.1, Chapter 19 Introduction): A class of compounds with two organic substituents bonded to a carbonyl group, $\text{R}_2\text{C}=\text{O}$.

Ketoses (Section 25.1): Carbohydrates with a ketone functional group.

Kiliani-Fischer synthesis (Section 25.6): A method for lengthening the chain of an aldose sugar.

Kinetic control (Section 14.3): A reaction that follows the lowest activation energy pathway is said to be kinetically controlled. The product is the most rapidly formed but is not necessarily the most stable.

Kinetics (Section 11.2): Referring to reaction rates. Kinetic measurements are useful for helping to determine reaction mechanisms.

Koenigs-Knorr reaction (Section 25.6): A method for the synthesis of glycosides by reaction of an alcohol with a pyranosyl bromide.

Krebs cycle (Section 29.7): An alternative name for the citric acid cycle, by which acetyl CoA is degraded to CO_2 .

L Sugar (Section 25.3): A sugar whose hydroxyl group at the chirality center farthest from the carbonyl group points to the left when drawn in Fischer projection.

Lactams (Section 21.7): Cyclic amides.

Lactones (Section 21.6): Cyclic esters.

Lagging strand (Section 28.3): The complement of the original 3' → 5' DNA strand that is synthesized discontinuously in small pieces that are subsequently linked by DNA ligases.

LD50 (Chapter 1 Chemistry Matters): The amount of a substance per kilogram body weight that is lethal to 50% of test animals.

LDA (Section 22.5): Lithium diisopropylamide, $\text{LiN}(i\text{-C}_3\text{H}_7)_2$, a strong base commonly used to convert carbonyl compounds into their enolate ions.

Leading strand (Section 28.3): The complement of the original 5' → 3' DNA strand that is synthesized continuously in a single piece.

Leaving group (Section 11.3): The group that is replaced in a substitution reaction.

Levorotatory (Section 5.3): An optically active substance that rotates the plane of polarization of plane-polarized light in a left-handed (counterclockwise) direction.

Lewis acid (Section 2.11): A substance with a vacant low-energy orbital that can accept an electron pair from a base. All electrophiles are Lewis acids.

Lewis base (Section 2.11): A substance that donates an electron lone pair to an acid. All nucleophiles are Lewis bases.

Lewis structures (Section 1.4): Representations of molecules showing valence electrons as dots.

Lindlar catalyst (Section 9.5): A hydrogenation catalyst used to convert alkynes to cis alkenes.

Line-bond structure (Section 1.4): An alternative name for a Kekulé structure, which represents a molecule by showing covalent bonds as lines between atoms.

1→4 Link (Section 25.8): A glycoside link between the C1 -OH group of one sugar and the C4 -OH group of another sugar.

Lipids (Chapter 27 Introduction): Naturally occurring substances isolated from cells and tissues by extraction with a nonpolar solvent. Lipids belong to many different structural classes, including fats, terpenoids, prostaglandins, and steroids.

Lipid bilayer (Section 27.3): The ordered lipid structure that forms a cell membrane.

Lipoprotein (Chapter 27 Chemistry Matters): A complex molecule with both lipid and protein parts that transports lipids through the body.

Locant (Section 3.4): A number in a chemical name that locates the positions of the functional groups and substituents in the molecule.

Lone-pair electrons (Section 1.4): Nonbonding valence-shell electron pairs. Lone-pair electrons are used by nucleophiles in their reactions with electrophiles.

Lowest unoccupied molecular orbital (LUMO) (Section 14.7, Section 30.1): The symmetries of the LUMO and the HOMO are important in determining the stereochemistry of pericyclic reactions.

Magnetic resonance imaging, MRI (Chapter 13 Chemistry

Matters): A medical diagnostic technique based on nuclear magnetic resonance.

Magnetogyric ratio (Section 13.1): A ratio of the isotope's magnetic moment to its angular momentum.

MALDI (Section 12.4): Matrix-assisted laser desorption ionization; a soft ionization method used for mass spectrometry of biological samples of very high molecular weight.

Malonic ester synthesis (Section 22.7): The synthesis of a carboxylic acid by alkylation of an alkyl halide with diethyl malonate, followed by hydrolysis and decarboxylation.

Markovnikov's rule (Section 7.8): A guide for determining the regiochemistry (orientation) of electrophilic addition reactions. In the addition of HX to an alkene, the hydrogen atom bonds to the alkene carbon that has fewer alkyl substituents.

Mass number (A) (Section 1.1): The total of protons plus neutrons in an atom.

Mass spectrometry (MS) (Section 12.1): A technique for measuring the mass, and therefore the molecular weight (MW), of ions.

McLafferty rearrangement (Section 12.3, Section 19.4): A mass-spectral fragmentation pathway for carbonyl compounds.

Mechanism (Section 6.2): A complete description of how a reaction occurs. A mechanism accounts for all starting materials and all products and describes the details of each individual step in the overall reaction process.

Meisenheimer complex (Section 16.6): An intermediate formed by addition of a nucleophile to a halo-substituted aromatic ring.

Melt transition temperature, T_m (Section 31.7): The temperature at which crystalline regions of a polymer melt to give an amorphous material.

Mercapto group (Section 18.7): An alternative name for the thiol group, -SH.

Meso compounds (Section 5.7): Compounds that contain chirality centers but are nevertheless achiral because they contain a symmetry plane.

Messenger RNA (mRNA) (Section 28.4): A kind of RNA formed by transcription of DNA and used to carry genetic messages from DNA to ribosomes.

Meta (m) (Section 15.1): A naming prefix used for 1,3-disubstituted benzenes.

Metabolism (Section 29.1): A collective name for the many reactions that go on in the cells of living organisms.

Metallacycle (Section 31.5): A cyclic compound that contains a metal atom in its ring.

Methylene group (Section 7.3): A $-\text{CH}_2-$ or $=\text{CH}_2$ group.

Micelles (Section 27.2): Spherical clusters of soaplike molecules that aggregate in aqueous solution. The ionic heads of the molecules lie on the outside, where they are solvated by water, and the organic tails bunch together on the inside of the micelle.

- Michael reaction** (Section 23.10): The conjugate addition reaction of an enolate ion to an unsaturated carbonyl compound.
- Molar absorptivity (ϵ)** (Section 14.7): A quantitative measure of the amount of UV light absorbed by a sample.
- Molecular ion** (Section 12.1): The cation produced in a mass spectrometer by loss of an electron from the parent molecule. The mass of the molecular ion corresponds to the molecular weight of the sample.
- Molecular mechanics** (Chapter 4 *Chemistry Matters*): A computer-based method for calculating the minimum-energy conformation of a molecule.
- Molecular orbital (MO) theory** (Section 1.11, Section 14.1): A description of covalent bond formation as resulting from a mathematical combination of atomic orbitals (wave functions) to form molecular orbitals.
- Molecule** (Section 1.4): A neutral collection of atoms held together by covalent bonds.
- Molozonide** (Section 8.8): The initial addition product of ozone with an alkene.
- Monomers** (Section 8.10, Section 21.9; Chapter 31 *Introduction*): The simple starting units from which polymers are made.
- Monosaccharides** (Section 25.1): Simple sugars.
- Monoterpenoids** (Chapter 8 *Chemistry Matters*, Section 27.5): Ten-carbon lipids.
- Multiplet** (Section 13.6): A pattern of peaks in an NMR spectrum that arises by spin-spin splitting of a single absorption because of coupling between neighboring magnetic nuclei.
- Mutarotation** (Section 25.5): The change in optical rotation observed when a pure anomer of a sugar is dissolved in water. Mutarotation is caused by the reversible opening and closing of the acetal linkage, which yields an equilibrium mixture of anomers.
- $n + 1$ rule** (Section 13.6): A hydrogen with n other hydrogens on neighboring carbons shows $n + 1$ peaks in its ^1H NMR spectrum.
- N-terminal amino acid** (Section 26.4): The amino acid with a free $-\text{NH}_2$ group at the end of a protein chain.
- Natural gas** (Chapter 3 *Chemistry Matters*): A naturally occurring hydrocarbon mixture consisting chiefly of methane, along with smaller amounts of ethane, propane, and butane.
- Natural product** (Chapter 7 *Chemistry Matters*): A catchall term generally taken to mean a secondary metabolite found in bacteria, plants, and other living organisms.
- New molecular entity, NME** (Chapter 6 *Chemistry Matters*): A new biologically active chemical substance approved for sale as a drug by the U.S. Food and Drug Administration.
- Newman projection** (Section 3.6): A means of indicating stereochemical relationships between substituent groups on neighboring carbons. The carbon-carbon bond is viewed end-on, and the carbons are indicated by a circle. Bonds radiating from the center of the circle are attached to the front carbon, and bonds radiating from the edge of the circle are attached to the rear carbon.
- Nitration** (Section 16.2): The substitution of a nitro group onto an aromatic ring.
- Nitriles** (Section 3.1, Section 20.1): A class of compounds containing the $\text{C}\equiv\text{N}$ functional group.
- Nitrogen rule** (Section 24.10): A compound with an odd number of nitrogen atoms has an odd-numbered molecular weight.
- Node** (Section 1.2): A surface of zero electron density within an orbital. For example, a p orbital has a nodal plane passing through the center of the nucleus, perpendicular to the axis of the orbital.
- Nonbonding electrons** (Section 1.4): Valence electrons that are not used in forming covalent bonds.
- Noncoding strand** (Section 28.4): An alternative name for the antisense strand of DNA.
- Noncovalent interactions** (Section 2.12): One of a variety of nonbonding interactions between molecules, such as dipole-dipole forces, dispersion forces, and hydrogen bonds.
- Nonessential amino acid** (Section 26.1): One of the eleven amino acids that are biosynthesized by humans.
- Normal alkanes** (Section 3.2): Straight-chain alkanes, as opposed to branched alkanes. Normal alkanes are denoted by the suffix n , as in $n\text{-C}_4\text{H}_{10}$ (n -butane).
- NSAID** (Chapter 15 *Chemistry Matters*): A nonsteroidal anti-inflammatory drug, such as aspirin or ibuprofen.
- Nuclear magnetic resonance (NMR) spectroscopy** (Chapter 13 *Introduction*): A spectroscopic technique that provides information about the carbon-hydrogen framework of a molecule. NMR works by detecting the energy absorptions accompanying the transitions between nuclear spin states that occur when a molecule is placed in a strong magnetic field and irradiated with radiofrequency waves.
- Nucleic acid** (Section 28.1): Deoxyribonucleic acid (DNA) and ribonucleic acid (RNA); biological polymers made of nucleotides joined together to form long chains.
- Nucleophile** (Section 6.3, Section 6.4): An electron-rich species that donates an electron pair to an electrophile in a polar bond-forming reaction. Nucleophiles are also Lewis bases.
- Nucleophilic acyl substitution reaction** (Section 21.2): A reaction in which a nucleophile attacks a carbonyl compound and substitutes for a leaving group bonded to the carbonyl carbon.
- Nucleophilic addition reaction** (Section 19.4): A reaction in which a nucleophile adds to the electrophilic carbonyl group of a ketone or aldehyde to give an alcohol.
- Nucleophilic aromatic substitution reactions** (Section 16.6): The substitution reactions of an aryl halide by a nucleophile.
- Nucleophilic substitution reactions** (Section 11.1): Reactions in which one nucleophile replaces another attached to a saturated carbon atom.

- Nucleophilicity (Section 11.3):** The ability of a substance to act as a nucleophile in an S_N2 reaction.
- Nucleoside (Section 28.1):** A nucleic acid constituent consisting of a sugar residue bonded to a heterocyclic purine or pyrimidine base.
- Nucleotides (Section 28.1):** Nucleic acid constituents consisting of a sugar residue bonded both to a heterocyclic purine or pyrimidine base and to a phosphoric acid. Nucleotides are the monomer units from which DNA and RNA are constructed.
- Nylons (Section 21.9):** Synthetic polyamide step-growth polymers.
- Okazaki fragments (Section 28.3):** Short segments of a DNA lagging strand that is biosynthesized discontinuously and then linked by DNA ligases.
- Olefin (Chapter 7 Introduction):** An alternative name for an alkene.
- Olefin metathesis polymerization (Section 31.5):** A method of polymer synthesis based on using an olefin metathesis reaction.
- Olefin metathesis reaction (Section 31.5):** A reaction in which two olefins (alkenes) exchange substituents on their double bonds.
- Oligonucleotides (Section 28.7):** Short segments of DNA.
- Optical isomers (Section 5.4):** An alternative name for enantiomers. Optical isomers are isomers that have a mirror-image relationship.
- Optically active (Section 5.3):** A property of some organic molecules wherein the plane of polarization is rotated through an angle when a beam of plane-polarized light is passed through a solution of the molecules.
- Orbital (Section 1.2):** A wave function, which describes the volume of space around a nucleus in which an electron is most likely to be found.
- Organic chemistry (Chapter 1 Introduction):** The study of carbon compounds.
- Organohalides (Chapter 10 Introduction):** Compounds that contain one or more halogen atoms bonded to carbon.
- Organometallic compound (Section 10.6):** A compound that contains a carbon–metal bond. Grignard reagents, $RMgX$, are examples.
- Organophosphate (Section 1.10):** A compound that contains a phosphorus atom bonded to four oxygens, with one of the oxygens also bonded to carbon.
- Ortho (o) (Section 15.1):** A naming prefix used for 1,2-disubstituted benzenes.
- Oxidation (Section 8.7, Section 10.8):** A reaction that causes a decrease in electron ownership by carbon, either by bond formation between carbon and a more electronegative atom (usually oxygen, nitrogen, or a halogen) or by bond-breaking between carbon and a less electronegative atom (usually hydrogen).
- Oximes (Section 19.8):** Compounds with the $R_2C=NOH$ functional group.
- Oxirane (Section 8.7):** An alternative name for an epoxide.
- Oxymercuration (Section 8.4):** A method for double-bond hydration by reaction of an alkene with aqueous mercuric acetate followed by treatment with $NaBH_4$.
- Ozonide (Section 8.8):** The product initially formed by addition of ozone to a carbon–carbon double bond. Ozonides are usually treated with a reducing agent, such as zinc in acetic acid, to produce carbonyl compounds.
- Para (p) (Section 15.1):** A naming prefix used for 1,4-disubstituted benzenes.
- Paraffins (Section 3.5):** A common name for alkanes.
- Parent peak (Section 12.1):** The peak in a mass spectrum corresponding to the molecular ion. The mass of the parent peak therefore represents the molecular weight of the compound.
- Pauli exclusion principle (Section 1.3):** No more than two electrons can occupy the same orbital, and those two must have spins of opposite sign.
- Peptide bond (Section 26.4):** An amide bond in a peptide chain.
- Peptides (Chapter 26 Introduction):** A type of short amino acid polymer in which the individual amino acid residues are linked by amide bonds.
- Pericyclic reaction (Chapter 30 Introduction):** A reaction that occurs in a single step by a reorganization of bonding electrons in a cyclic transition state.
- Periplanar (Section 11.8):** A conformation in which bonds to neighboring atoms have a parallel arrangement. In an eclipsed conformation, the neighboring bonds are syn periplanar; in a staggered conformation, the bonds are anti periplanar.
- Peroxides (Section 18.1):** Molecules containing an oxygen–oxygen bond functional group, $ROOR'$ or $ROOH$.
- Peroxyacid (Section 8.7):** A compound with the $-CO_3H$ functional group. Peroxyacids react with alkenes to give epoxides.
- Phenols (Chapter 17 Introduction):** A class of compounds with an $-OH$ group directly bonded to an aromatic ring, $ArOH$.
- Phenoxide ion, ArO^- (Section 17.2):** The anion of a phenol.
- Phenyl (Section 15.1):** The name for the $-C_6H_5$ unit when the benzene ring is considered as a substituent. A phenyl group is abbreviated as $-Ph$.
- Phosphine (Section 5.10):** A trivalent phosphorus compound, R_3P .
- Phosphite (Section 28.7):** A compound with the structure $P(OR)_3$.
- Phospholipids (Section 27.3):** Lipids that contain a phosphate residue. For example, glycerophospholipids contain a glycerol backbone linked to two fatty acids and a phosphoric acid.
- Phosphoramidite (Section 28.7):** A compound with the structure $R_2NP(OR)_2$.
- Phosphoric acid anhydride (Section 29.1):** A substance that contains PO_2PO link, analogous to the CO_2CO link in carboxylic acid anhydrides.

Photochemical reactions (Section 30.3): A reaction carried out by irradiating the reactants with light.

Physiological pH (Section 20.3): The pH of 7.3 that exists inside cells.

Pi (π) bond (Section 1.8): The covalent bond formed by sideways overlap of atomic orbitals. For example, carbon–carbon double bonds contain a π bond formed by sideways overlap of two p orbitals.

PITC (Section 26.6): Phenylisothiocyanate; used in the Edman degradation.

pK_a (Section 2.8): The negative common logarithm of the K_a ; used to express acid strength.

Plane of symmetry (Section 5.2): A plane that bisects a molecule such that one half of the molecule is the mirror image of the other half. Molecules containing a plane of symmetry are achiral.

Plane-polarized light (Section 5.3): Light that has its electromagnetic waves oscillating in a single plane rather than in random planes. The plane of polarization is rotated when the light is passed through a solution of a chiral substance.

Plasticizers (Section 31.7): Small organic molecules added to polymers to act as a lubricant between polymer chains.

Polar aprotic solvents (Section 11.3): Polar solvents that can't function as hydrogen ion donors. Polar aprotic solvents such as dimethyl sulfoxide (DMSO) and dimethylformamide (DMF) are particularly useful in S_N2 reactions because of their ability to solvate cations.

Polar covalent bond (Section 2.1): A covalent bond in which the electron distribution between atoms is unsymmetrical.

Polar reactions (Section 6.2, Section 6.3): Reactions in which bonds are made when a nucleophile donates two electrons to an electrophile and in which bonds are broken when one fragment leaves with both electrons from the bond.

Polarity (Section 2.1): The unsymmetrical distribution of electrons in a molecule that results when one atom attracts electrons more strongly than another.

Polarizability (Section 6.3): The measure of the change in a molecule's electron distribution in response to changing electrostatic interactions with solvents or ionic reagents.

Polycarbonates (Section 31.4): Polyesters in which the carbonyl groups are linked to two $-OR$ groups, $[O=C(OR)_2]$.

Polycyclic (Section 4.9): Containing more than one ring.

Polycyclic aromatic compound (Section 15.6): A compound with two or more benzene-like aromatic rings fused together.

Polymer (Section 8.10, Section 21.9; Chapter 31 Introduction): A large molecule made up of repeating smaller units. For example, polyethylene is a synthetic polymer made from repeating ethylene units, and DNA is a biopolymer made of repeating deoxyribonucleotide units.

Polymerase chain reaction (PCR) (Section 28.8): A method for amplifying small amounts of DNA to produce larger amounts.

Polysaccharides (Section 25.9): A type of carbohydrate that is made of many simple sugars linked together by glycoside

(acetal) bonds.

Polyunsaturated fatty acids (Section 27.1): Fatty acids that contain more than one double bond.

Polyurethane (Section 31.4): A step-growth polymer prepared by reaction between a diol and a diisocyanate.

Posttranslational modification (Section 28.6): A chemical modification of a protein that occurs after translation from DNA.

Primary, secondary, tertiary, and quaternary (Section 3.3): Terms used to describe the substitution pattern at a specific site. A primary site has one organic substituent attached to it, a secondary site has two organic substituents, a tertiary site has three, and a quaternary site has four.

	Primary	Secondary	Tertiary	Quaternary
Carbon	RCH_3	R_2CH_2	R_3CH	R_4C
Carbocation	RCH_2^+	R_2CH^+	R_3C^+	
Hydrogen	RCH_3	R_2CH_2	R_3CH	
Alcohol	RCH_2OH	R_2CHOH	R_3COH	
Amine	RNH_2	R_2NH	R_3N	

Primary structure (Section 26.9): The amino acid sequence in a protein.

pro- R (Section 5.11): One of two identical atoms or groups of atoms in a compound whose replacement leads to an R chirality center.

pro- S (Section 5.11): One of two identical atoms or groups of atoms in a compound whose replacement leads to an S chirality center.

Prochiral (Section 5.11): A molecule that can be converted from achiral to chiral in a single chemical step.

Prochirality center (Section 5.11): An atom in a compound that can be converted into a chirality center by changing one of its attached substituents.

Promoter sequence (Section 28.4): A short sequence on DNA located upstream of the transcription start site and recognized by RNA polymerase.

Propagation step (Section 8.10): A step in a radical chain reaction that carries on the chain. The propagation steps must yield both product and a reactive intermediate.

Prostaglandins (Section 27.4): Lipids derived from arachidonic acid. Prostaglandins are present in nearly all body tissues and fluids, where they serve many important hormonal functions.

Protecting group (Section 17.8, Section 19.10, Section 26.7): A group that is introduced to protect a sensitive functional group toward reaction elsewhere in the molecule. After serving its protective function, the group is removed.

Proteins (Chapter 26 Introduction): Large peptides containing

50 or more amino acid residues. Proteins serve both as structural materials and as enzymes that control an organism's chemistry.

Protein Data Bank (Chapter 26 Chemistry Matters): A worldwide online repository of X-ray and NMR structural data for biological macromolecules. To access the Protein Data Bank, go to <https://www.rcsb.org> (<https://www.rcsb.org>).

Protic solvents (Section 11.3): Solvents such as water or alcohol that can act as a proton donor.

Pyramidal inversion (Section 24.2): The rapid stereochemical inversion of a trivalent nitrogen compound.

Pyranose (Section 25.5): The six-membered, cyclic hemiacetal form of a simple sugar.

Quadrupole mass analyzer (Section 12.1): A type of mass spectrometer that uses four cylindrical rods to create an oscillating electrostatic field. Ion trajectories are determined by their m/z ratios. At a given field, only one m/z value will make it through the quadrupole region—the others will crash into the quadrupole rods or the walls of the instrument and never reach the detector.

Quartet (Section 13.6): A set of four peaks in an NMR spectrum, caused by spin–spin splitting of a signal by three adjacent nuclear spins.

Quaternary: See **Primary**.

Quaternary ammonium salt (Section 24.1): An ionic compound containing a positively charged nitrogen atom with four attached groups, $R_4N^+ X^-$.

Quaternary structure (Section 26.9): The highest level of protein structure, involving an ordered aggregation of individual proteins into a larger cluster.

Quinone (Section 17.10): A 2,5-cyclohexadiene-1,4-dione.

R configuration (Section 5.5): The configuration at a chirality center as specified using the Cahn–Ingold–Prelog sequence rules.

R (Section 3.3): A generalized abbreviation for an organic partial structure.

Racemate (Section 5.8): A mixture consisting of equal parts (+) and (–) enantiomers of a chiral substance; also called a racemic mixture.

Radical (Section 2.6, Section 6.2): A species that has an odd number of electrons, such as the chlorine radical, $Cl\cdot$.

Radical reactions (Section 6.2, Section 6.3): Reactions in which bonds are made by donation of one electron from each of two reactants and in which bonds are broken when each fragment leaves with one electron.

Rate constant (Section 11.2): The constant k in a rate equation.

Rate equation (Section 11.2): An equation that expresses the dependence of a reaction's rate on the concentration of reactants.

Rate-limiting step (Section 11.4): The slowest step in a multistep reaction sequence; also called the rate-determining step. The rate-limiting step acts as a kind of bottleneck in multistep reactions.

Re face (Section 5.11): One of two faces of a planar, sp^2 -hybridized atom.

Rearrangement reactions (Section 6.1): What occurs when a single reactant undergoes a reorganization of bonds and atoms to yield an isomeric product.

Reducing sugars (Section 25.6): Sugars that reduce silver ion in the Tollens test or cupric ion in the Fehling or Benedict tests.

Reduction (Section 8.6, Section 10.8): A reaction that causes an increase of electron ownership by carbon, either by bond-breaking between carbon and a more electronegative atom or by bond formation between carbon and a less electronegative atom.

Reductive amination (Section 24.6, Section 26.3): A method for preparing an amine by reaction of an aldehyde or ketone with ammonia and a reducing agent.

Refining (Chapter 3 Chemistry Matters): The process by which petroleum is converted into gasoline and other useful products.

Regiochemistry (Section 7.8): A term describing the orientation of a reaction that occurs on an unsymmetrical substrate.

Regiospecific (Section 7.8): A term describing a reaction that occurs with a specific regiochemistry to give a single product rather than a mixture of products.

Replication (Section 28.3): The process by which double-stranded DNA uncoils and is replicated to produce two new copies.

Replication forks (Section 28.3): The point of unraveling in a DNA chain where replication occurs.

Residues (Section 26.4): Amino acids in a protein chain.

Resolution (Section 5.8): The process by which a racemate is separated into its two pure enantiomers.

Resonance effect (Section 16.4): The donation or withdrawal of electrons through orbital overlap with neighboring π bonds. For example, an oxygen or nitrogen substituent donates electrons to an aromatic ring by overlap of the O or N orbital with the aromatic ring p orbitals.

Resonance forms (Section 2.4): Individual structural forms of a resonance hybrid.

Resonance hybrid (Section 2.4): A molecule, such as benzene, that can't be represented adequately by a single Kekulé structure but must instead be considered as an average of two or more resonance forms. The resonance forms themselves differ only in the positions of their electrons, not their nuclei.

Restriction endonucleases (Section 28.6): Enzymes that are able to cleave a DNA molecule at points in the chain where a specific base sequence occurs.

Retrosynthetic (Section 9.9, Section 16.10): Planning an organic synthesis by working backward from the final product to the starting material.

Ribonucleic acid (RNA) (Chapter 28 Introduction): The biopolymer found in cells that serves to transcribe the genetic information found in DNA and uses that information to direct the synthesis of proteins.

- Ribosomal RNA (rRNA)** (Section 28.4): A kind of RNA used in the physical makeup of ribosomes.
- Ring-current** (Section 15.7): The circulation of π electrons induced in aromatic rings by an external magnetic field. This effect accounts for the downfield shift of aromatic ring protons in the ^1H NMR spectrum.
- Ring-flip** (Section 4.6): A molecular motion that interconverts two chair conformations of cyclohexane. The effect of a ring-flip is to convert an axial substituent into an equatorial substituent.
- Ring-opening metathesis polymerization (ROMP)** (Section 31.5): A method of polymer synthesis that uses an olefin metathesis reaction of a cycloalkene.
- RNA** (Section 28.1): Ribonucleic acid.
- Robinson annulation reaction** (Section 23.12): A method for synthesis of cyclohexenones by sequential Michael reaction and intramolecular aldol reaction.
- S configuration** (Section 5.5): The configuration at a chirality center as specified using the Cahn–Ingold–Prelog sequence rules.
- s-Cis conformation** (Section 14.5): The conformation of a conjugated diene that is cis-like around the single bond.
- Saccharide** (Section 25.1): A sugar.
- Salt bridge** (Section 26.9): An ionic attraction between two oppositely charged groups in a protein chain.
- Sandmeyer reaction** (Section 24.8): The nucleophilic substitution reaction of an arenediazonium salt with a cuprous halide to yield an aryl halide.
- Sanger dideoxy method** (Section 28.6): A commonly used method of DNA sequencing.
- Saponification** (Section 21.6, Section 27.2): An old term for the base-induced hydrolysis of an ester to yield a carboxylic acid salt.
- Saturated** (Section 3.2): A molecule that has only single bonds and thus can't undergo addition reactions. Alkanes are saturated, but alkenes are unsaturated.
- Sawhorse representations** (Section 3.6): A manner of representing stereochemistry that uses a stick drawing and gives a perspective view of the conformation around a single bond.
- Schiff bases** (Section 19.8, Section 29.5): An alternative name for an imine, $\text{R}_2\text{C}=\text{NR}'$, used primarily in biochemistry.
- Second-order reaction** (Section 11.2): A reaction whose rate-limiting step is bimolecular and whose kinetics are therefore dependent on the concentration of two reactants.
- Secondary:** See **Primary**.
- Secondary metabolite** (Chapter 7 *Chemistry Matters*): A small naturally occurring molecule that is not essential to the growth and development of the producing organism and is not classified by structure.
- Secondary structure** (Section 26.9): The level of protein substructure that involves organization of chain sections into ordered arrangements such as β -pleated sheets or α helices.
- Semiconservative replication** (Section 28.3): The process by which DNA molecules are made containing one strand of old DNA and one strand of new DNA.
- Sense strand** (Section 28.4): The coding strand of double-helical DNA that contains the gene.
- Sequence rules** (Section 5.5, Section 7.5): A series of rules for assigning relative rankings to substituent groups on a double-bond carbon atom or on a chirality center.
- Sesquiterpenoids** (Section 27.5): 15-carbon lipids.
- Sharpless epoxidation** (Chapter 19 *Chemistry Matters*): A method for enantioselective synthesis of a chiral epoxide by treatment of an allylic alcohol with *tert*-butyl hydroperoxide, $(\text{CH}_3)_3\text{C}-\text{OOH}$, in the presence of titanium tetrakispropoxide and diethyl tartrate.
- Shielding** (Section 13.2): An effect observed in NMR that causes a nucleus to absorb toward the right (upfield) side of the chart. Shielding is caused by donation of electron density to the nucleus.
- Si face** (Section 5.11): One of two faces of a planar, sp^2 -hybridized atom.
- Sialic acid** (Section 25.7): One of a group of more than 300 carbohydrates based on acetylneuramic acid.
- Side chain** (Section 26.1): The substituent attached to the α carbon of an amino acid.
- Sigma (σ) bond** (Section 1.5): A covalent bond formed by head-on overlap of atomic orbitals.
- Sigmatropic reaction** (Section 30.8): A pericyclic reaction that involves the migration of a group from one end of a π electron system to the other.
- Silyl ether** (Section 17.8): A substance with the structure $\text{R}_3\text{Si}-\text{O}-\text{R}$. The silyl ether acts as a protecting group for alcohols.
- Simmons–Smith reaction** (Section 8.9): The reaction of an alkene with CH_2I_2 and $\text{Zn}-\text{Cu}$ to yield a cyclopropane.
- Simple sugars** (Section 25.1): Carbohydrates that cannot be broken down into smaller sugars by hydrolysis.
- Single bond** (Section 1.8): A covalent bond formed by sharing one electron pair between atoms.
- Skeletal structures** (Section 1.12): A shorthand way of writing structures in which carbon atoms are assumed to be at each intersection of two lines (bonds) and at the end of each line.
- Small RNAs** (Section 28.4): A type of RNA that has a variety of functions within the cell, including silencing transcription and catalyzing chemical modifications of other RNA molecules.
- $\text{S}_{\text{N}}1$ reaction** (Section 11.4): A unimolecular nucleophilic substitution reaction.
- $\text{S}_{\text{N}}2$ reaction** (Section 11.2): A bimolecular nucleophilic substitution reaction.
- Solid-phase synthesis** (Section 26.8): A technique of synthesis whereby the starting material is covalently bound to a solid polymer bead and reactions are carried out on the bound substrate. After the desired transformations have been effected, the product is cleaved from the polymer.

- Solvation** (Section 11.3): The clustering of solvent molecules around a solute particle to stabilize it.
- sp hybrid orbitals** (Section 1.9): Hybrid orbitals derived from the combination of an *s* and a *p* atomic orbital. The two *sp* orbitals that result from hybridization are oriented at an angle of 180° to each other.
- sp² hybrid orbitals** (Section 1.8): Hybrid orbitals derived by combination of an *s* atomic orbital with two *p* atomic orbitals. The three *sp*² hybrid orbitals that result lie in a plane at angles of 120° to each other.
- sp³ hybrid orbitals** (Section 1.6): Hybrid orbitals derived by combination of an *s* atomic orbital with three *p* atomic orbitals. The four *sp*³ hybrid orbitals that result are directed toward the corners of a regular tetrahedron at angles of 109° to each other.
- Specific rotation, [α]_D** (Section 5.3): The optical rotation of a chiral compound under standard conditions.
- Sphingomyelins** (Section 27.3): Phospholipids that have sphingosine as the backbone rather than glycerol.
- Spin–spin splitting** (Section 13.6): The splitting of an NMR signal into a multiplet because of an interaction between nearby magnetic nuclei whose spins are coupled. The magnitude of spin–spin splitting is given by the coupling constant, *J*.
- Staggered conformation** (Section 3.6): The three-dimensional arrangement of atoms around a carbon–carbon single bond in which the bonds on one carbon bisect the bond angles on the second carbon as viewed end-on.
- Statin** (Chapter 29 Chemistry Matters): A drug that controls cholesterol biosynthesis in the body by blocking the HMG-CoA reductase enzyme.
- Step-growth polymers** (Section 21.9, Section 31.4): Polymers in which each bond is formed independently of the others. Polyesters and polyamides (nylons) are examples.
- Stereocenter** (Section 5.2): An alternative name for a chirality center.
- Stereochemistry** (Section 3.5; Chapters 3, 4, 5): The branch of chemistry concerned with the three-dimensional arrangement of atoms in molecules.
- Stereogenic center** (Section 5.2): An alternative name for a chirality center.
- Stereoisomers** (Section 4.2): Isomers that have their atoms connected in the same order but have different three-dimensional arrangements. The term *stereoisomer* includes both enantiomers and diastereomers.
- Stereospecific** (Section 8.9, Section 14.5): A term indicating that only a single stereoisomer is produced in a given reaction rather than a mixture.
- Steric strain** (Section 3.7, Section 4.3, Section 4.7): The strain imposed on a molecule when two groups are too close together and try to occupy the same space. Steric strain is responsible both for the greater stability of trans versus cis alkenes and for the greater stability of equatorially substituted versus axially substituted cyclohexanes.
- Steroids** (Section 27.6): Lipids whose structure is based on a tetracyclic carbon skeleton with three 6-membered and one 5-membered ring. Steroids occur in both plants and animals and have a variety of important hormonal functions.
- Stork enamine reaction** (Section 23.11): The conjugate addition of an enamine to an α,β-unsaturated carbonyl compound, followed by hydrolysis to yield a 1,5-dicarbonyl product.
- STR loci** (Chapter 28 Chemistry Matters): Short tandem repeat sequences of noncoding DNA that are unique to every individual and allow DNA fingerprinting.
- Straight-chain alkanes** (Section 3.2): Alkanes whose carbon atoms are connected without branching.
- Substitution reactions** (Section 6.1): What occurs when two reactants exchange parts to give two new products. S_N1 and S_N2 reactions are examples.
- Sulfides** (Section 3.1, Section 18.7): A class of compounds that has two organic substituents bonded to the same sulfur atom, RSR'.
- Sulfonation** (Section 16.2): The substitution of a sulfonic acid group (–SO₃H) onto an aromatic ring.
- Sulfone** (Section 18.7): A compound of the general structure RSO₂R'.
- Sulfonium ions** (Section 18.7): A species containing a positively charged, trivalent sulfur atom, R₃S⁺.
- Sulfoxide** (Section 18.7): A compound of the general structure RSOR'.
- Suprafacial** (Section 30.5): A word used to describe the geometry of pericyclic reactions. Suprafacial reactions take place on the same side of the two ends of a π electron system.
- Suzuki–Miyaura reaction** (Section 10.7): The palladium-catalyzed coupling reaction of an aromatic or vinylic halide with an aromatic or vinylic boronic acid.
- Symmetry-allowed, symmetry-disallowed** (Section 30.1): A symmetry-allowed reaction is a pericyclic process that has a favorable orbital symmetry for reaction through a concerted pathway. A symmetry-disallowed reaction is one that does not have favorable orbital symmetry for reaction through a concerted pathway.
- Symmetry plane** (Section 5.2): A plane that bisects a molecule such that one half of the molecule is the mirror image of the other half. Molecules containing a plane of symmetry are achiral.
- Syn periplanar** (Section 11.8): Describing a stereochemical relationship in which two bonds on adjacent carbons lie in the same plane and are eclipsed.
- Syn stereochemistry** (Section 8.5): The opposite of anti. A syn addition reaction is one in which the two ends of the double bond react from the same side. A syn elimination is one in which the two groups leave from the same side of the molecule.
- Syndiotactic** (Section 31.2): A chain-growth polymer in which the stereochemistry of the substituents alternates regularly on opposite sides of the backbone.

- Tautomers** (Section 9.4, Section 22.1): Isomers that interconvert spontaneously, usually with the change in position of a hydrogen.
- Terpenoids** (Chapter 8 *Chemistry Matters*, Section 27.5): Lipids that are formally derived by head-to-tail polymerization of isoprene units.
- Tertiary:** See **Primary**.
- Tertiary structure** (Section 26.9): The level of protein structure that involves the manner in which the entire protein chain is folded into a specific three-dimensional arrangement.
- Thermodynamic control** (Section 14.3): An equilibrium reaction that yields the lowest-energy, most stable product is said to be thermodynamically controlled.
- Thermoplastics** (Section 31.7): Polymers that have a high T_g and are hard at room temperature but become soft and viscous when heated.
- Thermosetting resins** (Section 31.7): Polymers that become highly cross-linked and solidify into a hard, insoluble mass when heated.
- Thioesters** (Chapter 21 *Introduction*): A class of compounds with the RCOSR' functional group.
- Thiols** (Section 3.1, Chapter 18 *Introduction*): A class of compounds containing the -SH functional group.
- Thiolate ion** (Section 18.7): The anion of a thiol, RS^- .
- TMS** (Section 13.3): Tetramethylsilane; used as an NMR calibration standard.
- TOF** (Section 12.4): Time-of-flight mass spectrometry; a sensitive method of mass detection accurate to about 3 ppm.
- Tollens' reagent** (Section 25.6): A solution of Ag_2O in aqueous ammonia; used to oxidize aldehydes to carboxylic acids.
- Torsional strain** (Section 3.6, Section 4.3): The strain in a molecule caused by electron repulsion between eclipsed bonds. Torsional strain is also called eclipsing strain.
- Tosylate** (Section 11.1): A *p*-toluenesulfonate ester; useful as a leaving group in nucleophilic substitution reactions.
- Transamination** (Section 29.9): The exchange of an amino group and a keto group between reactants.
- Transcription** (Section 28.4): The process by which the genetic information encoded in DNA is read and used to synthesize RNA in the nucleus of the cell. A small portion of double-stranded DNA uncoils, and complementary ribonucleotides line up in the correct sequence for RNA synthesis.
- Transfer RNA (tRNA)** (Section 28.4): A kind of RNA that transports amino acids to the ribosomes, where they are joined together to make proteins.
- Transimination** (Section 29.9): The exchange of an amino group and an imine group between reactants.
- Transition state** (Section 6.9): An activated complex between reactants, representing the highest energy point on a reaction curve. Transition states are unstable complexes that can't be isolated.
- Translation** (Section 28.5): The process by which the genetic information transcribed from DNA onto mRNA is read by tRNA and used to direct protein synthesis.
- Tree diagram** (Section 13.8): A diagram used in NMR to sort out the complicated splitting patterns that can arise from multiple couplings.
- Triacylglycerols** (Section 27.1): Lipids, such as those found in animal fat and vegetable oil, that are a triester of glycerol with long-chain fatty acids.
- Tricarboxylic acid cycle** (Section 29.7): An alternative name for the citric acid cycle by which acetyl CoA is degraded to CO_2 .
- Triple bonds** (Section 1.8): A type of covalent bond formed by sharing three electron pairs between atoms.
- Triplet** (Section 13.6): A symmetrical three-line splitting pattern observed in the 1H NMR spectrum when a proton has two equivalent neighbor protons.
- Turnover number** (Section 26.10): The number of substrate molecules acted on by an enzyme molecule per unit time.
- Twist-boat conformation** (Section 4.5): A conformation of cyclohexane that is somewhat more stable than a pure boat conformation.
- Ultraviolet (UV) spectroscopy** (Section 14.7): An optical spectroscopy employing ultraviolet irradiation. UV spectroscopy provides structural information about the extent of π electron conjugation in organic molecules.
- Unimolecular reaction** (Section 11.4): A reaction that occurs by spontaneous transformation of the starting material without the intervention of other reactants. For example, the dissociation of a tertiary alkyl halide in the S_N1 reaction is a unimolecular process.
- Unsaturated** (Section 7.2): A molecule that has one or more multiple bonds.
- Upfield** (Section 13.3): The right-hand portion of the NMR chart.
- Urethane** (Section 31.4): A functional group in which a carbonyl group is bonded to both an -OR and an -NR₂.
- Uronic acid** (Section 25.6): A monocarboxylic acid formed by oxidizing the -CH₂OH end of an aldose without affecting the -CHO end.
- Valence bond theory** (Section 1.5): A bonding theory that describes a covalent bond as resulting from the overlap of two atomic orbitals.
- Valence shell** (Section 1.4): The outermost electron shell of an atom.
- van der Waals forces** (Section 2.12): Intermolecular forces that are responsible for holding molecules together in the liquid and solid states.
- Vegetable oils** (Section 27.1): Liquid triacylglycerols derived from a plant source.
- Vicinal** (Section 9.2): A term used to refer to a 1,2-disubstitution pattern. For example, 1,2-dibromoethane is a vicinal dibromide.
- Vinyl group** (Section 7.3): A $H_2C=CH-$ substituent.
- Vinyl monomer** (Section 8.10, Section 31.1): A substituted alkene monomer used to make a chain-growth polymer.

Vinyllic (Section 9.3): A term that refers to a substituent at a double-bond carbon atom. For example, chloroethylene is a vinyllic chloride, and enols are vinyllic alcohols.

Vitamin (Section 26.10): A small organic molecule that must be obtained in the diet and is required in trace amounts for proper growth and function.

Vulcanization (Section 14.6): A technique for cross-linking and hardening a diene polymer by heating with a few percent by weight of sulfur.

Walden inversion (Section 11.1): The inversion of configuration at a chirality center that accompanies an S_N2 reaction.

Wave equation (Section 1.2): A mathematical expression that defines the behavior of an electron in an atom.

Wave function (Section 1.2): A solution to the wave equation for defining the behavior of an electron in an atom. The square of the wave function defines the shape of an orbital.

Wavelength, λ (Section 12.5): The length of a wave from peak to peak. The wavelength of electromagnetic radiation is inversely proportional to frequency and inversely proportional to energy.

Wavenumber, $\tilde{\nu}$ (Section 12.6): The reciprocal of the wavelength in centimeters.

Waxes (Section 27.1): A mixture of esters of long-chain carboxylic acids with long-chain alcohols.

Williamson ether synthesis (Section 18.2): A method for synthesizing ethers by S_N2 reaction of an alkyl halide with an alkoxide ion.

Wittig reaction (Section 19.11): The reaction of a phosphorus

ylide with a ketone or aldehyde to yield an alkene.

Wohl degradation (Section 25.6): A method for shortening the chain of an aldose sugar by one carbon.

Wolff-Kishner reaction (Section 19.9): The conversion of an aldehyde or ketone into an alkane by reaction with hydrazine and base.

X-ray crystallography (Chapter 12 *Chemistry Matters*): A technique that uses X rays to determine the structure of molecules.

Ylide (Section 19.11): A neutral species with adjacent + and - charges, such as the phosphoranes used in Wittig reactions.

Z geometry (Section 7.5): A term used to describe the stereochemistry of a carbon-carbon double bond. The two groups on each carbon are ranked according to the Cahn-Ingold-Prelog sequence rules, and the two carbons are compared. If the higher ranked groups on each carbon are on the same side of the double bond, the bond has Z geometry.

Zaitsev's rule (Section 11.7): A rule stating that E2 elimination reactions normally yield the more highly substituted alkene as major product.

Ziegler-Natta catalysts (Section 31.2): Catalysts of an alkylaluminum and a titanium compound used for preparing alkene polymers.

Zwitterion (Section 26.1): A neutral dipolar molecule in which the positive and negative charges are not adjacent. For example, amino acids exist as zwitterions, $\text{H}_3\text{CN}^+\text{-CHR-CO}_2^-$

PROBLEM

4-13

PROBLEM Before the ring-flip, red and blue are equatorial and green is axial. After the ring-flip, red and blue are axial and green is equatorial.

4-14

PROBLEM 4.2 kJ/mol

4-15

PROBLEM Cyano group points straight up.

4-16

PROBLEM Equatorial = 70%; axial = 30%

4-17

PROBLEM (a) 2.0 kJ/mol (axial Cl) **(b)** 11.4 kJ/mol (axial CH₃) **(c)** 2.0 kJ/mol (axial Br)

4-18 **(d)** 8.0 kJ/mol (axial CH₂CH₃)

PROBLEM

4-19

PROBLEM *trans*-Decalin is more stable because it has no 1,3-diaxial interactions.

4-20

PROBLEM Both ring-fusions are *trans*.

4-21

Chapter 5

PROBLEM Chiral: screw, shoe

5-1

PROBLEM (a)

5-2

PROBLEM

5-3

PROBLEM (a)

5-4

PROBLEM Levorotatory

5-5

PROBLEM +16.1°

5-6

PROBLEM (a) -Br (b) -Br (c) -CH₂CH₃ (d) -OH (e) -CH₂OH (f) -CH=O

5-7

PROBLEM (a) -OH, -CH₂CH₂OH, -CH₂CH₃, -H (b) -OH, -CO₂CH₃, -CO₂H, -CH₂OH

5-8

PROBLEM (c) -NH₂, -CN, -CH₂NHCH₃, -CH₂NH₂ (d) -SSCH₃, -SH, -CH₂SCH₃, -CH₃

PROBLEM (a) S (b) R (c) S

5-9

PROBLEM (a) S (b) S (c) R

5-10

PROBLEM

5-11

PROBLEM S

5-12

PROBLEM Compound (a) is D-erythrose 4-phosphate, (d) is its enantiomer, and (b) and (c) are diastereomers.

5-13

PROBLEM Five chirality centers and 2⁵ = 32 stereoisomers

5-14

PROBLEM S,S

5-15

PROBLEM Compounds (a) and (d) are meso.

5-16

PROBLEM Compounds (a) and (c) have meso forms.

5-17

PROBLEM

5-18

PROBLEM Two diastereomeric salts: (R)-lactic acid plus (S)-1-phenylethylamine and (S)-lactic acid plus

5-20

(S)-1-phenylethylamine

PROBLEM (a) Constitutional isomers **(b)** Diastereomers

5-21

PROBLEM (S)-Lactate

5-24

PROBLEM The -OH adds to the *Re* face of C2, and -H adds to the *Re* face of C3. The overall addition has anti stereochemistry.

5-25

Chapter 6

PROBLEM (a) Substitution **(b)** Elimination **(c)** Addition

6-1

PROBLEM (a) Carbon is electrophilic. **(b)** Sulfur is nucleophilic. **(c)** Nitrogens are nucleophilic.

6-2

(d) Oxygen is nucleophilic; carbon is electrophilic.

PROBLEM

6-3

PROBLEM Bromocyclohexane; chlorocyclohexane

6-4

PROBLEM

6-5

The mechanism is shown in Figure 6.4

PROBLEM (a)

6-6

PROBLEM**6-7**

PROBLEM 6-8 1-Chloro-2-methylpentane, 2-chloro-2-methylpentane, 3-chloro-2-methylpentane,
2-chloro-4-methylpentane, 1-chloro-4-methylpentane

PROBLEM**6-9**

PROBLEM 6-10 Negative ΔG° is favored.

6-10

PROBLEM 6-11 Larger K_{eq} is more exergonic.

6-11

PROBLEM 6-12 Lower ΔG^\ddagger is faster.

6-12**PROBLEM****6-13****Chapter 7**

PROBLEM 7-1 (a) 1 (b) 2 (c) 2

7-1

PROBLEM 7-2 (a) 5 (b) 5 (c) 3 (d) 1 (e) 6 (f) 5

7-2

PROBLEM 7-3 $C_{16}H_{13}ClN_2O$

7-3

PROBLEM 7-4 (a) 3,4,4-Trimethyl-1-pentene (b) 3-Methyl-3-hexene (c) 4,7-Dimethyl-2,5-octadiene

7-4 (d) 6-Ethyl-7-methyl-4-nonene

PROBLEM 7-5 (a)

7-5

(b)

(c)

PROBLEM (a) 1,2-Dimethylcyclohexene (b) 4,4-Dimethylcycloheptene (c) 3-Isopropylcyclopentene
7-6

PROBLEM (a) 2,5,5-Trimethylhex-2-ene (b) 2,3-Dimethylcyclohexa-1,3-diene
7-7

PROBLEM Compounds (c), (e), and (f) have cis-trans isomers.
7-9

PROBLEM (a) *cis*-4,5-Dimethyl-2-hexene (b) *trans*-6-Methyl-3-heptene
7-10

PROBLEM (a) $-\text{CH}_3$ (b) $-\text{Cl}$ (c) $-\text{CH}=\text{CH}_2$ (d) $-\text{OCH}_3$ (e) $-\text{CH}=\text{O}$ (f) $-\text{CH}=\text{O}$
7-11

PROBLEM (a) $-\text{Cl}$, $-\text{OH}$, $-\text{CH}_3$, $-\text{H}$ (b) $-\text{CH}_2\text{OH}$, $-\text{CH}=\text{CH}_2$, $-\text{CH}_2\text{CH}_3$, $-\text{CH}_3$
7-12 (c) $-\text{CO}_2\text{H}$, $-\text{CH}_2\text{OH}$, $-\text{C}\equiv\text{N}$, $-\text{CH}_2\text{NH}_2$ (d) $-\text{CH}_2\text{OCH}_3$, $-\text{C}\equiv\text{N}$, $-\text{C}\equiv\text{CH}$, $-\text{CH}_2\text{CH}_3$

PROBLEM (a) *Z* (b) *E* (c) *Z* (d) *E*
7-13

PROBLEM (a) 2-Methylpropene is more stable than 1-butene.
7-15 (b) *trans*-2-Hexene is more stable than *cis*-2-hexene.
(c) 1-Methylcyclohexene is more stable than 3-methylcyclohexene.

PROBLEM (a) Chlorocyclohexane (b) 2-Bromo-2-methylpentane (c) 4-Methyl-2-pentanol
7-16 (d) 1-Bromo-1-methylcyclohexane

PROBLEM (a) Cyclopentene (b) 1-Ethylcyclohexene or ethylidenecyclohexane (c) 3-Hexene
7-17 (d) Vinylcyclohexane (cyclohexylethylene)

PROBLEM (a) 7-18

PROBLEM In the conformation shown, only the methyl- group C-H that is parallel to the carbocation *p* orbital can show hyperconjugation.
7-19

PROBLEM The second step is exergonic; the transition state resembles the carbocation.
7-20

Chapter 8

PROBLEM 2-Methyl-2-butene and 2-methyl-1-butene
8-1

PROBLEM Five

8-2

PROBLEM *trans*-1,2-Dichloro-1,2-dimethylcyclohexane

8-3

PROBLEM

8-4

**PROBLEM** *trans*-2-Bromocyclopentanol

8-5

PROBLEM Markovnikov

8-6

PROBLEM (a) 2-Pentanol (b) 2-Methyl-2-pentanol

8-7

PROBLEM (a) Oxymercuration of 2-methyl-1-hexene or 2-methyl-2-hexene

8-8 (b) Oxymercuration of cyclohexylethylene or hydroboration of ethylidenecyclohexane

PROBLEM (a)

8-9

(b)

**PROBLEM** (a) 3-Methyl-1-butene (b) 2-Methyl-2-butene (c) Methylene cyclohexane

8-10

PROBLEM

8-11

**PROBLEM** (a) 2-Methylpentane (b) 1,1-Dimethylcyclopentane (c) *tert*-Butylcyclohexane

8-12

PROBLEM

8-13

**PROBLEM** (a) 1-Methylcyclohexene (b) 2-Methyl-2-pentene (c) 1,3-Butadiene

8-14

PROBLEM (a) $\text{CH}_3\text{COCH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{H}$ (b) $\text{CH}_3\text{COCH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CHO}$

8-15

PROBLEM (a) 2-Methylpropene (b) 3-Hexene

8-16

PROBLEM (a)

8-17

**PROBLEM** (a) $\text{H}_2\text{C}=\text{CHOCH}_3$ (b) $\text{ClCH}=\text{CHCl}$

8-18

PROBLEM

8-19

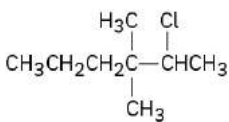

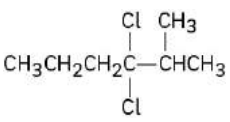

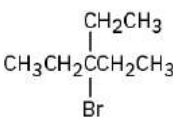

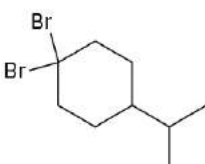

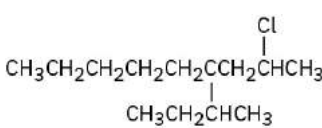

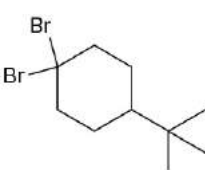

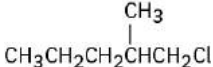

**PROBLEM** An optically inactive, non-50 : 50 mixture of two racemic pairs: (2*R*,4*R*) + (2*S*,4*S*) and (2*R*,4*S*) +8-20 (2*S*,4*R*)**PROBLEM** Non-50 : 50 mixture of two racemic pairs: (1*S*,3*R*) + (1*R*,3*S*) and (1*S*,3*S*) + (1*R*,3*R*)

8-21

Chapter 9

- PROBLEM (a)** 2,5-Dimethyl-3-hexyne **(b)** 3,3-Dimethyl-1-butyne **(c)** 3,3-Dimethyl-4-octyne
9-1 (d) 2,5,5-Trimethyl-3-heptyne **(e)** 2,4-Octadiene-6-yne
- PROBLEM** 1-Hexyne, 2-hexyne, 3-hexyne, 3-methyl-1-pentyne, 4-methyl-1-pentyne, 4-methyl-2-pentyne,
9-2 3,3-dimethyl-1-butyne
- PROBLEM (a)** 1,1,2,2-Tetrachloropentane **(b)** 1-Bromo-1-cyclopentylethylene
9-3 (c) 2-Bromo-2-heptene and 3-bromo-2-heptene
- PROBLEM (a)** 4-Octanone **(b)** 2-Methyl-4-octanone and 7-methyl-4-octanone
9-4
- PROBLEM (a)** 1-Pentyne **(b)** 2-Pentyne
9-5
- PROBLEM (a)** $C_6H_5C\equiv CH$ **(b)** 2,5-Dimethyl-3-hexyne
9-6
- PROBLEM (a)** Mercuric sulfate-catalyzed hydration of phenylacetylene
9-7 (b) Hydroboration/oxidation of cyclopentylacetylene
- PROBLEM (a)** Reduce 2-octyne with Li/NH_3 . **(b)** Reduce 3-heptyne with $H_2/Lindlar$ catalyst.
9-8 (c) Reduce 3-methyl-1-pentyne.
- PROBLEM** No: **(a), (c), (d)**; yes: **(b)**
9-9
- PROBLEM (a)** 1-Pentyne + CH_3I , or propyne + $CH_3CH_2CH_2I$ **(b)** 3-Methyl-1-butyne + CH_3CH_2I
9-10 (c) Cyclohexylacetylene + CH_3I
- PROBLEM**
9-11 $CH_3C\equiv CH \xrightarrow[2. CH_3I]{1. NaNH_2} CH_3C\equiv CCH_3 \xrightarrow[Lindlar\ cat.]{H_2} cis-CH_3CH=CHCH_3$
- PROBLEM (a)** $KMnO_4, H_3O^+$ **(b)** $H_2/Lindlar$ **(c)** 1. $H_2/Lindlar$; 2. HBr
9-12 (d) 1. $H_2/Lindlar$; 2. BH_3 ; 3. $NaOH, H_2O_2$ **(e)** 1. $H_2/Lindlar$; 2. Cl_2 **(f)** O_3
- PROBLEM (a)** 1. $HC\equiv CH + NaNH_2$; 2. $CH_3(CH_2)_6CH_2Br$; 3. 2 H_2/Pd
9-13 (b) $HC\equiv CH + NaNH_2$; 2. $(CH_3)_3CCH_2CH_2I$; 3. 2 H_2/Pd
(c) 1. $HC\equiv CH + NaNH_2$; 2. $CH_3CH_2CH_2CH_2I$; 3. BH_3 ; 4. H_2O_2
(d) 1. $HC\equiv CH + NaNH_2$; 2. $CH_3CH_2CH_2CH_2CH_2I$; 3. $HgSO_4, H_3O^+$

Chapter 10

- PROBLEM (a)** 1-Iodobutane **(b)** 1-Chloro-3-methylbutane **(c)** 1,5-Dibromo-2,2-dimethylpentane
10-1 (d) 1,3-Dichloro-3-methylbutane **(e)** 1-Chloro-3-ethyl-4-iodopentane
(f) 2-Bromo-5-chlorohexane
- PROBLEM**
10-2 (a)  **(b)**  **(c)**  **(d)** 
- (e)**  **(f)** 
- PROBLEM** Chiral: 1-chloro-2-methylpentane, 3-chloro-2-methylpentane, 2-chloro-4-methylpentane Achiral:
10-3 2-chloro-2-methylpentane, 1-chloro-4-methylpentane

PROBLEM 1-Chloro-2-methylbutane (29%), 1-chloro-3-methylbutane (14%), 2-chloro-2-methylbutane (24%),

10-4 2-chloro-3-methylbutane (33%)

PROBLEM

PROBLEM The intermediate allylic radical reacts at the more accessible site and gives the more highly

10-6 substituted double bond.

PROBLEM (a) 3-Bromo-5-methylcycloheptene and 3-bromo-6-methylcycloheptene (b) Four products

10-7

PROBLEM (a) 2-Methyl-2-propanol + HCl (b) 4-Methyl-2-pentanol + PBr₃

10-8 (c) 5-Methyl-1-pentanol + PBr₃ (d) 3,3-Dimethyl-cyclopentanol + HF, pyridine

PROBLEM Both reactions occur.

10-9

PROBLEM React Grignard reagent with D₂O.

10-10

PROBLEM (a) 1. NBS; 2. (CH₃)₂CuLi (b) 1. Li; 2. CuI; 3. CH₃CH₂CH₂CH₂Br

10-11 (c) 1. BH₃; 2. H₂O₂, NaOH; 3. PBr₃; 4. Li, then CuI; 5. CH₃(CH₂)₄Br

PROBLEM (a)

PROBLEM (a) Reduction (b) Neither

10-13

Chapter 11

PROBLEM (R)-1-Methylpentyl acetate, CH₃CO₂CH(CH₃)CH₂CH₂CH₂CH₃

11-1

PROBLEM (S)-2-Butanol

11-2

PROBLEM (S)-2-Bromo-4-methylpentane →

11-3

PROBLEM (a) 1-Iodobutane (b) 1-Butanol (c) 1-Hexyne (d) Butylammonium bromide

11-4

PROBLEM (a) (CH₃)₂N⁻ (b) (CH₃)₃N (c) H₂S

11-5

PROBLEM CH₃OTos > CH₃Br > (CH₃)₂CHCl > (CH₃)₃CCl

11-6

PROBLEM Similar to protic solvents

11-7

PROBLEM Racemic 1-ethyl-1-methylhexyl acetate

11-8**PROBLEM** 90.1% racemization, 9.9% inversion**11-9****PROBLEM****11-10****PROBLEM** $\text{H}_2\text{C}=\text{CHCH}(\text{Br})\text{CH}_3 > \text{CH}_3\text{CH}(\text{Br})\text{CH}_3 > \text{CH}_3\text{CH}_2\text{Br} > \text{H}_2\text{C}=\text{CHBr}$ **11-11****PROBLEM** The same allylic carbocation intermediate is formed.**11-12****PROBLEM** (a) $\text{S}_{\text{N}}1$ (b) $\text{S}_{\text{N}}2$ **11-13****PROBLEM****11-14****PROBLEM** (a) Major: 2-methyl-2-pentene; minor: 4-methyl-2-pentene**11-15** (b) Major: 2,3,5-trimethyl-2-hexene; minor: 2,3,5-trimethyl-3-hexene and 2-isopropyl-4-methyl-1-pentene

(c) Major: ethylidenecyclohexane; minor: cyclohexylethylene

PROBLEM (a) 1-Bromo-3,6-dimethylheptane (b) 4-Bromo-1,2-dimethylcyclopentane**11-16****PROBLEM** (Z)-1-Bromo-1,2-diphenylethylene**11-17****PROBLEM** (Z)-3-Methyl-2-pentene**11-18****PROBLEM** Cis isomer reacts faster because the bromine is axial.**11-19****PROBLEM** (a) $\text{S}_{\text{N}}2$ (b) E2 (c) $\text{S}_{\text{N}}1$ (d) E1cB**11-20**

Chapter 12

PROBLEM $\text{C}_{19}\text{H}_{28}\text{O}_2$ **12-1****PROBLEM** (a) 2-Methyl-2-pentene (b) 2-Hexene**12-2****PROBLEM** (a) 43, 71 (b) 82 (c) 58 (d) 86**12-3****PROBLEM** 102 (M^+), 84 (dehydration), 87 (alpha cleavage), 59 (alpha cleavage)**12-4****PROBLEM** X-ray energy is higher; $\lambda = 9.0 \times 10^{-6} \text{ m}$ is higher in energy.

12-5

PROBLEM (a) 2.4×10^6 kJ/mol] (b) 4.0×10^4 kJ/mol (c) 2.4×10^3 kJ/mol (d) 2.8×10^2 kJ/mol

12-6 (e) 6.0 kJ/mol (f) 4.0×10^{-2} kJ/mol

PROBLEM (a) Ketone or aldehyde (b) Nitro compound (c) Carboxylic acid

12-7

PROBLEM (a) $\text{CH}_3\text{CH}_2\text{OH}$ has an -OH absorption. (b) 1-Hexene has a double-bond absorption.

12-8 (c) $\text{CH}_3\text{CH}_2\text{CO}_2\text{H}$ has a very broad -OH absorption.

PROBLEM 1450–1600 cm^{-1} : aromatic ring; 2100 cm^{-1} : $\text{C}\equiv\text{C}$; 3300 cm^{-1} : $\text{C}\equiv\text{C}-\text{H}$

12-9

PROBLEM (a) 1715, 1640, 1250 cm^{-1} (b) 1730, 2100, 3300 cm^{-1}

12-10 (c) 1720, 2500–3100, 3400–3650 cm^{-1}

PROBLEM 1690, 1650, 2230 cm^{-1}

12-11

Chapter 13

PROBLEM 7.5×10^{-5} kJ/mol for ^{19}F ; 8.0×10^{-5} kJ/mol for ^1H

13-1

PROBLEM 1.2×10^{-4} kJ/mol

13-2

PROBLEM The vinylic C - H protons are nonequivalent.

PROBLEM (a) 7.27 δ (b) 3.05 δ (c) 3.46 δ (d) 5.30 δ

13-4

PROBLEM (a) 420 Hz (b) 2.1 δ (c) 1050 Hz

13-5

PROBLEM (a) 1.43 δ (b) 2.17 δ (c) 7.37 δ (d) 5.30 δ (e) 9.70 δ (f) 2.12 δ

13-6

PROBLEM There are seven kinds of protons labeled. The types and expected range of absorption of each

13-7 follow. **a**: ether, 3.5–4.5 δ ; **b**: aryl, 6.5–8.0 δ ; **c**: aryl, 6.5–8.0; **d**: vinylic, 4.5–6.5 δ ; **e**: vinylic, 4.5–6.5 δ ; **f**: alkyl (secondary), 1.2–1.6 δ ; **g**: alkyl (primary), 0.7–1.3 δ .

PROBLEM Two peaks; 3 : 2 ratio

13-8

PROBLEM (a) $-\text{CHBr}_2$, quartet; $-\text{CH}_3$, doublet (b) $\text{CH}_3\text{O}-$, singlet; $-\text{OCH}_2-$, triplet; $-\text{CH}_2\text{Br}$, triplet

13-9 (c) ClCH_2- , triplet; $-\text{CH}_2-$, quintet

(d) CH_3- , triplet; $-\text{CH}_2-$, quartet; $-\text{CH}-$, septet; $(\text{CH}_3)_2$, doublet

(e) CH_3- , triplet; $-\text{CH}_2-$, quartet; $-\text{CH}-$, septet; $(\text{CH}_3)_2$, doublet

(f) $=\text{CH}$, triplet, $-\text{CH}_2-$, doublet, aromatic C-H, two multiplets

PROBLEM (a) CH_3OCH_3 (b) $\text{CH}_3\text{CH}(\text{Cl})\text{CH}_3$ (c) $\text{ClCH}_2\text{CH}_2\text{OCH}_2\text{CH}_2\text{Cl}$

13-10 (d) $\text{CH}_3\text{CH}_2\text{CO}_2\text{CH}_3$ or $\text{CH}_3\text{CO}_2\text{CH}_2\text{CH}_3$

PROBLEM $\text{CH}_3\text{CH}_2\text{OCH}_2\text{CH}_3$

13-11

PROBLEM (a) Enantiotopic (b) Diastereotopic (c) Diastereotopic (d) Diastereotopic

13-12 (e) Diastereotopic (f) Homotopic

PROBLEM (a) 2 (b) 4 (c) 3 (d) 4 (e) 5 (f) 3

13-13

PROBLEM 4

13-14

PROBLEM $J_{1-2} = 16 \text{ Hz}$; $J_{2-3} = 8 \text{ Hz}$

13-15

PROBLEM 1-Chloro-1-methylcyclohexane has a singlet methyl absorption.

13-16

PROBLEM (a) 4 (b) 7 (c) 4 (d) 5 (e) 5 (f) 7

13-17

PROBLEM (a) 1,3-Dimethylcyclopentene (b) 2-Methylpentane (c) 1-Chloro-2-methylpropane

13-18

PROBLEM $-\text{CH}_3$, 9.3 δ ; $-\text{CH}_2-$, 27.6 δ ; $\text{C}=\text{O}$, 174.6 δ ; $-\text{OCH}_3$, 51.4 δ

13-19

PROBLEM

13-20

PROBLEM

13-21

PROBLEM

13-22

PROBLEM A DEPT-90 spectrum would show two absorptions for the non-Markovnikov product ($\text{RCH}=\text{CHBr}$)13-23 but no absorptions for the Markovnikov product ($\text{RBrC}=\text{CH}_2$).

Chapter 14

PROBLEM Expected $\Delta H^\circ_{\text{hydrog}}$ for allene is -252 kJ/mol . Allene is less stable than a nonconjugated diene, 14-1 which is less stable than a conjugated diene.

PROBLEM 1-Chloro-2-pentene, 3-chloro-1-pentene, 4-chloro-2-pentene

14-2

PROBLEM 4-Chloro-2-pentene predominates in both.

14-3

PROBLEM 1,2 Addition: 6-bromo-1,6-dimethylcyclohexene 1,4 Addition: 3-bromo-1,2-dimethylcyclohexene

14-4

PROBLEM Interconversion occurs by $\text{S}_{\text{N}}1$ dissociation to a common intermediate cation.

14-5

PROBLEM The double bond is more highly substituted.

14-6

PROBLEM**14-7****PROBLEM** Good dienophiles: **(a), (d)****14-8****PROBLEM** Compound **(a)** is *s*-cis. Compound **(c)** can rotate to *s*-cis.**14-9****PROBLEM****14-10****PROBLEM****14-11****PROBLEM****14-12****PROBLEM** 300–600 kJ/mol; UV energy is greater than IR or NMR energy.**14-13****PROBLEM** $1.46 \times 10^{-5} \text{ M}$ **14-14****PROBLEM** All except **(a)** have UV absorptions.**14-15**

Chapter 15

PROBLEM **(a)** Meta **(b)** Para **(c)** Ortho**15-1****PROBLEM** **(a)** *m*-Bromochlorobenzene **(b)** (3-Methylbutyl)benzene **(c)** *p*-Bromoaniline**15-2****(d)** 2,5-Dichlorotoluene **(e)** 1-Ethyl-2,4-dinitrobenzene **(f)** 1,2,3,5-Tetramethylbenzene**PROBLEM** **(a)****15-3****PROBLEM** Pyridine has an aromatic sextet of electrons.**15-4****PROBLEM** Cyclodecapentaene is not flat because of steric interactions.**15-5****PROBLEM** All C–C bonds are equivalent; one resonance line in both ^1H and ^{13}C NMR spectra.**15-6****PROBLEM** The cyclooctatetraenyl dianion is aromatic (ten π electrons) and flat.

15-7

**PROBLEM**

15-9

**PROBLEM** The thiazolium ring has six π electrons.

15-10

**PROBLEM** Yes, it's aromatic.

15-11

**PROBLEM** The three nitrogens in double bonds each contribute one; the remaining nitrogen contributes two.

15-12

Chapter 16

PROBLEM *o*-, *m*-, and *p*-Bromotoluene

16-1

PROBLEM

16-2

**PROBLEM** *o*-xylene: 2; *p*-xylene: 1; *m*-xylene: 3

16-3

PROBLEM D^+ does electrophilic substitutions on the ring.

16-4

PROBLEM No rearrangement: (a), (b), (e)

16-5

PROBLEM *tert*-Butylbenzene

16-6

PROBLEM (a) $(CH_3)_2CHCOCl$ (b) $PhCOCl$

16-7

PROBLEM (a) Phenol > Toluene > Benzene > Nitrobenzene

16-8 (b) Phenol > Benzene > Chlorobenzene > Benzoic acid

(c) Aniline > Benzene > Bromobenzene > Benzaldehyde

PROBLEM (a) *o*- and *p*-Bromonitrobenzene (b) *m*-Bromonitrobenzene (c) *o*- and *p*-Chlorophenol16-9 (d) *o*- and *p*-Bromoaniline**PROBLEM** Alkylbenzenes are more reactive than benzene itself, but acylbenzenes are less reactive.

16-10

PROBLEM Toluene is more reactive; the trifluoromethyl group is electron-withdrawing.

16-11

PROBLEM The nitrogen electrons are donated to the nearby carbonyl group by resonance and are less available to the ring.

16-12

PROBLEM The meta intermediate is most favored.

16-13

PROBLEM (a) Ortho and para to $-\text{OCH}_3$ (b) Ortho and para to $-\text{NH}_2$ (c) Ortho and para to $-\text{Cl}$

16-14

PROBLEM (a) Reaction occurs ortho and para to the $-\text{CH}_3$ group.

16-15 (b) Reaction occurs ortho and para to the $-\text{OCH}_3$ group.

PROBLEM The phenol is deprotonated by KOH to give an anion that carries out a nucleophilic acyl substitution reaction on the fluoronitrobenzene.

16-16

PROBLEM Only one benzyne intermediate can form from *p*-bromotoluene; two different benzyne

16-17 intermediates can form from *m*-bromotoluene.

PROBLEM (a) *m*-Nitrobenzoic acid (b) *p*-*tert*-Butylbenzoic acid

16-18

PROBLEM A benzyl radical is more stable than a primary alkyl radical by 52 kJ/mol and is similar in stability

16-19 to an allyl radical.

PROBLEM 1. $\text{CH}_3\text{CH}_2\text{Cl}$, AlCl_3 ; 2. NBS; 3. KOH, ethanol

16-20

PROBLEM 1. PhCOCl , AlCl_3 ; 2. H_2/Pd

16-21

PROBLEM (a) 1. HNO_3 , H_2SO_4 ; 2. Cl_2 , FeCl_3 (b) 1. CH_3COCl , AlCl_3 ; 2. Cl_2 , FeCl_3 ; 3. H_2/Pd

16-22

(c) 1. $\text{CH}_3\text{CH}_2\text{COCl}$, AlCl_3 ; 2. Cl_2 , FeCl_3 ; 3. H_2/Pd ; 4. HNO_3 , H_2SO_4

(d) 1. CH_3Cl , AlCl_3 ; 2. Br_2 , FeBr_3 ; 3. SO_3 , H_2SO_4

PROBLEM (a) Friedel–Crafts acylation does not occur on a deactivated ring.

16-23 (b) Rearrangement occurs during Friedel–Crafts alkylation with primary halides; chlorination

occurs ortho to the alkyl group.

Chapter 17

PROBLEM (a) 5-Methyl-2,4-hexanediol (b) 2-Methyl-4-phenyl-2-butanol (c) 4,4-Dimethylcyclohexanol

17-1

(d) *trans*-2-Bromocyclopentanol (e) 4-Bromo-3-methylphenol (f) 2-Cyclopenten-1-ol

PROBLEM (a)

17-2

PROBLEM Hydrogen-bonding is more difficult in hindered alcohols.

17-3

PROBLEM (a) $\text{HC}\equiv\text{CH} < (\text{CH}_3)_2\text{CHOH} < \text{CH}_3\text{OH} < (\text{CF}_3)_2\text{CHOH}$

17-4

(b) *p*-Methylphenol < Phenol < *p*-(Trifluoromethyl)phenol

(c) Benzyl alcohol < Phenol < *p*-Hydroxybenzoic acid

PROBLEM The electron-withdrawing nitro group stabilizes an alkoxide ion, but the electron-donating methoxyl group destabilizes the anion.

17-5

PROBLEM (a) 2-Methyl-3-pentanol (b) 2-Methyl-4-phenyl-2-butanol (c) *meso*-5,6-Decanediol

17-6

PROBLEM (a) NaBH_4 (b) LiAlH_4 (c) LiAlH_4

17-7

PROBLEM (a) Benzaldehyde or benzoic acid (or ester) **(b)** Acetophenone **(c)** Cyclohexanone17-8 **(d)** 2-Methylpropanal or 2-methylpropanoic acid (or ester)**PROBLEM (a)** 1-Methylcyclopentanol **(b)** 1,1-Diphenylethanol **(c)** 3-Methyl-3-hexanol

17-9

PROBLEM (a)

17-10

or

**2-Methyl-2-propanol****(b)****1-Methylcyclohexanol****(c)**

or

or

**3-Methyl-3-pentanol****(d)**

or

or

**2-Phenyl-2-butanol**

PROBLEM Cyclohexanone + $\text{CH}_3\text{CH}_2\text{MgBr}$

17-11

PROBLEM 1. *p*-TosCl, pyridine; 2. NaCN

17-12

PROBLEM (a) 2-Methyl-2-pentene (b) 3-Methylcyclohexene (c) 1-Methylcyclohexene

17-13 (d) 2,3-Dimethyl-2-pentene (e) 2-Methyl-2-pentene

PROBLEM (a) 1-Phenylethanol (b) 2-Methyl-1-propanol (c) Cyclopentanol

17-14

PROBLEM (a) Hexanoic acid, hexanal (b) 2-Hexanone (c) Hexanoic acid, no reaction

17-15

PROBLEM $\text{S}_{\text{N}}2$ reaction of F^- on silicon with displacement of alkoxide ion.

17-16

PROBLEM Protonation of 2-methylpropene gives the *tert*-butyl cation, which carries out an electrophilic aromatic substitution reaction.

17-17

PROBLEM Disappearance of $-\text{OH}$ absorption; appearance of $\text{C}=\text{O}$

17-18

PROBLEM (a) Singlet (b) Doublet (c) Triplet (d) Doublet (e) Doublet (f) Singlet

17-19

Chapter 18

PROBLEM (a) Diisopropyl ether (b) Cyclopentyl propyl ether

18-1 (c) *p*-Bromoanisole or 4-bromo-1-methoxybenzene (d) 1-Methoxycyclohexene

(e) Ethyl isobutyl ether (f) Allyl vinyl ether

PROBLEM A mixture of diethyl ether, dipropyl ether, and ethyl propyl ether is formed in a 1 : 1 : 2 ratio.

18-2

PROBLEM (a) $\text{CH}_3\text{CH}_2\text{CH}_2\text{O}^- + \text{CH}_3\text{Br}$ (b) $\text{PhO}^- + \text{CH}_3\text{Br}$ (c) $(\text{CH}_3)_2\text{CHO}^- + \text{PhCH}_2\text{Br}$

18-3 (d) $(\text{CH}_3)_3\text{CCH}_2\text{O}^- + \text{CH}_3\text{CH}_2\text{Br}$

PROBLEM

18-4

PROBLEM (a) Either method (b) Williamson (c) Alkoxymercuration (d) Williamson

18-5

PROBLEM (a) Bromoethane > 2-Bromopropane > Bromobenzene

18-6 (b) Bromoethane > Chloroethane > 1-Iodopropane

PROBLEM 18-7 (a)

(b)

PROBLEM 18-8 Protonation of the oxygen atom, followed by E1 reaction

PROBLEM 18-9 Br⁻ and I⁻ are better nucleophiles than Cl⁻.

PROBLEM 18-10

PROBLEM 18-11 Epoxidation of *cis*-2-butene yields *cis*-2,3-epoxybutane, while epoxidation of *trans*-2-butene yields *trans*-2,3-epoxybutane.

PROBLEM 18-12 (a)

(b)

PROBLEM 18-13 (a) 1-Methylcyclohexene + OsO₄; then NaHSO₃

(b) 1-Methylcyclohexene + *m*-chloroperoxybenzoic acid, then H₃O⁺

PROBLEM 18-14 (a)

(b)

(c)

PROBLEM 18-15

PROBLEM 18-16 (a) 2-Butanethiol (b) 2,2,6-Trimethyl-4-heptanethiol (c) 2-Cyclopentene-1-thiol

(d) Ethyl isopropyl sulfide (e) *o*-Di(methylthio)benzene (f) 3-(Ethylthio)cyclohexanone

PROBLEM 18-17 (a) 1. LiAlH₄; 2. PBr₃; 3. (H₂N)₂C=S; 4. H₂O, NaOH

(b) 1. HBr; 2. (H₂N)₂C=S; 3. H₂O, NaOH

PROBLEM 18-18 1,2-Epoxybutane

PROBLEM 18-69 Acetyl chloride is more electrophilic than acetone.

PROBLEM 18-70

PROBLEM 18-71 (a) Nucleophilic acyl substitution (b) Nucleophilic addition (c) Carbonyl condensation

Chapter 19

PROBLEM 19-1 (a) 2-Methyl-3-pentanone (b) 3-Phenylpropanal (c) 2,6-Octanedione

(d) *trans*-2-Methylcyclohexanecarbaldehyde (e) 4-Hexenal

(f) *cis*-2,5-Dimethylcyclohexanone

PROBLEM 19-3 (a) Dess–Martin periodinane (b) 1. O₃; 2. Zn (c) DIBAH

(d) 1. BH₃, then H₂O₂, NaOH; 2. Dess–Martin periodinane

PROBLEM 19-4 (a) HgSO₄, H₃O⁺ (b) 1. CH₃COCl, AlCl₃; 2. Br₂, FeBr₃ (c) 1. Mg; 2. CH₃CHO; 3. H₃O⁺; 4. CrO₃

(d) 1. BH₃; 2. H₂O₂, NaOH; 3. CrO₃

PROBLEM

PROBLEM 19-6 The electron-withdrawing nitro group in *p*-nitrobenzaldehyde polarizes the carbonyl group.

PROBLEM 19-7 CCl₃CH(OH)₂

PROBLEM 19-8 Labeled water adds reversibly to the carbonyl group.

PROBLEM 19-9 The equilibrium is unfavorable for sterically hindered ketones.

PROBLEM 19-11 The steps are the exact reverse of the forward reaction shown in Figure 19.7.

PROBLEM 19-13 (a) H₂/Pd (b) N₂H₄, KOH (c) 1. H₂/Pd; 2. N₂H₄, KOH

PROBLEM 19-14 The mechanism is identical to that between a ketone and 2 equivalents of a monoalcohol, shown in Figure 19.11.

PROBLEM 19-16 (a) Cyclohexanone + (Ph)₃P=CHCH₃ (b) Cyclohexanecarbaldehyde + (Ph)₃P=CH₂

(c) Acetone + (Ph)₃P=CHCH₂CH₂CH₃ (d) Acetone + (Ph)₃P=CHPh

(e) PhCOCH₃ + (Ph)₃P=CHPh (f) 2-Cyclohexenone + (Ph)₃P=CH₂

PROBLEM

β-Carotene

PROBLEM 19-18 Intramolecular Cannizzaro reaction

PROBLEM 19-19 Addition of the pro-*R* hydrogen of NADH takes place on the Re face of pyruvate.

PROBLEM The -OH group adds to the Re face at C2, and -H adds to the Re face at C3, to yield (2*R*,3*S*)-isocitrate.

19-20

PROBLEM

19-21

PROBLEM (a) 3-Buten-2-one + $(\text{CH}_3\text{CH}_2\text{CH}_2)_2\text{CuLi}$ **(b)** 3-Methyl-2-cyclohexenone + $(\text{CH}_3)_2\text{CuLi}$

19-22 (c) 4-*tert*-Butyl-2-cyclohexenone + $(\text{CH}_3\text{CH}_2)_2\text{CuLi}$ **(d)** Unsaturated ketone + $(\text{H}_2\text{C}=\text{CH})_2\text{CuLi}$

PROBLEM Look for appearance of either an alcohol or a saturated ketone in the product.

19-23

PROBLEM (a) 1715 cm^{-1} **(b)** 1685 cm^{-1} **(c)** 1750 cm^{-1} **(d)** 1705 cm^{-1} **(e)** 1715 cm^{-1}

19-24 (f) 1705 cm^{-1}

PROBLEM (a) Different peaks due to McLafferty rearrangement

19-25 (b) Different peaks due to α cleavage and McLafferty rearrangement

(c) Different peaks due to McLafferty rearrangement

PROBLEM IR: 1750 cm^{-1} ; MS: 140, 84

19-26

Chapter 20

PROBLEM (a) 3-Methylbutanoic acid **(b)** 4-Bromopentanoic acid **(c)** 2-Ethylpentanoic acid

20-1 (d) *cis*-4-Hexenoic acid **(e)** 2,4-Dimethylpentanenitrile

(f) *cis*-1,3-Cyclopentanedicarboxylic acid

PROBLEM (a)

20-2

(b)

(c)

(d)

(e)

(f)

PROBLEM Dissolve the mixture in ether, extract with aqueous NaOH, separate and acidify the aqueous layer, and extract with ether.

20-3

PROBLEM 43%

20-4

PROBLEM (a) 82% dissociation **(b)** 73% dissociation

20-5

PROBLEM Lactic acid is stronger because of the inductive effect of the -OH group.

20-6

PROBLEM The dianion is destabilized by repulsion between charges.

20-7

PROBLEM More reactive

20-8

PROBLEM (a) *p*-Methylbenzoic acid < Benzoic acid < *p*-Chlorobenzoic acid

20-9 (b) Acetic acid < Benzoic acid < *p*-Nitrobenzoic acid

PROBLEM (a) 1. Mg; 2. CO_2 ; 3. H_3O^+ **(b)** 1. Mg; 2. CO_2 ; 3. H_3O^+ or 1. NaCN; 2. H_3O^+

20-10

PROBLEM 1. NaCN; 2. H_3O^+ ; 3. LiAlH_4

20-11

PROBLEM 1. PBr_3 ; 2. NaCN; 3. H_3O^+ ; 4. LiAlH_4

20-12

PROBLEM (a) Propanenitrile + $\text{CH}_3\text{CH}_2\text{MgBr}$, then H_3O^+ **(b)** *p*-Chlorobenzonitrile + CH_3MgBr , then H_3O^+

20-13

PROBLEM 1. NaCN; 2. $\text{CH}_3\text{CH}_2\text{MgBr}$, then H_3O^+

20-14

PROBLEM A carboxylic acid has a very broad -OH absorption at $2500\text{--}3300\text{ cm}^{-1}$.

20-15

PROBLEM 4-Hydroxycyclohexanone: H-C-O absorption near $4\ \delta$ in the ^1H spectrum and C=O absorption near $210\ \delta$ in the ^{13}C spectrum. Cyclopentanecarboxylic acid: $\text{-CO}_2\text{H}$ absorption near $12\ \delta$ in the ^1H spectrum and $\text{-CO}_2\text{H}$ absorption near $170\ \delta$ in the ^{13}C spectrum.

Chapter 21

PROBLEM (a) 4-Methylpentanoyl chloride (b) Cyclohexylacetamide (c) Isopropyl 2-methylpropanoate

21-1 (d) Benzoic anhydride (e) Isopropyl cyclopentanecarboxylate

(f) Cyclopentyl 2-methylpropanoate (g) *N*-Methyl-4-pentenamide

(h) (*R*)-2-Hydroxypropanoyl phosphate (i) Ethyl 2,3-dimethyl-2-butenethioate

PROBLEM (a) $\text{C}_6\text{H}_5\text{CO}_2\text{C}_6\text{H}_5$ (b) $\text{CH}_3\text{CH}_2\text{CH}_2\text{CON}(\text{CH}_3)\text{CH}_2\text{CH}_3$ (c) $(\text{CH}_3)_2\text{CHCH}_2\text{CH}(\text{CH}_3)\text{COCl}$

21-2

PROBLEM

21-3

PROBLEM (a) Acetyl chloride > Methyl acetate > Acetamide

21-4 (b) Hexafluoroisopropyl acetate > 2,2,2-Trichloroethyl acetate > Ethyl acetate

PROBLEM (a) $\text{CH}_3\text{CO}_2^- \text{Na}^+$ (b) CH_3CONH_2 (c) $\text{CH}_3\text{CO}_2\text{CH}_3 + \text{CH}_3\text{CO}_2^- \text{Na}^+$ (d) $\text{CH}_3\text{CONHCH}_3$

21-5

PROBLEM

21-6

PROBLEM (a) Acetic acid + 1-butanol (b) Butanoic acid + methanol

21-7 (c) Cyclopentanecarboxylic acid + isopropyl alcohol

PROBLEM

21-8

PROBLEM (a) Propanoyl chloride + methanol (b) Acetyl chloride + ethanol

21-9 (c) Benzoyl chloride + ethanol

PROBLEM Benzoyl chloride + cyclohexanol

21-10

PROBLEM This is a typical nucleophilic acyl substitution reaction, with morpholine as the nucleophile and chloride as the leaving group.

PROBLEM (a) Propanoyl chloride + methylamine (b) Benzoyl chloride + diethylamine

21-12 (c) Propanoyl chloride + ammonia

PROBLEM (a) Benzoyl chloride + $[(\text{CH}_3)_2\text{CH}]_2\text{CuLi}$, or 2-methylpropanoyl chloride + Ph_2CuLi

21-13 (b) 2-Propenoyl chloride + $(\text{CH}_3\text{CH}_2\text{CH}_2)_2\text{CuLi}$, or butanoyl chloride + $(\text{H}_2\text{C}=\text{CH})_2\text{CuLi}$

PROBLEM This is a typical nucleophilic acyl substitution reaction, with *p*-hydroxyaniline as the nucleophile

21-14 and acetate ion as the leaving group.

PROBLEM Monomethyl ester of benzene-1,2-dicarboxylic acid

21-15

PROBLEM Reaction of a carboxylic acid with an alkoxide ion gives the carboxylate ion.

21-16

PROBLEM LiAlH_4 gives $\text{HOCH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{OH}$; DIBALH gives $\text{HOCH}_2\text{CH}_2\text{CH}_2\text{CHO}$.

21-17

PROBLEM (a) $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}(\text{CH}_3)\text{CH}_2\text{OH} + \text{CH}_3\text{OH}$ **(b)** $\text{PhOH} + \text{PhCH}_2\text{OH}$

21-18

PROBLEM (a) Ethyl benzoate + 2 CH_3MgBr **(b)** Ethyl acetate + 2 PhMgBr

21-19 (c) Ethyl pentanoate + 2 $\text{CH}_3\text{CH}_2\text{MgBr}$

PROBLEM (a) H_2O , NaOH **(b)** Benzoic acid + LiAlH_4 **(c)** LiAlH_4

21-20

PROBLEM 1. Mg ; 2. CO_2 , then H_3O^+ ; 3. SOCl_2 ; 4. $(\text{CH}_3)_2\text{NH}$; 5. LiAlH_4

25-24

- PROBLEM (a)** The hemiacetal ring is reduced. **(b)** The hemiacetal ring is oxidized.
25-25 (c) All hydroxyl groups are acetylated.

Chapter 26

PROBLEM Aromatic: Phe, Tyr, Trp, His; sulfur-containing: Cys, Met; alcohols: Ser, Thr; hydrocarbon side chains: Ala, Ile, Leu, Val, Phe

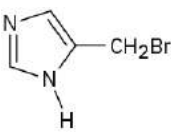

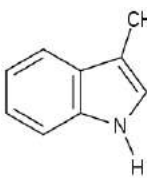

PROBLEM The sulfur atom in the $-\text{CH}_2\text{SH}$ group of cysteine makes the side chain higher in ranking than the $-\text{CO}_2\text{H}$ group.

PROBLEM
26-3

PROBLEM Net positive at pH = 5.3; net negative at pH = 7.3
26-4

PROBLEM (a) Start with 3-phenylpropanoic acid: 1. Br_2 , PBr_3 ; 2. NH_3

26-5 (b) Start with 3-methylbutanoic acid: 1. Br_2 , PBr_3 ; 2. NH_3

PROBLEM (a) $(\text{CH}_3)_2\text{CHCH}_2\text{Br}$ **(b)**  **(c)**  **(d)** $\text{CH}_3\text{SCH}_2\text{CH}_2\text{Br}$

PROBLEM
26-7

PROBLEM Val-Tyr-Gly (VYG), Tyr-Gly-Val (YGV), Gly-Val-Tyr (GVY), Val-Gly-Tyr (VGY), Tyr-Val-Gly (YVG), Gly-Tyr-Val (GYV)

PROBLEM
26-9

PROBLEM**26-10****PROBLEM****26-11****PROBLEM** Trypsin: Asp-Arg + Val-Tyr-Ile-His-Pro-Phe**26-12** Chymotrypsin: Asp-Arg-Val-Tyr + Ile-His-Pro-Phe**PROBLEM** Methionine**26-13****PROBLEM****26-14****PROBLEM (a)** Arg-Pro-Leu-Gly-Ile-Val **(b)** Val-Met-Trp-Asp-Val-Leu (VMWNVL)**26-15****PROBLEM** This is a typical nucleophilic acyl substitution reaction, with the amine of the amino acid as the**26-16** nucleophile and *tert*-butyl carbonate as the leaving group. The *tert*-butyl carbonate then loses CO_2 and gives *tert*-butoxide, which is protonated.**PROBLEM (1)** Protect the amino group of leucine.**26-17 (2)** Protect the carboxylic acid group of alanine.**(3)** Couple the protected amino acids with DCC.**(4)** Remove the leucine protecting group.**(5)** Remove the alanine protecting group.**PROBLEM (a)** Lyase **(b)** Hydrolase **(c)** Oxidoreductase**26-18****Chapter 27****PROBLEM** $\text{CH}_3(\text{CH}_2)_{18}\text{CO}_2\text{CH}_2(\text{CH}_2)_{30}\text{CH}_3$ **27-1****PROBLEM** Glycerol tripalmitate is higher melting.**27-2****PROBLEM** $[\text{CH}_3(\text{CH}_2)_7\text{CH}=\text{CH}(\text{CH}_2)_7\text{CO}_2^-]_2 \text{Mg}^{2+}$ **27-3****PROBLEM** Glycerol dioleate monopalmitate \rightarrow glycerol + 2 sodium oleate + sodium palmitate**27-4****PROBLEM****27-5****PROBLEM** The pro-*S* hydrogen is cis to the $-\text{CH}_3$ group; the pro-*R* hydrogen is trans.**27-6**

PROBLEM (a)
27-7

(b)

PROBLEM (a)
27-8

(b)

**PROBLEM
27-9**

PROBLEM 27-10 Three methyl groups are removed, the side-chain double bond is reduced, and the double bond in the B ring is migrated.

Chapter 28**PROBLEM
28-1****PROBLEM
28-2****PROBLEM (5') ACGGATTAGCC (3')
28-3**

PROBLEM**28-4****PROBLEM** (3') CUA AUG GCA U (5')**28-5****PROBLEM** (5') ACT CTG CGA A (3')**28-6****PROBLEM** (a) GCU, GCC, GCA, GCG (b) UUU, UUC (c) UUA, UUG, CUU, CUC, CUA, CUG (d) UAU, UAC**28-7****PROBLEM** (a) AGC, GGC, UGC, CGC (b) AAA, GAA (c) UAA, CAA, GAA, GAG, UAG, CAG (d) AUA, GUA**28-8****PROBLEM** Leu-Met-Ala-Trp-Pro-Stop**28-9****PROBLEM** (5') TTA-GGG-CCA-AGC-CAT-AAG (3')**28-10****PROBLEM** The cleavage is an S_N1 reaction that occurs by protonation of the oxygen atom followed by loss of the stable triarylmethyl carbocation.**28-11****PROBLEM****28-12**

Chapter 29

PROBLEM $\text{HOCH}_2\text{CH}(\text{OH})\text{CH}_2\text{OH} + \text{ATP} \rightarrow \text{HOCH}_2\text{CH}(\text{OH})\text{CH}_2\text{OPO}_3^{2-} + \text{ADP}$ **29-1****PROBLEM** Caprylyl CoA \rightarrow Hexanoyl CoA \rightarrow Butyryl CoA \rightarrow 2 Acetyl CoA**29-2****PROBLEM** (a) 8 acetyl CoA; 7 passages (b) 10 acetyl CoA; 9 passages**29-3****PROBLEM** The dehydration is an E1cB reaction.**29-4****PROBLEM** At C2, C4, C6, C8, and so forth**29-5****PROBLEM** The Si face**29-6****PROBLEM** Steps 7 and 10**29-7****PROBLEM** Steps 1, 3: Phosphate transfers; steps 2, 5, 8: isomerizations; step 4: retro-aldol reaction; step 5: oxidation and nucleophilic acyl substitution; steps 7, 10: phosphate transfers; step 9: E1cB dehydration**29-8****PROBLEM** C1 and C6 of glucose become $-\text{CH}_3$ groups; C3 and C4 become CO_2 .**29-9****PROBLEM** Citrate and isocitrate**29-10****PROBLEM** E1cB elimination of water, followed by conjugate addition**29-11****PROBLEM** pro-*R*; anti geometry

29-12

PROBLEM The reaction occurs by two sequential nucleophilic acyl substitutions, the first by a cysteine residue
29-13 in the enzyme, with phosphate as leaving group, and the second by hydride donation from NADH, with the cysteine residue as leaving group.

PROBLEM Initial imine formation between PMP and α -ketoglutarate is followed by double-bond
29-14 rearrangement to an isomeric imine and hydrolysis.

PROBLEM $(\text{CH}_3)_2\text{CHCH}_2\text{COCO}_2^-$

29-15

PROBLEM Asparagine

29-16

Chapter 30

PROBLEM Ethylene: ψ_1 is the HOMO and ψ_2^* is the LUMO in the ground state; ψ_2^* is the HOMO and there is no
30-1 LUMO in the excited state. 1,3-Butadiene: ψ_2 is the HOMO and ψ_3^* is the LUMO in the ground state; ψ_3^* is the HOMO and ψ_4^* is the LUMO in the excited state.

PROBLEM Disrotatory: *cis*-5,6-dimethyl-1,3-cyclohexadiene;

30-2 conrotatory: *trans*-5,6-dimethyl-1,3-cyclohexadiene. Disrotatory closure occurs.

PROBLEM The more stable of two allowed products is formed.

30-3

PROBLEM *trans*-5,6-Dimethyl-1,3-cyclohexadiene; *cis*-5,6-dimethyl-1,3-cyclohexadiene

30-4

PROBLEM *cis*-3,6-Dimethylcyclohexene; *trans*-3,6-dimethylcyclohexene

30-5

PROBLEM A [6 + 4] suprafacial cycloaddition

30-6

PROBLEM An antarafacial [1,7] sigmatropic rearrangement

30-7

PROBLEM

30-8

PROBLEM A series of [1,5] hydrogen shifts occur.

30-9

PROBLEM *o*-(1-Methylallyl)phenol

30-10

PROBLEM Claisen rearrangement is followed by a Cope rearrangement.

30-11

PROBLEM (a) Conrotatory (b) Disrotatory (c) Suprafacial (d) Antarafacial (e) Suprafacial

30-12

Chapter 31

PROBLEM $\text{H}_2\text{C}=\text{CHCO}_2\text{CH}_3 < \text{H}_2\text{C}=\text{CHCl} < \text{H}_2\text{C}=\text{CHCH}_3 < \text{H}_2\text{C}=\text{CH}-\text{C}_6\text{H}_5$

31-1

PROBLEM $\text{H}_2\text{C}=\text{CHCH}_3 < \text{H}_2\text{C}=\text{CHC}_6\text{H}_5 < \text{H}_2\text{C}=\text{CHC}\equiv\text{N}$

31-2

PROBLEM The intermediate is a resonance-stabilized benzylic carbanion, $\text{Ph}-\overset{\ominus}{\text{C}}\text{HR}$

31-3

PROBLEM The polymer has no chirality centers.

31-4

PROBLEM The polymers are racemic and have no optical rotation.

31-5

PROBLEM**31-6****PROBLEM****31-7****PROBLEM****31-8****PROBLEM****31-9**

PROBLEM 31-10 Vestenamer: ADMET polymerization of 1,9-decadiene or ROMP of cyclooctene; Norsorex: ROMP of norbornene.

**PROBLEM****31-11****PROBLEM****31-12**
